

RAT AND FLEA CONDITIONS IN A RURAL ENDEMIC PLAGUE AREA IN KENYA

By J. I. ROBERTS
Medical Research Laboratory, Nairobi

(With 4 Figures in the Text)

THE survey of rats and fleas in the main endemic plague area of Kenya (Keruguya) has been continued over a further period of two years, September 1935 to August 1937, with the following results.

A. DOMESTIC RATS AND FLEAS

Table I

	Rainfall in.		<i>Rattus rattus</i> trapped

The following species of fleas were also collected from *Rattus* during 1935-6 and 1936-7:

1935-6		1936-7	
30 ♂♂	42 ♀♀ <i>X. cheopis</i>	12 ♂♂	596 ♀♀ <i>E. gallinaceus</i>
1511 ♂♂	892 ♀♀ <i>X. robertsi</i>	30 ♂♂	34 ♀♀ <i>C. felis</i>
16 ♂♂	22 ♀♀ <i>D. lypusus</i>	11 ♂♂	11 ♀♀ <i>S. tortus</i>
104 ♂♂	168 ♀♀ <i>C. cabirus</i>	5 ♂♂	9 ♀♀ <i>L. segnis</i>
1936-7			
4 ♂♂	3 ♀♀ <i>X. cheopis</i>	39 ♂♂	457 ♀♀ <i>E. gallinaceus</i>
1231 ♂♂	598 ♀♀ <i>X. robertsi</i>	22 ♂♂	30 ♀♀ <i>C. felis</i>
3 ♂♂	10 ♀♀ <i>D. lypusus</i>	8 ♂♂	5 ♀♀ <i>S. tortus</i>
103 ♂♂	111 ♀♀ <i>C. cabirus</i>	1 ♀	<i>C. fasciatus</i>

The higher numbers of *X. cheopis* in 1935-6 are due to trapping in a wood and iron store in a chief's village. This occurred in November 1935, when 28 ♂♂ 33 ♀♀ *X. cheopis* were collected from *Rattus* trapped.

The behaviour of the new *Xenopsylla* species, *X. robertsi*, is interesting. The following table shows its erratic occurrence on *Rattus*.

	1934-5		1935-6		1936-7		1937

Total	273	160	1511	892	1231	678	286	138

The following graphs give a comparison between the results obtained in the three periods. From these it can be seen that the factor exercising the greatest

influence on the incidence of plague is the *Rattus* population density. When the *Rattus* population density remains low, the incidence of plague has diminished considerably as seen in the figures for 1937. The flea index figures have remained fairly constant over the three years.

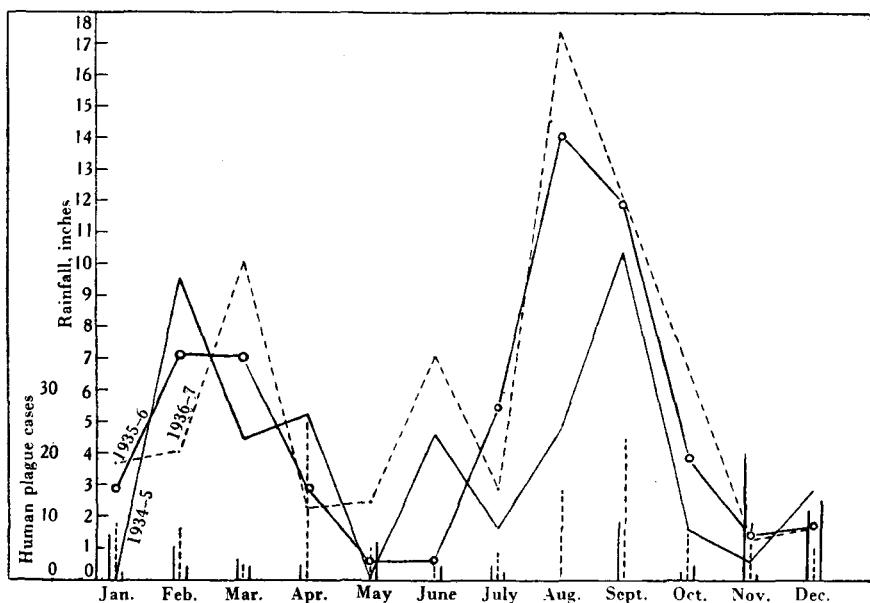

Fig. 1. Rainfall and human plague (vertical lines).

