Background: Right ventricular cardiomyopathy (RVCMP) in children and adolescents is a poorly described entity. Conventional transthoracic echocardiogram is a suboptimal tool to evaluate the right ventricle. But, cardiac magnetic resonance imaging (CMR) is emerging as the modality of choice for comprehensive evaluation, including tissue characterization in cardiomyopathies. We present CMR features of 5 children with cardiomyopathy predominately involving the right ventricle.
Material and Methods: Our study group consists of children aged 7months – 15 yrs, weighing 4 kgs - 53 kgs, with 4 boys and 3 girls. All presented with features of right heart failure without arrhythmia. All appropriate seqences were acquired. Gadolinium was used as contrast agent. Late gadolinium enhancement (LGE) images were obtained to look for myocardial fibrosis.
Results: All 7 children had significantly dilated, IVC , RA and RV. The body surface area Indexed RV EDV ranged from 120 ml/M2 to 395 ml/M2. The RVEF varied from 11% to 38%. Four children had exclusive RV failure with normal LV systolic function. In 2 other children there was more RV failure than LV (RVEF 20% vs LVEF of 35%, 23% vs 31%). All had siginificant TR, one had severe PR and another moderate MR. 2 had preserved RV apical function, distal to the moderator band while the rest had global hypokinesia. LGE imaging showed, patchy enhancement in 4. 3 children showed no LGE, which may suggest an absence of RV myocardium as biopsy suggestive of uhl's anomaly.
Conclusions: RVCMP in childhood is a rare entity and the aetiology is not clearly understood. Whether it is a childhood form of the better-described ARVD in the adults is unclear. CMR is a very useful comprehensive tool for evaluation.

P2810 - SPONTANEOUSLY REGRESSION OF THE RIGHT VENTRICULAR DIVERTICULUM AND VENTRICULAR SEPTAL ANEURISM

Tayfun Ucar, Melih Dogan, Ercan Tutar, Semra Atalay
Ankara University Medical School, Pediatric Cardiology, Ankara-Turkey

Background: Right ventricular diverticulum (RVD) and ventricular septal aneurysm (VSA) are rare congenital cardiac malformations.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

RVD are scarcely diagnosed during the fetal period. To our knowledge, this is the first case that VSA associated with RVD. In the present study, we report a case of RVD associated with VSA and its spontan regression.
Case Report: A 34 year old multigravida was referred to our ultrasound unit at 22 weeks gestation for suspected echogenic focus. The four chambers view of the fetal heart revealed an aneurysmatic enlargement was observed in the right ventricular lateral-apical wall. This aneurysmatic enlargement is separated from the right ventricle by an area of 4 millimeters. Color Doppler detected blood flowing into and out from this sac, suggesting a right ventricular diverticulum. Echocardiograpy performed every 4 weeks during pregnancy did not detect any progression in the size of the diverticulum. A female infant was born spontaneously at 39 weeks. In addition RVD, ventricular septal aneurysm was detected by postnatal echocardiograpy and cardiac-MRI (figure 1,2, white arrow: RVD, black arrow: VSA). Conservative management was planned. He was followed by echocardiography and electrocardiography at intervals of 10 days. RVD and VSA were spontaneously regression. It was observed that RVD and VSA were fully recovered at the second month control.
Conclusion: We present a case of prenatal diagnosis of right ventricular diverticulum at 22 weeks gestation. In addition RVD, VSA was detected by postnatal echocardiography. The diverticulum and VSA disappeared before the age of 2 months. Echocardiography of the patient at 5 months of age revealed no cardiac diverticulum and aneurism or any cardiac anomaly and showed normal heart function.

P2818 - CORRELATION OF ECHOCARDIOGRAPHIC MEASUREMENTS TO EXERCISE PARAMETERS IN FONTAN PATIENTS A PROSPECTIVE BLINDED STUDY

Suma Goudar, Daniel Forsha, David White, Mark Gelatt, Tyler Johnson, Rita France, William Chew, Girish Shirali
Children, Cardiology, Kansas City-United States

Background/Hypothesis: While many echocardiographic (echo) parameters are used to quantify ventricular function, it is unclear which measurements correlate with functional capacity in patients with single ventricle physiology. The purpose of this study is to compare quantitative echo measurements of ventricular function to measurements of functional capacity by exercise stress test (EST) in single ventricle children post-Fontan completion.
Materials and Methods: EST was performed via cycle ergometer (James protocol) to measure peak oxygen consumption (VO2peak) and VE/VCO2 slope in 28 Fontan subjects from December 2015-January 2017. Resting echocardiograms were performed on the same day as EST using GE Vivid9. Separate, blinded observers performed all Echo and EST measures. Global longitudinal strain (GLS) calculated via speckle-tracking analysis using EchoPAC. Qualitative atrioventricular valve regurgitation (AVVR) and ventricular function was graded an ordinal scale, with the highest score equal to worsened AVVR. Correlation was performed using Pearson Correlation. Multivariable regression model was used to determine interaction between variables with significant correlation.
Results: 28 subjects aged 10-17 years were analyzed. VO2peak ranged from 13-31.06 ml/kg/min and global longitudinal strain (GLS) ranged from -7.4 to –22.6. GLS and AVVR were the only two echo variables with significant correlation with VO2peak (-0.45 and -0.46 respectively, $p = 0.01$). There is no significant interaction between GLS and AVVR ($p = 0.11$) and each variable is an independent predictor of VO2 max on multivariate regression. All other echo variables (notably E/A, E/E', S', fractional shortening, fractional area change, and 2D ejection fraction and AV valve annular plane systolic excursion) had poor correlation with peak VO2. No echo variables correlated with VE/VCO2 slope.
Conclusions: In this cohort, GLS and AVVR severity were the only echo measures associated with peak VO2 by exercise testing. These findings should be considered in designing protocols for quantification of ventricular function by echo post Fontan.

P2836 - POSTOPERATED TETRALOGY OF FALLOT AND FONTAN PROCEDURE CHILDREN WHY SIMILAR CPET RESULTS

Luisa García-Cuenllas Álvarez[1], Angeles Fuertes Moure[2], Reyes Álvarez García-Rovés[3], Miriam Centeno Jiménez[3], Enrique Maroto Álvaro[3], Constancio Medrano López[3], Juan Ignacio Castillo Martin[4]
Hospital Universitario De Salamanca, Pediatric Cardiology, Salamanca-Spain[1]; Hospital Materno-infantil Teresa Herrera, Pediatric Cardiology, A Coruña-Spain[2]; Hospital Universitario Gregorio Marañón, Pediatric Cardiology, Madrid-Spain[3]; Hospital Universitario 12 De Octubre, Pediatric Cardiology, Madrid-Spain[4]

Introduction: Postoperated children with complex congenital heart disease (CHD) have a decreased functional capacity (FxC) associated with death and hospitalization. Cardio pulmonary exercise test (CPET) assesses their FxC and different specific patterns are expected, according to different physiological adaptations depending on the type of CHD.
Objective: The aim of this investigation was to compare CPET between postoperated Tetralogy of Fallot children (PTF) and subjects that had undergone a Fontan procedure (FP).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Methods: Retrospective observational study of 25 PTF (mean age 12 ± 3.2 years, weight 43.2 ± 14.55 kg, height 146.7 ± 14.4 cm,58% male) and 63 Fontan (mean age 11.8 ± 3.4years, weight 41.9 ± 17 kg,height 146.5 ± 17.5 cm, 56% male). Inclusion criteria admited pulmonary atresia with VSD in the PTF group and both right or left systemic ventricles in the FT group.Patients with pacemakers, sinus node dysfunction or junctional rhythm were excluded. Ramp treadmill ergometry (Bruce protocol) was performed with expired gas in all cases.
Results: Submaximal exercise tests limited by symptoms were performed, clinically and electrically negative in all cases,with no significant arrhythmias. We found no significant differences between both groups ($p > 0.05$) despite some comparisons were remarkable: 38% of FP reached 85% MPHR vs 32% in PTF, in FP group 62% showed a normal spirometric pattern and 28.6% restrictive vs 56% with normal pattern and 20% restrictive in PTF group. CPET results were:(image1) From a cardiovascular stadpoint VO_2 was decreased in both groups, revealing impaired ExC with normal O_2 pulse (appropriate stroke volume). FP group showed ventilatory inefficiency with higher V slope and CO_2 equivalents (V/Q disturbance), whilst in the PTF group those parameters were limit.
Conclusions: FxC is decreased in both PTF and FP patients. We found no significant differences beetwen them that may be attributable to a bigger sample of FP and their heterogenicity.Ventilatory efficiency variables revealed V/Q imbalance for FP subjects (according to their condition). This disturbance is only appreciated in PF when significant RV dysfunction develops.

P2849 - SINGLE CASE OF RIGHT CORONARY ARTERY ANOMALY IN INFANCY IN 15 YEAR STUDY IN OUR TERTIARY CARDIOLOGY CENTRE

Ramona Onita, Ioanna Giannakopoulou, Mirasol Uy, Manjit Josen, Giovanni Disalvo
Royal Brompton Hospital, Paediatric Cardiology, London-United Kingdom

Background: Anomalous right coronary artery from the pulmonary artery (ARCAPA) is a rare congenital defect affecting 0.002% of the population. Unlike anomalous left coronary artery from the pulmonary artery (ALCAPA), ARCAPA generally has not been considered to be a lethal defect in infancy. High risk group for sudden cardiac death is common after vigorous exertion in children and teenagers, and majority are asymptomatic without previous complaints of cardiac symptoms (palpitations, chest pains, collapse).
Methods: We describe a case of 1 yr old asymptomatic boy, who was referred from local hospital for evaluation of a heart murmur. Patient had echocardiography study and CT angiography of coronary arteries which demonstrated an anomalous right coronary artery from the pulmonary artery with dilatation of the left coronary artery and numerous tortuous left coronary artery collaterals. Myocardial strain and tissue Doppler showed preserved function of the right ventricle. The management decision was to proceed with elective surgical correction of right coronary artery within 3 months post diagnosis.
Conclusion: Anomalous right coronary artery from pulmonary artery is a rare congenital coronary abnormality. We described for the first time right ventricle deformation in an asymptomatic patient.

P2852 - MYOCARDIAL EXTRACELLULAR VOLUME FRACTION QUANTIFIED BY CARDIAC MAGNETIC RESONANCE IN CHILDREN

Johan Jamaluddin[1], Ashish Chikermane[1], Simon Mcguirck[2], Ben Pinkey[2], John Stickley[1]
Birmingham Children, Cardiology, Birmingham-United Kingdom[1]; Birmingham Children, Radiology, Birmingham-United Kingdom[2]

Background: Disturbances in the myocardial extracellular volume fraction (ECV), such as diffuse or focal myocardial fibrosis or oedema, are hallmarks of heart disease. Diffuse ECV changes are difficult to assess or quantify with cardiovascular magnetic resonance (CMR) using conventional late gadolinium enhancement (LGE), or pre- or post-contrast T1-mapping alone. ECV measurement circumvents factors that confound T1-weighted images or T1-maps, and has been shown to correlate well with diffuse myocardial fibrosis. The aims were to assess paediatric data for a variety of clinical conditions and to detect sub-clinical abnormalities in 'normal appearing' ventricular function.
Methods: ECV maps were generated from T1-maps acquired pre- and post-contrast calibrated by blood hematocrit. As a part of the CMR study (between March-December 2016), they underwent a pre- & pos-contrast acquisition of a single breath-hold Modified Look-Locker Inversion-recovery (MOLLI) pulse sequence in a single mid-ventricular short axis imaging plane.
Results: 20 paediatric patients (mean age 12.2 years, range: 5-18 years) were assessed with full CMR study. We looked at all the 6 segments (based on conventional 17-segment model) and their ECV values from 0.3 to 0.4, with incremental of 0.01 to see for the number of segments affected and compared this to the normal adult data and also with the global ejection fraction. As expected, those with lower ejection fraction tended to have more affected segments, but we showed that even those with normal function had abnormal segments.
Conclusions: Extracellular volume fraction imaging can quantitatively characterise segmental changes, and subtle myocardial abnormalities not clinically apparent on global LV function & LGE images. Taken within the context of adult literature, and paucity of paediatric data, more work needs to be done to develop this as a clinical tool within paediatric cardiology.

