activity when cells are exposed to autophagy inhibitors such as chloroquine [5]. To this date it remains elusive whether increased autophagy phenotype is the result of IDH1 mutation or if it either represents a secondary co-existing condition in the setting of the IDH1 mutation. Autophagy is also a mechanism of detoxification induced by chronic heavy metal exposure in both normal and cancer cells. Thus, we hypothesized that autophagy activity in IDH1 mt glioma is partially induced by chronic heavy metal exposure, leading to increased cell survival and abnormal DNA repair. Our approach included characterization and quantification of metal content on IDH1 mt glioma cell lines and tissues, in addition to correlation analyses of the celullar metallome with autophagy markers, ROS and DNA repair of IDH1 mt glioma cells allowed us to explore targets responsible for cell survival and DNA repair response. Furthermore, we evaluated the potential therapeutic value of Chloroquine (CQ) and bafylomicin for IDH1 mutant gliomas targeting autophagy pathway in combination with TMZ and radiation. We demonstrated that 2-HG induces autophagy activity via LC3B activation, and autophagy inhibiton by beclin gene silencing results in a reduction of 2-HG leading to cell starvation and apoptosis. Remarkably, we observed a positive correlation on at least six different metals with autophagy induced LC3B and beclin1 expression that significantly differed between the mutant and the wt genotype in glioma cell lines. ROS and DNA repair were also positively associated with at least 6 different metals and only seen in the IDH1 mt cell lines, then suggesting a possible explanation for the increase on autophagy, analysis of both LC3B and beclin 1 expression demonstrated a positive correlation with Mo98, Fe54, and Zn 66 on IDH1 mt cell lines and a positively correlation with Mo98 and V concentrations in relation to H2AX expression. Co, SeO Mo, V and Mg were positively correlated to ROS expression. TMZ and CQ induced autophagy pathway activation as measured by LC3B, Beclin, Atg expression. Silencing beclin in IDH1 mutant glioma cell lines induced apoptosis and reduction on 2-HG production after treatment with TMZ and radiation. Overall the results contained in this study 1) identify cellular metal content in relationship to mechanisms leading to increased autophagy on IDH1 mt glioma cells. 2) evaluate the combination of CQ and TMZ to potentially target and inhibit autophagy as a mechanism downstream the 2-HG production in IDH1 mt glioma cells.

Disparities in survival for patients with glioblastoma multiforme

Mostafa Fatehi, Camille Hunt, Roy Ma, Brian Toyota.
fatehi@alumni.ubc.ca

Background: Glioblastoma multiforme (GBM) is the most common malignant primary brain cancer in adults. Recent efforts have elucidated genetic features of tumor cells and thus enhanced our knowledge of GBM pathophysiology. The most recent clinical trials report median overall survival between 14 and 20 months. However, real-world outcomes are quite variable and there is a paucity of data within the literature. Methods: Three hundred seventy two GBM patients were diagnosed in the province of British Columbia between January 2013 and January 2015. We have performed a retrospective review on the survival outcomes of the 278 patients who underwent surgical resection as part of the initial treatment. Results: Our results indicate a median age of 61.8y at time of diagnosis with a slight preponderance of males. The median overall survival was 10 months for patients who underwent surgery. As expected, patients over the age of 65 and those with worse initial Karnofsy Performance Status (KPS) scores had a poorer prognosis. Moreover, we have found extent of resection (EOR), treatment strategies and treatment location affect overall survival. Conclusion: The present study highlights factors which affect patient survival after surgery in British Columbia. Our outcomes are slightly worse than survival reported in the US. Variability in pathologic classification and in treatment strategy likely contribute to this difference. Further efforts should ensure access to the gold-standard of care.

Inhibiting PARP-1 to restore temozolomide sensitivity and prevent resistance in glioblastoma

E. A. Bering, A. L. Yuan, J. G. Cairncross, M. D. Blough.
elizabeth.bering1@ucalgary.ca

Adult Glioblastomas (GBMs) remain one of the least curable brain cancers despite the discovery and use of DNA alkylating agent Temozolomide (TMZ). TMZ provides a moderate survival benefit to sensitive patients whose O6-methylguanine-methyltransferase (MGMT) gene is silenced by promoter methylation. Unfortunately, TMZ potential is stunted because of the rapid onset of tumour recurrence and acquired resistance believed to result from the upregulation of DNA damage repair by the base excision repair (BER), mismatch repair (MMR), or homologous recombination (HR) systems. Our laboratory previously demonstrated that cell lines obtained from recurrent, TMZ-resistant GBMs could be re-sensitized to TMZ when treated with an inhibitor of poly (ADP-ribose) polymerase-1 (PARP-1) – a protein instrumental in the recruitment of BER machinery. From this preliminary research, we postulate that PARP-1 inhibition may not only be used to overcome established resistance in GBM but may also be used to prevent its emergence altogether. To test this hypothesis, we utilized the MGMT-methylated GBM cell line U251N and developed an in vitro model of inducible TMZ resistance. We verified that prolonged treatment of U251N cells with TMZ resulted in the emergence of resistant colonies that resembled recurrent GBM clinically observed in TMZ-treated patients. However, when the parental U251N line was co-treated with TMZ and PARP-1 inhibitor ABT-888, resistant colonies failed to appear. Therefore, PARP-1 inhibition may possess the potential to maintain tumour sensitivity to TMZ as well as evade the otherwise inevitable development of resistance in GBM.

Long-term survivors of brain metastases

Archya Dasgupta, Fabio Y Moraes, Jayson Co, Jeff Winter, Catherine Coolens, Barbara-Ann Millar, Normand Laperriere, Derek S. Tsang, Mark Bernstein, Paul Kongkham, Gelareh Zadeh, Tatiana Conrad, Alejandro Berlin, David B Shultz.
archya.dasgupta@rmp.uhn.ca

Purpose: We identified key clinicopathologic features of brain metastasis (BM) patients who are long-term survivors (LTS).
