

# **MULTIDIMENSIONAL RANDOM MOTIONS WITH A NATURAL NUMBER OF FINITE VELOCITIES**

FABRIZIO CINOUE<sup>D\*</sup> \*\* AND MATTIA CINTOLI,<sup>∗</sup> *Sapienza University of Rome*

#### **Abstract**

We present a detailed analysis of random motions moving in higher spaces with a natural number of velocities. In the case of the so-called minimal random dynamics, under some broad assumptions, we give the joint distribution of the position of the motion (for both the inner part and the boundary of the support) and the number of displacements performed with each velocity. Explicit results for cyclic and complete motions are derived. We establish useful relationships between motions moving in different spaces, and we derive the form of the distribution of the movements in arbitrary dimension. Finally, we investigate further properties for stochastic motions governed by non-homogeneous Poisson processes.

*Keywords:* Motions in higher space; telegraph process; convexity; partial differential equations; non-homogeneous Poisson process

## **1. Introduction**

Since the papers of Goldstein  $[12]$  and Kac  $[16]$ , who first studied the connection between random displacements of a particle moving back and forth on the line with stochastic times and hyperbolic partial differential equations (PDEs), researchers have shown increasing interest in the study of finite-velocity stochastic dynamics. The (initial) analytic approach led to fundamental results such as the explicit derivation of the distribution of the so-called telegraph process [\[1,](#page-29-2) [14,](#page-29-3) [27\]](#page-30-0), the progenitor of all random motions that later appeared in the literature (also see [\[2,](#page-29-4) [9\]](#page-29-5) for further explicit results and Cinque [\[3\]](#page-29-6) for the description of a reflection principle holding for one-dimensional finite-velocity motions). However, as the number of possible directions increases, the order of the PDE governing the probability distribution of the absolutely continuous component of the stochastic movement increases as well; in particular, as shown for the planar case by Kolesnik and Turbin [\[20\]](#page-29-7), the order of the governing PDE coincides with the number of velocities that the motion can undertake. To overcome the weakness of the analytical approach, different ways have been presented to deal with motions in spaces of higher order. One of the first explicit results for multidimensional processes concerned a

two-dimensional motion moving with three velocities (see [\[8,](#page-29-8) [28\]](#page-30-1)), which was extended to different rules for change of directions in [\[23\]](#page-29-9). We also point out the papers of Kolesnik and Orsingher [\[18\]](#page-29-10), which dealt with a planar motion choosing between the continuum of possible directions in the plane, ( $\cos \alpha$ ,  $\sin \alpha$ ),  $\alpha \in [0, 2\pi]$ , and of De Gregorio [\[7\]](#page-29-11) and Orsingher and De Gregorio [\[29\]](#page-30-2), which respectively analyzed the corresponding motions on the line and on higher spaces (note that here we only consider motions with a finite number of velocities). Very interesting results concerning motions in arbitrary dimensions were also presented by Samoilenko [\[33\]](#page-30-3) and then further investigated by Lachal *et al.* [\[22\]](#page-29-12) and Lachal [\[21\]](#page-29-13); see [\[11,](#page-29-14) [17,](#page-29-15) [32\]](#page-30-4) as well. It is worth recalling that explicit and fascinating results have been derived under some specific assumptions—for example, in the case of motions moving with orthogonal directions  $[4, 5, 30, 31]$  $[4, 5, 30, 31]$  $[4, 5, 30, 31]$  $[4, 5, 30, 31]$  $[4, 5, 30, 31]$  $[4, 5, 30, 31]$  $[4, 5, 30, 31]$ . We also reference the papers  $[10, 15]$  $[10, 15]$  $[10, 15]$  for motions driven by geometric counting processes. Over the years, stochastic motions with finite velocities have also been studied in depth by physicians, who have obtained interesting outcomes; see for instance [\[24,](#page-30-7) [26,](#page-30-8) [34\]](#page-30-9).

Random evolutions represent a realistic alternative to diffusion processes for suitably modeling real phenomena in several fields: in geology, to represent the oscillations of the ground [\[35\]](#page-30-10); in physics, to describe the random movements of electrons in a conductor, bacterial dynamics [\[25\]](#page-30-11), or the movements of particles in gases; and in finance, to model stock prices [\[19\]](#page-29-20).

In this paper we present some general results for a wide class of random motions moving with a natural number of finite velocities. After a detailed introduction on the probabilistic description of these stochastic processes, we begin our study focusing on minimal motions, i.e. those moving with the minimum number of velocities to ensure that the state space has the same dimension as the space in which they occur. In this case we derive the exact probability in terms of their basic components, generalizing known results in the current literature. The probabilities concern both the inner part and the boundary of the support of the moving particle. Furthermore, thanks to a one-to-one correspondence between minimal stochastic dynamics, we introduce a *canonical (minimal) motion* to help with the analysis and to show explicit results. The examples provided concern different types of motions governed by both Poisson-type processes and geometric counting processes. In Section [3](#page-16-0) we derive the distribution of a motion moving with an arbitrary number of velocities by connecting the problem to minimal movements. Finally, in Section [4,](#page-19-0) we recover the analytic approach to show some characteristics of stochastic dynamics driven by a non-homogeneous Poisson process—in particular, the relationships between the conditional probability of movements in higher order and lower-dimensional dynamics.

### **1.1. Random motions with a natural number of finite velocities**

Let  $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, P)$  be a filtered probability space and  $D \in \mathbb{N}$ . In the following we assume that every random object is suitably defined on the above probability space (i.e. if we introduce a stochastic process, this is adapted to the given filtration).

Let  $\{W_n\}_{n\in\mathbb{N}_0}$  be a sequence of random variables such that  $W_n \geq 0$  almost surely (a.s.) for all *n* and  $W_0 = 0$  a.s. Let us define  $T_n = \sum_{i=0}^n W_i$ ,  $n \in \mathbb{N}_0$ , and the corresponding point process  $N = \{N(t)\}_{t \geq 0}$  such that  $N(t) = \max\{n \in \mathbb{N}_0 : \sum_{i=1}^n W_i \leq t\}$   $\forall$  *t*. Unless differently described, we assume *N* such that  $N(t) < \infty$  for all  $t \ge 0$  a.s. Also, let  $V = \{V(t)\}_{t \ge 0}$  be a stochastic vector process taking values in a finite state space  $\{v_0, \ldots, v_M\} \subset \mathbb{R}^D$ ,  $M \in \overline{\mathbb{N}}$ , and such that  $\mathbb{P}\{V(t + \overline{v})\}$  $dt \neq V(t) | N(t, t + dt] = 0$  = 0,  $t \geq 0$ . Now we can introduce the main object of our study, the *D*-dimensional *random motion* (with a natural number of finite velocities)  $X = \{X(t)\}_{t>0}$  with velocity given by *V*, i.e. moving with the velocities  $v_0, \ldots, v_M$  and with displacements governed by the random process *N*,

<span id="page-2-0"></span>
$$
X(t) = \int_0^t V(s) \, ds = \sum_{i=0}^{N(t)-1} (T_{i+1} - T_i)V(T_i) + (t - T_{N(t)})V(T_{N(t)}), \quad t \ge 0,
$$
\n(1.1)

where  $V(T_i)$  denotes the random speed after the *i*th event recorded by N, therefore after the potential switch occurring at time  $T_i$  (clearly,  $T_{i+1} - T_i = W_{i+1}$ ). The stochastic process *X* describes the position of a particle moving in a *D*-dimensional (real) space with velocities  $v_0, \ldots, v_M$  and which can change its velocity only when the process N records a new event.

For the sake of brevity we also call *X* a *finite-velocity random motion* (even though this definition would also apply to a motion with an infinite number of finite velocities).

<span id="page-2-3"></span>**Example 1.1.** (*Telegraph process and cyclic motions.*) If  $D = 1$ , and N is a homogeneous Poisson process with rate  $\lambda > 0$  and  $v_0 = -v_1 = c > 0$  such that these velocities alternate, i.e.  $V(t) = V(0)(-1)^{N(t)}$ ,  $t \ge 0$ , then we have the well-known symmetric telegraph process, describing the position of a particle moving back and forth on the line with exponential displacements of average length *c*/λ.

In literature, random motions where the velocities change with a deterministic order are usually called *cyclic* motions. If *X* is a *D*-dimensional motion with  $M + 1$  velocities, we say that it is cyclic if (without any loss of generality)  $\mathbb{P}{V(t + dt) = v_h | V(t) = v_i, N(t, t + dt)}$  $1$ } = 1 for  $h = j + 1$ , and 0 otherwise, for all *j*, *h*, where *N* is the point process governing the displacements (and  $v_{h+k(M+1)} = v_h$ ,  $k \in \mathbb{Z}$ ,  $h = 0, \ldots, M$ ). For a complete analysis of this type of motion, see [\[21,](#page-29-13) [22\]](#page-29-12).

<span id="page-2-2"></span>**Example 1.2.** (*Complete random motions.*) If  $\mathbb{P}{V(0) = v_h} > 0$  and  $p_{i,h} = \mathbb{P}{V(t + dt)} =$  $\nu_h$  |  $V(t) = v_i$ ,  $N(t, t + dt] = 1$ } > 0 for each *j*,  $h = 0, \ldots, M$ , we call *X* a *complete* random motion. In this case, at each event recorded by the counting process *N*, the particle can switch velocity to any of the available ones (with strictly positive probability).

**Example 1.3.** (*Random motion with orthogonal velocities*.) Put *D* = 2. Consider the motion  $(X, Y)$  moving in  $\mathbb{R}^2$  with the four orthogonal velocities  $v_h = (\cos(h\pi/2), \sin(h\pi/2)), h =$ 0, 1, 2, 3, such that  $\mathbb{P}{V(t + dt) = v_h | V(t) = v_i, N(t, t + dt) = 1} = 1/2$  if  $j = 0, 2$  and  $h = 1, 3$ or  $j = 1, 3$  and  $h = 0, 2$  (i.e. it always switches 'to a different dimension').  $(X, Y)$  is the so-called *standard orthogonal planar random motion*, which, if *N* is a non-homogeneous Poisson process, can be expressed as a linear function of two independent and equivalent onedimensional (non-homogeneous) telegraph processes; see [\[4\]](#page-29-16). One can imagine also other rules for the changes of velocity; we refer to [\[4,](#page-29-16) [5,](#page-29-17) [30\]](#page-30-5) for further details.

The support of the random variable  $X(t)$  expands as the time increases, and it reads

<span id="page-2-1"></span>
$$
Supp(X(t)) = Conv(v_0t, \dots, v_Mt), \quad t \ge 0,
$$
\n
$$
(1.2)
$$

where  $Conv(\cdot)$  denotes the convex hull of the input vectors. Therefore, the motion *X* moves in a convex polytope of dimension

$$
\dim\bigl(\mathrm{Conv}(v_0,\ldots,v_M)\bigr)=\mathrm{rank}(v_1-v_0\ \cdots\ v_M-v_0)=\mathrm{rank}\begin{pmatrix}1^T\\V\end{pmatrix}-1,
$$

where  $V = (v_0 \cdots v_M)$  is the matrix with the velocities as columns and  $1^T$  is a row vector of all ones (with suitable dimension). For  $H = 0, \ldots, M$ , if the particle takes all, and only, the

velocities  $v_{i_0}, \ldots, v_{i_H}$  in the time interval [0, *t*], then it is located in the set  $\overset{\circ}{\text{Conv}}(v_{i_0}t, \ldots, v_{i_H}t)$ (where  $\hat{S}$  denotes the inner part of the set  $S \subset \mathbb{R}^D$  and we assume the notation  $\hat{\text{Conv}}(v) =$  $\{v\}, v \in \mathbb{R}^D$ ).

Our analysis involves the relationships between motions moving in spaces of different orders or with state spaces of different dimensions. From [\(1.1\)](#page-2-0) it is easy to check that if *A* is an  $(R \times D)$ -dimensional real matrix, then the motion  $X' = \{AX(t)\}_{t>0}$  is an *R*-dimensional motion governed by *N* and with velocities  $v'_0, \ldots, v'_M \in \mathbb{R}^R$  such that  $v'_h = Av_h$ ,  $\forall h$ .

In the following we will use the lemma below, from the theory of affine geometry.

<span id="page-3-0"></span>**Lemma 1.1.** *Let*  $v_0, \ldots, v_M \in \mathbb{R}^D$  *such that dim*(  $Conv(v_0, ..., v_M)) = R$ . For  $k = 0, ..., M$ , *there exists the set IR*,*<sup>k</sup> of the indexes of the first R linearly independent rows of the matrix*  $\left[v_h - v_k\right]_{\substack{h=0,\dots,M\ h\neq k}}$ *and*  $I^R = I^{R,k} = I^{R,l} \forall k, l$ .

*Let*  $e_1, \ldots, e_D$  *be the vectors of the standard basis of*  $\mathbb{R}^D$ . Then the orthogonal projection  $p_R: \mathbb{R}^D \longrightarrow \mathbb{R}^R$ ,  $p_R(x) = \begin{bmatrix} e_i \end{bmatrix}^T$  $\int_{i\in I^R}$  *x*, *is such that, with*  $v_h^R = p_R(v_h)$  ∀ *h*,

$$
dim(Conv(v_0^R,\ldots,v_M^R))=R
$$

*and*

$$
\forall x^R \in Conv(v_0^R, \ldots, v_M^R) \exists! x \in Conv(v_0, \ldots, v_M) \ s.t. \ p_R(x) = x^R.
$$

See [A](#page-22-0)ppendix A for the proof. Also note that if  $R = M < D$ , i.e. the  $R + 1$  vectors are affinely independent, then the projected vectors  $p_R(v_0), \ldots, p_R(v_R)$  are affinely independent as well. Obviously, if  $R = D$ ,  $p_R$  is the identity function.

For our aims, the core of Lemma [1.1](#page-3-0) is that, for a collection of vectors  $v_0, \ldots, v_M \in$  $\mathbb{R}^D$  such that dim  $(\text{Conv}(v_0, \ldots, v_M)) = R$ , there exists an orthogonal projection,  $p_R$ , onto an  $R$ -dimensional space such that to each element of this projection of the convex hull,  $x^R \in Conv(v_0^R, \ldots, v_M^R)$ , corresponds (one and) only one element of the original convex hull,  $x \in \text{Conv}(v_0, \ldots, v_M).$ 

### **2. Minimal random motions**

A random motion in  $\mathbb{R}^D$  needs  $D+1$  affinely independent velocities in order to have a  $D$ dimensional state space. Therefore, we say that the *D*-dimensional stochastic motion *X*, defined as in [\(1.1\)](#page-2-0), is *minimal* if it moves with  $D + 1$  affinely independent velocities  $v_0, \ldots, v_D \in \mathbb{R}^D$ .

The support of the position  $X(t)$ ,  $t > 0$ , of a minimal random motion is given in [\(1.2\)](#page-2-1); it can be decomposed as follows:

<span id="page-3-1"></span>
$$
Supp(X(t)) = \bigcup_{H=0}^{D} \bigcup_{i \in C_{H+1}^{[0,...,D]}} \widehat{Conv}(v_{i_0}t, \dots, v_{i_H}t),
$$
\n(2.1)

where  $C_k^S$  denotes the combinations of *k* elements from the set *S*, with  $0 \le k \le |S| < \infty$ . Since *X* is a minimal motion, it lies on each convex hull appearing in [\(2.1\)](#page-3-1) if and only if it moves with all, and only, the corresponding velocities in the time interval [0, *t*].