P2856 - TETRALOGY OF FALLOT – LESSONS LEARNED FROM PRENATAL DIAGNOSIS. 15 YEAR EXPERIENCE OF A TERTIARY REFERENCE CENTER

Agnieszka Grzyb[1], *Adam Koleśnik*[1], *Renata Bokiniec*[2], *Marzena Dębska*[3], *Joanna Szymkiewicz-Dangel*[4]
Warsaw Hospice for Children Foundation, Reference Center for Fetal Cardiology, Warsaw-Poland[1]; *Medical University of Warsaw, Neonatology And Neonatal Intensive Care Department, Warsaw-Poland*[2]; *The Center of Medical Postgraduate Education, Department of Obstetrics And Gynecology, Warsaw-Poland*[3]; *Medical University of Warsaw, Reference Center For Fetal Cardiology, 2nd Department of Obstetrics And Gynecology, Warsaw-Poland*[4]

Background: Tetralogy of Fallot (TOF) is the most common cyanotic congenital heart disease. Detailed information from prenatal diagnosis help to ensure appropriate perinatal management.
Materials and Methods: We evaluated echocardiographic examinations and perinatal follow-up data of fetuses with TOF diagnosed between 2002–2016 in the reference center for fetal cardiology.
Results: TOF was diagnosed in 239 fetuses (M/F≈1): 169 with pulmonary stenosis, 58- pulmonary atresia (TOF-PA; 5 evolving from stenosis) and 12- absent pulmonary valve (TOF-APV). The number of cases increased yearly (3-38 cases), with simultaneous drop in the median time of diagnosis (32-22 weeks). Karyotype was checked in 180 fetuses and showed abnormalities in 39 cases, mostly trisomy (T21-n = 20, T18-n = 4, T13-n = 7). Molecular examinations (FISH or microarray) were performed in 128 fetuses and found anomalies in 28, including 26 cases of microdeletion 22q11 (most common in TOF-APV). Hypoplastic thymus, right aortic arch (RAA) and polihydramnios were indicative of DiGeorge syndrome and AVSD- of T21 ($p < 0.05$). Coexisting anomalies were common, both cardiac (45%, most often: RAA, AVSD, LSVC) and extracardiac (47%, most often: hypoplastic thymus, urinary and skeletal anomalies; small for gestational age-6%). Ductus arteriosus was absent in all TOF-APV fetuses and in single cases of TOF and TOF-PA, significantly affecting perinatal management. Follow-up was known in 211 cases, most children were live-born (n = 176, 83.4%) in good condition, except for TOF-APV (only 1 child living). Stillbirths (n = 20, 9.5%) and terminations of pregnancy were rare (n = 15, 7%), all in cases with coexisting serious genetic or structural anomaly or severely hypoplastic pulmonary arteries.
Conclusions: Introducing 3-vessels-trachea-view into screening ultrasound improved prenatal detection of TOF. Fetuses with TOF require detailed anatomy-focused ultrasound scan and genetic examination (possibly microarray). Thymus hypoplasia is a specific marker of microdeletion 22q11. Repeated examinations are important to assess progression of RVOTO. Perinatal outcome is usually good (except for TOF-APV fetuses), however significantly affected by coexisting anomalies.

P2859 - FETAL DIAGNOSIS OF COMPLETE VASCULAR RING IN RIGHT AORTIC ARCH AND LEFT DUCTUS ARTERIOSUS

Cosimo Marco Campanale[1], *Luciano Pasquini*[1], *Marco Masci*[2], *Sonia Albanese*[3], *Roberta Iacobelli*[2], *Aurelio Secinaro*[4], *Adriano Carotti*[3], *Fabrizio Drago*[2], *Fiore Salvatore Iorio*[2], *Alessandra Toscano*[2]
Ospedale Pediatrico Bambino Gesù, Perinatal Cardiology, Rome-Italy[1]; *Ospedale Pediatrico Bambino Gesù, Cardiology, Roma-Italy*[2]; *Ospedale Pediatrico Bambino Gesù, Cardiac Surgery, Roma-Italy*[3]; *Ospedale Pediatrico Bambino Gesù, Radialogy, Roma-Italy*[4]

Background: Right Aortic Arch with Aberrant Left Subclavian Artery and Left Ductus Arteriosus (RAA + ALSA + LDA) is a common type of vascular rings. Clinical presentation is subtle and post-natal echocardiographic diagnosis is often challenging. Fetal ultrasound, with visualization of wide open LDA, can make identification of this anomaly easier. We reviewed our experience of pre and postnatal diagnosis of RAA + ALSA + LDA.
Methods: Data from all patients with diagnosis of RAA + ALSA + LDA between 2010 and 2014 referred at our tertiary centre were reviewed. All patients underwent CT and/or MRI for airway compression. Indication for surgery was the presence of symptoms and/or tracheal compression (as defined as a narrowing of the tracheal lumen ≥ 50% than the maximum proximal diameter) and/or tracheomalacia.
Results: we observed 52 consecutive patients with RAA + ALSA + LDA. Prenatal diagnosis was made in 26 (50%) patients. Five were lost at follow-up. Six (11.5%) patients had associated Ventricular Septal Defect (VSD), 1 (2%) atrioventricular septal defect, 1 (2%) Ebstein anomaly and 1 (2%) Tetralogy of Fallot (TOF). De George Syndrome was present in 6 (11.5%), of them 2 (4%) had VSD and1 (2%) TOF. One patient (2%) had CHARGE and 1 (2%) Goldenhar Syndrome. Relevant tracheal compression and/or tracheomalacia was identified in 14/42 patients (33%), of which 50% were symptomatic. Overall 15/42 (36%) had clinically evident symptoms. Surgery was performed in 22/42 (52%) patients. One of them had persistent tirage. Patients with prenatal diagnosis had lower incidence of symptoms and tracheal

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

compression with/out tracheomalacia than those with postnatal diagnosis (22% vs 44%, 44% vs 67%, p = NS).
Conclusion: RAA + ALSA + LDA has a good prognosis and mostly asymptomatic. Compression and/or malacia are not always associated with symptoms, potentially increasing the number of missed diagnosis. Since post-natal echocardiographic diagnosis is challenging, prenatal identification of this anomaly is essential for the early management and to avoid irreversible damage of the upper airways.

P2861 - CAN SIMPLE ECHOCARDIOGRAPHIC RIGHT VENTRICLE DIAMETERS Z SCORE PREDICT RIGHT VENTRICULAR ENLARGEMENT IN CONGENITAL HEART DISEASE

Luisa Garcia-Cuenllas Álvarez[1], Ana Rodriguez-López Domingo[2], Federico Gutierrez Larraya[3], Enrique Maroto Álvaro[4], Constancio Medrano López[4]
Hospital Universitario De Salamanca, Pediatric Cardiology, Salamanca-Spain[1]; Hospital Hospiten, Cardiology, Tenerife-Spain[2]; Gregorio Marañón, Pediatric Cardiology, Madrid-Spain[3]; Hospital Universitario Gregorio Marañón, Pediatric Cardiology, Madrid-Spain[4]

Introduction: echocardiographic measurement of RV diameters represents an easy, fast and reproducible way to quantify this chamber. Reference values and Zscores of RV diameters are provided. Accurate assessment of RV size is important in treatment and follow up of congenital heart disease (CHD). Cardiac magnetic resonance (CMR) is the gold standard to measure RV dilatation. Disagreement between linear measurements and CMR volumes (indexed RV end-diastolic volume, iRVEDV) had been proved, but not between Zscore and CMR.
Methods: 700 healthy children (0 days to 18 years old) were enrolled. RV end-diastolic diameters (basal, midcavity and longitudinal) were measured and indexed using body surface area (Haycock formula). Zscore were computed according to literature requirements. These parameters were validated against 50 post-operated Tetralogy of Fallot patients (PTF) iRVEDV obtained by CMR.
Results: Exponential and square root regression models resulted in the best fit with R2 of 0.81, 0.82 and 0.9 respectively for each diameter. They all satisfied the assumption of homoscedasticidy and normality of residuals (Bresch-Pagan and Saphiro-Wilk tests). Confounders as gender and inter/intraobserver variability were considered. Predicted Z scores of basal, midcavity and longitudinal diameters plus plots of standardized residuals are presented: Image 1

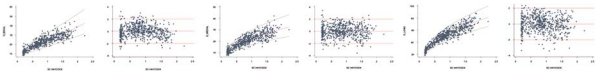

Image 1.

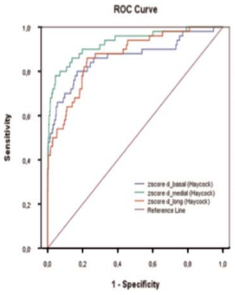
There was a weak correlation between diameters and RVEDVi (Rho Spearman < 33%). But diameter´s Zscore in ROC curves showed a very good discriminating capacity with AUC >0.8, able to determine which RV were normal sized and which were not (dilated PTF, iRVEDV >110 ml/m2). A cut-off point of > + 2 Zscore provided high specificity (>97%). Image 2
Conclusions: reference values for RV diameters represent a valid diagnostic tool for RV quantification in children. RV diameter´s Zscores could discriminate between normal and dilated RV. Diameter´s Zscores could predict RV enlargement in PTF patients. We offer an easy tool to guide follow up and decision making relating to RV dimensions in healthy and CHD children.



Z-score	AUC (area under curve)	IC 95%	
Basal diameter	0.86	0.79	0.93
Medial diameter	0.93	0.88	0.97
Longitudinal diameter	0.87	0.82	0.92

Image 2.

P2867 - THE AORTA IN TURNER SYNDROME IT'S NOT ALL ABOUT THE SIZE

Anitha Parthiban[1], Rita France[1], Amy Lay[1], Kimberly Reid[2], Girish Shirali[1], Michael Silberbach[3]
Children's Mercy Hospital, Pediatric Cardiology, Kansas City-United States[1]; Children's Mercy Hospital, Biostatistics, Kansas City-United States[2]; Oregan Health Sciences University, Pediatric Cardiology, Portland-United States[3]

Background: Aortic dissection occurs more frequently in TS than in the general population, at younger ages and smaller aortic sizes, suggesting that aortic dilation is not the only etiology. We hypothesized that aortic stiffness indices in TS, as measured by echo, differ from normal controls (NC).
Methods: 102 TS subjects and 88 age matched healthy NC females were prospectively enrolled. 2-dimensional and M-mode echo images of the ascending aorta were acquired using a standard protocol. Aortic stiffness (ASI), aortic distensibility index (ADI) and elastic modulus (EM) for the ascending aorta were calculated. TS subjects were grouped as "with risk" if one or more of the following risk factors were present: bicuspid aortic valve, coarctation, hypertension, hyperlipidemia or diabetes mellitus (n = 60), and as "no risk" (n = 42) if none were present. The 3 groups were

Table.

Variable	GROUP NC n = 88	TS n = 102	P-Value
Age (years)	37.9 ± 13.8	34.3 ± 16.3	0.100
Body Surface Area (m^2)	1.7 ± 0.2	1.6 ± 0.3	**<0.001**
Body Mass Index (kg/m^2)	25.6 ± 14.7	27.9 ± 7.1	0.171
Heat Rate (bpm)	65.9 ± 10.2	81.1 ± 15.5	**<0.001**
Systolic Blood Pressure (mmHg)	119.5 ± 13.2	120.3 ± 19.3	0.755
Diastolic Blood Pressure (mmHg)	70.9 ± 9.4	69.7 ± 10.2	0.400
Aortic root- 2D (cm)	2.6 ± 0.3	2.7 ± 0.3	**0.034**
Ascending Aorta- 2D (cm)	2.8 ± 0.3	2.7 ± 0.4	0.764
Ascending Aorta-M mode (cm)	2.8 ± 0.4	2.7 ± 0.5	0.064
ADI -M-mode ($mmHg^1.10^{-3}$)	7.1 ± 3.6	5.3 ± 2.7	**<0.001**
2 (Aorta systole - Aorta diastole)/ Aorta diastolex(systolic blood pressure-diastolic blood pressure)			
ASI-M-mode (no unit)	3.9 ± 2.2	5.3 ± 2.9	**<0.001**
[In (systolic blood pressure/diastolic blood pressure)]/[Aorta systole-Aorta diastole/Aorta diastole].			
Ascending aorta EM -M mode (kilo -pascal)	49.7 ± 26.8	66.2 ± 39.6	**0.002**
[(Systolic blood pressure- diastolic blood pressure)x Aorta diastole] / (Aorta systole-Aorta diastole)			

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

compared using ANOVA; individual groups were compared using Student's t –test. A multivariate regression model estimated independent group associations after adjusting for age and aortic size. Pearson correlation coefficients were used to assess the correlation of stiffness indices with systolic blood pressure.
Results: Table shows the comparison between TS and NC. TS subjects had larger aortic root and aortic size indexed to BSA ($p < 0.001$) but comparable sized ascending aorta as NC. Ascending aorta ASI, ADI and EM (M-mode) differed significantly between TS and NC ($p < 0.001$); this difference persisted when adjusted for age and aortic size. Aortic stiffness indices did not differ between the two TS risk groups ($p > 0.17$). ASI and EM correlated positively with SBP ($r = 0.3$ and $r = 0.49$ respectively) while ADI correlated negatively ($r = -0.41$).
Conclusion: Women with TS have stiffer and less distensible ascending aortas when compared to age matched NC. This difference is independent of aortic dilation and previously described risk factors, suggesting that the aorta may be innately abnormal in TS.

P2868 - FETAL DIAGNOSIS OF SUBAORTIC OUTFLOW TRACT OBSTRUCTION WITH AORTIC ARCH COARTATION OR INTERRRUPTION DIAGNOSIS AND MIDTERM POSTNATAL OUTCOME

Queralt Ferrer[1], Alberto Rafael Guerra[2], Silvia Arevalo[3], Gemma Giralt[2], Anna Sabate-Rotés[2], Ferran Gran[2], Irene Ribera[3], Joaquin Fernandez-Doblas[4], Raul Abella[4], Ferran Roses[2]
Vall Hebron, Pediatric Fetal Cardiology, Barcelona-Spain[1]; Vall Hebron, Pediatric Cardiology, Barcelona-Spain[2]; Vall Hebron, Fetal Medecine, Barcelona-Spain[3]; Vall Hebron, Pediatric Cardiac Surgery, Barcelona-Spain[4]

Introduction: Borderline hypoplastic left heart syndrome is an inaccurate term that includes a whole spectrum of left heart hypoplasia. Due to the unique nature of the foetal circulation, prenatal diagnosis of subaortic left ventricular outflow tract obstruction (SLVOTO) in context of borderline left heart structures is very difficult and there are no specific definitions. We present clinical outcome of foetuses with SLVOTO with either Aortic arch hypoplasia + Coarctation or Interrupted aortic arch (IAA).
Methods: We retrospectively reviewed 19 foetuses with SLVOTO, defined as subaortic left ventricular outflow tract <4mm(measured at 32 GW), in fetuses with either Aortic arch hypoplasia + Coarctation or IAA between Jan-2010 and Oct-2016. Main Foetal echocardiography mesures were: left ventricle diastolic diameter, mitral annulus, aortic annulus and ascending aorta and Isthmus z-scores and subaortic LVOT in mm.
Results: Out of 19 foetuses, 12 were females(63,2%), with a medium gestational age at time of CHD diagnosis of 26 GW. 16 (84%) had Aortic arch hypoplasia + Coarctation and 3(16%) IAA. Of all 19 foetuses, 9(47%) had a large unrestrictive VSD. 14(74%) foetuses had mitral valve annulus z-score < -3. All had neonatal surgical biventricular repair without hospital mortality. Interestingly, out of 5 foetuses with severe SLVOT < 3 mm, 4(80%) required subaortic stenosis surgical relieve, whereas out of 14 with SLVOT >3mm, only 1(7,2%) required postnatal subaortic surgical relieve ($p = 0.02$). After a medium follop-up of 2.2years (3months-7years), all 19 patients were alive. 2 patients developed late subaortic stenosis, 26% developed mild-moderate mitral stenosis. 10% had mild aortic valve stenosis and 26% required aortic arch balloon dilation . In addition, 2 patients had post-operative complete heart block that required pacemaker implantation.
Conclusions: Severe Prenatal diagnosis of SLVOTO in patients with either Aortic arch hypoplasia + Coarctation or IAA is a risk factor for postnatal subaortic surgical relieve but still all foetuses underwent a biventricular repair with no mortality.

