

regression was conducted (using SPSS 28), with resilient coping as the dependent variable and the other variables entered as potential predictor variables.

Results: A total of 1522 students (75.1% women and 24.9% men) took part in this study. Most participants were single (91.2%), had no children (93%), and the ages ranged from 18 to 59, with a mean age of 22.88 ± 6.93 years. In terms of study level, the majority of students (73.7%) are at the undergraduate level and are not working (76.6%). Among the participants, 35.7%, 36.2%, and 28.5% had symptoms of stress, anxiety, and depression above the normal range, respectively. High resilience scores were found in 215 participants (14.1%). The mean hope (HHI) was 35.53 (SD = 5.92). Our results also demonstrated that hope is the only predictor of resilient coping ($p < 0.001$). A higher level of hope is expected to affect people's psychological adjustment by influencing both their appraisal of, and their coping with, the stressors confronted by them.

Conclusions: Establishing and improving protective factors should increase the likelihood of the individual successfully avoiding negative outcomes and increase their ability to function normally, thus promoting resilient outcomes. We were able to draw practical implications for developing resilience-promoting methods in a university context. These results can be used to help students build resilience by preparing for future problems.

Introduction: Chronic fatigue and psychiatric manifestations (depression, anxiety and sleep disturbances) appear to be key features of post-COVID-19 syndrome and increase significantly in prevalence over time (Lavienraj et al. *J Neurol Sci* 2022;434:120162). Several studies have suggested an association between altered levels of arginine metabolites and depression, anxiety and stress severity (Arisoy et al. *J Psychiatr Res* 2020;120:21-28). L-arginine supplementation has also been shown to improve walking performance, muscle strength, endothelial function and fatigue in adults with Long COVID (Tosato et al. *Nutrients* 2022;14(23):4984).

Objectives: To study effects of L-arginine oral supplementation on chronic fatigue and depressive symptoms reported 3 months or more after acute COVID-19 onset in elderly outpatients without severe comorbid conditions.

Methods: This is a parallel-group, double-blind, randomized controlled trial conducted on 96 over 65 non-hospitalized patients suffering from Long Covid-related fatigue and depression. The first

group included patients that received 1,66 g L-arginine twice a day in addition to a standard antidepressant therapy based on Selective Serotonin Reuptake Inhibitors (SSRIs), whereas the second group received antidepressant only. Severity of fatigue and depressive symptoms was evaluated at baseline and after 8 weeks of treatment using Fatigue Symptom Inventory (FSI) and Hamilton Rating Scale for Depression (HAM-D), respectively.

Results: At baseline, 64 patients (66,7%) reported moderate fatigue (4-6) and the remaining 32 (33,3%) reported severe fatigue (7-10). In this phase the average HAM-D score was $12,85 \pm 5,97$; among patients, 57,3% experienced mild symptoms of depression, 32,3% experienced moderate symptoms and 6,4% experienced severe symptoms. After two months, patients treated with L-arginine supplementation exhibited a 30% greater improvement in fatigue-related symptom severity ($p=0.008$) and a significantly decrease in average HAM-D score ($p=0.002$) compared to the group treated with SSRI only.

Conclusions: According to our results, adding oral L-arginine to standard antidepressant therapy in elders with Long Covid-related fatigue and depression significantly decreases severity of both physical and affective symptoms. Further studies are needed to clarify the intriguing role of L-arginine in the treatment of Post Covid-19 syndrome and its potential effects in promoting geriatric patients' health, wellbeing and quality of life.

doi: 10.1192/j.eurpsy.2024.258

Introduction: Although over 100 million pregnant women worldwide are at risk of infection with SARS-CoV-2, little data exists on the impact of COVID-19 and related treatments on maternal/neonatal health.

Objectives: 1) To quantify the prevalence of medication use in pregnancy to treat COVID-19; 2) To quantify and compare the risk of adverse pregnancy/neonatal outcomes in those with and without COVID-19.

Methods: In the Canadian Mother-Child population-based cohort (CAMCCO), two key sub-cohorts were identified using prospective data collection of medical services, prescription drugs, hospitalization archives data, and COVID-19 surveillance testing program (02/28/2020-2021). The first cohort included all pregnant women with at least one completed trimester of pregnancy during the study