Let us denote by  $T_{(h)} = \{T_{(h)}(t)\}_{t\geq 0}$  the stochastic process describing, for each  $t \geq 0$ , the random time that the process *X* spends moving with velocity  $v_h$  in the time interval [0, *t*],

with  $h = 0, \ldots, D$ . In formula,  $T_{(h)}(t) = \int_0^t \mathbb{1}(V(s) = v_h) \, ds$ ,  $\forall t, h$ . Furthermore, we denote by  $T_{\theta} = (T_{(0)}, \ldots, T_{(D)})$  the vector process describing the times spent by the motion moving with each velocity, and by  $T_{(k^-)} = (T_{(0)}, \ldots, T_{(k-1)}, T_{(k+1)}, \ldots, T_{(D)})$  the vector process describing the time that *X* spends with each velocity except for the *k*th one,  $k = 0, \ldots, D$ . In the next proposition we express *X* as an affine function of  $T_{(k^-)}$ .

<span id="page-4-2"></span>**Proposition 2.1.** *Let*  $X = \{X(t)\}_{t \geq 0}$  *be a finite-velocity random motion in*  $\mathbb{R}^D$  *moving with velocities*  $v_0, \ldots, v_D$ . *For*  $k = 0, \ldots, D$ ,

<span id="page-4-0"></span>
$$
X(t) = g_k(t, T_{(k-)}(t)) = v_k t + \begin{bmatrix} v_h - v_k \end{bmatrix}_{\substack{h=0,\dots,D\\ h \neq k}} T_{(k-)}(t), \quad t \ge 0,
$$
\n(2.2)

 $\nu h = \left[ v_h - v_k \right]_{\substack{h=0,\ldots,D\ h \neq k}}$ *denotes the matrix with columns*  $v_h - v_k$ *,*  $h \neq k$ *. Furthermore, for fixed*  $t \geq 0$ ,  $g_k$  *is bijective for all k if and only if*  $v_0, \ldots, v_D$  *are affinely independent (i.e. if and only if X is minimal).*

Hereafter we will omit the direct dependence of  $g_k$  (and the similar functions) on the time variable *t*, since we are always working with fixed  $t \geq 0$ ; thus, we will more briefly write, for instance,  $X(t) = g_k(T_{(k-)}(t)).$ 

*Proof.* Fix  $t \ge 0$ . By definition  $\sum_{h=0}^{D} T_{(h)}(t) = t$  a.s., and  $X(t) = \sum_{h=0}^{D} v_h T_{(h)}(t)$ ; therefore, for each  $k = 0, \ldots, D$ , we have

$$
X(t) = \sum_{h \neq k} (v_h - v_k) T_{(h)}(t) + v_k t,
$$

which in matrix form is  $(2.2)$ .

The matrix  $\left[v_h - v_k\right]$ *h*≠*k* is invertible for all *k* if and only if all the differences *v<sub>h</sub>* − *v<sub>k</sub>*, *h*  $\neq$  *k*, are linearly independent for all *k*, and thus if and only if the velocities  $v_0, \ldots, v_D$  are affinely independent.

<span id="page-4-3"></span>**Remark 2.1.** Another useful representation of a finite-velocity random motion *X* is, with  $t \ge 0$ ,

<span id="page-4-1"></span>
$$
\begin{pmatrix} t \\ X(t) \end{pmatrix} = g\left(T_{\theta}(t)\right) = \begin{pmatrix} 1^T \\ V \end{pmatrix} T_{\theta}(t),\tag{2.3}
$$

and *g* is bijective if and only if *X* is minimal (indeed,  $\int_{-\infty}^{1}$ V  $\setminus$ is invertible if and only if the velocities, the columns of V, are affinely independent). In this case we write

$$
T_{\theta}(t) = g^{-1}(t, X(t)) = \left(g_{\cdot,h}^{-1}(t, X(t))\right)_{h=0,\dots,D} = \begin{pmatrix} 1^T \\ V \end{pmatrix}^{-1} \begin{pmatrix} t \\ X(t) \end{pmatrix}.
$$

Now, for  $k = 0, \ldots, D$ , we write the inverse of [\(2.2\)](#page-4-0) as

$$
T_{(k^-)}(t) = g_k^{-1}(X(t)) = \left(g_{k,h}^{-1}(X(t))\right)_{h \neq k} = \left[v_h - v_k\right]_{h \neq k}^{-1}(X(t) - v_k t) = \left(g_{\cdot,h}^{-1}(t, X(t))\right)_{h \neq k}.
$$
\n(2.4)

 $\Diamond$ 

The notation  $(2.4)$  is going to be useful below. Clearly,

$$
t - \sum_{h \neq k} g_{\cdot,h}^{-1}(t, X(t)) = t - \sum_{h \neq k} T_{(h)}(t) = T_{(k)}(t) = g_{\cdot,k}^{-1}(t, X(t)).
$$

<span id="page-5-0"></span>**Theorem 2.1.** *Let*  $X = \{X(t)\}_{t>0}$  *be a minimal random motion moving with velocities*  $v_0, \ldots, v_D \in \mathbb{R}^D$  *and whose displacements are governed by a point process N. Let*  $X' =$  ${X'(t)}_{t\geq0}$  *be a random motion with velocities*  $v'_0, \ldots, v'_D$  *whose displacements are governed by a point process N'*  $\stackrel{d}{=}$  N and with the same rule for changes of velocity as X. Then, *for*  $t > 0$ *,* 

$$
X'(t) \stackrel{d}{=} f(X(t)) = \mathbf{V}' \begin{pmatrix} 1^T \\ \mathbf{V} \end{pmatrix}^{-1} \begin{pmatrix} t \\ X(t) \end{pmatrix},
$$
\n(2.5)

where  $V' = (v'_0, \ldots, v'_D)$ . Furthermore, f is bijective if and only if X' is minimal.

*Proof.* Fix  $t \ge 0$ . Since the changes of velocity of *X* and *X'* have the same rule and  $N(t) \stackrel{d}{=}$ *N'*(*t*) ∀ *t*, we have  $T_{(h)}(t) \stackrel{d}{=} T'_{(h)}(t)$  ∀ *h*, *t*. For  $k = 0, ..., D$ ,

$$
X'(t) = \mathbf{V}'T'_{\Theta}(t) \stackrel{d}{=} \mathbf{V}' \begin{pmatrix} 1^T \\ \mathbf{V} \end{pmatrix}^{-1} \begin{pmatrix} t \\ X(t) \end{pmatrix}.
$$

Now, for Proposition [2.1,](#page-4-2) for every  $k$ ,  $X(t)$  is in bijective correspondence with  $T_{(k^-)}(t)$  and then with  $T'_{(k^-)}(t)$  (in distribution). Therefore  $X(t)$  is in bijective correspondence with  $X'(t)$  if and only if  $X'(t)$  is in bijective correspondence with  $T'_{(k^-)}(t)$ , so if  $X'$  is minimal.  $□$ 

<span id="page-5-2"></span>**Remark 2.2.** (*Canonical motion*.) Theorem [2.1](#page-5-0) states that all minimal random motions in R*D*, with displacements and changes of directions governed by the same probabilistic rules, are in bijective correspondence (in distribution). Therefore, it is useful to introduce a minimal motion  $X = \{X(t)\}_{t \geq 0}$  moving with the *canonical* velocities of  $\mathbb{R}^D$ ,  $e_0 = 0, e_1, \ldots, e_D$ , where  $e_h$  is the *h*th vector of the standard basis of  $\mathbb{R}^D$ . At time  $t \geq 0$ , the support of the position *X*(*t*) is given by the convex set  $\{x \in \mathbb{R}^D : x \ge 0, \sum_{i=1}^D x_i \le t\}$ . Put  $t \ge 0$  and  $\mathbf{E} = (e_0 \cdots e_D) = (0 I_D)$ , the matrix having the canonical velocities as columns. In view of Remark [2.1,](#page-4-3) the canonical motion can

be expressed as  $\begin{pmatrix} t \\ t \end{pmatrix}$ *X*(*t*)  $\setminus$ =  $\sqrt{1^T}$ E  $\setminus$  $T_{\Theta}(t)$  and

<span id="page-5-1"></span>
$$
T_0(t) = g^{-1}(t, X(t)) = \begin{pmatrix} 1 & -1^T \ 0 & I_D \end{pmatrix} \begin{pmatrix} t \\ X(t) \end{pmatrix} = \begin{pmatrix} t - \sum_{j=1}^D X_j(t) \\ X_1(t) \\ \vdots \\ X_D(t) \end{pmatrix}.
$$
 (2.6)

Keeping in mind the notation [\(2.4\)](#page-4-1), the inverse functions  $g_k^{-1}$ ,  $k = 0, \ldots, D$ , are given by [\(2.6\)](#page-5-1) excluding the  $(k + 1)$ th term (which concerns the time  $T_{(k)}(t)$ ).

Finally, if *Y* is a random motion with affinely independent velocities  $v_0, \ldots, v_D$ , under the hypotheses of Theorem [2.1,](#page-5-0) we can write

<span id="page-5-3"></span>
$$
Y(t) \stackrel{d}{=} v_0 t + \left[ v_h - v_0 \right]_{h=1,\dots,D} X(t), \quad t \ge 0. \tag{2.7}
$$

#### **2.1. Probability law of the position of minimal motions**

In order to study the probability law of the position  $X(t)$ ,  $t \ge 0$ , of a minimal random motion in  $\mathbb{R}^D$ , we need to make some hypotheses on the probabilistic mechanisms of the process, i.e. on the velocity process *V* and the associated point process *N*, which governs the displacements.

(H1) The changes of velocity, which can only occur when the point process *N* records an event, depend only on the previously selected velocities (but not on the moment of the switches or the time spent with each velocity). Therefore, we assume that, for  $t > 0$ ,

<span id="page-6-0"></span>
$$
\mathbb{P}\{V(t+dt) = v_h \mid N(t, t+dt) = 1, \mathcal{F}_t\}
$$
  
= 
$$
\mathbb{P}\{V(t+dt) = v_h \mid N(t, t+dt) = 1, V(T_j), j = 0, ..., N(t)\},
$$
 (2.8)

where  $T_0 = 0$  a.s. and  $T_1, \ldots, T_{N(t)}$  are the arrival times of the process N (see [\(1.1\)](#page-2-0)). Note that if  $N$  and  $V$  are Markovian, then the conditional event in  $(2.8)$  can be reduced to  $\{N(t, t + dt) = 1, V(T_{N(t)})\}$ , and  $(X, V)$  is Markovian (see for instance [\[6\]](#page-29-21)).

Now, for  $t \ge 0$ ,  $h = 0, \ldots, D$ , we define the processes  $N_h(t) = |0 \le j \le N(t): V(T_j) =$  $\{v_h\}$  counting the number of displacements with velocity  $v_h$  in the time interval [0, *t*]. Clearly  $\sum_{h=0}^{D} N_h(t) = N(t) + 1$  a.s. (because the displacements are one more than the switches since the initial movement). Let us also define the random vector  $C_{N(t)+1} =$  $(C_{N(t)+1,0},\ldots,C_{N(t)+1,D}) \in \mathbb{N}_0^{D+1}$ , which provides the allocation of the selected velocities in the  $N(t) + 1$  displacements.

For  $t > 0$  and  $n_0, \ldots, n_D$ , we have the following relationship:

$$
\left\{\bigcap_{h=0}^{D} N_h(t) = n_h\right\} \iff \{N(t) = n_0 + \dots + n_D - 1, \ C_{n_0 + \dots + n_D} = (n_0, \dots, n_D)\}.
$$

**Example 2.1.** (*Complete random motions.*) Consider the motion in Example [1.2](#page-2-2) with  $p_{j,h} =$  $p_h = \mathbb{P}{V(0) = v_h} > 0$ , *j*, *h* = 0, ..., *D*, so that the probability of selecting a velocity does not depend on the current velocity. Then, for every *t*,  $C_{N(t)+1} \sim Multinomial(N(t) + 1, p =$  $(p_0, \ldots, p_D)$ . The contract of the contract of the contract of  $\phi$ 

(H2) The times of the displacements along different velocities are independent; i.e. the waiting times  ${W_n}_{n \in \mathbb{N}_0}$  (see [\(1.1\)](#page-2-0)) are independent if they concern different velocities. For each  $h = 0, \ldots, D$ , let  $\left\{W_n^{(h)}\right\}_{n \in \mathbb{N}}$  be the sequence of the times related to the displacements with velocity  $v_h$ . Specifically,  $W_n^{(h)}$  denotes the time of the *n*th movement with velocity  $v_h$ , and  $W_n^{(h)}$ ,  $W_m^{(k)}$  are independent if  $h \neq k$ ,  $\forall m, n$ . Let  $N_{(h)} = \{N_{(h)}(s)\}_{s \geq 0}$  be the associated point process, i.e. such that  $N_{(h)}(s) = \max\{n : \sum_{i=1}^{n} W_i^{(h)} \leq s\}$ ,  $\forall s$ . Then  $N_{(0)}, \ldots, N_{(D)}$  are independent counting processes.

From the hypothesis (H1) we have that the random times  $W_n^{(h)}$  are independent of the allocation of the velocities among the steps, i.e. for measurable  $A \subset \mathbb{R}$ ,

<span id="page-6-1"></span>
$$
\mathbb{P}\Big\{W_m^{(h)}\in A,\ V(T_n)=\nu_h,\ C_{n+1,h}=m\Big\}=\mathbb{P}\Big\{W_m^{(h)}\in A\Big\}\ \mathbb{P}\{V(T_n)=\nu_h,\ C_{n+1,h}=m\}\tag{2.9}
$$

for each  $m \le n \in \mathbb{N}$ ,  $h = 0, \ldots, D$ . In words, the first member of [\(2.9\)](#page-6-1) concerns the *m*th displacement with speed  $v_h$  to be in *A*, also requiring that this is the  $(n + 1)$ th movement of the motion (counting the initial one as well).

Below we use the following notation: for any suitable function *g* and any suitable absolutely continuous random variable *X* with probability density  $f_X$ , we write  $\mathbb{P}{X \in d g(x)}$  =  $f_X(g(x))$   $|J_g(x)|$  dx, where  $J_g$  is the Jacobian matrix of *g*.

<span id="page-7-0"></span>**Theorem 2.2.** *Let X be a minimal finite-velocity random motion in* R*<sup>D</sup> satisfying (H1)–(H2).*  $For t \geq 0, x \in \mathit{Supp}(X(t)), n_0, \ldots, n_D \in \mathbb{N}, and k = 0, \ldots, D, we have$ 

<span id="page-7-4"></span>
$$
\mathbb{P}\left\{X(t) \in \text{d}x, \bigcap_{h=0}^{D} \{N_h(t) = n_h\}, \ V(t) = v_k\right\}
$$
 (2.10)

$$
= \prod_{\substack{h=0 \ h\neq k}}^D f_{\sum_{j=1}^{n_h} W_j^{(h)}}(g_{k,h}^{-1}(x)) dx \left| [v_h - v_k]_{h\neq k} \right|^{-1} \mathbb{P} \left\{ N_{(k)} \left( t - \sum_{\substack{h=0 \ h\neq k}}^D g_{k,h}^{-1}(x) \right) = n_k - 1 \right\}
$$
  
×  $\mathbb{P} \{ C_{n_0 + \dots + n_D} = (n_0, \dots, n_D), V(t) = v_k \},$ 

*where*  $g_k^{-1}$  *is given in* [\(2.4\)](#page-4-1)*.* 

Theorem [2.2](#page-7-0) provides a general formula for the distribution of the position of the minimal motion at time *t* joint with the number of displacements for each velocity in the interval [0, *t*] and the current direction (meaning at time *t*).