Fetal I + d. Bcnatal - Barcelona Center for Maternal-Fetal and Neonatal Medicine (Hospital Clínic and Hospital Sant Joan De Deu), Materno-Fetal Department, Barcelona-Spain[1]; Fetal I + d. Bcnatal - Barcelona Center for Maternal-Fetal and Neonatal Medicine (Hospital Clínic and Hospital Sant Joan De Deu), Pediatric Cardiology, Barcelona-Spain[2]

Background: Atrial Septal Aneurysm (ASA) has been associated with cardiac defects including atrial septal defects, atrioventricular valve obstruction, pulmonary venous obstruction and arrhythmias. It has also been identified prenatally as an isolated finding, in which the significance is not clearly known.
Materials,Methods: Retrospective study including 29 fetuses with ASA diagnosed by fetal echocardiography between 2011 and 2016. Fetal ASA was defined as a redundant atrial septal tissue extending at least halfway across the left atrium diameter. Data on prenatal, perinatal and postnatal outcome was reviewed.
Results: ASA was diagnosed in 29 fetuses at a mean gestational age (GA) of 33.2 weeks (range 21.3–37.3weeks). The main indication for fetal echocardiography was the suspicion of an abnormal foramen ovale on screening ultrasound. Associated extracardiac anomalies were detected in one case. However, nineteen fetuses (66%) presented other cardiac anomalies:1 fetal arrhythmia, 1 mild pulmonary stenosis, 1 perimembranous ventricular septal defect (VSD), and 15 cases with significant right heart dominance (defined by a ratio of right-to-left cavities greater than 1.4). Overall there were 10 fetuses with isolated fetal ASA. A chromosomal anomaly (46,XY,del(13)(q13q14)) was identified in one fetus with associated perimembranous VSD, and parents opted for termination. The remaining cases were confirmed to be chromosomally normal either pre or postnatally. Perinatal outcome was normal in all newborns.
Postnatal outcome: Postnatal follow-up was available for 28 newborns. Mean follow-up was 29 months (range 4-60 months). Pulmonary hypertension and mitral stenosis was diagnosed in one case with right heart dominance. Aortic coarctation was not confirmed in any case. Atrial-septal defect was diagnosed in 11 cases after delivery (39%), of which 7 closed spontaneously before one year of life.
Conclusions: In our series, fetal ASA was not associated with pulmonary venous obstruction, significant neonatal arrhythmias or aortic coarctation. However, our results support the need for postnatal echocardiography in order to exclude atrial-septal defects.

P2879 - ECHOCARDIOGRAPHIC PREDICTORS OF COIL VERSUS DEVICE CLOSURE IN CHILDREN UNDERGOING PERCUTANEOUS PDA CLOSURE

Alaa Roushdy, Yasmeen Abdel Razek, Ahmed Tawfeek
Ain Shams University, Cardiology, Cairo-Egypt

Introduction: The need to determine whether a PDA could be closed by coil or device remains an important issue in planning the mode of closure especially in developing countries where the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

availability and cost of such devices are important factors in decision making.
Patients and Methods: This study included 66 patients who were referred for elective trans-catheter closure of PDA. All patients underwent full echocardiogram before closure to measure the pulmonary arterial end diameter, PDA color flow width and extent, the peak and diastolic Doppler gradients across the duct, diastolic flow reversal across the descending thoracic aorta, Qp/Qs, left atrial dimensions and volume, left ventricular sphericity index, left ventricular dimensions, volumes and systolic function. The patients were then subdivided into 2 groups based on the mode of closure whether by coil (n = 37) or device (n = 29) and the different parameters measured were compared between the 2 groups.
Results: Using univariate analysis the device closed group had statically significant higher end systolic and diastolic volumes indexed measured by both M-mode and modified Simpsons method, Left atrial volume, Qp/Qs, pulmonary end diameter measured from both the ductal view and parasternal short axis view, color flow width, color flow extent and diastolic flow reversal. Using multivariate analysis the independent predictors for Device closure included: PDA pulmonary end >2.5 mm measured from supra sternal view, Color flow width of PDA jet >2.3, Diastolic flow reversal time >96.6% of the entire diastole, color flow extent of PDA jet in the main pulmonary artery >70% of pulmonary artery length and Qp/Qs >1.5.
Conclusion: The study concluded that the selection between coil or device closure methods can be done on the basis of non-invasive anatomic and hemodynamic data obtained by 2D and Doppler echocardiography.

P2884 - THE DISTRIBUTION OF CONGENITAL HEART DISEASES IN RELATIONSHIP WITH ALTITUDE

Alexandra Heath, Franz Freudenthal, Inge Von Alvensleben, Natalia Medina, Carla Arteaga
Kardiozentrum, Pediatric Cardiology, La Paz-Bolivia

Introduction: Congenital heart diseases (CHD) have a direct incidence increase with altitude. Aim of the study: To analyze the occurrence of the most frequent CHD at different altitudes.
Method: A team of pediatric cardiologists performed echocardiographic studies in children with suspicion of CHD in different cities of Bolivia during missions, in places where there is no pediatric cardiology service. The patients were distributed in two groups: One: Living at more than 3600 m and two: Living below 3000 m. The protocol was unique and the examinations were conducted by a single echocardiographist.
Results: Between 2008 and 2016 4453 patients were examined; Group 1: 3179 patients and Group 2: 1274. 340 Patients with trisomy 21 were included and represented 10,7% of the total number. In group 1 complete AV channel represented only 2,4% of the total number. At high altitude 11,6% Patients showed pulmonary hypertension in absence of CHD, this number decreases at lower altitude. In Group 1: We examined 3179 patients. The VSD together with the ductus are the most frequent diseases. The isolated pulmonary arterial hypertension was present in % patients. In Group 2 the VSD is the most frequent disease followed by ASD. Speaking of severe CHD In group 1 tricuspid atresia and Ebstein malformation are the most common severe CHD, transposition of great arteries and hypoplastic left heart showed a very low percentage in the occurrence. This number increase in inverse proportion with altitude. In group 2 we founded hypoplastic left heart syndrome as the most seen severe CHD.
Conclusions: Hypoxic Hypobaric Hypoxia has an influence in the distribution of CHD and in the occurrence of pulmonary hypertension.

P2890 - MORPHOLOGY OF PULMONARY ARTERIES IN PULMONARY ATRESIA WITH INTERVENTRICULAR SEPTAL DEFECT A VISION OF COMPUTED TOMOGRAPHY ANGIOGRAPHY

Alexandre Abla, Adriana Innocenzi, Renata Mattos, Gabriela Mesquita, Maritza Anzanello, Lina Miura, Sallem Fraga, Raiza Costa, Marilia Domingues, Carla Verona
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Introduction: Pulmonary atresia with ventricular septal defect (PA + VSD) is a rare cardiac malformation, comprising a complex variation of pulmonary artery morphology and pulmonary arterial supply. Correct identification of this anatomy is essential for treatment planning.
Objective: Study the different subtypes of pulmonary arterial supply through computerized angiography in children with PA + VSD applying the classifications described by Jane Somerville (1970) and Barbero-Marcial (1990) and their applicability in treatment orientation.
Material and Methods: We reviewed the medical records of 47 children with PA + VSD, of a children's cardiology service at a tertiary center. The volumetric data acquisition was performed after venous contrast, in a Siemens 64 detector row scanners with 80 / 100kv, 60/100 mAs and thickness of 0.6 mm.
Results: 55.5% of the patients were male (26 patients), with a mean age of 5.1 ± 5.24 years. According to Jane Somerville's classification, 11% of the patients belonged to subgroup I, 52% to subgroup II, 26% to subgroup III and 11% to subgroup IV. In the Barbero-Martial classification, 26% of the cases are of group A, 63% of group B and 11% of group C.
Conclusions: CT angiography is a noninvasive method able to identify all morphological arteries subtypes within the classifications proposed by Jane Somerville and Barbero-Marcial. The results showed concordance between the classifications being the most common subtype B, in 63% of the cases (B3 the most frequent) according to the Barbero-Marcial classification and the subgroups II/III in 78%, according to Jane Sommerville. These findings facilitate the surgical decision in the approach of collateral, reducing the need for invasive angiography.

P2896 - THE IMPACT OF CORONARY ANGIOTOMOGRAPHY IN THE EVALUATION OF KAWASAKI DISEASE

Adriana Innocenzi, Renata Mattos, Alexandre Abla, Gabriela Mesquita, Maritza Anzanello, Lina Miura, Danielle Soares, Luiz Carlos Simoes, Aline Bereta, Paulo Renato Travancas
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Introduction: Kawasaki disease (KD) is an acute, self-limiting vasculitis that affects infants and young children. Giant coronary aneurysms are the most serious complication, with a mortality rate reaching 25% of untreated patients and 4% of treated ones. Even patients with giant aneurysms may be asymptomatic. The echocardiogram is the routine examination on the follow-up of these patients, since the initial portion of the coronary arteries can be analyzed in younger children. However, coronary angiography (CT angiography) is a more accurate method of evaluating all the coronary branches, diagnosing dilatation, stenosis and calcification even of the most distal vessels.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Methods: Retrospective analysis of patients with a diagnosis of KD in outpatient follow-up at Instituto Nacional de Cardiologia. Descriptive analysis of the findings of echocardiography, CT angiography and functional class.
Results: Five patients were evaluated, 4 male and 1 female, aged 4 to 13 years. Four received immunoglobulin and platelet aggregation inhibitor during the acute fase. The echocardiogram showed dilatation or aneurysm of the proximal left coronary artery in all patients and some involvement of the right coronary (RC) artery in 3 cases. All patients underwent CT angiography in a 64-channel CT scanner with cardiac trigger and venous beta-blocker. Thrombus and occlusion of the anterior descending (AD) artery was seen in 3 patients. In the circumflex artery we observed thrombus and occlusion in one case and dilation without occlusion in another case. One patient had RC occlusion and another had RC stenosis. All are in clinical follow-up and NYHA functional class 1.
Conclusion: Studying our series, we acknowledged that CT was better than echocardiography due to the possibility of three-dimensional evaluation, precise quantification of the lesion even in distal branches and identification of intraluminal thrombi. Although exposure to ionising radiation and contrast are still a concern with the method, it was decisive to the clinical decision.

P2898 - CARDIAC RHYTHM DISTURBANCES PRENATAL DIAGNOSIS AND FETAL POSTNATAL OUTCOMES

Lorhena Luz[1], Carolina Capuruço[2], Cleonice Mota [2]
Hospital Das Clinicas, Federal University of Minas Gerais, Paedriatric Cardiology, Belo Horizonte-Brazil[1]; Hospital Das Clinicas, Federal University of Minas Gerais, Paediatric Cardiology, Belo Horizonte-Brazil[2]

Objectives: The aims were to investigate the prevalence of fetal arrhythmias, the maternal/ fetal risk factors involved and the postnatal outcomes.
Methods: From 06/2011 to 03/2016, 1984 pregnant women were prospectively investigated, considering the following groups of variables: diagnostic investigation, hemodynamic/functional repercussions, risk factors and evolution.
Results: Rhythm disturbances in 267 fetuses showed different distribution along the gestational age (GA): atrial flutter (AF) and supraventricular tachycardia(SVT) in 6.0% and 11.0%, respectively (26-28w); congenital atrioventricular block (CAVB) in 9.0%, before 24w; transient sinus taqui/bradicardia (TST/B) with regular distribution, and premature atrio/ventricular contraction (PAVC), were seen in 71,2%, before 24w and after 33w and tri/bigeminy (26-28w) in 3.0%. TST was related with fetal anemia, fetal/maternal infection and maternal intake of thermogenic foods ($p < 0{,}005$); SVT was associated with Ebstein anomaly and complete CAVB with isomerism and maternal autoimmune antibodies ($p < 0{,}005$). Isolated pericardial effusion was present in 74/267 and hydrops in 22/267; 8/36 with TST showed cardiomegaly/pericardial effusion and 1/36 hydrops, all of them with anemia. More severe repercussions were seen in those with AF or complete CAVB (pericardial effusion:88.0%; hydrops and/or cardiomegaly: 60.0%) and SVT (pericardial effusion:86.7%; hydrops and/or cardiomegaly:49.7%). Among patients with SVT or AF, the majority improved with monoterapy (29/52) and 17/52 demanded multitherapy; there were no deaths and eight were preterm due to fetal arrhythmia with hydrops. Among those with complete CAVB and complex congenital heart disease ($n = 8$) there were seven intrauterine deaths and one postnatal pacing; no death was seen in the group of immune-mediated damage ($n = 16$): 12.5% had premature deliveries and 43.8,% postnatal pacing. One patient of unknown aetiology was born at term without complications.
Conclusions: Most arrhythmias are benign, but SVT, AF and CAVB were associated with poor prognosis and high mobimortality. The continuous prenatal surveillance is important to make