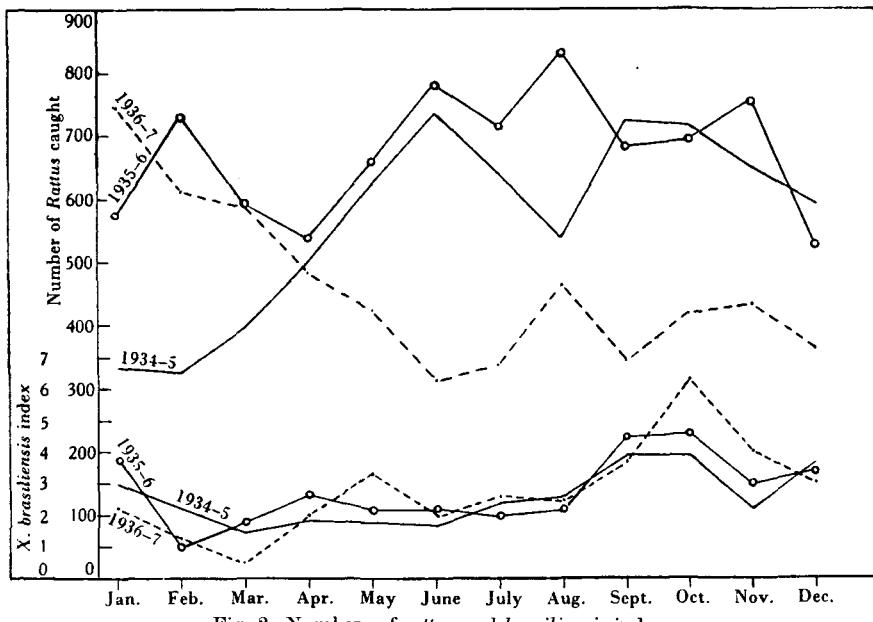

Fig. 2. Numbers of *ratus* and *brasiliensis* index.

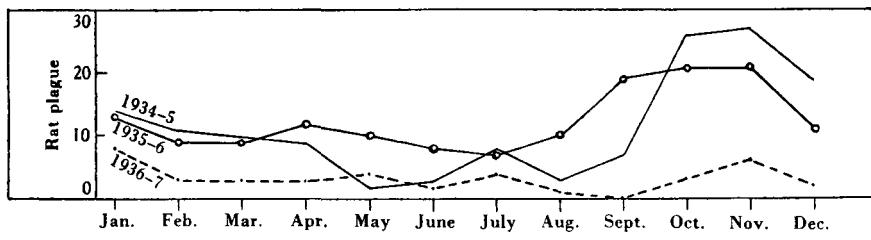

Fig. 3. Rat plague.

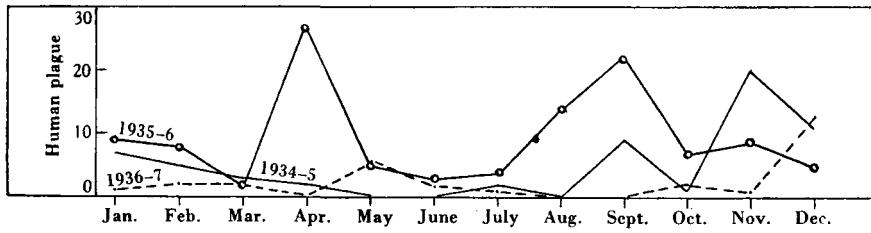

Fig. 4. Human plague.

B. FIELD RODENTS AND FLEAS

The total figures for the two yearly periods are given.

Mastomys coucha. 103 ♂♂ 54 ♀♀ = 157. 18 ♀♀ were pregnant with a total of 121 embryos. Average per female = 9.8.