*Proof.* Fix  $k = 0, \ldots, D$  and  $t > 0$ . We have

<span id="page-7-1"></span>
$$
\mathbb{P}\left\{X(t) \in \mathrm{d}x, \bigcap_{h=0}^{D} \{N_h(t) = n_h\}, V(t) = v_k\right\}
$$
\n
$$
= \mathbb{P}\left\{X(t) \in \mathrm{d}x, \bigcap_{h=0}^{D} \{N_h(t) = n_h\}, \sum_{h=0}^{D} T_{(h)}(t) = t, V(t) = v_k\right\}
$$
\n
$$
= \mathbb{P}\left\{X(t) \in \mathrm{d}x, \bigcap_{\substack{h=0\\h \neq k}}^{D} \{T_{(h)}(t) = \sum_{j=1}^{n_h} W_j^{(h)}\}, N_{(k)}\big(T_{(k)}(t)\big) = n_k - 1,\tag{2.11}
$$

<span id="page-7-3"></span><span id="page-7-2"></span>
$$
C_{n_0+\cdots+n_D} = (n_0, \ldots, n_D), \ V(t) = v_k
$$
\n
$$
= \mathbb{P}\left\{T_{(k-)}(t) \in d g_k^{-1}(x), \bigcap_{h \neq k} \left\{T_{(h)}(t) = \sum_{j=1}^{n_h} W_j^{(h)}\right\}, N_{(k)}(T_{(k)}(t)) = n_k - 1, (2.12)
$$
\n
$$
C_{n_0+\cdots+n_D} = (n_0, \ldots, n_D), \ V(t) = v_k\right\}
$$
\n
$$
= \mathbb{P}\left\{\left(\sum_{j=1}^{n_h} W_j^{(h)}\right)_{h \neq k} \in d g_k^{-1}(x), N_{(k)}\left(t - \sum_{h \neq k} g_{k,h}^{-1}(x)\right) = n_k - 1\right\}
$$
\n
$$
\times \mathbb{P}\left\{C_{n_0+\cdots+n_D} = (n_0, \ldots, n_D), \ V(t) = v_k\right\}.
$$
\n(2.13)

The step  $(2.11)$  follows from considering that, in the time interval  $[0, t]$ , the motion performs *n<sub>h</sub>* steps with velocity  $v_h$ ,  $\forall h$ , and it has  $V(t) = v_k$  if and only if the total amount of time spent with  $v_h$  is given by the sum of the  $n_h$  waiting times  $W_j^{(h)}$ , for  $h \neq k$ , and if the point process  $N_{(k)}$  is waiting for the *n<sub>k</sub>*th event at the time  $T_{(k)}(t)$  (because  $V(t) = v_k$ , so the motion has completed  $n_k - 1$  displacements with velocity  $v_k$  and is now performing the  $n_k$ th). Finally, the event  $C_{n_0+\cdots+n_D} = (n_0,\ldots,n_D)$  pertains to the randomness in the allocation of the velocities.

The steps [\(2.12\)](#page-7-2) and [\(2.13\)](#page-7-3) respectively follow from considering Equation [\(2.2\)](#page-4-0) and the independence of the waiting times  $W_j^{(h)}$  from the allocation of the displacements, for all *j*, *h*; see [\(2.9\)](#page-6-1).

Note that  $(2.13)$  holds for a random motion where the hypothesis  $(H2)$  (concerning the independence of the displacements with different velocities) is not assumed. By taking into account (H2) and using [\(2.4\)](#page-4-1), we see that [\(2.13\)](#page-7-3) coincides with [\(2.10\)](#page-7-4).

We point out that if  $x \rightarrow \overline{x} \in \partial \text{Supp}(X(t))$ , then for at least one  $l \in \{0, \ldots, D\}$ ,  $T_{(l)}(t) \rightarrow 0$ . Therefore, in [\(2.10\)](#page-7-4) either  $g_{k,h}^{-1}(x) = T_{(h)}(t) \longrightarrow 0$  for at least one  $h \neq k$  or  $t - \sum_{h \neq k} g_{k,h}^{-1}(x) =$  $T_{(k)}(t) \longrightarrow 0$ . In light of this observation, for *x* that tends to the boundary of the support, the probability [\(2.10\)](#page-7-4) goes to 0 if the density function related to the time  $T_{(l)}(t)$  (representing the time which converges to 0) tends to 0. See Examples [2.2](#page-8-0) and [2.3](#page-11-0) for more details.

<span id="page-8-2"></span>**Remark 2.3.** (*Canonical motion.*) If *X* is a canonical minimal random motion in  $\mathbb{R}^D$  (see Remark [2.2\)](#page-5-2), then, with  $(2.6)$  in hand, we immediately have the corresponding probability [\(2.10\)](#page-7-4) by considering

$$
g_{\cdot,h}^{-1}(x) = \begin{cases} t - \sum_{i=1}^{D} x_i, & \text{if } h = 0, \\ x_h, & \text{if } h \neq 0, \end{cases}
$$

and the Jacobian determinant is equal to 1.

<span id="page-8-0"></span>**Example 2.2.** (*Cyclic motions*.) Let *X* be a cyclic (see Example [1.1\)](#page-2-3) minimal motion with velocities  $v_0, \ldots, v_D \in \mathbb{R}^D$ , and let  $v_{h+k(D+1)} = v_h$ ,  $h = 0, \ldots, D$ ,  $k \in \mathbb{Z}$ . Let *N* be the point process governing the displacements of *X*; then for fixed  $t > 0$ , the knowledge of  $N(t)$  and  $V(t)$ is sufficient to determine  $N_h(t)$  for all *h*. Let  $\mathbb{P}{V(0) = v_h} = p_h > 0$  and  $p_{h+k(D+1)} = p_h$ , for all *h* and  $k \in \mathbb{Z}$ .

Let  $n \in \mathbb{N}$  and  $k = 0, \ldots, D$ . With  $j = 1, \ldots, D$ , if the motion performs  $n(D + 1) + j$  displacements in [0, *t*], i.e.  $N(t) = n(D + 1) + j - 1$ , and  $V(t) = v_k$ , then  $n + 1$  displacements occur for each of the velocities  $v_{k-j+1}, \ldots, v_k$  (the  $(n+1)$ th displacement with velocity  $v_k$  is not complete), and *n* displacements occur for each of the other velocities *vk*<sup>+</sup>1,..., *vk*<sup>+</sup>1+*D*−*j*. On

the other hand, if *j* = 0, then each velocity is taken *n* times. Hence, for  $x \in \text{Supp}(X(t))$ ,

$$
\mathbb{P}\{X(t) \in dx\} = \sum_{j=0}^{D} \sum_{n=1}^{\infty} \sum_{k=0}^{D} \mathbb{P}\{X(t) \in dx, \ N(t) = n(D+1) + j - 1, \ V(t) = v_k\}
$$
\n
$$
= \sum_{j=0}^{D} \sum_{k=0}^{\infty} \sum_{n=1}^{\infty} \mathbb{P}\left\{X(t) \in dx, \ \bigcap_{h=k-j+1}^{k} \{N_h(t) = n+1\}, \ \bigcap_{h=k+1}^{k+1+D-j} \{N_h(t) = n\}, \ V(t) = v_k\right\},\tag{2.14}
$$

where the probability appearing in  $(2.14)$  can be derived from  $(2.10)$  (note that, for  $j = 0$ , we have  $\mathbb{P}\{C_{n(D+1)} = (n, \ldots, n), V(t) = v_k\} = \mathbb{P}\{V(0) = v_{k+1}\} = p_{k+1}$ , and for  $j = 1, \ldots, D$ ,

<span id="page-8-1"></span>
$$
\Diamond
$$

with  $n_h = n + 1$  if  $h = k - j + 1, \ldots, k$  and  $n_h = n$  if  $h = k + 1, \ldots, k + 1 + D - j$ , we have  $\mathbb{P}\{C_{n(D+1)+j}=(n_0,\ldots,n_D), V(t)=v_k\}=\mathbb{P}\{V(0)=v_{k-j+1}\}=p_{k-j+1}).$ 

Now we assume *X* is a cyclic canonical motion and we derive the probabilities appearing in [\(2.14\)](#page-8-1). For *t* ≥ 0, in light of Theorem [2.2](#page-7-0) and Remark [2.3,](#page-8-2) by setting  $x_0 = t - \sum_{i=1}^{D} x_i$ , we readily arrive at the following distributions, for

<span id="page-9-0"></span>
$$
x \in \text{Supp}(X(t)) = \left\{ x \in \mathbb{R}^D : x > 0, \sum_{i=1}^D x_i < t \right\}
$$

and  $k = 0, ..., D$ . For  $j = 1, ..., D$ ,  $_{\mathbb{P}}\{$ *X*(*t*) ∈ d*x*,  $\begin{bmatrix} \infty \\ \infty \end{bmatrix}$ *n*=1  $N(t) = n(D+1) + j - 1$ ,  $V(t) = e_k$  $\mathbf{I}$ / d*x*  $=\sum^{\infty}$ *n*=1  $\mathbb{P}{V(0) = v_{k-j+1}}$ 

$$
\times \left( \prod_{h=k-j+1}^{k-1} f_{\sum_{i=1}^{n+1} W_i^{(h)}(x_h)} \right) \mathbb{P} \{ N_{(k)}(x_k) = n \} \left( \prod_{h=k+1}^{k+1+D-j} f_{\sum_{i=1}^n W_i^{(h)}(x_h)} \right), \tag{2.15}
$$

and for  $j = 0$ ,

<span id="page-9-1"></span>
$$
\mathbb{P}\left\{X(t) \in \mathrm{d}x, \bigcup_{n=1}^{\infty} N(t) = n(D+1) - 1, \ V(t) = e_k\right\} / \mathrm{d}x
$$
\n
$$
= \sum_{n=1}^{\infty} \mathbb{P}\{V(0) = v_{k+1}\} \left(\prod_{\substack{h=0 \ h \neq k}}^{D} f_{\sum_{i=1}^{n} W_i^{(h)}}(x_h)\right) \mathbb{P}\{N(k)(x_k) = n-1\}.
$$
\n(2.16)

We point out that thanks to the relationship  $(2.7)$ , from the probabilities  $(2.15)$  and  $(2.16)$ we immediately obtain the distribution of the position of any *D*-dimensional cyclic minimal random motion, *Y*, moving with velocities  $v_0, \ldots, v_D$  and governed by a Poisson-type process  $N_Y \stackrel{d}{=} N$ .

<span id="page-9-2"></span>We now present explicit results for two different types of point processes for *N*.

(*a*) *Homogeneous Poisson-type process.* Assume *N* is a Poisson-type process such that  $W_i^{(h)} \sim Exp(\lambda_h)$ ,  $i \in \mathbb{N}$ ,  $h = 0, \ldots, D$ . Then the formula [\(2.15\)](#page-9-0) turns into

$$
\mathbb{P}\left\{X(t) \in \mathrm{d}x, \bigcup_{n=1}^{\infty} N(t) = n(D+1) + j - 1, V(t) = e_k\right\} / \mathrm{d}x
$$
\n
$$
= \sum_{n=1}^{\infty} p_{k-j+1} \Biggl(\prod_{h=k-j+1}^{k-1} \frac{\lambda_h^{n+1} x_h^n e^{-\lambda_h x_h}}{n!} \Biggr) \frac{e^{-\lambda_k x_k} (\lambda_k x_k)^n}{n!} \Biggl(\prod_{h=k+1}^{k+1+D-j} \frac{\lambda_h^n x_h^{n-1} e^{-\lambda_h x_h}}{(n-1)!} \Biggr)
$$
\n
$$
= e^{-\sum_{h=0}^{D} \lambda_h x_h} \Biggl(\prod_{h=0}^{D} \lambda_h\Biggr) p_{k-j+1} x_k \Biggl(\prod_{h=k-j+1}^{k-1} \lambda_h x_h\Biggr) \tilde{I}_{j,D+1} \Biggl((D+1)^{D+1} \Biggl(\prod_{h=0}^{D} \lambda_h x_h\Biggr), \quad (2.17)
$$

where

<span id="page-10-0"></span>
$$
\tilde{I}_{\alpha,\nu}(z) = \sum_{n=0}^{\infty} \left(\frac{z}{\nu}\right)^{n\nu} \frac{1}{n!^{\nu-\alpha}(n+1)!^{\alpha}},
$$

with  $0 \le \alpha \le \nu$ ,  $z \in \mathbb{C}$ , is a Bessel-type function. Similarly, the formula [\(2.16\)](#page-9-1) reads

$$
\mathbb{P}\left\{X(t) \in \mathrm{d}x, \bigcup_{n=1}^{\infty} N(t) = n(D+1) - 1, \ V(t) = e_k\right\} / \mathrm{d}x
$$

$$
= e^{-\sum_{h=0}^{D} \lambda_h x_h} p_{k+1} \left(\prod_{\substack{h=0 \ h \neq k}}^{D} \lambda_h\right) \tilde{I}_{0,D+1} \left((D+1)^{D+1} \sqrt{\prod_{h=0}^{D} \lambda_h x_h}\right). \tag{2.18}
$$

Note that if  $x \longrightarrow \bar{x} \in \partial \text{Supp}(X(t))$ , then there exists  $l \in \{0, \ldots, D\}$  such that the total time spent with velocity *l* goes to 0, meaning that  $T_{(I)}(t) = x_I \rightarrow 0$ . With this in hand, we observe that the probability  $(2.18)$  reduces to

$$
e^{-\sum_{h \notin I_0} \lambda_h x_h} p_{k+1} \left( \prod_{h \neq k} \lambda_h \right),
$$

where  $I_0 \subset \{0, \ldots, D\}$  denotes the set of indexes of the times going to 0. Hence, for all *k*, the distribution [\(2.18\)](#page-10-0) never converges to 0 for *x* tending to the boundary of the support. Intuitively, this follows because the probability concerns the event where every velocity is taken exactly *n* times, with  $n \geq 1$ , and therefore it includes also the case  $n = 1$ , where the random times have exponential density function which is right-continuous and strictly positive in 0.

On the other hand, [\(2.17\)](#page-9-2) can converge to 0. In fact, for fixed *j*, if  $D + 1 - j$  times  $T_{(h)}(t) =$  $x_h$  tends to 0, then for each  $k$ , at least one of these times appears in

$$
x_k \left( \prod_{h=k-j+1}^{k-1} \lambda_h x_h \right),
$$

leading it to 0. This follows because the event in the probability does not include the case where each velocity whose time converges to 0 is taken just once.

(*b*) *Geometric counting process.* Assume that  $N_{(h)}$ ,  $h = 0, \ldots, D$ , are independent geometric counting processes with parameter  $\lambda_h > 0$ ; then the waiting times  $W_i^{(h)}$ ,  $W_j^{(k)}$  are independent for all  $h \neq k$ , and they are dependent for  $h = k$  and  $i \neq j$ . In particular, if *M* is a geometric counting process with parameter  $\lambda > 0$ , then

<span id="page-10-1"></span>
$$
\mathbb{P}\{M(s+t) - M(s) = n\} = \frac{1}{1+\lambda t} \left(\frac{\lambda t}{1+\lambda t}\right)^n, \quad s, t \ge 0, \ n \in \mathbb{N}_0,
$$
\n(2.19)

and its arrival times have a modified Pareto (Type I) distribution, that is,

<span id="page-10-2"></span>
$$
\mathbb{P}\{T_n \in dt\} = \frac{n\lambda}{(1+\lambda t)^2} \left(\frac{\lambda t}{1+\lambda t}\right)^{n-1} dt, \quad t \ge 0, \ n \in \mathbb{N}.
$$
 (2.20)

We refer to [\[10,](#page-29-18) [15\]](#page-29-19) for further details about geometric counting processes for random motions and to [\[13\]](#page-29-22) for a complete overview of mixed Poisson processes.