P2901 - ECHOCARDIOGRAPHIC QUANTIFICATION OF SYSTOLIC FUNCTION IN THE SINGLE SYSTEMIC RIGHT VENTRICLE CORRELATION WITH MAGNETIC RESONANCE IMAGING DERIVED EJECTION FRACTION

Angela Kelle[1], Muhammad Yasir Qureshi[1], Chelsea Reece[1], Angela Miller[1], Sara Martineau[1], Megan Obyrne[2], Phillip Young[3], Patrick Oleary[1]
Mayo Clinic, Division of Pediatric Cardiology, Rochester, MN-United States[1]; Mayo Clinic, Biomedical Statistics & Informatics, Rochester, MN-United States[2]; Mayo Clinic, Diagnostic Radiology, Rochester, MN-United States[3]

Background: Preservation of systolic function is of paramount importance in patients with single systemic right ventricles (RV). Ejection fraction (EF) is considered the most useful measurement of systolic function but is difficult to calculate by transthoracic echocardiography (TTE). Alternative TTE parameters have been proposed, however contraction patterns of the systemic RV differ from the biventricular heart. Our objective was to determine which TTE parameters best reflect systemic RV EF.
Methods: Subjects with hypoplastic left heart syndrome (after bidirectional or total cavopulmonary anastomosis) were prospectively recruited. Cardiac magnetic resonance imaging (cMRI) was performed and RV EF calculated. TTE was performed at a median interval of 1 day from cMRI; parameters of systolic performance were assessed as outlined in Results. Biplane fractional area change (FAC) was obtained by averaging apical and short axis FAC; triplane FAC included the RV inflow/outflow view. Spearman's rank correlation was used for comparisons between cMRI-derived EF and TTE measurements.
Results: A total of 59 cMRI/TTE pairs from 45 subjects were analyzed. Median age was 10.2yrs (range, 9mos -27.9yrs). Results with absolute rank correlation values >0.6 are summarized in the Table; correlation was <0.6 for global longitudinal systolic strain, TAPSE, MPI, IVA, and peak tricuspid lateral annulus systolic velocity.
Conclusion: Many TTE parameters of RV function did not correspond well to cMRI-derived EF in the single systemic RV. Quantitative parameters with the most promising correlations included FAC, particularly biplane FAC, as well as short axis values for circumferential strain and RV-end systolic area. In the systemic RV, short axis views may provide more robust quantitative TTE assessments of systolic function, given the altered geometry and contraction patterns of the single systemic RV. No one TTE parameter correlates optimally with EF, therefore research into a multivariable algorithm may be beneficial.

Table.

	Mean ± SD	P-value	Spearman's Rank coefficient
CMR			
Ejection Fraction	45.2 ± 9.1%	-	-
TTE Variables with Correlation > 0.6			
Biplane FAC	41.1 ± 8.4%	<0.001	0.69
Triplane FAC	38.7 ± 6.7%	<0.001	0.68
Short axis circumferential strain (VVI)	14.3 ± 5.2%	<0.001	−0.68
Short axis FAC	43.4 ± 10.7%	<0.001	0.66
Short axis indexed RV end-systolic area	11.8 ± 6.1 cm^2	<0.001	−0.64
Visually estimated EF	50.0 ± 9.3%	<0.001	0.63

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

P2902 - THE IMPORTANCE OF EARLY DIAGNOSIS OF THE ANOMALOUS ORIGIN OF THE CORONARY ARTERY

Alexandre Abla, Gabriela Mesquita, Andrea Viviani, Andrea Bonaventura, Aline Bereta, Renata Mattos, Lara Malan, Marilia Domingues, Salem Fraga, Raizza Costa
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Introduction: The anomalous origin of the left coronary artery from the pulmonary artery (ALCAPA) is a rare disorder, estimated at 1:300,000 live births, comprising 0.24% to 0.46% of all congenital heart defects. These number might be underestimated because the diagnosis is very difficult. Early diagnosis and treatment may be crucial for the prognosis of these patients.
Objectives: We aim to report a series of 10 patients with various clinical presentations related to the diagnosis of ALCAPA undergoing treatment between April 2011 and 2016, at the same institution, describe their treatments and results and analyze their clinical evolution.
Methods: Ten patients, 7 females and 3 males, aged 16 days to 14 years at the time of surgery and weighing between 3.2 and 50 kg were analyzed retrospectively and evaluated according to their signs and symptoms in the time of diagnosis and during their clinical evolution.
Results: Of the patients evaluated, 3 presented only systolic murmur, 5 had also dyspnea and symptoms of heart failure, 1 had unstable angina and 1 cardiogenic shock and need of mechanical ventilation. The 10 patients assessed had ALCAPA. Nine patients underwent surgical treatment, with 7 cases of coronary reimplantation, one exclusion of the anomalous vessel, one case of coronary artery bypass from the anterior descending artery (DA) with DA ligation in the pulmonary trunk and 1 patient died before surgery. Follow-up ranged from 6 months to 5 years. Seven patients remained asymptomatic, 5 of which with supravalvar pulmonary stenosis, 1 with pulmonary insufficiency and 1 with no residual lesion. Two patients died (1 in the preoperative and 1 in the immediate post operative period).
Conclusion: Of the 9 patients submitted to surgery, 8 had complete remission of symptoms. Early diagnosis is vital, so it's important to remember ALCAPA when evaluating heart murmurs, myocardial ischemia and myocardial dilation of unknown ethiology.

P2904 - PRENATAL DIAGNOSIS OF COARCTATION OF AORTA ECHOCARDIOGRAPHIC PREDICTORS

Carolina Capuruço[1], Raquel Santos[2], Guilherme Rezende[2], Marcos Taveira[2], Cleonice Mota[1]
Hospital Das Clínicas, Federal University of Minas Gerais, Paediatric and Fetal Cardiology, Belo Horizonte-Brazil[1]; Hospital Das Clínicas, Federal University of Minas Gerais, Obstetrics/Fetal Medicine, Belo Horizonte-Brazil[2]

Introduction/ Objectives: The prenatal diagnosis of CoAo is challenging and can be suspected when there is cardiac ventricular or great vessels disproportion. The sensitivity and specificity of several criteria have a high false positive rate. The aim was to establish the echocardiographic (ECHO) diagnose based on predictors for the prenatal diagnosis of coarctation of aorta (CoAo).
Methods: The study included pregnant women referred for fetal ECHO between June 2011 and December 2015 due to ventricular and/or great vessels asymmetry. The fetuses were scanned from 28 to 38 weeks (mean = 32 ± 4 weeks). Fetal ECHO parameters for suggestive cases were: right/left ventricular (RV /LV) diameters ratio ≥1.7, main pulmonary artery/ascending aorta (MPA/AAo) ratio ≥1.7, z-score of ascending aorta (AAo) ≤ − 1.5 and z-score of aortic isthmus ≤ − 1.5. Multivariable analysis and logistic regression were used to assess the interdependence of significant variables.
Results: A total of 52 women were scanned and 28 had criteria for prenatal suspicion of CoAo. The CoAo was confirmed after birth in 19 fetuses (67.9%). The isthmal Z-score ≤ − 1.5 and MPA/AAo ratio ≥1.7 demonstrated a high sensitivity (88% and 82%) and positive predictive value (79 and 77%). Although ventricular asymmetry and AAo Z-score had great sensitivity (74% and 76%) they had poor specificity (34% and 32%). The association of two or more parameters showed 94% of accuracy. Nine patients with mild/moderate hypoplastic aortic arch did not develop CoAo during the follow up of one year. Those were considered false-positive diagnoses.
Conclusions: Antenatal diagnosis of CoAo is critically important for improved preoperative hemodynamic stability of the neonate and reduced mortality. Prenatal diagnosis of aortic coarctation shows high false-negative rates at screening and poor specificity by fetal ECHO . A combination of echocardiographic parameters can improve the likelihood of a correct diagnostic.

P2908 - CONVENTIONAL ECHOCARDIOGRAPHIC PROFILE AND BY MEANS OF STRAIN IN PATIENTS WITH MUCOPOLYSACCHARIDOSIS IN BAHIA BRAZIL

Mirela Frederico[1], Maurício Cardeal[2], Angelina Acosta[2], Emilia Embiruçu[2], Moises Moreira[3], Tais Alves[2], Isabel Guimarães[1]
Federal University of Bahia, Department of Pediatric Cardiology, Salvador-Brazil[1]; Federal University of Bahia, Department of Genetics, Salvador-Brazil[2]; Federal University of Bahia, Department of Cardiology, Salvador-Brazil[3]

Background: Mucopolysaccharidosis (MPS) is a genetic disease, a lisossomal storage of glycosaminoglycans. It affects various organs, with frequent cardiovascular compromise, characterized mainly by left valvular lesions and left ventricle (LV) hypertrophy. The cardiovascular signs and symptoms are underestimated due to the simultaneous involvement of the disease in other organs. Enzyme replacement therapy (ERT) can be used in MPS I, II, IV and VI. In face of this scenario, the knowledge of the application of new tools of conventional and advanced echocardiography is relevant in order to improve cardiac care.
Materials and Methods: This is an outpatient sectional descriptive study, from the genetic services of the Federal University of Bahia-Brazil. The patients underwent conventional echocardiography and strain by speckle-tracking from January to June, 2016.
Results: 16 patients have been evaluated with median age of 14.2 years (deviation: 5.2 years); 12 (75%) were male. The most common type: MPS VI (8 patients - 50%), MPS II (4 patients - 25%), MPS I (3 patients - 18.8%) and MPS III (1 patient - 6.2%). Left valve lesion was found in 15 patients (93.3%) with a higher prevalence of mitral lesions - 13 patients (81.2%) all of which had insufficiency. Twelve (75%) showed concentric LV remodeling. All patients had LV systolic function preserved (Simpson and Teichholz). Three (18.8%) patients had abnormal LV MPI (myocardial performance index). Nine (56.2%) patients had change in LV global longitudinal strain (SGL). The study showed a positive association between mass and change the LV MPI and LV SGL and start time of ERT and LV MPI and LV SGL.
Conclusions: Echocardiographic changes in patients with MPS are frequent, especially the left valve changes, change in LV geometry and subclinical LV dysfunction. The use of the new tools of conventional and advanced echocardiography can improve this follow-up.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

P2914 - FIBROUS SKELETON LESION DIAGNOSTIC AND THERAPEUTIC CHALLENGE

Adriana Innocenzi, Luiz Carlos Simoes, Alexandre Abla, Gabriela Mesquita, Viviane Sena, Rosangela Almeida, Ana Helena Dorigo, Salem Fraga, Raizza Costa, Marilia Domingues
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Introduction: The heart's fibrous skeleton consists of dense connective tissue that surround the base of the semilunar and atrioventricular valves. The connective tissue that separates the atria and ventricles comprises the mitral, tricuspid and aortic valves designing a fibrous triangle.
Case Report: Boy diagnosed at birth with perimembranous ventricle septal defect (VSD) and subaortic membrane. Cardiac catheterization was performed at one year of age showing a left ventricular outflow gradient of 50 mmHg. At 2 years of age, surgery was performed to close the VSD and resect the membrane. He was again referred to surgery after 9 years due to severe aortic regurgitation. A repair the right coronary leaflet was unsuccessful, therefore he underwent a metallic aortic valve replacement surgery. Post operative showed moderate aortic regurgitation. After 3 years, he presented dyspnea and chest pain. With progressive worsening of symptoms, the aortic valve was replaced after 1 year. Postoperative echocardiogram showed a mild regurgitation and a maximum antegrade gradient of 30 mmHg. After another year, he presented with fever, weight loss and dyspnea. Infective endocarditis was ruled out. Echocardiography showed pulmonary artery hypertension, right ventricular overload and a rupture of the anterior leaflet of the mitral valve. He then underwent a successful surgery and has been clinically well.
Discussion: Patients with previous manipulation of the fibrous triangle should be cautiously examined due to risk of lesions requiring complex techniques of diagnosis and therapy.

P2917 - EVALUATION OF AORTIC ANOMALIES IN THE NEONATAL PERIOD THROUGH ANGIOTOMOGRAPHY

Adriana Innocenzi, Renata Mattos, Alexandre Abla, Gabriela Mesquita, Luciana Almenara, Luiz Carlos Simoes, Viviane Xavier, Salem Fraga, Raizza Costa, Marilia Domingues
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Introduction: The hemodynamic severity and clinical manifestations of aortic malformations range from mild narrowing or tortuosity of the aortic isthmus in an asymptomatic patient to severe obstruction associated with cardiogenic shock. In addition to clinical symptoms, several imaging methods have been used to assess the severity of these malformations. Aortic angiotomography is able to evaluate the entire aortic arch with high spatial resolution, and in the newborn it is essential to complement the echocardiogram in cases in which the acoustic window does not allow evaluation of the entire anatomy.
Methods: We report the cases of 7 neonates (3 males and 4 females) with malformations of the aorta, aged between 8 and 27 days. At admission, all of them had clinical signs of congestive heart failure and were on intravenous prostaglandin. The examinations were performed on a 64-channel SIEMENS scanner under general anesthesia. The aortic angiotomography imaging aided the therapeutic approach, adding information to the echocardiogram. Interruption of the aortic arch was observed in 3 cases, coarctation of the complex aorta in 3 cases and aortic hypoplasia in one case. Associated malformations were: atrial septal defect, ventricular septal defect, right ventricular outflow tract obstruction, patent foramen ovale, patent ductus arteriosus, single ventricle and mitral agenesis. All patients underwent surgical correction after angiotomography.
Results: Diagnosis by transthoracic echocardiography alone may present some limitations. The chest angiotomography was able to evaluate the ascending, transverse and descending aorta, vessels of the base with their variations, besides evaluating and quantifying the presence of collateral circulation. Nowadays, with low-dose radiation protocols, diagnostic complementation with angiotomography should be part of the preoperative approach.

