Introduction: Patients suffering from psychiatric illness represent a population that is particularly vulnerable to the SARS-CoV-2 virus and to the pandemic situation due to several factors.

Objectives: We aimed in our study to determine the rate of COVID-19 infection and to identify its correlated factors in outpatients of the psychiatry department of Monastir, Tunisia.

Methods: This is a descriptive and analytical cross-sectional study conducted on 178 outpatients at the department of psychiatry (Monastir, Tunisia) over a period of one month (from March 2022 to April 2022). Data was collected via a questionnaire focused on two main attributes: (1) sociodemographic and clinical characteristics; (2) questions about the COVID-19 personal and family history.

Results: The mean age of our population was 44.9 ± 13.7 years. The majority of them (81.5%) had a chronic evolution of their psychiatric disorder (> 2 years) and 68.7% were hospitalized at least once in psychiatry. Psychosis was the most represented disorder with 57.3% compared to mood disorders and anxiety disorders. Among our population, thirty seven patients (21%) had a SARS-CoV-2 infection and 3.1% required hospital care. The infection by the virus of a family member was reported by 46% of cases and 2.5% had intrafamilial death due to COVID-19 disease. Patients with depressive disorder were the most affected (55%). COVID-19 infection was significantly associated with gender ($p=0.02$), marital status ($p=0.016$), diagnosis ($p=0.001$), treatment ($p=0.02$) and intrafamilial spread of the disease ($p<10^{-3}$).

Conclusions: Patients with psychiatric disorders experience a distinct burden of the COVID-19 disease. Awareness of the vulnerability of this population and psychiatric institutions is necessary in order to adapt mental health care planning and implement preventive measures during potential subsequent pandemics.

COVID-19-associated schizophrenia-like psychosis during the COVID-19 pandemic

L. Bravve* and N. Zakharova

Psychiatric Hospital no. 1 Named after N.A. Alexeev of the Department of Health of Moscow, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2023.1689

Introduction: The viral theory of the development of psychoses was formulated in the 19th century, but the role of viral agents in the

pathogenesis of psychoses remains a matter of debate. In the context of the 2020 pandemic, the results of several papers on the characteristics of psychotic disorders in COVID-19 have been published. Coronaviruses are neuroinvasive, capable of affecting mental and body functions.

Objectives: The aim of the study was to identify patients with acute psychosis without a history of mental disorders in order to test the hypothesis about the possibility of manifestation of schizophreniform psychosis due to a viral attack.

Methods: Within a year and a half, 50 patients with mental disorders associated with COVID-19 were identified. The reason for hospitalization in a psychiatric hospital is the development of acute schizophreniform psychosis against the background of a new coronavirus infection. The diagnosis was verified according to traditional clinical criteria and modern psychometric tools. Inclusion criteria: no previous visits to a psychiatrist; verified acute polymorphic psychotic disorder and coronavirus infection COVID-19 (ICD-10); manifestation of psychosis against the background of infection with COVID-19; age 18-60 years; consent to participate in the study. Exclusion criteria: signs of organic brain damage; indications of substance abuse; delirium of any etiology; somatic pathology in the stage of decompensation.

Results: 27 women (54%) and 23 men (46%), aged 20 to 57 years (average age 34.5 ± 7.6), of which 18 people (36%) worked, 2 (4%) studied, 29 (58%) people are unemployed. 27 people (54%) are single, 16 (32%) are married, 7 (14%) are divorced; 18 people (36%) were raising children, which indirectly indicated a relatively favorable premorbid functioning. At the time of the examination, the condition was determined by polymorphic psychotic symptoms with a predominance of dissociative-delusional, paraphrenic and oneiric phenomena with plots containing plots of infection and the spread of coronavirus. At the same time, the sum of PANSS is from 53 to 130 (85) points, including PANSS P - from 15 to 37 (27), PANSS N - from 7 to 44 (18), PANSS G - from 23 to 57 (39.9); P1 - 5.7; P3 - 5.1. When comparing the obtained data with the world experience, we found some differences. Delusional symptoms were diagnosed twice as rarely, cases with tactile hallucinations were not detected, but catatonic symptoms were observed twice as often, and manic arousal was twice as rare. In general, the studied data are comparable with the results published in the world practice.

Conclusions: The unique experience of the coronavirus pandemic will allow us to assess the influence of environmental factors, namely the role of infections, in the manifestation or predisposition to schizophrenia spectrum disorders. It is planned to evaluate the dynamics of the course of the disorder after the relief of the acute period.