<span id="page-11-1"></span>In light of  $(2.19)$  and  $(2.20)$ , the formula  $(2.15)$  turns into

$$
\mathbb{P}\left\{X(t) \in \mathrm{d}x, \sum_{n=1}^{\infty} N(t) = n(D+1) + j - 1, V(t) = e_k\right\} / \mathrm{d}x
$$
\n
$$
= \frac{p_{k-j+1}}{1 + \lambda_k x_k} \left(\prod_{h=k-j+1}^k \frac{\lambda_h x_h}{1 + \lambda_h x_h}\right) \left(\prod_{\substack{h=0 \ h \neq k}}^D \frac{\lambda_h}{(1 + \lambda_h x_h)^2}\right) \sum_{n=1}^{\infty} n^{D+1-j} (n+1)^{j-1} \prod_{h=0}^D \left(\frac{\lambda_h x_h}{1 + \lambda_h x_h}\right)^{n-1} .
$$
\n(2.21)

Similarly, the formula [\(2.16\)](#page-9-1) reads

<span id="page-11-2"></span>
$$
\mathbb{P}\left\{X(t)\in\mathrm{d}x,\ \bigcup_{n=1}^{\infty}N(t)=n(D+1)-1,\ V(t)=e_k\right\}/\mathrm{d}x
$$
\n
$$
=\frac{p_{k+1}}{1+\lambda_kx_k}\left(\prod_{\substack{h=0\\h\neq k}}^{D}\frac{\lambda_h}{(1+\lambda_hx_h)^2}\right)\sum_{n=0}^{\infty}(n+1)^D\prod_{h=0}^{D}\left(\frac{\lambda_hx_h}{1+\lambda_hx_h}\right)^n.\tag{2.22}
$$

Finally, for  $x \longrightarrow \bar{x} \in \partial \text{Supp}(X(t))$ , similar considerations to those in (*a*) apply.

We point out that from the above formulas it is easy to obtain several results appearing in previous papers such as [\[10,](#page-29-18) [15,](#page-29-19) [21,](#page-29-13) [22,](#page-29-12) [28\]](#page-30-1). For instance, if we consider  $\lambda_h = \lambda > 0 \forall h$  and  $k = j - 1$ , then [\(2.17\)](#page-9-2) coincides with the distribution in [\[21,](#page-29-13) Section 4.4]; with *D* = 1, from the formulas  $(2.21)$  and  $(2.22)$  it is straightforward to derive the elegant distributions in [\[10,](#page-29-18) Theorem 1] (consider  $k = j - 1 = 0$  in [\(2.21\)](#page-11-1) and  $k = D = 1$  in [\(2.22\)](#page-11-2)).

For further details about the cyclic motions we refer to [\[21,](#page-29-13) [22\]](#page-29-12).

<span id="page-11-0"></span>**Example 2.3.** (*Complete motions.*) Let *X* be a *D*-dimensional complete canonical (minimal) random motion with  $\mathbb{P}{V(0) = e_h} = \mathbb{P}{V(t + dt) = e_h | V(t) = e_i, N(t, t + dt) = 1}$  $p_h > 0$  for each *j*,  $h = 0, \ldots, D$ , and governed by a homogeneous Poisson process with rate  $\lambda > 0$ . Now, with  $t \ge 0$ , in light of Remark [2.3,](#page-8-2) by setting  $x_0 = t - \sum_{j=0}^{D} x_j$  and using

Theorem [2.2,](#page-7-0) we readily arrive at the following, for  $x \in \text{Supp}(X(t))$ , integers  $n_0, \ldots, n_D \ge 1$ , and  $k = 0, \ldots, D$ :

<span id="page-11-3"></span>
$$
\mathbb{P}\left\{X(t) \in \mathrm{d}x, \bigcap_{h=0}^{D} \{N_h(t) = n_h\}, V(t) = e_k\right\} / \mathrm{d}x
$$
\n
$$
= \left(\prod_{\substack{h=0 \ h\neq k}}^{D} \frac{\lambda^{n_h} x_h^{n_h - 1} e^{-\lambda x_h}}{(n_h - 1)!}\right) \frac{e^{-\lambda x_k} (\lambda x_k)^{n_k - 1}}{(n_k - 1)!} \left(n_0, \dots, n_{k-1}, n_k - 1, n_{k+1}, \dots, n_D\right) \prod_{h=0}^{D} p_h^{n_h}
$$
\n
$$
= \frac{e^{-\lambda t}}{\lambda} \left(\sum_{h=0}^{D} n_h - 1\right)! n_k \prod_{h=0}^{D} \frac{(\lambda p_h)^{n_h} x_h^{n_h - 1}}{(n_h - 1)! n_h!}. \tag{2.23}
$$

Then it is straightforward to see that

$$
\mathbb{P}\left\{X(t) \in \mathrm{d}x, \, \bigcap_{h=0}^{D} \{N_h(t) = n_h\}\right\} / \, \mathrm{d}x = \frac{e^{-\lambda t}}{\lambda} \left(\sum_{h=0}^{D} n_h\right)! \, \prod_{h=0}^{D} \frac{(\lambda p_h)^{n_h} x_h^{n_h - 1}}{(n_h - 1)! \, n_h!}. \tag{2.24}
$$

Finally,

<span id="page-12-1"></span>
$$
\mathbb{P}\{X(t) \in dx\} / dx = \frac{e^{-\lambda t}}{\lambda} \sum_{n_0, \dots, n_D \ge 1} \left( \sum_{h=0}^{D} n_h \right)! \prod_{h=0}^{D} \frac{(\lambda p_h)^{n_h} x_h^{n_h - 1}}{(n_h - 1)! n_h!}
$$
(2.25)  

$$
= \frac{e^{-\lambda t}}{\lambda} \sum_{m_0, \dots, m_D \ge 0} \left( \sum_{h=0}^{D} m_h + D + 1 \right)! \prod_{h=0}^{D} \frac{(\lambda p_h)^{m_h + 1} x_h^{m_h}}{m_h! (m_h + 1)!}
$$
  

$$
= \frac{e^{-\lambda t}}{\lambda} \prod_{h=0}^{D} \sqrt{\lambda p_h} \sum_{m_0, \dots, m_D \ge 0} \int_0^{\infty} e^{-w} w^{D+1} \prod_{h=0}^{D} \frac{(\lambda p_h)^{m_h + \frac{1}{2}} (x_h w)^{m_h}}{m_h! (m_h + 1)!} dw
$$
  

$$
= \frac{e^{-\lambda t}}{\lambda} \prod_{h=0}^{D} \sqrt{\frac{\lambda p_h}{x_h}} \int_0^{\infty} e^{-w} w^{\frac{D+1}{2}} \prod_{h=0}^{D} I_1 \left( 2\sqrt{w\lambda p_h x_h} \right) dw,
$$
(2.26)

<span id="page-12-0"></span>where

$$
I_1(z) = \sum_{n=0}^{\infty} \left(\frac{z}{2}\right)^{2n+1} \frac{1}{n! (n+1)!}
$$

is the modified Bessel function of order 1, for  $z \in \mathbb{C}$ . Note that if  $x \rightarrow \bar{x} \in \partial \text{Supp}(X(t))$ , then there exists at least one  $l \in \{0, \ldots, D\}$  such that  $x_l \longrightarrow 0$ . For instance, if we assume that there is just one *l* satisfying the given condition, then the formula  $(2.26)$  turns into

$$
\mathbb{P}\{X(t)\in dx\}/\,dx\longrightarrow p_l e^{-\lambda t} \prod_{\substack{h=0\\h\neq l}}^D \sqrt{\frac{\lambda p_h}{x_h}} \int_0^\infty e^{-w} w^{\frac{D}{2}+1} \prod_{\substack{h=0\\h\neq l}}^D I_1\left(2\sqrt{w\lambda p_h x_h}\right) dw.
$$

Similarly to the cyclic case (see  $(a)$ , on the limit behavior of  $(2.16)$ ), the probability  $(2.26)$ never converges to 0, because we are including the event where each velocity is chosen once. This can easily be observed from the formula [\(2.23\)](#page-11-3) by putting  $n_l = 1$ .

It is interesting to observe that

$$
\int_{\text{Supp}(X(t))} \mathbb{P}\{X(t) \in dx\} = \frac{e^{-\lambda t}}{\lambda} \sum_{n_0, ..., n_D \ge 1} \left(\sum_{h=0}^{D} n_h\right)! \prod_{h=0}^{D} \frac{(\lambda p_h)^{n_h}}{(n_h - 1)! n_h!}
$$
\n
$$
\times \int_0^t x_1^{n_1 - 1} dx_1 \int_0^{t - x_1} x_2^{n_2 - 1} dx_2 \dots \int_0^{t - x_1 - \dots - x_{D-2}} x_{D-1}^{n_{D-1} - 1} dx_{D-1}
$$
\n
$$
\times \int_0^{t - x_1 - \dots - x_{D-1}} x_D^{n_D - 1} \left(t - \sum_{j=1}^D x_j\right)^{n_0 - 1} dx_D
$$
\n
$$
= \frac{e^{-\lambda t}}{\lambda t} \sum_{n_0, ..., n_D \ge 1} \left(\sum_{h=0}^D n_h\right) \prod_{h=0}^D \frac{(\lambda t p_h)^{n_h}}{n_h!}
$$

$$
= e^{-\lambda t} \sum_{h=0}^{D} p_h \sum_{n_0, ..., n_D \ge 1} \frac{(\lambda t p_h)^{n_h - 1}}{(n_h - 1)!} \prod_{\substack{j=0 \ j \ne h}}^{D} \frac{(\lambda t p_j)^{n_j}}{n_j!}
$$
  

$$
= e^{-\lambda t} \sum_{h=0}^{D} p_h e^{\lambda t p_h} \prod_{\substack{j=0 \ j \ne h}}^{D} (e^{\lambda t p_j} - 1)
$$
  

$$
= 1 - \mathbb{P} \left\{ \bigcup_{h=0}^{D} \{N_h(t) = 0\} \right\}.
$$
 (2.27)

For details about the last equality, see Appendix [B.1.](#page-23-0) If  $p_0 = \cdots = p_D = 1/(D+1)$ , then the probability  $(2.27)$  reduces to

$$
e^{\frac{-\lambda tD}{D+1}}(e^{\frac{-\lambda t}{D+1}}-1)^D.
$$

We can easily obtain the distribution of the position of an arbitrary *D*-dimensional complete minimal random motion governed by a homogeneous Poisson process, by using the above probabilities and the relationship  $(2.7)$ .

2.1.1. *Distribution on the boundary of the support.* Let *X* be a minimal random motion with velocities  $v_0, \ldots, v_p$ . Theorem [2.2](#page-7-0) describes the joint probability in the inner part of the support of the position  $X(t)$ , i.e. Conv( $v_0t$ , ...,  $v_Dt$ ),  $t \ge 0$ . Now we deal with the distribution over the boundary of Supp $(X(t))$ , which can be partitioned into  $\sum_{H=0}^{D-1} {D+1 \choose H+1}$  $\binom{D+1}{H+1}$  components, corresponding to those in  $(2.1)$  with  $H < D$ .

Fix  $H \in \{0, ..., D-1\}$  and let  $I_H = \{i_0, ..., i_H\} \in C_{H+1}^{\{0, ..., D\}}$  be a combination of  $H + 1$ indexes in  $\{0, \ldots, D\}$ . At time  $t \ge 0$ , the motion *X* lies on the set  $\overset{\circ}{\text{Conv}}(v_{i_0}t, \ldots, v_{i_H}t)$  if and only if it moves with all, and only, the velocities  $v_{i_0}, \ldots, v_{i_H}$  in the time interval [0, *t*]. Hence,

if  $X(t) \in \text{Conv}(v_{i_0}t, \ldots, v_{i_H}t)$  a.s. we can write the following: for  $k = 0, \ldots, H$ ,

$$
X(t) = \sum_{h=0}^{H} v_{i_h} T_{(i_h)}(t) = v_{i_k} t + \sum_{\substack{h=0 \ h \neq k}}^{H} (v_{i_h} - v_{i_k}) T_{(i_h)}(t) = g_k \left( T_{(i_k^-)}^H(t) \right), \tag{2.28}
$$

where  $T_{\theta}^{H}(t) = (T_{(i_0)}(t), \ldots, T_{(i_H)}(t))$  and

<span id="page-13-2"></span><span id="page-13-1"></span>
$$
T_{(i_k^-)}^H(t) = \left(T_{(i_h)}(t)\right)_{\substack{h=0,\ldots,H\\h\neq k}}.
$$

The function  $g_k : [0, +\infty)^H \longrightarrow \mathbb{R}^D$  in [\(2.28\)](#page-13-1) is an affine relationship.

Keeping in mind that  $v_0, \ldots, v_p$  are affinely independent, we have that  $\dim$  $(\text{Conv}(v_{i_0}t, \ldots, v_{i_H}t)) = H$ , and from Lemma [1.1,](#page-3-0) there exists an orthogonal projection onto a *H*-dimensional space,  $p_H : \mathbb{R}^D \longrightarrow \mathbb{R}^H$ , such that  $v_{i_0}^H = p_H(v_{i_0}), \dots, v_{i_H}^H = p_H(v_{i_H})$  are affinely independent and such that we can characterize the vector  $X(t)$ , when it lies on the set  $\overrightarrow{Conv}(v_{i_0}t, \ldots, v_{i_H}t)$  a.s., through its projection  $X^H(t) = p_H(X(t))$ . Hence, we just need to study the projected motion

<span id="page-13-0"></span>

$$
X^{H}(t) = v_{i_k}^{H}t + \sum_{\substack{h=0 \ h \neq k}}^{H} \left( v_{i_h}^{H} - v_{i_k}^{H} \right) T_{(i_h)}(t) = g_k^{H} \left( T_{(i_k)}^{H}(t) \right), \quad t \ge 0, \ k = 0, \dots, H. \tag{2.29}
$$

It is straightforward to see that the vector  $X^{H^-}(t)$  containing the components of  $X(t)$  that are not included in  $X^H(t)$  is such that, for  $x \in \text{Conv}(v_{i_0}t, \ldots, v_{i_H}t)$  with  $x^H = p_H(x) \in \mathbb{R}^H$  and  $x^{H^-} \in$ R*D*−*<sup>H</sup>* denoting the other entries of *x*,

<span id="page-14-0"></span>
$$
\mathbb{P}\left\{X^{H^-}(t) \in \mathrm{d}y \; \Big| \; X^H(t) = x^H, \; \bigcap_{i \in \{0, \ldots, D\} \setminus I_H} \{N_i(t) = 0\} \right\} = \delta\left(y - x^{H^-}\right) \mathrm{d}y,\tag{2.30}
$$

with  $y \in \mathbb{R}^{D-H}$  and  $\delta$  the Dirac delta function centered in 0.

Now, the function  $g_k^H : \mathbb{R}^H \longrightarrow \mathbb{R}^H$  in [\(2.29\)](#page-13-2) is a bijection, and we can write, for all *k*,

$$
T_{(i_k^-)}^H(t) = (g_k^H)^{-1} \left( X^H(t) \right) = \left( \left( g_k^H \right)_h^{-1} \left( X^H(t) \right) \right)_{\substack{h=0,\dots,H \\ h \neq k}} = \left[ v_i^H - v_{i_k}^H \right]_{\substack{i \in I_H \\ i \neq i_k}}^{-1} \left( X^H(t) - v_{i_k}^H t \right).
$$
\n(2.31)

Note that the formula  $(2.31)$  coincides with  $(2.4)$  if  $H = D$ .