P2923 - IMPACT OF VENTRICULOTOMY ON THE SYSTEMIC RIGHT VENTRICLE IN HYPOPLASTIC LEFT HEART SYNDROME

Angela Kelle[1], Chelsea Reece[1], Phillip Young[2], Megan Obyrne[3], Muhammad Yasir Qureshi[1], Patrick Oleary[1]
Mayo Clinic, Division of Pediatric Cardiology, Rochester, MN-United States[1]; Mayo Clinic, Diagnostic Radiology, Rochester, MN-United States[2]; Mayo Clinic, Biomedical Statistics & Informatics, Rochester, MN-United States[3]

Background: In hypoplastic left heart syndrome (HLHS), right ventricle (RV) to pulmonary artery shunts (RVPAS) have been increasingly used during stage I palliation. RVPAS requires an RV incision, whereas modified Blalock-Taussig shunt (MBTS) does not, leading to concerns about long term effects of ventriculotomy on the systemic RV after RVPAS. This study evaluated for RV myocardial changes after RVPAS by cardiac magnetic resonance imaging (cMRI) and transthoracic echocardiography (TTE).
Methods: Subjects with HLHS were prospectively recruited and underwent cMRI and TTE. A subset of patients with prior RVPAS was compared to an age-matched group with prior MBTS.
Results: Twenty subjects with prior RVPAS participated. Median age was 2.0 years (range, 9 months - 11 years). Thirteen were post-Stage II palliation and 7 were post-Stage III. By cMRI, all 20 subjects had a thinned, dyskinetic section of the anterior RV wall

Table 1. Comparison of Age-and Stage-Matched HLHS Patients with History of MBTS of RVPAS

	MBTS (n = 9)	RVPAS (N = 9)	
Patient characteristics			
Age (years)	5.3 ± 3.3	5.2 ± 3.4	NS
Stage II, n	3	3	NS
Stage III, n	6	6	NS
Male sex, n (%)	6 (67%)	8 (89%)	NS
Weight (kg)	17.3 ± 4.9	17.5 ± 6.5	NS
Cardiac magnetic resonance imaging analysis			
RVEDVi (mL/m^2)	97.2 ± 23.8	117.5 ± 26.6	NS
RVESVi (mL/m^2)	49.2 ± 16.8	67.0 ± 21.0	NS
RVEF (%)	50.0 ± 7.6	43.9 ± 5.4	NS
RV global mean peak circumferential strain (%)	−18.5 ± 4.8	− 13.9 ± 3.2	NS
RV global mean peak radial strain (%)	37.1 ± 15.1	25.0 ± 7.4	NS
RV global mean peak longitudinal strain (%)	− 16.0 ± 5.0	14.5 ± 2.8	NS

Data are presented as mean values. P values <0.05 are considered significant. legend: HLHS, hypoplastic left heart syndrome; MBTS, modified blalock-taussig shunt; RV, right ventricle; RVEDVi, indexed right ventricular end-diastolic volume; RVESVi, indexed right ventricular end systolic volume; RVEF, right ventricular ejection fraction; RVPAS, right ventricle-to-pulmonary artery shunt.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

at the presumed previous ventriculotomy site. Aneurysm orifice size measured 5–27 mm (median, 9 mm), and was not related to time interval since RVPAS (p = NS). Late gadolinium enhancement was present near the aneurysm in 7/20 (35%). Strain analysis by cMRI showed regional abnormalities at the aneurysm site as expected, with regional abnormalities extending to adjacent myocardial segments. The aneurysm was prospectively noted by TTE in only 1 subject. Nine age and stage matched RVPAS and MBTS subjects were compared (Table). MBTS group tended to have less RV enlargement and greater values of EF/strain, without reaching statistical significance.
Conclusion: HLHS patients with prior RVPAS universally had a dyskinetic aneurysm of the RV anterior wall. This defect may provide a nidus for ventricular arrhythmia, thrombosis and/or dysfunction in the long-term. Further research including cMRI analysis with larger number of subjects is needed.

P2925 - CARDIAC EVALUATION IN INFANTS WITH CONGENITAL ZIKA SYNDROME

Fabiana Feitosa, Maria Ribeiro, Cleusa Santos, Isabella Lira, Paulo Menge
IMIP, Pediatric Cardiology, Recife-Brazil

An outbreak of Zika virus (ZIKV) infection associated with congenital microcephaly has been reported in Brazil, especially in Northeast region. Prenatal Zica virus infection has been linked to adverse pregnancy and birth outcomes, most notably microcephaly and other serious brain anomalies. For these reasons, besides neurological defects, other abnormalities as cardiac involvement should also be excluded in infants with congenital Zika syndrome. To determine whether Zica virus infection during pregnancy causes cardiac malformation we performed echocardiogram in 113 patients diagnosed with Zica virus infection from November 2015 to May 2016. The patients were forwarded from the ambulatory independent of symptoms. From 113 patients, 61 were female. In 69 patients we observed some alterations considered as normal for the age group, as patent foramen oval, patent ductus arteriosus and small atrial septal defect. Only in 3 cases were diagnosed with ventricular septal defect, witch corresponds to 2,6% of the cases. This is in agreement with the findings of the literature in normal population. A few reports have described congenital malformation linked to Zika virus infection most of them in central nervous system. We found no association with congenital heart disease and Zika virus infection. Other studies are necessary to confirm this.

P2931 - VENTRICULAR FUNCTION ANALYSIS AT EXERCISE AS MEASURED BY REAL TIME CARDIAC MAGNETIC RESONANCE IMPROVES PREDICTION OF METABOLIC EXERCISE PERFORMANCE IN FONTAN PATIENTS

Kevin Whitehead[1], Zhenglun Wei[2], Laura Mercer-Rosa[1], Matthew Harris[1], Ajit Yoganathan[2], Stephen Paridon[1], Mark Fogel[1]
Children, Pediatrics/Cardiology, Philadelphia, PA-United States[1]; Georgia Institute of Technology, Biomedical Engineering, Atlanta, GA-United States[2]

Background: We wished to study the relationship between ventricular performance and exercise capacity in Fontan patients using a cardiac magnetic resonance (CMR) exercise protocol.
Methods: Fontan patients underwent standard graded metabolic exercise testing (MET) to evaluate metrics at peak exercise and anaerobic threshold (AT). A subsequent resting CMR included real-time (RT) cine imaging to quantify end-diasotlic (EDV), end-systolic (ESV), and stroke (SV) volumes, ejection fraction (EF) and indexed ventricular output (CI). Patients then underwent a graded exercise protocol on a supine ergometer to achieve the heart rate associated with AT on prior MET. Real-time measurements were repeated immediately after exercise. Flows were indexed to BSA and volumes to $BSA^{1.3}$ as previously described. VO2 at AT and peak Ex were indexed to body weight and compared with resting and exercise volumetric data using Pearson correlation. Significant factors were analyzed with multiple regression analysis.
Results: 46 patients age 16 years (range 12-42) had a mean EF of 65% (42-85%) at rest and 71% (53-87%) at exercise ($p < 0.001$). There was significant correlation between VO2 at AT and both resting CI ($r = 0.45$, $p = 0.001$) and change in CI from rest to exercise ($r = 0.34$, $p = 0.02$). In multiple regression analysis, both resting CI and change in CI remained significant. Other significant correlations with VO2 included both resting and ex SV, and ex CI. There was no significant correlation between EF, EDV, or ESV at rest or Ex with any MET parameter.
Conclusions: MET performance correlates with CI at rest, as well as change in CI from rest to exercise. Change in CI from rest to exercise improves the prediction of exercise performance compared to resting data alone. Characterizing ventricular function at exercise may yield a better understanding of how ventricular performance affects exercise capacity in Fontan patients.

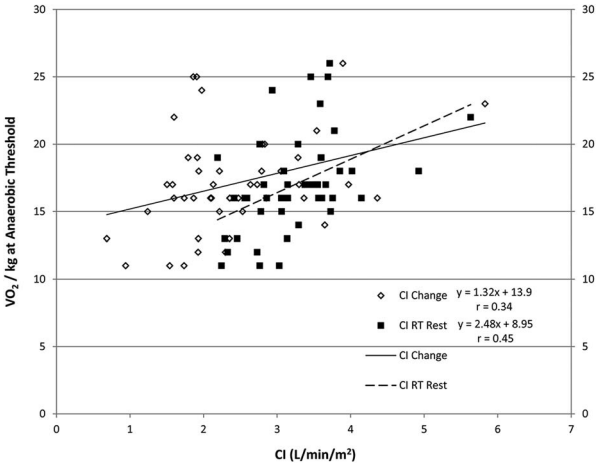

Figure.

P2936 - IMPACT OF PRENATAL DIAGNOSIS OF D TRANSPOSITION OF THE GREAT ARTERIES IN THE NEWBORN WHO REQUIRES A BALLOON ATRIAL SEPTOSTOMY

Joanna Rosenthal, Prasad Ravi, Luke Eckersly, Medhi Houshmandi, Winnie Savard, Lisa Hornberger
University of Alberta, Pediatric Cardiology, Edmonton-Canada

Background/Hypothesis: It has always been assumed that a prenatal diagnosis of critical congenital heart disease would significantly improve postnatal outcomes by providing time to appropriately plan for management at delivery. However, for some conditions, the data has not been consistently supportive. We sought to investigate the clinical impact of a prenatal diagnosis in comparison to a postnatal diagnosis of simple D-transposition of the great arteries (DTGA) in newborns requiring urgent balloon atrial septostomy (BAS).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: We identified all newborns with simple DTGA (+/- small ventricular septal defect) who required BAS encountered in the province of Alberta between 2003 and 2015. Newborns delivered at <34 weeks and those with more complex congenital heart disease were excluded. We reviewed their postnatal charts and evaluated parameters indicative of their clinical status prior to BAS.
Results: We included 19 newborns with a prenatal diagnosis and 31 newborns with a postnatal diagnosis of simple DTGA. All infants were intubated and ventilated for BAS. Prior to BAS, postnatally diagnosed newborns had a significantly lower pH and higher peak arterial lactate compared to those with a prenatal diagnosis. Inotrope support was needed for 15% of those with a prenatal diagnosis versus 36% of those with a postnatal diagnosis. Nitric oxide was not required in any patients with a prenatal diagnosis, but 4/28 (14%) with a postnatal diagnosis. No patient required CPR or greater support and all patients survived to surgery. Median length of hospital stay was 18 days (range 9-45 days) for prenatally diagnosed and 21 days (range 11-92 days) for postnatally diagnosed groups ($p = 0.11$).
Conclusion: Prenatal diagnosis of DTGA significantly improves the preoperative clinical status of newborns requiring urgent BAS. The impact of improved preoperative condition secondary to prenatal diagnosis on enhancing long-term outcomes is the subject of ongoing investigations.

P2940-10 YEAR REVIEW OF PEDIATRIC CARDIAC MRI WITH DELAYED GADOLINIUM ENHANCEMENT; IMPACT ON OUTCOME

Ravneet Sekhon[1], Lillian Lai[2], Derek Wong[2]
Children, Pediatrics, Ottawa-Canada[1]; Children, Cardiology, Ottawa-Canada[2]

Background/Hypothesis: In adults, the presence of delayed enhancement (DE) on cardiac magnetic resonance imaging (CMRI) is a useful modality in diagnosis and risk stratification. These practices have been applied in pediatrics at times without rigorous study. A pediatric CMRI study is not an easy undertaking due to requirements of patient compliance with need for general anesthetic for quality studies.
Our aim is to determine the types of patients currently undergoing DE on CMRI and to define the number of positive DE studies with a view to associate outcomes in our next study in order to better define which populations of cardiac patients truly benefit from the information acquired.
Materials & Methods: A retrospective review of all CMRIs performed at CHEO from September 2006-January 2016 and associated patient charts.
Results: At this time, our preliminary data shows there were 835 studies performed. In 50% (424/835) delayed enhancement was requested; 0.2% (2/835) studies could not be analyzed. Of the 424 patients, 10% (44/424) DGE was positive, 72% (305/424) DGE was negative, 5% (23/424) DGE could not be performed due to patient or technical factors, 11% (49/424) DGE was performed but not reported, and in 0.7% (3/424) studies there was either artifact or suboptimal imaging. The most common indications for studies were: ARVD in 28% (120/424) patients, TOF in 12% (50/424), and TGA or DORV in 16% (70/424). The male: female ratio was 1:6:1 with 516/838 males and 322/838 females receiving studies.
Conclusions: Over the last 10-year period, the observed finding of positive delayed enhancement in pediatrics was 10%. Our next study will determine the impact on outcomes.