Fleas.	9 ♂♂ 21 ♀♀	<i>X. brasiliensis</i>	26 ♂♂ 56 ♀♀	<i>C. cabirus</i>
	8 ♂♂ 15 ♀♀	<i>X. cheopis</i>	6 ♂♂ 18 ♀♀	<i>S. tortus</i>
	4 ♂♂	<i>X. robertsi</i>	1 ♀	<i>E. gallinaceus</i>
	23 ♂♂ 21 ♀♀	<i>D. lypusus</i>		

Otomys angoniensis. 109 ♂♂ 93 ♀♀ = 202. 62 ♀♀ were pregnant with a total of 134 embryos. Average per female = 2.1.

Fleas.	18 ♂♂ 13 ♀♀	<i>X. brasiliensis</i>	61 ♂♂ 75 ♀♀	<i>C. cabirus</i>
	3 ♂♂ 2 ♀♀	<i>X. cheopis</i>	3 ♂♂ 4 ♀♀	<i>S. tortus</i>
	1 ♂	<i>X. robertsi</i>	1 ♂ 2 ♀♀	<i>C. felis</i>
	6 ♂♂ 5 ♀♀	<i>D. lypusus</i>	5 ♀♀	<i>E. gallinaceus</i>

Lemniscomys massaicus. 450 ♂♂ 350 ♀♀ = 800. 111 ♀♀ were pregnant with a total of 499 embryos. Average per female = 4.5.

Fleas.	87 ♂♂ 81 ♀♀	<i>X. brasiliensis</i>	447 ♂♂ 607 ♀♀	<i>C. cabirus</i>
	2 ♂♂ 5 ♀♀	<i>X. cheopis</i>	5 ♂♂ 13 ♀♀	<i>S. tortus</i>
	5 ♂♂ 2 ♀♀	<i>X. robertsi</i>	1 ♂ 2 ♀♀	<i>C. felis</i>
	13 ♂♂ 15 ♀♀	<i>D. lypusus</i>	1 ♀ <i>C. fasciatus</i>	
			1 ♀ <i>E. gallinaceus</i>	

Lophuromys aquilus. 352 ♂♂ 269 ♀♀ = 621. 127 ♀♀ were pregnant with a total of 316 embryos. Average per female = 2.5.

Fleas.	89 ♂♂ 53 ♀♀	<i>X. brasiliensis</i>	235 ♂♂ 305 ♀♀	<i>C. cabirus</i>
	5 ♂♂ 4 ♀♀	<i>X. cheopis</i>	16 ♂♂ 19 ♀♀	<i>S. tortus</i>
	6 ♂♂ 9 ♀♀	<i>X. robertsi</i>	1 ♂	<i>C. felis</i>
	46 ♂♂ 57 ♀♀	<i>D. lypusus</i>	2 ♀♀ <i>C. fasciatus</i>	
			6 ♀♀ <i>E. gallinaceus</i>	

Arvicanthis abyssinicus. 1 ♂ 1 ♀ = 2. 1 female pregnant with 3 embryos.

Fleas. 1 ♂ *X. cheopis*. 2 ♂♂ 2 ♀♀ *C. cabirus*.

SUMMARY

The female percentage figures for *Rattus* for the three years are 57.8, 57.7 and 57.5 respectively. Pregnancy records were obtained by counting embryos sufficiently advanced to be recognizable to the naked eye. The average number of embryos per pregnant female agree closely for the three years, and the error of underestimating invisible embryos appears to be constant. There is a slight suggestion of two enhanced breeding periods for *Rattus* in the area, both periods being coincident with higher rainfall and the growing season. The main interest in these figures lies in the large number of embryos recorded over the nipple provision, the greatest number observed being seventeen.

The average number of fleas per rat shows that the period of their maximum incidence agrees closely with the higher incidence of plague.

The number of traps set out daily in huts has remained constant over the three years. Little reliance could be placed on detailed trapping figures as the trapping varies considerable from village to village and even hut to hut, and gross figures only can be employed. Not only do these figures demonstrate that endemic areas have a much higher *Rattus* density and higher breeding rates than plague-free areas, but they indicate that the incidence of plague, both in man and rats, is more closely associated with rat population densities than any other factor.