<span id="page-14-2"></span>**Theorem 2.3.** *Let X be a minimal finite-velocity random motion in* R*<sup>D</sup> satisfying (H1)– (H2). Let H* = 0, ..., *D* − 1 *and*  $I_H$  = {*i*<sub>0</sub>, ..., *i*<sub>H</sub>} ∈  $C_{H+1}^{\{0,\ldots,D\}}$ *. Then the orthogonal projection*  $p_H: \mathbb{R}^D \longrightarrow \mathbb{R}^H$  defined in Lemma [1.1](#page-3-0) (there  $p_R$ ) exists, and  $v_{i_0}^H = p_H(v_{i_0}), \ldots, v_{i_H}^H = p_H(v_{i_H})$  $\alpha$  *re affinely independent. Furthermore, for*  $t \geq 0$ ,  $x \in \text{Conv}(v_{i_0}t, \ldots, v_{i_H}t)$ ,  $n_{i_0}, \ldots, n_{i_H} \in \mathbb{N}$ , *and*  $k = 0, ..., H$ ,

<span id="page-14-3"></span>
$$
\mathbb{P}\left\{X(t)\in\mathrm{d}x,\,\bigcap_{h=0}^{H}\{N_{i_h}(t)=n_{i_h}\},\,\bigcap_{i\in I_H-}\{N_i(t)=0\},\,V(t)=v_{i_k}\right\}/\mathrm{d}x\tag{2.32}
$$

$$
= \prod_{\substack{h=0 \ h\neq k}}^H f_{\sum_{j=1}^{n_{i_h}} W_j^{(i_h)}} \left( \left( g_k^H \right)_h^{-1} (x^H) \right) \left| \left[ v_i^H - v_{i_k}^H \right]_{\substack{i \in I_H \\ i \neq i_k}} \right|^{-1} \mathbb{P} \left\{ N_{(i_k)} \left( t - \sum_{\substack{h=0 \ h\neq k}}^H (g_k^H)^{-1}_h (x^H) \right) = n_{i_k} - 1 \right\}
$$
  
×  $\mathbb{P} \left\{ C_{n_{i_0} + \dots + n_{i_H}} = (n_0, \dots, n_D), V(t) = v_{i_k} \right\},$ 

*with*  $x^H = p_H(x)$ ,  $(g_k^H)^{-1}$  given in [\(2.31\)](#page-14-0),  $I_{H}$ - = {0, ..., *D*} \ *I<sub>H</sub>*, and suitable  $n_0, ..., n_D$ .

Note that the projection defined in Lemma [1.1](#page-3-0) is usually not the only suitable one.

*Proof.* In light of the considerations above, the proof follows equivalently to the proof of Theorem [2.2.](#page-7-0)  $\Box$ 

<span id="page-14-1"></span>**Remark 2.4.** (*Canonical motion*.) Let *X* be a canonical (minimal) random motion, governed by a point process *N*, and  $I_H = \{i_0, ..., i_H\} \in C_{H+1}^{\{0, ..., D\}}$ ,  $H = 0, ..., D - 1$ . We build the projection  $p_H$  so that it selects the first *H* linearly independent rows of  $(e_{i_0} \cdots e_{i_H})$ , if  $i_0 = 0$ ,

and the last ones if  $i_0 \neq 0$ . Then  $\left(e_{i_0}^H \cdots e_{i_H}^H\right) = (0 \ I_H)$ , and by proceeding as shown in Remark [2.2,](#page-5-2) we obtain

$$
T_{\theta}^{H}(t) = \left(t - \sum_{h=1}^{H} X_{i_h}^{H}(t), X^{H}(t)\right);
$$

note that in this case the indexes of the velocities  $(i_1, \ldots, i_H)$  coincide with the indexes of the selected coordinates of the motion.

Now, if *Y* is a minimal random motion with velocities  $v_0, \ldots, v_D$  and governed by  $N_Y \stackrel{d}{=} N$ , for each  $I_H = \{i_0, \ldots, i_H\} \in C_{H+1}^{\{0, \ldots, D\}}$ ,  $H = 0, \ldots, D-1$ , by using the arguments leading to [\(2.7\)](#page-5-3), we can write

<span id="page-15-0"></span>
$$
Y^{H}(t) \stackrel{d}{=} v_{i_0}^{H} t + \left[ v_i^{H} - v_{i_k}^{H} \right]_{\substack{i \in I_H \\ i \neq i_k}} X^{H}(t).
$$
 (2.33)

We point out that the motions are related through the times of the displacements with each velocity and not directly through their coordinates. This means that  $X^H$  and  $Y^H$  are not necessarily obtained through the same projection, but they are respectively related to processes  $T^H_{\theta}$ and  $T_0^{Y,H}$  that have the same finite-dimensional distributions, since  $N_Y \stackrel{d}{=} N$  (see the proof of Theorem [2.1\)](#page-5-0).

Note that Remark [2.4](#page-14-1) holds even though the hypotheses (H1)–(H2) are not assumed.

By comparing Theorem [2.2](#page-7-0) with Theorem [2.3,](#page-14-2) we note that there is a strong similarity between the distribution of a *D*-dimensional minimal motion over its singularity of dimension *H* (in fact, dim  $(\text{Conv}(v_{i_0}t, \ldots, v_{i_H}t)) = H$ ,  $t > 0$ ) and the distribution of an *H*-dimensional minimal motion moving with velocities  $v_{i_0}^H = p_H(v_{i_0}), \ldots, v_{i_H}^H = p_H(v_{i_H})$ . These kinds of relationships are further investigated in the next sections (see also the next example); in particular, Theorem [4.1](#page-20-0) states a result concerning a wide class of random motions.

**Example 2.4.** (*Complete motions: distribution over the singular components.*) Let us consider the complete canonical random motion *X* studied in Example [2.3.](#page-11-0) Let  $I_H = \{i_0, \ldots, i_H\}$  $\mathcal{C}_{H+1}^{\{0,\ldots,D\}}$  and  $I_{H^-} = \{0,\ldots,D\} \setminus I_H$ , with  $H = 0,\ldots,D-1$ . We now compute the probability density of being in  $x \in \text{Conv}(e_{i_0}t, \ldots, e_{i_H}t)$  at time  $t \ge 0$ . Keeping in mind Theorem [2.3](#page-14-2) and Remark [2.4](#page-14-1) (and proceeding as shown for the probability [\(2.23\)](#page-11-3)), for integers  $n_{i_0}, \ldots, n_{i_H} \ge 1$ and  $k = 0, \ldots, H$ , we have that

$$
\mathbb{P}\left\{X(t) \in \mathrm{d}x, \bigcap_{h=0}^{H} \{N_{i_h}(t) = n_{i_h}\}, \bigcap_{i \in I_{H^-}} \{N_i(t) = 0\}, \ V(t) = e_{i_k}\right\} / \mathrm{d}x
$$
\n
$$
= \frac{e^{-\lambda t}}{\lambda} \left(\sum_{h=0}^{H} n_{i_h} - 1\right)! n_{i_k} \prod_{h=0}^{H} \frac{(\lambda p_{i_h})^{n_{i_h}} x_{i_h}^{n_{i_h} - 1}}{(n_{i_h} - 1)! n_{i_h}!},
$$

where  $x_{i0} = t - \sum_{j=1}^{H} x_{i_j}$ . Clearly, by working as shown in Example [2.3,](#page-11-0) we obtain

$$
\mathbb{P}\left\{X(t) \in dx, \bigcap_{i \in I_{H^{-}}} \{N_{i}(t) = 0\}\right\} / dx = \frac{e^{-\lambda t}}{\lambda} \sum_{n_{i_{0}}, \dots, n_{i_{H}} \ge 1} \left(\sum_{h=0}^{H} n_{i_{h}}\right)! \prod_{h=0}^{H} \frac{(\lambda p_{i_{h}})^{n_{i_{h}}} x_{i_{h}}^{n_{i_{h}}-1}}{(n_{i_{h}}-1)! n_{i_{h}}!}
$$

$$
= \frac{e^{-\lambda t}}{\lambda} \prod_{h=0}^{H} \sqrt{\frac{\lambda p_{i_{h}}}{x_{i_{h}}}} \int_{0}^{\infty} e^{-w} w^{\frac{H+1}{2}} \prod_{h=0}^{H} I_{1}\left(2\sqrt{w\lambda p_{i_{h}}x_{i_{h}}}\right) dw
$$

and

<span id="page-16-3"></span>
$$
\int_{\text{Conv}(e_{i_0}t,\ldots,e_{i_H}t)} \mathbb{P}\left\{X(t) \in \text{d}x, \bigcap_{i \in I_{H^-}} \{N_i(t) = 0\}\right\} = e^{-\lambda t} \sum_{h=0}^{H} p_{i_h} e^{\lambda t p_{i_h}} \prod_{\substack{j=0 \ j \neq h}}^{H} \{e^{\lambda t p_{i_j}} - 1\}
$$
\n
$$
= \mathbb{P}\left\{\bigcap_{i \in I_{H^-}} \{N_i(t) = 0\}\right\} - \mathbb{P}\left\{\bigcup_{i \in I_H} \{N_i(t) = 0\}, \bigcap_{i \in I_{H^-}} \{N_i(t) = 0\}\right\}.
$$
\n(2.34)

Further details about the last equality are in Appendix **[B.1.](#page-23-0)** 

Let *Y* be a complete minimal motion governed by a counting process  $N_Y \stackrel{d}{=} N$  and moving with velocities  $v_0, \ldots, v_D$ . By suitably applying the relationship [\(2.33\)](#page-15-0) and the above probabilities, we can easily obtain the distribution of the position *Y*(*t*) over its singular components.

### **3. Random motions with a finite number of velocities**

<span id="page-16-1"></span><span id="page-16-0"></span>**Proposition 3.1.** *Let X be a random motion governed by a point process N and moving*  $W$  *with velocities*  $v_0, \ldots, v_M \in \mathbb{R}^D$ ,  $M \in \mathbb{N}$ , such that  $dim(Conv(v_0, \ldots, v_M)) = R \le D$ . Then *the orthogonal projection*  $p_R : \mathbb{R}^D \longrightarrow \mathbb{R}^R$  *defined in Lemma [1.1](#page-3-0) exists, and for*  $t > 0$ *, we can characterize X(t) through its projection*  $X^R(t) = p_R(X(t))$ , representing the position of an *R*-dimensional motion moving with velocities  $p_R(v_0), \ldots, p_R(v_M)$  and governed by N.

*Proof.* The projection  $p_R$  exists since the hypotheses of Lemma [1.1](#page-3-0) are satisfied. By keeping in mind the characteristics of  $p_R$  (see Lemma [1.1\)](#page-3-0), we immediately obtain that for any  $A \subset$ Conv( $v_0, \ldots, v_M$ ) and its projection through  $p_R$ ,  $A^R \subset \text{Conv}(p_R(v_0), \ldots, p_R(v_M))$ , we have  $\{\omega \in \Omega : X(\omega, t) \in A\} = \{\omega \in \Omega : X^R(\omega, t) \in A^R\}.$ 

Proposition [3.1](#page-16-1) states that if  $\dim(\text{Conv}(v_0, \ldots, v_M)) = R \le D$ , then we can equivalently study either the process *X*, a random motion with  $M + 1$  velocities in  $\mathbb{R}^D$ , or its projection  $X^R$ , a random motion of  $M + 1$  velocities in  $\mathbb{R}^R$ . This means that we can limit ourselves to the study of random motions where the dimension of the space coincides with the dimension of the state space. Clearly, for  $R = D$  Proposition [3.1](#page-16-1) is not of interest since  $p<sub>R</sub>$  is the identity function.

<span id="page-16-2"></span>**Remark 3.1.** (*Motions with affinely independent velocities*.) Let *X* be a random motion moving with affinely independent velocities  $v_0, \ldots, v_H \in \mathbb{R}$ ,  $H \leq D$ . In light of Proposition [3.1,](#page-16-1) there exists an orthogonal projection  $p<sub>H</sub>$ , as given in Lemma [1.1,](#page-3-0) such that studying  $X<sup>H</sup>$  =  $\{p_H(X(t))\}_{t\geq 0}$  is equivalent to studying *X*. The process  $X^H$  is a minimal random motion moving with velocities  $p_H(v_0), \ldots, p_H(v_H)$ , and if it satisfies (H1)–(H2), then Theorems [2.2](#page-7-0) and [2.3](#page-14-2) provide its probability law.

**Example 3.1.** (*Motion with canonical velocities*.) Let *X* be a *D*-dimensional motion moving with the first  $H+1$  canonical velocities  $e_0$ , ...,  $e_H$  and satisfying (H1)–(H2). For  $t \ge 0$ ,  $\text{Supp}(X(t)) = \{x \in \mathbb{R}^D : x \ge 0, x_{H+1}, \dots, x_D = 0, \sum_{i=1}^H x_i = t\}$ , and by following the arguments of Section 2.1.1, we can derive the probability distribution of  $X(t)$  in the inner part of its support by using the formula [\(2.32\)](#page-14-3), which uses the connection to the projected position  $p_H(X(t))$ . In this case, the last probability of [\(2.32\)](#page-14-3) becomes  $\mathbb{P}\left\{C_{n_0+\dots+n_H}=\right\}$  $(n_0, \ldots, n_H)$ ,  $V(t) = v_{i_k}$  with  $n_0, \ldots, n_H \neq 0$ , and therefore it coincides with the probability of the *H*-dimensional canonical motion.

# **3.1. Motions in** R*<sup>D</sup>* **with** *D***-dimensional state space**

Thanks to Proposition [3.1](#page-16-1) and Remark [3.1,](#page-16-2) in order to cover the analysis of all the possible motions (under the given assumptions), we need to deal with random motions in  $\mathbb{R}^D$  moving with  $M + 1$  velocities,  $M > D$ , and with state space of dimension *D*.

<span id="page-17-0"></span>**Proposition 3.2.** *Let X be a random motion governed by a point process N and moving with*  $v$ elocities  $v_0, \ldots, v_M \in \mathbb{R}^D$ ,  $D < M \in \mathbb{N}$ , such that  $dim(Conv(v_0, \ldots, v_M)) = D$ . Then there *exists a minimal random motion*  $\tilde{X}$  *in*  $\mathbb{R}^M$  *such that* X *is the marginal vector process of*  $\tilde{X}$ *represented by its first D components.*

*Proof.* Let *V*, *N* be the processes respectively governing the velocity and the displacements of *X*. Let  $\pi_D : \mathbb{R}^M \longrightarrow \mathbb{R}^D$ ,  $\pi_D(\tilde{x}) = (I_D \ 0) \tilde{x}$ ,  $\tilde{x} \in \mathbb{R}^M$ . Then there exist  $\tilde{v}_0, \ldots, \tilde{v}_M \in \mathbb{R}^M$ affinely independent such that  $\pi_D(\tilde{v}_h) = v_h$  for all *h*. The random motion  $\tilde{X}$  with displacements governed by *N* and velocity process  $\tilde{V}$ , with state space  $\{\tilde{v}_0, \ldots, \tilde{v}_M\}$  and such that  $\pi_D(\tilde{V}(t)) = V(t)$  (i.e.  $\{\tilde{V}(t) = \tilde{v}_h\} \iff \{V(t) = v_h\} \forall h, t$ ), is a minimal random motion in  $\mathbb{R}^M$ , and  $\pi_D(\tilde{X}(t)) = X(t) \forall t$ .

From the proof of Proposition [3.2](#page-17-0) it is obvious that there exist infinitely many *M*dimensional stochastic motions  $\tilde{X}$  of the required form.

<span id="page-17-2"></span>**Remark 3.2.** (*Distribution of the position of the motion*.) Let *X* be a random motion with velocities  $v_0, \ldots, v_M \in \mathbb{R}^D$ ,  $M \in \mathbb{N}$ , such that dim $(\text{Conv}(v_0, \ldots, v_M)) = D$ . In light of Proposition [3.2,](#page-17-0) we provide the distribution of  $X(t)$ ,  $t > 0$ , in terms of the probabilities of the positions of minimal random motions.