P2941 - IMAGING OF THE DUCTUS ARTERIOSUS NORMAL ANATOMY PHYSIOLOGY AND CONGENITAL ABNORMALITIES

Sanket Shah, Suma Goudar, Mark Gelatt, Erin Opfer, Joshua Knowlton
Children's Mercy Hospital, Cardiology, Kansas City-United States

Introduction: Ductus arteriosus [DA] is an artery that usually extends from the aortic isthmus, just distal to the left subclavian artery to the junction of the main and left pulmonary artery in fetal life. Knowledge of anatomy and physiology of DA is critical in management of a wide spectrum of congenital heart disease. Previously, variations in size and shape of the left sided DA have been well described. We aimed to describe variations in course, flow pattern, number, caliber in various patho-physiological conditions.
Methods: Our Radiology database of CT angiograms of the chest and cardiovascular MRIs, performed between January 1, 2008 and December 31, 2016, was interrogated for presence of DA. A total of 89 DA were reported, out of which 70 were beyond the first year of life. Descriptive text will be used to describe the features of the data in a study. We will discuss and illustrate the echo, CT and MR appearance of several clinically significant variations of the DA and discuss anomalies of the DA in terms of number, site, shape, course and size. Additionally, we will suggest techniques for CT and MR imaging of the DA with emphasis on determining their hemodynamic significance and importance in pre-procedural planning.
Findings: Variations in course of DA can be classified into -Vertical, reverse orientated, tortuous, cervical, right sided and bilateral. Other abnormalities of DA include enlargement of the DA, Abnormal flow in the DA, Absence of DA, DA aneurysm, thrombus in DA and endarteritis of DA.
Conclusion: CT and MR imaging provide excellent noninvasive depiction of the anatomy, flow and anomalies of the DA. Abnormalities of the DA range from numerical and morphologic variations to clinically significant anomalies. It can be important to identify these variations, to ensure appropriate treatment of congenital heart disease.

P2944 - CARDIAC FUNCTION ASSOCIATED WITH HOME VENTILATOR CARE IN DUCHENNE MUSCULAR DYSTROPHY

Lucy Eun[1], Seong Woong Kang[2], Jae Young Choi[1]
Yonsei University Severance Hospital, Pediatric Cardiology, Seoul-Korea, South[1]; Yonsei University Severance Hospital, Rehabilitation Medicine, Seoul-Korea, South[2]

Background: Duchenne muscular dystrophy (DMD) is prevalent neuromuscular disorder that affects one in 3600 live male births. Most leading cause of mortality in DMD patients is usually respiratory complications or cardiomyopathy. But nowadays, cardiomyopathy is becoming the leading cause of death in DMD patients because mechanically assisted lung ventilation and assisted coughing help resolving respiratory complication. We investigated to reveal the relation of cardio-pulmonary function in DMD patients.
Method: We retrospectively reviewed the DMD patients diagnosed from 2010 January to 2016 March in Gangnam Severance Hospital. Demographic characteristics, pulmonary function factor, Echocardiography data were assessed.
Results: We reviewed 54 case of DMD and divided into two groups (Home-ventilator assisted group vs Non-ventilator assisted group). In pulmonary function analysis, Home-ventilator group (1038 ± 620.41 ml) show lower sitting Functional vital capacity than Non-ventilator group (1455 ± 603.12 ml). In echocardiographic measurement, mean LV Ejection fraction and Fractional shortening were higher in Home-ventilator group. Home-ventilator

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

assisted group's E/A ratio(1.7 ± 0.44) was more stable than Non-ventilator assisted group(2.02 ± 0.62). With estimation by the multiple linear regression test, TDI S' was higher in Home-ventilator group (Estimated β : 1.06, Standard error : 0.48).
Conclusion: DMD patients with ventilator care might have better systolic and diastolic cardiac function. Especially, patients without ventilator assistance may need more meticulous evaluation for cardiopulmonary function, which may help to care the early cardiopulmonary dysfunction.

P2947 - CORONARY ARTERY LESIONS IN COSTA RICAN CHILDREN WITH KAWASAKI DISEASE A 5 YEAR RETROSPECTIVE STUDY (PERIOD 2009 2013)

Mariella Vargas-Gutierrez[1], Susan Li-Chan[2], María L Avila-Aguero[3], Kattia Camacho-Badilla[3], Alejandra Soriano-Fallas[3], Andrea P Salgado[4], Adriana H Tremoulet[5], Rolando Ulloa-Gutierrez[3]
Hospital Nacional De Niños "dr. Carlos Sáenz Herrera", Unidad De Cuidados Intensivos Pediátricos, San José-Costa Rica[1]; Universidad De Costa Rica, Posgrado De Pediatría, San José-Costa Rica[2]; Hospital Nacional De Niños "dr. Carlos Sáenz Herrera", Servicio De Infectología Pediátrica, San José-Costa Rica[3]; Pontificia Universidad Católica De Chile, Servicio De Infectología Pediátrica, Santiago-Chile[4]; University Of California San Diego, Pediatric Infectious Diseases, Kawasaki Disease Research Center San Diego, San Diego, Ca-United States[5]

Background/Objectives: Kawasaki disease (KD) is the leading cause of acquired heart disease in Costa Rican (CR) children (ch). Despite its importance, no recent analysis focusing on children who develop coronary artery lesions (CALs) has been made at our institution. We describe the epidemiology, clinical aspects and treatment of patients (pts) with KD who developed CALs.
Materials and Methods: Retrospective descriptive study of hospitalized pts with a KD diagnosis, who developed CALs and were attended at the only national pediatric tertiary referral teaching hospital of CR. Study period: Jan-1st-2009 to December-31st-2013.
Results: Among 149 enrolled pts with KD, a baseline echocardiogram (ECHO) was performed in all. CALs were detected in 15 (10.1%) pts as follows: dilation, 8 pts (53.3%); aneurysms, 7 (46.7%) pts. Incomplete KD occurred in 3 (20%) pts, all of which developed coronary aneurysms. All pts were hospitalized; 9 (60%) pts were male. Mean age at admission was 32 (3-92) months, distribution by age groups was: <6 months, 3 (20%) pts; 7-24 m, 6 (40%) pts; 25-60 m, 3 (20%), and >60 m, 3 (20%) pts. Mean length of fever at admission was 13 (3-30) days. Prior to admission and KD diagnosis, all 19 pts had at least >1 recent medical visit and all pts received antibiotics for other presumed diagnoses. IVIG treatment was administered in 13 (86.7%) pts: 1 dose, 9 (69.2%), and 2 doses, 4 (30.8%), respectively. Aspirin and steroids were given in 19 (100%) and 1 (6.7%) pts, respectively. No deaths occurred.
Conclusions: Among children with CAL's, the rate of IVIG resistance is higher than other reports from LA. The high rate of antibiotic use prior to final KD diagnosis suggests that clinical suspicion of the disease is low.

P2965 - USEFULNESS OF MYOCARDIAL PARAMETRIC IMAGING TO EVALUATE PHYSIOLOGICAL CHANGING IN LEFT VENTRICULAR NONCOMPACTION ASSOCIATED VIRAL MYOCARDITIS BEFORE AND AFTER REDUCING VOLUME OVERLOAD

Abdul Muhaimin Ahmad, Haifa Abdul Latiff, Hasri Samion
National Heart Institute Malaysia, Pediatric and Heart Congenital Center, Kuala Lumpur-Malaysia

The left ventricular sponge morphology fulfilling the diagnostic criteria for left ventricular noncompaction (LVNC) may occur in association with acute deterioration in left ventricular function of various causes. This may occur as consequence an adaptive mechanism aimed at increasing endocardial surface area and optimizing stroke volume. The combination of viral myocarditis and LVNC become dillema piffall missdiagnosis of main caused left ventricular function depress. We report the case of a 1 year old girl with diagnosis patent ductus arteriosus (PDA) presented heart failure symptoms and viral myocarditis infection. Three dimensional echocardiography (3DE) accidently finding LVNC morphology. The patient was evaluated by 3DE parametric imaging , Mitral Valve (MV) inflow, Tissue doppler imaging (TDI) for before, intermediate, after 1 day and after 3 day PDA occlussion procedure. This evaluation study to define the changing in left ventricular (LV) delay contraction, myocardium contraction and MV inflow after reducing left ventricular volume overload by closing PDA shunt. The result; End diastolic LV volume reducing from 43.5 ml into 36.6 ml and LV ejection fraction improved from 26% to 44%. The MV inflow has showed significant change from absent A wave into normal patent of MV inflow. The parametric imaging of bull eye has demonstrated signicant change timing delay contraction and myocardium contraction except basal and apex region. Conclusion; The use of 3DE parametric imaging allowed evaluation of hemodynamic change based echocardiography.

P2974 - PRENATAL FINDINGS IN HYPOPLASTIC LEFT HEART SYNDROME

Sofia Grinenco[1], Mercedes Saenz Tejeira[1], Lucas Otaño[2], Horacio Aiello[2], César Meller[2], Antonela Córdoba[3], Natalia Napoli[3], Alejandra Villa[3], Pablo Marantz[1]
Hospital Italiano De Buenos Aires, Pediatric Cardiology, Fetal Medicine Unit, Buenos Aires-Argentina[1]; Hospital Italiano De Buenos Aires, Obstretrics And Gynecology, Fetal Medicine Unit, Buenos Aires-Argentina[2]; Hospital Italiano De Buenos Aires, Pediatric Cardiology, Buenos Aires-Argentina[3]

Background/Hypothesis: Hypoplastic left heart syndrome (HLHS) is one of the most common congenital heart defects detected prenatally. The aim of this study was to describe the prenatal findings in a cohort of patients with HLHS.
Materials And Methods: Retrospective descriptive study. Clinical records and fetal echocardiographic clips of patients with HLHS diagnosed prenatally in 2 tertiary health care centers in a 5-year period were reviewed.
Results: Sixty seven patients with prenatal diagnosis of HLHS were assessed in 2 tertiary health care centers, with median maternal age of 35 years old (range 17 to 42 years old) and median gestational age at initial assessment of 33 weeks (range 21 weeks 6 days to 38 weeks 3 days). Five/67 (7.5%) cases had associated major extracardiac and/or genetic anomalies. There were 35/67 (52.2%) fetuses with aortic and mitral atresia, 14/67 (20.9%) with aortic atresia and mitral stenosis, and 18/67 (26.9%) with aortic and mitral stenosis. Eight/67 (11.9%) patients had a severely restrictive or intact atrial septum, 3/67 (4.5%) severe tricuspid regurgitation, and 2/67(3%) right ventricular dysfunction. The median of right/left ventricular ratio was 2.14 (range 1 to 14.4), of pulmonary/aortic artery ratio was 2.2 (range 1,18 to 5,33), and of pulmonary /aortic annulus ratio was 2,55 (range 1,3 to 5,5). There were 12/67 (17.9%) patients lost to follow up, 4/67 (6%) received comfort care and 51/67 (76.1%) underwent multisage palliative surgery.
Conclusion: The prenatal findings in a cohort of patients with HLHS are described. In this cohort a low association with

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

extracardiac and genetic anomalies was observed, and most patients underwent multisage palliative surgery.

P2977 - HYPOPLASTIC LEFT HEART SYNDROME EARLY MORTALITY

Sofia Grinenco[1], Natalia Napoli[1], Mercedes Saenz Tejeira[1], Antonela Córdoba[1], Juan Osuna[2], Alejandra Villa[1], Jorge Barretta[2], Pablo Marantz[1]
Hospital Italiano De Buenos Aires, Pediatric Cardiology, Buenos Aires-Argentina[1]; Hospital Italiano De Buenos Aires, Pediatric Cardiovascular Surgery, Buenos Aires-Argentina[2]

Background/Hypothesis: Survival of patients with hypoplastic left heart syndrome (HLHS) has steadily improved since the advent of the multistage reconstructive approach for surgical palliation. Poor outcome has been associated to patients´ high-risk factors. The aim of this study was to examine early survival in a cohort of patients with HLHS, assessing the impact of high-risk factors.
Material and Methods: Clinical records of patients born in a 5-year period with HLHS in 2 tertiary specialized hospitals were reviewed. Early survival was evaluated in relation to the presence of 1 or more of the following high-risk factors: major extracardiac, genetic or chromosomal anomalies; prematurity (<34 weeks of gestation at birth); low birth weight (<2500grs); intact or highly restrictive atrial septum; severe tricuspid regurgitation, or severe ventricular dysfunction. Differences in survival were assessed using contingency table and Fisher exact test analysis.
Results: Of 62 patients 55 (88.7%) had prenatal diagnosis, there was 1 premature and 3 low birth-weight patients. There were major extracardiac malformations and/or genetic disorders in 5/62 (8.1%) patients. There was intact or highly restrictive atrial septum in 8/62 (12.9%), severe tricuspid regurgitation in 2/62 (3.2%) and right ventricular dysfunction in 1/62 (1.6%). Among the 17/62 (27.4%) patients with 1 or more risk factors: 3 received comfort care, 3 died before surgery, and 5 died after Norwood surgery (57.1% early mortality). Forty five/62 (72.6%) patients did not have risk factors, and 2 of them died before surgery and 13 after Norwood surgery (33.3% early mortality). Early mortality was increased in the group with high-risk factors (p 0.0423).
Conclusions: Nearly one third of patients with HLHS had associated high-risk factors, which increased their early mortality. Identifying these risk-factors in the perinatal period is important for assessing prognosis in patients with HLHS.