Let  $\tilde{X}$  be a minimal random motion as in Proposition [3.2](#page-17-0) and  $\pi_D$  the orthogonal projection in the proof above. Now, for  $t \ge 0$ ,  $x \in \text{Conv}(v_0t, \ldots, v_Mt)$ , natural numbers  $n_0, \ldots, n_M \ge 1$ , and  $k = 0, \ldots, M$ , we can write

<span id="page-17-1"></span>
$$
\mathbb{P}\left\{X(t)\in\mathrm{d}x,\bigcap_{h=0}^{M}\{N_h(t)=n_h\},\ V(t)=v_k\right\}
$$
\n
$$
=\int_{A_x}\mathbb{P}\left\{\tilde{X}(t)\in\mathrm{d}(x,y),\bigcap_{h=0}^{M}\{N_h(t)=n_h\},\ \tilde{V}(t)=\tilde{v}_k\right\},\tag{3.1}
$$

where  $A_x = \{ y \in \mathbb{R}^{M-D} : (x, y) \in Conv(\tilde{v}_0 t, ..., \tilde{v}_M t) \}$ ; clearly,  $\pi_D(x, y) = (I_D \ 0)(x, y) = x$ . Under the assumptions  $(H1)$ – $(H2)$ , the probability  $(3.1)$  can be written explicitly by means of Theorem [2.2.](#page-7-0)

Remember that, unlike in the minimal-motion case, the support of  $X(t)$  is not partitioned by the elements appearing in [\(2.1\)](#page-3-1) (since they are not disjoint). Thus, for fixed  $t > 0$  and  $x \in$ Conv $(v_0t, \ldots, v_Mt)$  there may exist several combinations of velocities (and their corresponding times) such that the motion is in position *x* at time *t*. With  $H = 1, \ldots, M$ , let  $I_{x,t,H}^{(1)}, \ldots, I_{x,t,H}^{(L_H)} \in$  $\mathcal{C}_{H+1}^{\{0,\ldots,M+1\}}$  be the  $L_H \leq \binom{M+1}{H+1}$  $H_{H+1}^{M+1}$ ) possible combinations of  $H+1$  velocities such that the motion can lie in *x* at time *t*, i.e.  $x \in \text{Conv}(v_{i_0}t, \ldots, v_{i_H}t)$  with  $i_0 \ldots, i_H \in I_{x,t,H}^{(l)}$ ,  $\forall l, H$  (clearly, for some *H* it can happen that there are no suitable combinations in  $C_{H+1}^{\{0,\ldots,M+1\}}$ , so  $L_H = 0$ ). In general we can write (omitting the indexes *x*, *t* of  $I_{x,t,H}^{(l)}$ )

<span id="page-18-0"></span>
$$
\mathbb{P}\{X(t)\in\mathrm{d}x\}/\mathrm{d}x
$$

$$
= \sum_{k=0}^{M} \mathbb{P} \left\{ X(t) \in dx, \bigcup_{H=1}^{M} \bigcup_{l=1}^{L_{H}} \left\{ \bigcap_{i \in I_{H}^{(l)}} \{ N_{i}(t) \ge 1 \}, \bigcap_{i \in I_{H}^{(l)}} \{ N_{i}(t) = 0 \} \right\}, V(t) = v_{k} \right\} / dx
$$
  

$$
= \sum_{k=0}^{M} \sum_{H=1}^{M} \sum_{l=1}^{L_{H}} \sum_{\substack{n_{h}=1 \\ h \in I_{H}^{(l)}}} \mathbb{P} \left\{ X(t) \in dx, \bigcap_{i \in I_{H}^{(l)}} \{ N_{i}(t) = n_{i} \}, \bigcap_{i \in I_{H}^{(l)}} \{ N_{i}(t) = 0 \}, V(t) = v_{k} \right\} / dx, (3.2)
$$

where  $I_{H^-}^{(l)} = \{0, \ldots, M\} \setminus I_H^{(l)}$  for all *l*, *H*.

Now, under the hypotheses  $(H1)$ – $(H2)$ , the probabilities appearing in  $(3.2)$  can be obtained by using previous results. Consider the combination of velocities  $I_H^{(l)} = \{i_0, \ldots, i_H\}$ :

- (a) If  $\dim$   $\left(\text{Conv}(v_{i_0}, \ldots, v_{i_H})\right) = H(\leq D)$ , then we can compute the corresponding proba-bility in [\(3.2\)](#page-18-0) by suitably using Theorem [2.3](#page-14-2) (if  $H = D$ , then the projection described in Theorem [2.3](#page-14-2) turns into the identity function).
- (b) If  $\dim$   $\big(\text{Conv}(v_{i_0}, \ldots, v_{i_H})\big) = R \lt H$ , then we use the following argument. In light of Proposition [3.1,](#page-16-1) we can consider the orthogonal projection  $p_R$  defined in Lemma [1.1](#page-3-0) and study the process  $X^R$  with velocities  $v_{i_0}^R = p_R(v_{i_0}), \ldots, v_{i_H}^R = p_R(v_{i_H})$ . Then  $X^R$  is an *R*-dimensional motion with  $H + 1$  velocities, and we can proceed as shown for the probability [\(3.1\)](#page-17-1). Let us denote by  $\tilde{X}^R$  the *H*-dimensional minimal motion such that  $\overline{x}_R(\tilde{X}^R(t)) = (I_R \ 0) \tilde{X}(t) = X^R(t), t \ge 0$ , and with  $\tilde{V}^R$  the corresponding velocity process, with state space  $\{\tilde{v}_{i_0}^R, \ldots, \tilde{v}_{i_H}^R\}$ , where  $\pi_R(\tilde{v}_{i_h}^R) = v_{i_h}^R \forall h$ . Now, for  $n_{i_0}, \ldots, n_{i_H} \in \mathbb{N}$  and  $k = 0, \ldots, H$ ,

$$
\mathbb{P}\left\{X(t)\in\mathrm{d}x,\ \bigcap_{i\in I_H^{(l)}}\{N_i(t)=n_i\},\ \bigcap_{i\in I_{H^-}^{(l)}}\{N_i(t)=0\},\ V(t)=v_{i_k}\right\}/\mathrm{d}x\tag{3.3}
$$

$$
= \int_{A_x} \mathbb{P}\left\{\tilde{X}^R(t) \in d(x^R, y), \bigcap_{i \in I_H^{(l)}} \{N_i(t) = n_i\}, \bigcap_{i \in I_{H^-}^{(l)}} \{N_i(t) = 0\}, \ \tilde{V}^R(t) = \tilde{v}_{i_k}^R\right\} / dx^R,
$$

where  $A_x = \{y \in \mathbb{R}^{H-R} : (x^R, y) \in \text{Conv}(\tilde{v}_{i_0}t, \ldots, \tilde{v}_{i_H}t)\}\)$ , and clearly  $\pi_R(x^R, y) = x^R$ .  $\diamond$ 

 $\overline{a}$ 

**Example 3.2.** Let *X* be a one-dimensional cyclic motion moving with velocities  $v_0 = 0$ ,  $v_1 =$ 1,  $v_2 = -1$  and  $p_h = \mathbb{P}{V(0) = v_h} > 0$  ∀ *h*. Let *N* be its governing Poisson-type process such that  $W_j^{(h)} \sim Exp(\lambda_h)$ ,  $h = 0, 1, 2, j \in \mathbb{N}$ . We now consider the two-dimensional minimal random motion  $(X, Y)$  moving with velocities  $\tilde{v}_0 = (0, 1), \tilde{v}_1 = (1, 0), \tilde{v}_2 = (-1, 0)$  governed by *N*. Let  $t \ge 0$  and  $x \in (0, t)$ . In order to reach *x*, the motion must perform at least one displacement with *v*<sub>1</sub>. Thus, keeping in mind the cyclic routine for the velocities ( $\cdots \rightarrow v_0 \rightarrow v_1 \rightarrow$  $v_2 \rightarrow \ldots$ ), we see that the probability reads

<span id="page-19-1"></span>
$$
\mathbb{P}\{X(t) \in dx\}
$$
\n
$$
= \mathbb{P}\{X(t) \in dx, N_0(t) = 1, N_1(t) = 1, N_2(t) = 0\}
$$
\n
$$
+ \mathbb{P}\{X(t) \in dx, N_0(t) = 0, N_1(t) = 1, N_2(t) = 1\}
$$
\n
$$
+ \sum_{j=0}^{2} P\left\{X(t) \in dx, \bigcup_{n=1}^{\infty} N(t) = 3n + j - 1\right\}
$$
\n
$$
= \mathbb{P}\left\{W_1^{(0)} \in d(t - x), V(0) = v_0\right\} + \mathbb{P}\left\{W_1^{(1)} \in d\frac{(t + x)}{2}, V(0) = v_1\right\}
$$
\n
$$
+ \sum_{j=0}^{2} \int_0^{t - x} \mathbb{P}\left\{X(t) \in dx, Y(t) \in dy, \bigcup_{n=1}^{\infty} N(t) = 3n + j - 1\right\}.
$$
\n(3.4)

The first two terms are respectively given by  $p_0\lambda_0e^{-\lambda_0(t-x)}$  dx and  $p_1\lambda_1e^{-\lambda_1\frac{t+x}{2}}$  dx. By suitably applying Theorem [2.2](#page-7-0) or Example [2.2,](#page-8-0) the interested reader can explicitly compute [\(3.4\)](#page-19-1). Note that the integral in  $(3.4)$  is of the form

$$
\int_0^{t-x} y^{n_0} \left(\frac{t+x-y}{2}\right)^{n_1} \left(\frac{t-x-y}{2}\right)^{n_2} dy
$$

<span id="page-19-0"></span>with suitable natural numbers  $n_0$ ,  $n_1$ ,  $n_2$ .

### **4. Random motions governed by a non-homogeneous Poisson process**

Here we consider a random motion *X* moving with a natural number of finite velocities  $v_0, \ldots, v_M \in \mathbb{R}^D, M \in \mathbb{N}$ , whose movements are governed by a non-homogeneous Poisson process *N* with rate function  $\lambda : [0, \infty) \longrightarrow [0, \infty)$ . In this case N cannot explode in a bounded time interval if and only if  $\Lambda(t) = \int_0^t \lambda(s) ds < \infty$ ,  $t \ge 0$ . We note that the process *X* satisfies (H2) if and only if  $\lambda(t) = \lambda > 0 \ \forall t$ .

Let us assume that for all *t*, we have  $p_i = \mathbb{P}{V(0) = v_i}$  and  $p_{i,j} = \mathbb{P}{V(t + dt) = v_j | V(t) = v_j}$  $v_i$ ,  $N(t, t + dt] = 1$   $\geq 0$  for each  $i, j = 0, \ldots, M$ . Let us also consider the notation, with  $t \geq 0$ ,  $x \in \text{Supp}(X(t)),$ 

<span id="page-19-2"></span>
$$
p(x, t) dx = \mathbb{P}{X(t) \in dx} = \sum_{i=0}^{M} \mathbb{P}{X(t) \in dx}, \ V(t) = v_i = \sum_{i=0}^{M} f_i(x, t) dx.
$$

It can be proved that the functions  $f_i$  satisfy the differential problem (with  $\langle \cdot, \cdot \rangle$  denoting the dot product in R*D*)

$$
\begin{cases}\n\frac{\partial f_i}{\partial t} = - < \nabla_x f_i, \, v_i > -\lambda(t) f_i + \lambda(t) \sum_{j=0}^M p_{j,i} f_j, \quad i = 0, \dots, M, \\
f_i(x, t) \ge 0, \quad \forall \, i, x, t, \\
\int_{\text{Conv}(v_0 t, \dots, v_M t)} \sum_{i=0}^M f_i(x, t) \, dx = 1 - \mathbb{P} \Big\{ \bigcup_{h=0}^M \{N_h(t) = 0\} \Big\},\n\end{cases} \tag{4.1}
$$

where ∇*xf* represents the *x*-gradient vector of *f* and

<span id="page-20-1"></span>
$$
\mathbb{P}\left\{\bigcup_{h=0}^M \{N_h(t)=0\}\right\}>0 \iff \Lambda(t)<\infty \,\forall\, t.
$$

We refer to  $[4, 5, 20, 27]$  $[4, 5, 20, 27]$  $[4, 5, 20, 27]$  $[4, 5, 20, 27]$  $[4, 5, 20, 27]$  $[4, 5, 20, 27]$  $[4, 5, 20, 27]$  for proofs similar to the one leading to  $(4.1)$ .

**Remark 4.1.** (*Complete minimal motions.*) Let *X* be a complete canonical (minimal) random motion (see Example [2.3\)](#page-11-0) such that for all  $i, j, p_{i,j} = p_j$ . The differential problem governing the probability law of *X* satisfies

$$
\begin{cases}\n\frac{\partial f_0}{\partial t} = \lambda(t)p_0 \sum_{j=1}^D f_j + \lambda(t)(p_0 - 1)f_0, \\
\frac{\partial f_i}{\partial t} = -\frac{\partial f_i}{\partial x_i} + \lambda(t)p_i \sum_{\substack{j=0 \ j \neq i}}^D f_j + \lambda(t)(p_i - 1)f_i, \quad i = 1, ..., D, \\
f_i(x, t) \ge 0, \quad \forall \ i, x, t, \quad \int_{\text{Supp}}(x(t)) \sum_{i=0}^D f_i(x, t) dx = 1 - \mathbb{P}\left\{\bigcup_{h=0}^D \{N_h(t) = 0\}\right\}.\n\end{cases} \tag{4.2}
$$

Through a direct calculation, it is easy to show that the probabilities obtained by suitably adapting the distributions [\(2.23\)](#page-11-3), i.e. by summing with respect to  $n_0, \ldots, n_D \ge 1$ , satisfy the PDEs in [\(4.2\)](#page-20-1) with  $\lambda(t) = \lambda > 0$   $\forall$  *t*. Furthermore, as shown in Example [2.3,](#page-11-0) the sum of these probabilities, i.e. [\(2.25\)](#page-12-1), satisfies the condition in the system [\(4.2\)](#page-20-1) (see [\(2.27\)](#page-13-0)).

It is also possible to show that if  $\lambda(t) = \lambda > 0$  for all *t*, then the probability [\(2.25\)](#page-12-1) (that is,  $p = \sum_i f_i$ ) is a solution to the following *D*th-order PDE:

<span id="page-20-3"></span>
$$
\sum_{k=0}^{D} \sum_{i \in C_k^{(1,\dots,D)}} \sum_{h=0}^{D+1-k} \lambda^{D+1-(h+k)} \left[ \binom{D+1-k}{h} - \left(p_0 + \sum_{j \notin i} p_j \right) \binom{D-k}{h} \right] \frac{\partial^{h+k} p}{\partial t^h \partial x_{i_1} \cdots \partial x_{i_k}} = 0. \tag{4.3}
$$

The proof of this result is given in Appendix [B.2.](#page-23-0)  $\Diamond$ 

The next statement concerns the distribution over the singular components when *N* cannot explode in finite time intervals.

<span id="page-20-0"></span>**Theorem 4.1.** Let X be a finite-velocity random motion moving with velocities  $v_0, \ldots, v_M \in$  $\mathbb{R}^D$ ,  $M \in \mathbb{N}$ , governed by a non-homogeneous Poisson process N with rate function  $\lambda \in$  $C^M([0, \infty), [0, \infty))$  such that  $\Lambda(t) = \int_0^t \lambda(s) ds < \infty$ ,  $t \ge 0$ . Let  $p_i = \mathbb{P}{V(0) = v_i} > 0$  and  $p_{i,j} = \mathbb{P}\big\{V(t + dt) = v_j \mid V(t) = v_i, N(t, t + dt) = 1\big\} \ge 0$  *for each i*, *j* = 0, ..., *M*,  $\forall$  *t. Set H* = 0, ..., *M* − 1*, I<sub>H</sub>* = {*i*<sub>0</sub>, ..., *i<sub>H</sub>*} ∈  $C_{H+1}^{[0, ..., M]}$ , *and I<sub>H</sub>*− = {0, ..., *M*} \ *I<sub>H</sub>. If* 

<span id="page-20-2"></span>
$$
\sum_{j \in I_H} p_{i_k, j} = \mathbb{P}\big\{ V(t + dt) \in \{v_{i_0}, \dots, v_{i_H}\} \mid V(t) = v_{i_k}, N(t, t + dt] = 1 \big\} = \alpha_{I_H} > 0 \tag{4.4}
$$

*for*  $k = 0, \ldots, H$  and  $t \ge 0$ , then, with  $dim(Conv(v_{i_0}, \ldots, v_{i_H})) = R \le D$ , there exists an  $\alpha$  *orthogonal projection p<sub>R</sub>* :  $\mathbb{R}^D \longrightarrow \mathbb{R}^R$  *such that, for t*  $\geq 0$ ,  $x \in Conv(v_{i_0}t, \ldots, v_{i_H}t)$ , with  $x^R =$  $p_R(x)$ 

$$
\mathbb{P}\left\{X(t)\in dx \Big|\bigcap_{j\in I_{H^-}} \{N_j(t)=0\}\right\}/dx = \mathbb{P}\left\{Y^R(t)\in dx^R\right\}/dx^R,
$$
\n(4.5)

*where Y<sup>R</sup> is an R-dimensional finite-velocity random process governed by a non-homogeneous Poisson process with rate function*  $\lambda \alpha_{I_H}$ , *moving with velocities*  $v_{i_0}^R = p_R(v_{i_0}), \ldots, v_{i_H}^R =$  $p_R(v_{i_H})$  and such that  $p_i^Y = p_i / \sum_{j \in I_H} p_j$  and  $p_{i,j}^Y = p_{i,j} / \alpha_{I_H}$  for all  $i, j \in I_H$ .

Theorem [4.1](#page-20-0) states that if the probability of keeping a velocity with index in  $I_H$  is constant  $(\alpha_{I_H})$ , then, with respect to the conditional measure  $\mathbb{P}\left\{\cdot \mid \bigcap_{j\in I_{H^-}} \{N_j(t)=0\}\right\}$ , *X* is equal in distribution (in terms of finite-dimensional distributions) to an *R*-dimensional motion governed by a non-homogeneous Poisson process with rate function  $\lambda \alpha_{I_H}$  and suitably scaled transition probabilities, where  $R = \dim \left( \text{Conv}(v_{i_0}, \ldots, v_{i_H}) \right)$  (if  $R = D$ , the identity function fits  $p_R$ ).

*Proof.* First we note that, in light of  $(4.4)$ , for  $t \ge 0$ ,

$$
\mathbb{P}\big\{V(t+dt)\in\{v_{i_0},\ldots,v_{i_H}\}\mid V(t)\in\{v_{i_0},\ldots,v_{i_H}\},\ N(t,t+dt)=1\big\}=\alpha_{I_H},
$$

and thus

<span id="page-21-0"></span>
$$
\mathbb{P}\left\{\bigcap_{j\in I_{H^-}} \{N_j(t) = 0\}\right\} = \mathbb{P}\left\{V(0) \in \{v_{i_0}, \dots, v_{i_H}\}\right\} \sum_{n=0}^{\infty} \mathbb{P}\{N(t) = n\} \alpha_{I_H}^n
$$
\n
$$
= e^{-\Lambda(t)(1-\alpha_{I_H})} \sum_{i\in I_H} p_i.
$$
\n(4.6)

Now, by Proposition [3.1,](#page-16-1) Lemma [1.1,](#page-3-0) and the same argument used in point (*b*) of Remark [3.2,](#page-17-2) there exists a projection  $p_R : \mathbb{R}^D \longrightarrow \mathbb{R}^R$  such that  $X^R(t) = p_R(X(t))$  and

$$
\mathbb{P}\left\{X(t)\in dx \Bigg|\bigcap_{j\in I_{H^-}}\{N_j(t)=0\}\right\}/dx = \mathbb{P}\left\{X^{R}(t)\in dx^{R}\bigg|\bigcap_{j\in I_{H^-}}\{N_j(t)=0\}\right\}/dx^{R},
$$

with  $x \in \operatorname{Conv}(v_{i_0}t, \ldots, v_{i_H}t)$ . The *R*-dimensional motion  $X^R$  moves with velocities  $v_0^R =$  $p_R(v_0), \ldots, v_M^R = p_R(v_M)$ , and its probability functions

<span id="page-21-1"></span>
$$
f_i(y, t) dy = \mathbb{P} \left\{ X^R(t) \in dy, \bigcap_{j \in I_{H^-}} \{ N_j(t) = 0 \}, \ V_{X^R}(t) = v_i^R \right\}, \ i \in I_H,
$$

with  $t \ge 0$ ,  $y \in \text{Conv}(v_{i_0}^R t, \ldots, v_{i_H}^R t)$ , satisfy the differential system

$$
\begin{cases}\n\frac{\partial f_i}{\partial t} = - \langle \nabla_y f_i, v_i^R \rangle - \lambda(t) f_i + \lambda(t) \sum_{j \in I_H} p_{j,j} f_j, & i \in I_H, \\
f_i(y, t) \ge 0, & i \in I_H, \forall y, t, \\
\int_{\text{Conv}\left(v_{i_0}^R t, \dots, v_{i_H}^R t\right)} \sum_{i \in I_H} f_i(y, t) \, dy = \int_{\text{Conv}\left(v_{i_0}^R t, \dots, v_{i_H}^R t\right)} \mathbb{P}\left\{ X^R(t) \in dy, \bigcap_{j \in I_{H^-}} \{N_j(t) = 0\} \right\} \\
= \mathbb{P}\left\{ \bigcap_{j \in I_{H^-}} \{N_j(t) = 0\} \right\} - \mathbb{P}\left\{ \bigcup_{i \in I_H} \{N_i(t) = 0\}, \bigcap_{j \in I_{H^-}} \{N_j(t) = 0\} \right\}.\n\tag{4.7}\n\end{cases}
$$

In light of [\(4.6\)](#page-21-0) we consider

$$
f_i(y, t) = g_i(y, t)e^{-\Lambda(t)(1-\alpha_{I_H})}\sum_{h \in I_H} p_h,
$$

for any *i*, i.e.

$$
g_i(y, t) dy = \mathbb{P} \left\{ X^R(t) \in dy, \ V_{X^R}(t) = v_i^R \mid \bigcap_{j \in I_{H^-}} \{N_j(t) = 0\} \right\}.
$$

The system [\(4.7\)](#page-21-1) becomes

$$
\begin{cases}\n\frac{\partial g_i}{\partial t} = - \langle \nabla_y g_i, v_i^R \rangle - \lambda(t) \alpha_{I_H} g_i + \lambda(t) \alpha_{I_H} \sum_{j \in I_H} \frac{p_{j,i}}{\alpha_{I_H}} g_j, & i \in I_H, \\
g_i(y, t) \ge 0, & i \in I_H, \forall y, t, \\
\int_{\text{Conv}(v_{i_0}^R t, \dots, v_{i_H}^R t)} \sum_{i \in I_H} g_i(y, t) \, dy = \int_{\text{Conv}(v_{i_0}^R t, \dots, v_{i_H}^R t)} P\left\{ X^R(t) \in dy \mid \bigcap_{j \in I_H -} \{N_j(t) = 0\} \right\} \\
= 1 - \mathbb{P}\left\{ \bigcup_{i \in I_H} \{N_i(t) = 0\} \mid \bigcap_{j \in I_{H^-}} \{N_j(t) = 0\} \right\},\n\end{cases} (4.8)
$$

which coincides with the system satisfied by the distribution of the position of the stochastic motion  $Y^R$  in the statement.

<span id="page-22-0"></span>Theorems 3.1 and 3.2 of Cinque and Orsingher [\[5\]](#page-29-17) are particular cases of Theorem [4.1.](#page-20-0)

## **Appendix A. Proof of Lemma [1.1](#page-3-0)**

If dim  $\left(\text{Conv}(v_0, ..., v_M)\right) = R$ , the matrix  $V_{(k)} = \left[v_h - v_k\right]_{\substack{h=0,...,M \\ h \neq k}}$ has *R* linearly independent rows for any *k*. Now, the matrix  $V_{(k)}^R = \left[ v_h^R - v_k^R \right]_{\substack{h=0,\dots,M \\ h \neq k}}$ , obtained by keeping the first *R* linearly independent rows of  $V_{(k)}$ , has rank *R*, and therefore dim $($ Conv $(v_0^R, ..., v_M^R)$  $) = R$ . Thus, for *l*, the matrix  $V_{(l)}^R = \left[ v_h^R - v_l^R \right]_{h=0,...,M}$ also has rank *R*, and these must be the first *R* linearly independent rows of  $V_{(l)}$  (if not, by proceeding as above for k, we would obtain that the *R* selected rows were not the first linearly independent rows of  $V_{(k)}$ , which is a contradiction).

Finally, the second part of the lemma follows from the equivalence of the linear systems

<span id="page-23-1"></span>
$$
x = \begin{bmatrix} v_h \end{bmatrix}_{h=0,\dots,M} a \quad \text{and} \quad x^R = \begin{bmatrix} v_h^R \end{bmatrix}_{h=0,\dots,M} a,
$$
 (A.1)

where  $a = (a_0, \ldots, a_M) \in \mathbb{R}^{M+1}$ , such that  $a_i \in [0, 1]$   $\forall i$  and  $\sum_{i=0}^{M} a_i = 1$ , is the unknown variable. Indeed, for  $k = 0, \ldots, M$ , thanks to the constraints on *a*, the systems in  $(A.1)$  can be written as

$$
x - v_k = \left[v_h - v_k\right]_{h \neq k} a_{(k)} \text{ and } x^R - v_k^R = \left[v_h^R - v_k^R\right]_{h \neq k} a_{(k)},
$$

with  $a_{(k)} = (a_0, \ldots, a_{k-1}, a_{k+1}, \ldots, a_M).$ 

## <span id="page-23-2"></span>**Appendix B. Complete canonical random motion**

Let *X* be a complete canonical random motion as in Example [2.3.](#page-11-0)

### <span id="page-23-0"></span>**B.1. Probability mass of the singularity**

Before computing the probability mass of the singularities of the complete uniform random motion, we need to prove some useful relationships.

Let  $c_1, \ldots, c_H \in \mathbb{R}$ ,  $H \in \mathbb{N}$ , and let  $C_h^{\{1, \ldots, H\}}$  denote the combinations of *h* elements among  $\{1, \ldots, H\}, h = 1, \ldots, H$ . We have that

$$
\sum_{h=1}^{H} (-1)^{H-h} \sum_{i \in C_h^{(1,\ldots,H)}} (c_{i_1} + \ldots c_{i_h})^m = \begin{cases} 0, & m < H, \\ \sum_{\substack{n_1,\ldots,n_H \ge 1 \\ n_1 + \cdots + n_H = m}} c_1^{n_1} \cdots c_H^{n_H} {m \choose n_1,\ldots,n_H}, & m \ge H, \end{cases}
$$
(B.1)

and, with  $\beta \in \mathbb{R}$ ,

<span id="page-23-5"></span>
$$
\sum_{h=1}^{H} c_h e^{\beta c_h} \prod_{\substack{j=1 \ j \neq h}}^{H} (e^{\beta c_j} - 1) = \sum_{h=1}^{H} (-1)^{H-h} \sum_{i \in C_h^{(1,...,H)}} (c_{i_1} + \dots + c_{i_h}) e^{\beta (c_{i_1} + \dots + c_{i_h})}.
$$
 (B.2)

To prove [\(B.1\)](#page-23-2), we denote by  $\mathcal{C}_{h,\{i_1,...,i_j\}}^{(1,...,H)}$  the combinations of *h* elements in  $\{1,...,H\}$ containing  $i_1, \ldots, i_j$ , with  $1 \le j \le h \le H$  and suitable  $i_1, \ldots, i_j$ . Then

$$
\sum_{h=1}^{H} (-1)^{H-h} \sum_{i \in \mathcal{C}_h^{(1,\dots,H)}} (c_{i_1} + \dots + c_{i_h})^m
$$
\n
$$
= \sum_{h=1}^{H} (-1)^{H-h} \sum_{i \in \mathcal{C}_h^{(1,\dots,H)}} \sum_{\substack{n_1,\dots,n_h \ge 0 \\ n_1 + \dots + n_h = m}} c_{i_1}^{n_1} \cdots c_{i_h}^{n_h} {m \choose n_1, \dots, n_h}
$$
\n(B.3)\n
$$
= \sum_{i=1}^m \sum_{i \in \mathcal{C}_h^{(1,\dots,H)}} \sum_{\substack{m_1,\dots,m_h \ge 0 \\ m_1 + \dots + m_h = m}} c_{k_1}^{m_1} \cdots c_{k_j}^{m_j} {m \choose m_1, \dots, m_j} \sum_{h=i}^H (-1)^{H-h} \left| c_{h,\{k_1,\dots,k_j\}}^{(1,\dots,H)} \right| \tag{B.4}
$$

<span id="page-23-4"></span>*h*=*j*

*<sup>k</sup>*∈*C*{1,...,*H*} *j*

*m*1,...,*mj*≥1 *m*1+···+*mj*=*m*

<span id="page-23-3"></span>*j*=1

<span id="page-24-0"></span>
$$
= \sum_{j=1}^{m} \sum_{k \in C_j^{\{1,\dots,H\}}} \sum_{\substack{m_1,\dots,m_j \ge 1 \\ m_1 + \dots + m_j = m}} c_{k_1}^{m_1} \cdots c_{k_j}^{m_j} {m_1, \dots, m_j} (-1)^{H+j} \sum_{l=0}^{H-j} (-1)^l {H-j \choose l} \quad (B.5)
$$
  

$$
= \begin{cases} 0, & m < H, \\ \sum_{\substack{n_1,\dots,n_H \ge 1 \\ n_1 + \dots + n_H = m}} c_1^{n_1} \cdots c_H^{n_H} {m \choose n_1, \dots, n_H}, & m \ge H. \end{cases}
$$

In fact, in [\(B.5\)](#page-24-0), the last sum (with index *l*) is equal to 0 for  $j \neq H$  and 1 for  $j = H$ . In [\(B.4\)](#page-23-3) we express [\(B.3\)](#page-23-4) by summing every possible combination of indexes  $(k_1, \ldots, k_j)$  and every possible allocation of exponents  $(m_1, \ldots, m_j \ge 1, m_1 + \cdots + m_j = m)$ . Each of these elements,  $c_{k_1}^{m_1} \cdots c_{k_j}^{m_j}$ , appears one time in the expansion of  $(c_{i_1} + \cdots + c_{i_h})^m$  for each  $i \in C_{h, \{k_1, \ldots, k_j\}}^{(1, \ldots, H)}$ with  $1 \le j \le h \le H$ , i.e.

$$
\left| \mathcal{C}_{h,\{k_1,\ldots,k_j\}}^{(1,\ldots,H)} \right| = \binom{H-j}{h-j}
$$

times.

To prove [\(B.2\)](#page-23-5) we proceed as follows, denoting by  $C_{k,(h)}^{\{1,\ldots,H\}}$  the combinations of *k* elements not containing *h*:

<span id="page-24-1"></span>
$$
\sum_{h=1}^{H} c_{h} e^{\beta c_{h}} \prod_{\substack{j=1 \ j \neq h}}^{H} (e^{\beta c_{j}} - 1) = \sum_{h=1}^{H} c_{h} e^{\beta c_{h}} \sum_{k=0}^{H-1} (-1)^{H-1-k} \sum_{i \in C_{k,(h)}^{\{1,\ldots,H\}}} e^{\beta (c_{i_{1}} + \cdots + c_{i_{k}})}
$$
\n
$$
= \sum_{k=0}^{H-1} (-1)^{H-1-k} \sum_{h=1}^{H} c_{h} \sum_{i \in C_{k,(h)}^{\{1,\ldots,H\}}} e^{\beta (c_{h} + c_{i_{1}} + \cdots + c_{i_{k}})} \qquad (B.6)
$$
\n
$$
= \sum_{k=0}^{H-1} (-1)^{H-1-k} \sum_{i \in C_{k+1}^{\{1,\ldots,H\}}} (c_{i_{1}} + \cdots + c_{i_{k+1}}) e^{\beta (c_{i_{1}} + \cdots + c_{i_{k+1}})},
$$

which coincides with [\(B.2\)](#page-23-5). The last step follows from observing that for each combination  $i \in C_{k+1}^{(1,\ldots,H)}$ , the corresponding exponential term appears once for each  $h \in i = (i_1,\ldots,i_{k+1})$ , with  $h$  being the index of the second sum of  $(B.6)$ .