P2979 - FETAL AORTIC VALVULOPLASTY

Pablo Marantz[1], Sofia Grinenco[1], Horacio Aiello[2], César Meller[2], Mercedes Saenz Tejeira[1], Marcelo Rivarola[3], Natalia Napoli[3], Lucía Vázquez[2], Jorge Barretta[4], Lucas Otaño[2]
Hospital Italiano De Buenos Aires, Pediatric Cardiology, Fetal Medicine Unit, Buenos Aires-Argentina[1]; Hospital Italiano De Buenos Aires, Obstetrics And Gynecology, Fetal Medicine Unit, Buenos Aires-Argentina[2]; Hospital Italiano De Buenos Aires, Pediatric Cardiology, Buenos Aires-Argentina[3]; Hospital Italiano De Buenos Aires, Pediatric Cardiovascular Surgery, Buenos Aires-Argentina[4]

Background/Hypothesis: Fetal aortic valvuloplasty has been proposed for preventing the progression to hypoplastic left heart syndrome (HLHS) in patients with critical aortic stenosis and specific echocardiographic criteria. The aim of this study is to report the experience of our group in this disease.
Materials and Methods: The medical records of patients with critical aortic stenosis diagnosed prenatally between February 2005 and February 2016 were reviewed. Measures of central tendency and frequency distribution were calculated.
Results: Critical aortic stenosis at risk of progression to HLHS was found in 16 cases, and 14/16 (87.5%) underwent fetal aortic valvuloplasty at a median gestational age of 27 weeks (range 20.1 to 30.5 weeks), with technical success in 12/14 (85.7%). In 4/14 (28.6%) fetuses death occurred within 48 hours of the intervention. At birth HLHS was observed in 2 cases that had not been intervened prenatally, in one patient with technical failure and in 1 of those who underwent fetal aortic valvuloplasty. Regarding patients with technically successful procedures, 7/8 patients had biventricular physiology and left ventricles with preserved dimensions or borderline cases. No significant maternal complications were observed.
Conclusions: Fetal aortic valvuloplasty is feasible, without significant maternal risks, to be performed by trained intervention teams in selected patients. The results so far are encouraging, but given the complexity of the pathology clinical impact is still under study.

P3014 - LEFT VENTRICULAR MYOCARDIAL REMODELING IN FOETAL LIFE

Biagio Castaldi[1], Irene Cattapan[1], Marny Fedrigo[2], Annalisa Angelini[2], Ornella Milanesi[1]
University of Padova, Pediatrics, Padova-Italy[1]; University of Padova, Cardio-thoracic Sciences, Padova-Italy[2]

Background: Left ventricular myocardium is a strongly anisotropic tissue in adults. Cardiomyocytes are arranged in a complex three-dimensional network which forms a counterclockwise helix in the endocardial layer and a clockwise helix in the epicardial layer. This peculiar organization is fundamental to myocardial functionality because left ventricular contraction is not only longitudinally and radially oriented, but also characterized by ventricular twisting. Foetal physiological myocardial development dynamics has not been completely explained yet and the few studies about this topic focused mainly on the histology of mammalian hearts and not human ones.
Aim of the study: Speckle Tracking Echocardiography allows to study separately endocardial and epicardial functionality in vivo. Combining this data with morphometrical observation on histological sections of fetal human heart, we compared the development of the different myocardial layers with advancing gestational age.
Methods: To study foetal myocardial function, we enrolled 72 foetuses and 39 premature babies without cardiac pathologies. We studied longitudinal endocardial and epicardial strain in these patients. For the histological section, we studied 20 foetal hearts without cardiac pathologies from autoptical investigation. We determined every layer's thickness and cardiac fibres orientation in comparison with gestational age.
Results: Endocardial values of deformation are higher than epicardial ones. Epi/endocardial values ratio increase with gestational age (figure). The epicardial layer, in fact, becomes more influencing. Histological data confirm our observations. All the layers increase their thickness during gestation but epicardium increases fourfold while trabecular and endocardial layers maintain the same value throughout pregnancy.
Conclusions: Left ventricular myocardium maturation is a process that begins early during fetal life. It starts from the differentiation of a subendocardial layer. The development of the epicardial is slower and is completed late in the foetal life. Probably this process is led by the increasing pre- and after-load in the third trimester of gestation.

P3016 - CAROTID SUBCLAVIAN ARTERY INDEX IMPORTANT TWO DIMENSIONAL ECHOCARDIOGRAPHIC PARAMETER FOR DETECTION OF COARCTATION OF AORTA IN NEONATES

Bikash Bhojnagarwala[1], Abdul Salam[2], Nilesh Oswal[3], Nitha Naqvi[2]
Chelsea and Westminsiter Hospital, Neonatology, London-United Kingdom[1]; Royal Brompton and Harefield NHS Foundation Trust, Paediatric Cardiology, London-United Kingdom[2]; Alder Hey Children, Paediatric Cardiology, Liverpool-United Kingdom[3]

Background: Coarctation of aorta is a very common congenital heart malformation occurring in 6-8% of all congenital heart diseases. However in neonates coarctation may be missed or underestimated by echocardiography, especially with patent ductus arteriosus. The carotid-subclavian artery index: the ratio of the aortic arch diameter at the left subclavian artey to the distance between left carotid artery and the left subclavian artery, has been proposed in previous studies for establishing the diagnosis of coarctation of the aorta.
Objective: To evaluate such indexes and to look for other echocardiographic predicators of coarctation of the aorta. *Design/Methods:* Echocardiographic evaluations was retrospectively reviewed in patients with coractation of the aorta as well as control group admitted at a tertiary cardiac center in the period between January 2010 to December 2014. All patients admitted with coarctation of aorta either had surgery or catheter intervention which confirmed the diagnosis. 39 patients with Coarctation as well as 20 patients in controls were included in the study. End systolic measurements were obtained from 6 different sites of the aortic arch.
Results: The distance between the origins of the great vessels: Brachiochepahic to Left carotid artery (median 2.8 mm vs 1.5 mm in controls) and Left carotid artery to Left Subclavian artery (median 6.22mm vs 2.3mm in controls) were longer in patients with coarctation than in controls. Carotid-subclavian artery index was significantly smaller (Median 0.59, Range 0.28-2.67) in the coractation group in comparison to the control group (Median 2.8, Range 1.56 -4). 92% patients with coarctation had a Carotid-subclavian artery index <1.
Conclusion(s): A carotid-subclavian artery index of <1 is a useful noninvasive screening parameter for coarctation and may be useful in unstable patients or in those with a patent ductus artersious in which coarctation may be overlooked.

P3017 - TRADICIONAL AND ADVANCED PARAMETERS OF CARDIAC MECHANICS IN CHILDREN WITH END STAGE RENAL DISEASE AT HOSPITAL INFANTIL DE MÉXICO FEDERICO GÓMEZ

Rosario Becerra[1], Linmhi Segura[2], Fabiola Perez[3], Almudena Cervantez[4], Julio Erdmenger[5], Jose Carlos Romo[6], Tania Tamayo[5], Liborio Solano[1], Francisco Bustillo[5], Carlos Alomia[2]
Hospital Infantil De México Federico Gómez, Cardiology, Mexico City-Mexico[1]; Hospital Infantil De Mexico Federico Gomez, Cardiology, Mexico City-Mexico[2]; Instituto Nacional De Pediatria, Cardiology, Mexico City-Mexico[3]; Hospital Infantil De Mexico Federico Gomez, Evidence-based Medicine, Mexico City-Mexico[4]; Hospital Infantil De México Federico Gomez, Cardiology, Mexico City-Mexico[5]; Hospital Infantil De México Federico Gomez, Nephrology, Mexico City-Mexico[6]

Background and Objectives: Cardiovascular disease is recognized as a major cause of death in children with end-stage renal disease (ESRD). The aim of this study was to identify prevalence of abnormalities in left ventricular function through the analysis of tradicional and advanced indices of cardiac mechanics in children with ESRD.
Methods: Between 2015 and 2016, the cross sectional, prospective and observational study enrolled children with ESRF ages 1–17 years old undergoing hemodialysis. Cardiac morphology and function were assessed through transthoracic echocardiography. The analysis presented encompasses global radial, longitudinal, circumferential and torsión strain. The patients were divided en two groups: from 1 to 9 years (group 1) and from 10 to 17 years (group 2). Data were matched with children with comparable age and sex.
Results: Data on 47 patients with ESRF with complete echocardiographic assessment are reported (age = 11.1 ±4.8 years). Patients with ESRD showed mildly higher office Blood Pressure values and higher prevalence of left ventricular hypertrophy, but no differences were observed among groups in left ventricular ejection fraction. In group 1, strain analysis showed significantly lower epicardial (-14.75 ± 3.58 vs -17.7 ± 3.71 p 0.05) and endocardial strain (-19.04 ± 3.77 vs -22.52 ± 4.23 p 0.03) in patients with ESRD, resulting in a significant difference in global longitudinal strain (-16.25 ± 3.00 vs -19.01 ±3.7 p 0.03). In group 2, Strain analysis showed significantly lower global radial strain in patients with ESRD (25.72 ± 9.53 vs 33.98 ± 14.16 p 0.006) without differences among groups in global radial, circunferencial and torsion strain.
Conclusions: A significant proportion of children with ESRD undergoing hemodialysis show impaired systolic mechanics. In younger patients, impaired systolic function is characterized by lower endocardial and epicardial longitudinal strain. In teenagers impaired systolic function characterized by lower global radial strain.

P3041 - MITRAL REGURGITATION CAUSED BY A CLEFT IN THE POSTERIOR MITRAL VALVE LEAFLET. CASE REPORT

Carlos Alomía[1], Rosario Becerra[1], Tania Tamayo[1], Julio Erdmenger[2], Linhmi Segura[3]
Hospital Infantil De México Federico Gómez, Echocardiography, Mexico City-Mexico[1]; Hospital Infantil De México Federico Gómez, Cardiology Chief, Mexico City-Mexico[2]; Hospital Infantil De México Federico Gómez, Cardiology, Mexico City-Mexico[3]

The cleft in the posterior mitral valve leaflet is a very rare congenital anomaly that causes mitral regurgitation. Most of the clefts involve the anterior leaflet and isolated clefts of the posterior leaflet have been anecdotally identified.
Case 1: We report the case of a 17 years old female, with Down syndrome. She was referred for evaluation of a cardiac murmur. Auscultation revealed a systolic murmur at high parasternal border. Transthoracic two-dimensional and transesophageal three-dimensional echocardiography showed moderate mitral regurgitation originated through the cleft of the posterior valve.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

In addition, a prolapse of the anterior mitral leaflet was observed, contributing with the regurgitation. Additionally we found an atrial septal defect.

Case 2: A ten years old female with Marfan syndrome. She was referred for evaluation of a cardiac murmur and as part of Marfan syndrome evaluation. She was asymptomatic and auscultation revealed a systolic murmur at midline fifth intercostal space. Transthoracic two and three dimensional echocardiography showed 2 jets of moderate mitral regurgitation caused by a cleft in the posterior mitral valve leaflet and a prolapse of the anterior mitral valve (A2 scallop), also we found a tricuspid septal leaflet prolapse with mild regurgitation, an atrial septal defect and a dilated aortic root.

In summary, in mitral regurgitation caused by a cleft in the posterior mitral valve the severity of regurgitation is variable. We found just one case reported in a child previously and the cases reported here are even rare because of its occurrence with Marfan and Down Syndromes.

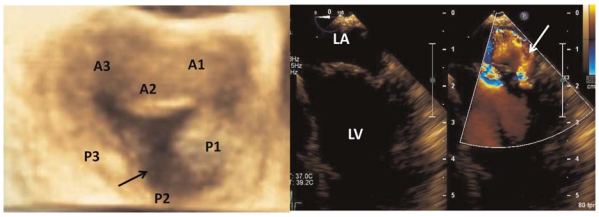

Figure 1.
Patient 2, transesophageal echocardiogram three dimensional image of the cleft in the posterior mitral valve leaflet and two dimensional color of mitral regurgitation. Black arrow shows the cleft, white arrow sohws the mitral regurgitation. AL: anterior leaflet of the mitral valve; PL: posterior leaflet of the mitral valve LV: left ventricle, LA: left atrium.

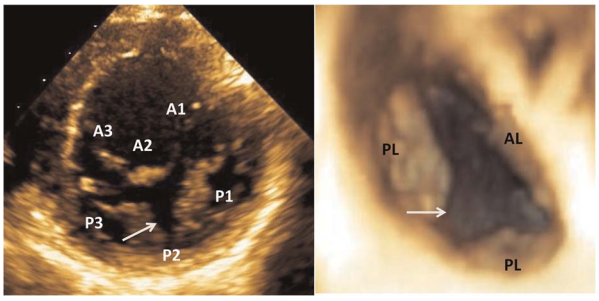

Figure 2.
Patient 2, two and three dimensional image of the cleft in the posterior mitral valve leaflet. White arrow shows the cleft. AL: anterior leaflet of the mitral valve; PL: posterior leaflet of the mitral valve

INTENSIVE CARE

P1011 - A NEW LOOK AT BRONCHOPULMONARY DYSPLASIA POST CAPILLARY PATHOPHYSIOLOGY AND CARDIAC DYSFUNCTION

Arvind Sehgal[1], *Andra Malikiwi*[1], *Eldho Paul*[2], *Samuel Menahem*[3], *Kenneth Tan*[1]

Monash Children, Monash Newborn, Melbourne-Australia[1]; *Monash Medical Centre, Monash Centre for Health Research and Implementation, Melbourne-Australia*[2]; *Monash Medical Centre, Emeritus Head, Paediatric and Foetal Cardiac Units, Melbourne-Australia*[3]

Background: In preterm infants, pulmonary hypertension (PH) and right ventricular function are the focus of cardiovascular effects of bronchopulmonary dysplasia (BPD). The impact of left sided (systemic) indices is not well understood.

Objective: To assess cardiac indices reflecting systemic afterload and pulmonary venous back pressure as pathophysiologic factors in infants with 'severe' BPD.

Methods: Cardiac parameters were measured by conventional echocardiography in 20 preterm infants with severe BPD and compared with 10 preterm infants with no BPD and 20 healthy term infants.