We now compute the probability mass that the motion moves with all  $H + 1$  precise velocities, and only these, for  $H = 0, ..., D - 1$ . Let  $I_H = \{i_0, ..., i_H\} \in C_{H+1}^{\{0, ..., D\}}$ ; then

<span id="page-24-2"></span>
$$
\mathbb{P}\Big\{X(t) \in \mathring{\text{Conv}}(\nu_{i_0}t, \dots, \nu_{i_H}t)\Big\} = \mathbb{P}\Big\{\bigcap_{i \in I_H} \{N_i(t) \ge 1\}, \bigcap_{i \notin I_H} \{N_i(t) = 0\}\Big\}
$$
\n(B.7)\n
$$
= \sum_{n=H}^{\infty} \mathbb{P}\{N(t) = n\} \sum_{\substack{n_0, \dots, n_H \ge 1 \\ n_0 + \dots + n_H = n+1}} p_{i_0}^{n_0} \cdots p_{i_H}^{n_H} {n+1 \choose n_0, \dots, n_H}
$$

$$
(B.9)

<span id="page-25-1"></span>
$$
-e^{-\lambda t} \sum_{n=0}^{H-1} \frac{(\lambda t)^n}{n!} \sum_{h=1}^{H+1} (-1)^{H+1-h} \sum_{i \in C_h^{(0,\dots,H)}} (p_{i_0} + \dots + p_{i_h})^{n+1}
$$
(B.10)

$$
= (p_0 + \dots + p_H) e^{-\lambda t (1 - p_0 - \dots - p_H)} - \sum_{h=1}^H (-1)^{H-h} \sum_{i \in C_h^{(0, \dots, H)}} (p_{i_0} + \dots + p_{i_h}) e^{-\lambda t (1 - p_{i_0} - \dots - p_{i_h})}
$$
  
=  $\mathbb{P} \left\{ \bigcap \{N_i(t) = 0\} \right\} - \mathbb{P} \left\{ \bigcup \{N_i(t) = 0\}, \bigcap \{N_i(t) = 0\} \right\},$ 

$$
= \mathbb{P}\left\{\bigcap_{i \notin I_H} \{N_i(t) = 0\}\right\} - \mathbb{P}\left\{\bigcup_{i \in I_H} \{N_i(t) = 0\}, \bigcap_{i \notin I_H} \{N_i(t) = 0\}\right\},\
$$
  
where we used the second equality of (B.1) to derive (B.8). Thanks to

where we used the second equality of  $(B.1)$  to derive  $(B.8)$ . Thanks to the first case of  $(B.1)$ , it is easy to see that the term  $(B.10)$  is 0, and thus, by means of  $(B.2)$ , we also obtain the equivalence between  $(B.9)$  and the probability mass  $(2.34)$ .

Note that if the motion is *uniform*, i.e.  $p_0 = \cdots = p_D = 1/(D+1)$ , then the probability [\(B.7\)](#page-24-2) reduces to

$$
\frac{H+1}{D+1}e^{\frac{-\lambda t D}{D+1}}\left(e^{\frac{-\lambda t}{D+1}}-1\right)^H
$$

(see also [\(2.34\)](#page-16-3)).

In light of  $(B.9)$ , the probability that the motion moves with exactly  $H + 1$  velocities in the time interval [0, *t*] is

<span id="page-25-3"></span>
$$
\mathbb{P}\left\{\bigcup_{I\in C_{H+1}^{(0,\ldots,D)}}\left\{\bigcap_{i\in I}\{N_{i}(t)\geq 1\},\bigcap_{i\notin I}\{N_{i}(t)=0\}\right\}\right\}
$$
\n
$$
=\sum_{I\in C_{H+1}^{(0,\ldots,D)}}\mathbb{P}\left\{\bigcap_{i\in I}\{N_{i}(t)\geq 1\},\bigcap_{i\notin I}\{N_{i}(t)=0\}\right\}
$$
\n
$$
=\sum_{h=1}^{H+1}(-1)^{H+1-h}\sum_{I\in C_{H+1}^{(0,\ldots,D)}}\sum_{i\in C_{h}^{(0,\ldots,D)}}(p_{i_{0}}+\cdots+p_{i_{h}})e^{-\lambda t(1-p_{i_{0}}-\cdots-p_{i_{h}})}
$$
\n
$$
=\sum_{h=1}^{H+1}(-1)^{H+1-h}\left(\frac{D+1-h}{H+1-h}\right)\sum_{i\in C_{h}^{(0,\ldots,D)}}(p_{i_{0}}+\cdots+p_{i_{h}})e^{-\lambda t(1-p_{i_{0}}-\cdots-p_{i_{h}})},\qquad (B.11)
$$

where in the last step we observe that each combination  $i \in C_h^{\{0,\dots,D\}}$  appears in  $\binom{D+1-h}{H+1-h}$ *H*+1−*h* combinations in  $C_{H+1}^{\{0,\ldots,D\}}$  (i.e. all those which contain the *h* elements in *i*).

Finally, by using the expression  $(B.11)$ , we obtain

<span id="page-26-0"></span>
$$
\mathbb{P}\left\{X(t) \in \partial \text{Supp}(X(t))\right\} = \mathbb{P}\left\{\bigcup_{h=0}^{D} \{N_h(t) = 0\}\right\}
$$
\n
$$
= \mathbb{P}\left\{\bigcup_{H=0}^{D-1} \bigcup_{I \in C_{H+1}^{(0,...,D)}} \left\{\bigcap_{i \in I} \{N_i(t) \ge 1\}, \bigcap_{i \notin I} \{N_i(t) = 0\}\right\}\right\}
$$
\n
$$
= \sum_{H=0}^{D-1} \sum_{h=1}^{H+1} (-1)^{H+1-h} \binom{D+1-h}{H+1-h} \sum_{i \in C_{h}^{(0,...,D)}} (p_{i_0} + \dots + p_{i_h}) e^{-\lambda t(1-p_{i_0}-\dots-p_{i_h})}
$$
\n
$$
= \sum_{h=1}^{D} \sum_{i \in C_{h}^{(0,...,D)}} (p_{i_0} + \dots + p_{i_h}) e^{-\lambda t(1-p_{i_0}-\dots-p_{i_h})} \sum_{H=h-1}^{D-1} (-1)^{H+1-h} \binom{D+1-h}{H+1-h}
$$
\n
$$
= \sum_{h=1}^{D} \sum_{i \in C_{h}^{(0,...,D)}} (p_{i_0} + \dots + p_{i_h}) e^{-\lambda t(1-p_{i_0}-\dots-p_{i_h})} \left(0 - (-1)^{D+1-h}\right)
$$
\n
$$
= \sum_{h=1}^{D} (-1)^{D-h} \sum_{i \in C_{h}^{(0,...,D)}} (p_{i_0} + \dots + p_{i_h}) e^{-\lambda t(1-p_{i_0}-\dots-p_{i_h})}.
$$
\n(B.12)

Note that, with  $(B.12)$  in hand, and also keeping in mind  $(B.2)$  and the fact that  $p_0 + \cdots + p_D = 1$ , we obtain the last step in the probability [\(2.27\)](#page-13-0).

It is interesting to observe that if the point process governing  $X$  is a non-homogeneous Poisson process with rate function  $\lambda : [0, \infty) \longrightarrow [0, \infty)$  such that  $\Lambda(t) = \int_0^t \lambda(s) ds < \infty \forall t$ , then the above probability masses hold with  $\Lambda(t)$  replacing  $\lambda t$ .

### **B.2. PDE governing the absolutely continuous component**

From the differential system [\(4.2\)](#page-20-1) we obtain [\(4.3\)](#page-20-3) through the following iterative argument. First we consider  $w_1 = f_0 + f_1$  and easily obtain

<span id="page-26-1"></span>
$$
\frac{\partial w_1}{\partial t} = \lambda (p_0 + p_1 - 1) w_1 - \frac{\partial f_1}{\partial x_1} + \lambda (p_0 + p_1) \sum_{j=2}^{D} f_j
$$
  
=  $Aw_1 + Bf_1 + C \sum_{j=2}^{D} f_j,$  (B.13)

with *A*, *B*, *C* being suitable operators. Next we rewrite the equations of [\(4.2\)](#page-20-1) by means of the operators  $E_i = \left(\frac{\partial}{\partial x_i} + \lambda\right)$  and  $G_i = \lambda p_i$ :

<span id="page-26-2"></span>
$$
\frac{\partial f_i}{\partial t} = -E_i f_i + G_i \sum_{j=0}^{i} f_j + G_i \sum_{j=i+1}^{D} f_j, \quad i = 1, \dots D.
$$
 (B.14)

Keeping in mind  $(B.13)$ ,  $(B.14)$  (for  $i = 1$ ), and the exchangeability of the differen- $\sum_{j=2}^D f_j$ : tial operators, we can express the second-order time derivative of  $w_1$  in terms of  $w_1$  and

<span id="page-27-2"></span>
$$
\frac{\partial^2 w_1}{\partial t^2} = A \frac{\partial w_1}{\partial t} + B \frac{\partial f_1}{\partial t} + C \frac{\partial}{\partial t} \sum_{j=2}^D f_j
$$
\n
$$
= A \frac{\partial w_1}{\partial t} + B \left( -E_1 f_1 + G_1 w_1 + G_1 \sum_{j=2}^D f_j \right) + C \frac{\partial}{\partial t} \sum_{j=2}^D f_j
$$
\n
$$
= \left( A \frac{\partial}{\partial t} + B G_1 \right) w_1 - E_1 \left( \frac{\partial w_1}{\partial t} - A w_1 - C \sum_{j=2}^D f_j \right) + \left( B G_1 + C \frac{\partial}{\partial t} \right) \sum_{j=2}^D f_j
$$
\n
$$
= \left( (A - E_1) \frac{\partial}{\partial t} + B G_1 + E_1 A \right) w_1 + \left( B G_1 + C \left( \frac{\partial}{\partial t} + E_1 \right) \right) \sum_{j=2}^D f_j
$$
\n
$$
= \left( \lambda^2 (p_0 + p_1 - 1) + \lambda (p_0 + p_1 - 2) \frac{\partial}{\partial t} + \lambda (p_0 - 1) \frac{\partial}{\partial x_1} - \frac{\partial^2}{\partial t \partial x_1} \right) w_1
$$
\n
$$
+ \left( \lambda (p_0 + p_1) \left( \frac{\partial}{\partial t} + \lambda \right) + \lambda p_0 \frac{\partial}{\partial x_1} \right) \sum_{j=2}^D f_j
$$
\n
$$
= \Lambda_1 w_1 + \Gamma_1 \sum_{j=2}^D f_j.
$$
\n(B.15)

By iterating the above argument, at the *n*th step,  $n = 2, ..., D$ , we have, with  $w_n = w_{n-1} +$ *f<sub>n</sub>* (meaning that  $w_i = \sum_{j=0}^i f_j$ ,  $i = 1, \ldots, D$ ),

<span id="page-27-0"></span>
$$
\begin{cases}\n\frac{\partial^n w_{n-1}}{\partial t^n} = \Lambda_{n-1} w_{n-1} + \Gamma_{n-1} \sum_{j=n}^D f_j \implies \left(\frac{\partial^n}{\partial t^n} - \Lambda_{n-1}\right) w_{n-1} = \Gamma_{n-1} f_n + \Gamma_{n-1} \sum_{j=n+1}^D f_j, \\
\left(\frac{\partial}{\partial t} + E_n\right) f_n = G_n w_n + G_n \sum_{j=n+1}^D f_j, \\
\left(\frac{\partial}{\partial t} + E_i\right) f_i = G_i w_i + G_i \sum_{j=i+1}^D f_j, \quad i = n+1, \dots, D.\n\end{cases} \tag{B.16}
$$

<span id="page-27-1"></span>Thus, using the first two equations of  $(B.16)$ , we have

$$
\left(\frac{\partial^n}{\partial t^n} - \Lambda_{n-1}\right)\left(\frac{\partial}{\partial t} + E_n\right)w_n\tag{B.17}
$$

$$
= \left(\frac{\partial^n}{\partial t^n} - \Lambda_{n-1}\right)G_n w_n + \Gamma_{n-1}\left(\frac{\partial}{\partial t} + E_n\right) f_n + \left[\left(\frac{\partial}{\partial t} + E_n\right) \Gamma_{n-1} + \left(\frac{\partial^n}{\partial t^n} - \Lambda_{n-1}\right) G_n\right] \sum_{j=n+1}^D f_j
$$
  

$$
= \left(\frac{\partial^n}{\partial t^n} - \Lambda_{n-1} + \Gamma_{n-1}\right)G_n w_n + \left[\left(\frac{\partial}{\partial t} + E_n\right) \Gamma_{n-1} + \left(\frac{\partial^n}{\partial t^n} - \Lambda_{n-1} + \Gamma_{n-1}\right) G_n\right] \sum_{j=n+1}^D f_j.
$$

Hence, by reordering the terms in  $(B.17)$ , for  $n = 2, \ldots, D$ , we see that

$$
\Lambda_n = \left(\frac{\partial}{\partial t} + \frac{\partial}{\partial x_n} + \lambda\right) \Lambda_{n-1} + \lambda (p_0 - 1) \frac{\partial^n}{\partial t^n} + \lambda p_0 (\Gamma_{n-1} - \Lambda_{n-1}) - \frac{\partial^{n+1}}{\partial t^n \partial x_n}
$$

and

$$
\Gamma_n = \left(\frac{\partial}{\partial t} + \frac{\partial}{\partial x_n} + \lambda\right) \Gamma_{n-1} + \lambda p_n \left(\frac{\partial^n}{\partial t^n} + \Gamma_{n-1} - \Lambda_{n-1}\right),
$$

with  $\Lambda_1$ ,  $\Gamma_1$  given in [\(B.15\)](#page-27-2).

 $\overline{a}$ 

The interested reader can check (for instance by induction) that the operators  $\Lambda_n$  and  $\Gamma_n$  are such that

<span id="page-28-0"></span>
$$
\frac{\partial^{n+1} w_n}{\partial t^{n+1}} = \Lambda_n w_w + \Gamma_n \sum_{j=n+1}^D f_j
$$
\n(B.18)

<span id="page-28-3"></span>
$$
= \left(\sum_{k=0}^{n} \sum_{i \in C_k^{(1,\ldots,n)}} \sum_{h=0}^{n-k} \lambda^{n+1-(h+k)} \left[ \binom{n-k}{h} \left(p_0 + \sum_{\substack{j=1 \ j \notin i}}^n p_j\right) - \binom{n+1-k}{h} \right] \frac{\partial^{h+k}}{\partial t^h \partial x_{i_1} \cdots x_{i_k}} \right]
$$
(B.19)

<span id="page-28-2"></span>
$$
-\sum_{k=1}^{n}\sum_{i\in C_k^{\{1,\dots,n\}}}\frac{\partial^{n+1}}{\partial t^{n+1-k}\partial x_{i_1}\cdots x_{i_k}}\bigg) w_n
$$
 (B.20)

<span id="page-28-1"></span>
$$
+\sum_{k=0}^{n} \sum_{i \in C_{k}^{(1,...,n)}} \sum_{h=0}^{n-k} \lambda^{n+1-(h+k)} {n-k \choose h} \left(p_{0} + \sum_{\substack{j=1 \ j \notin i}}^{n} p_{j}\right) \frac{\partial^{h+k}}{\partial t^{h} \partial x_{i_{1}} \cdots x_{i_{k}}} \sum_{j=n+1}^{D} f_{j}.
$$
\n(B.21)

Finally, for  $n = D$  and  $w_D = \sum_{j=0}^{D} f_j = p$ , which is the probability density of the position of the motion, the formula  $(B.18)$  reduces to  $(4.3)$ ; indeed, the term in  $(B.21)$  becomes 0, the  $(D+1)$ th-order time derivative can be included in the sum in [\(B.20\)](#page-28-2) as  $k = 0$ , and this new sum becomes the term with  $h = D + 1 - k$  in [\(B.19\)](#page-28-3).