Results: The gestational age and birthweight amongst preterm infants with and without BPD were comparable (26.2 ± 1.7 vs 26.2 ± 0.6 weeks and 772 ± 271 vs 704 ± 53 g). All the infants belonged to the 'severe BPD' category (need for $\geq$ 30% oxygen and/or positive pressure at 36 weeks post menstrual age). None of them were intubated and mechanically ventilated at the time of the study. In infants with severe BPD, PH was noted in [5 (25%), tricuspid regurgitation Doppler jet ≥ 2.8 m/s and 15 (75%), by the Time to peak velocity/Right ventricular ejection time < 0.34]. Amongst systemic cardiac indices, significant impairment of diastolic function was noted in the BPD group compared to no BPD infants and term infants. The significance persisted after adjusting for gestational age and birthweight. A higher end systolic wall stress (surrogate for afterload) had a significant correlation with lower mean velocity of circumferential fibre shortening (contractility) ($r = -0.74$, $p = 0.0002$).

Conclusions: Altered systemic (left sided) cardiac function was noted in the infants with BPD which may lead to pulmonary venous congestion contributing to a continued need for respiratory support. Impaired left ventricular relaxation and high left atrial pressure may be oedemagenic factors.

Table 1. Comparison of echocardiographic parameters

Variable	BPD group (n = 20)	Preterm no BPD group (n = 10)	Term infants (n = 20)	Unadjusted overall group effect (p value)	GA adjusted group effect (p value)	BW adjusted group effect (p value)	GA and BW adjusted group effect (p value)
Heart rate (beats/min)	146 ± 10	152 ± 11	145 ± 8	0.24	0.2	0.13	0.44
Diastolic parameters

P1013 - A LONG TERM FOLLOW UP OF AN EXTREMELY LOW BIRTH WEIGHT INFANT WITH RIGHT ISOMERISM AND MULTIPLE CONGENITAL HEART ANOMALIES

Tamaki Hayashi
Nara Medical University, Pediatrics, Kashihara-Japan

Background: The prognosis of right isomerism heart with total anomalous pulmonary vein connection is still not satisfactory. And complex congenital heart disease in extremely low birth weight patient is also not favorable.
Case: We experience an extremely low birth weight infant, born 29 weeks 4 days and birth weight was 879 g. She also had the right isomerism heart with complete atrioventricular septal defect, double outlet right ventricle, pulmonary atresia, and patent ductus arteriosus. Initially, pulmonary blood flow was controlled by using intermittent prostaglandin infusion. At the age of 5 months, left modified Blalock-Taussig shunt was done. Bidirectional Glenn shunt was performed at the age of 12 months old. And finally total cavo-pulmonary connection was done at the age of 24 months. After Fontan operation, hemodynamic status remained stable with using some anti-failure medications, but she shows mild pulmonary vein stenosis at the recent follow-up examination. We are planning to do the catheter examination. She suffered severe streptococcus pneumoniae sepsis when she was 2 years 10 months old. Other than that, no critical infection was issued till today. Regarding her development, she is slow in learning. She is now 10 years old but her emotional development is 6 years old and language development is 7 years. Now she is going to special supportive class in the municipal elementary school.
Conclusion: Prognosis of an extremely low birth weight patient with complex heart anomalies is not known. No case reports are found by PubMed search. Our case shows satisfactory clinical course. Aggressive treatment for this patient group may be acceptable.

P1017 - VASOACTIVE VENTILATION RENAL SCORE AND ICU LOS IN PATIENTS UNDERGOING RE ENTRY STERNOTOMY FOR CONGENITAL HEART DISEASE A SINGLE INSTITUTE EXPERIENCE

Vicki Mahan[1], Monika Gupta[2], Randy Stevens[1], Achintya Moulick[1]
St. Christopher, Cardiothoracic Surgery, Philadelphia-United States[1]; St. Christopher, Critical Care, Philadelphia-United States[2]

Purpose: Severity of injury scores have not reliably predicted ICU LOS in patients undergoing surgery for congenital heart disease (CHD.) In those patients undergoing re-entry sternotomy, limited information regarding outcomes is available. A newer score, the Vasoactive-Ventilation-Renal Score (VVR score) may be used to predict ICU LOS after re-entry sternotomy for CHD.
Methods: Retrospective analysis of patients undergoing reentry sternotomy for CHD at our center between August 1, 2009 and May 31, 2016 was performed. Vasoactive-Ventilation-Renal (VVR) scores were calculated at admission post-procedure, 24-hours after admission, and at 48-hours. We evaluated injury of structures on entry, cardiopulmonary bypass time, cross-clamp time, blood requirements within 48 hours, duration of mechanical ventilation, ICU and hospital LOS, low cardiac output syndrome, sepsis, bleeding, renal failure, arrhythmias, and death. The response variable was ICU length of stay in days. Recursive partition analysis was used to identify the variables predicting length of stay. Of the initial 25 features, 5 were removed for near zero variance and 3 categorical features were removed for non-information. Covariance analysis did not demonstrate any significant correlation among the remaining features. Initial recursive tree regression using ANOVA, cross validation and cp = 0.01 produced 4 trees. To avoid over-fitting, the tree with lowest cross validation error was selected.
Conclusions: The resulting 2 split trees identified ventilator days and VVR at 48 hours to be predictive of ICU LOS.

P1018 - A RETROSPECTIVE COHORT STUDY TO EVALUATE THE USE OF PARACETAMOL COMPARED TO IBUPROFEN IN THE MEDICAL CLOSURE OF PATENT DUCTUS ARTERIOSUS AMONG PRETERM INFANTS IN A PRIVATE TERTIARY HOSPITAL

Maria Ronella Francisco-Mallari, Hannalae Grace Dulay-See
Makati Medical Center, Pediatrics, Metro Manila-Philippines

Background: Persistent Patent Ductus Arteriosus (PDA) results from failure of the physiologic closure of the fetal ductus which renders the preterm newborn vulnerable to pulmonary overcirculation with diminished systemic blood flow. In this case, therapeutic intervention to facilitate ductal closure might be indicated. Objective: To determine the effectiveness and safety of oral and intravenous paracetamol compared to oral ibuprofen in the closure of a PDA in preterm infants.
Method: A retrospective cohort study was performed involving 28 cases of premature infants at a private tertiary hospital from January 1,2010 to June 30, 2014. Each patient received either oral paracetamol at a dose of 15 mg/kg every 6 hours for 3 days or oral ibuprofen at an initial dose of 10 mg/kg followed by 5 mg/kg at 24 and 48 hours.
Results: The PDA closure rates for both paracetamol and ibuprofen were identical at 64.3% (9/14). The mean days of closure for the paracetamol group was shorter at 1.5 ± .46 days in contrast to the ibuprofen group which is 2.7 ± .48 days (P = 0.00) There were no significant differences between the two groups in the incidence of adverse events. There were more preterms that had gastrointestinal bleeding in the ibuprofen group (28.6%) compared to the paracetamol group (7.1%) (P = 0.32) Platelet counts in the ibuprofen group decreased after one week of treatment at -87 ± 115.84, while that of paracetamol group increased by 12 ± 92.34 (P = 0.48)
Conclusions: Paracetamol may have a place with equal efficiency with Ibuprofen, the standard drug of choice, in the medical treatment for closure of PDA. Paracetamol with its lower incidence of adverse events may be a better alternative drug in the treatment of PDA in preterm infants.

P1040 - PAROXYSMALSUPRAVENTRICULAR TACHYCARDIA (PSVT) IN CHILDREN – THERAPEUTIC APPROACH IN URGENT PEDIATRICS

Maria Neamtu
Clinical Hospital, Pediatrics Departament, Balti-Moldova

Objectives: 1. Determination of trigger factors against the background of congenital heart defect. 2. Clinical manifestations of PSVT depending on age. 3. Effectiveness of treatment depending on age. Relevance of the topic: PSVT is one of major urgencies in children.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: The study included a group of 22 children and was based on survey and monitoring in dynamics in Emergency Receiving Pediatrics Unit Department, Clinical Hospital Balti in 2014.
Study results: 1. Age separation: 1st lot 0-4 years old (8 children – 36,36%), 2nd lot 5-18 years old (14 children – 63,63%) 2. Etiology separation: 1st lot PSVT with acute respiratory infection, pneumonia, congenital heart defect (atrial septal defect (ASD), ventricular septal defect (VSD)) – 36,36% 2nd lot PSVT in intact heart (stress, fear) – 63,63% 3. Clinical manifestation separation: 1st lot – cyanosis, extreme pallor, dyspnea – 36,36% 2nd lot – palpitation, heart pain, pallor, asthenia – 63,63% 4. Treatment separation: 1st lot – attack treatment with Adenosine – 36,36% 2nd lot – attack treatment with Amiodarone – 39,28%, Verapamil – 24,35%.
Conclusions: 1) High frequency of PSVT in children with concomitant diseases against the background of congenital heart defects (ASD, VSD) 2) High effectiveness of attack treatment in 1st lot with Adenosine, 2nd lot with Amiodarone and Verapamil 3) In Emergency Receiving Pediatrics Unit Department it is possible to treat PSVT attack in children.

P1065 - RISK FACTORS FOR THE DEVELOPMENT OF GIANT CORONARY ANEURYSMS IN THE ACUTE PHASE OF KAWASAKI DISEASE IN MEXICAN PATIENTS

Luis Martin Garrido-Garcia[1], Edna Moran-Villaseñor[2], Patricia Cravioto-Quintana[3], Fernando Galvan-Castillo[4]
Insituto Nacional De Pediatria, Cardiology, Mexico City-Mexico[1]; Instituto Nacional De Pediatria, Pediatrics, Mexico City-Mexico[2]; Insituto Nacional De Pediatria, Teaching Department, Mexico City-Mexico[3]; Instituto Nacional De Pediatria, Teaching Department, Mexico City-Mexico[4]

Background: An important complication of Kawasaki disease is the developement of giant coronary aneurysms. Risk factors for their development are not still clear.
Methods: A retrospective analysis was conducted at the Instituto Nacional de Pediatría in Mexico City, Mexico. It included all patients with diagnosis of Kawasaki disease between 1995 and 2015. Clinical and laboratory findings, as well as echocardiographic measurements were recorded. Patients with giant coronary aneurysms were used as the case group and all the other patients as a control group. P <0.05 was considered to be statistically significant. OR and their 95% CI were calculated to delinate the risk factors.
Results: 416 patients were diagnosed as Kawasaki disease from 1995 to 2015. 34 developed giant coronary aneurysms at the acute stage of the disease. In multivariate analyses, patients aged younger than 1 year (p <0.001 OR = 3.827 IC 95% 1.862-7.867) showed significantly higher OR for giant coronary aneurysms. In univariate analyses changes in the palms (p <0.028), the presence of congestive heart failure (p < 0.000472), or neurological findings (p < 0.01), as well as atypical manifestations (p <0.044) were found to significantly increase the risk of developing giant coronary aneurysms. Those who received additional intravenous immunoglobulin (p <0.023), and patients with higher duration of illness at time of presentation to hospital, showed significantly higher risk for giant coronary aneurysms. Anemia, leukocytosis, thrombocytosis, a lower erythrocyte sedimention rate and hipoalbuminemia were also found as risk factors. The presence of extracoronal findings on echocardiography (myocarditis, pericardial effusion, pericarditis and hypokinesia) were significantly associated with the development of giant coronary aneurysms.
Conclusions: One of the main factors associated with the development of giant coronary aneurysms was the delay in diagnosis of Kawasaki disease. This findings demonstrate the importance of maintaining a high suspicion of the disease, enabling early diagnosis and prompt.

P1066 - ACUTE MYOCARDIAL INFARCTION IN THE ACUTE PHASE IN KAWASAKI DISEASE IN MEXICAN CHILDREN

Luis Martín Garrido-Garcia[1], William Sarmiento-Robles[2]
Instituto Nacional De Pediatria, Cardiology, Mexico City-Mexico[1]; Instituto Nacional De Pediatria, Pediatrics, Mexico City-Mexico[2]

Background: Kawasaki disease is an acute febrile vasculitis of unknown origin. Despite treatment with intravenous immunoglobulin during the acute phase of the disease, up to 5% of those affected will develop coronary aneurysms predisposing them to thrombotic complications that could result in myocardial infarction (AMI). In Mexico there are few reports of ischemic complications secondary to KD.
Objective: To describe the clinical features, the laboratory parameters, treatment used and the outcome of children who presented with myocardial infarction during the acute phase of KD in a third level facility in Mexico City.
Methods: From our Institutional Database of KD we search for children who presented AMI in the acute phase of the disease from August 1995 to August 2016. We analyzed gender, age, clinical manifestations, time from the onset of the symptoms to diagnosis, laboratory parameters, treatment used, and outcome in the acute phase of the disease.
Results: Eight infants were diagnosed with AMI during the study period. The median age at diagnosis was 8 months (range 2 to 53 months). Seven patients were male (87.5%). The median from the onset of the clinical manifestations to diagnosis of KD was 22 days (range 4 to 26 days). All patients developed giant coronary aneurysms (median Z-score 18.98, with a range of Z-score from 11.58-27.70). An abnormal EKG and abnormal perfusion tests demonstrated the myocardial infarction in all cases. Two patients died in the acute phase of cardiogenic shock, one more patient died of dilated cardiomyopathy 12 months after coronary bypass surgery with an overall mortality of 62.5% of this group.
Conclusions: AMI is a fatal complication of KD. In our small series it was associated with a delayed diagnosis of the disease and therefore the development of giant coronary aneurysms. Treatment of AMI in children after KD is a medical challenge.

P1093 - INTERSTAGE READMISSIONS IN SINGLE VENTRICLE PATIENTS UNDERGOING STAGED PALLIATION

Christina Phelps, Kristin Kirchner, Kirby-Rose Carpenito, Robin Allen, Holly Miller-tate, Janet Simsic
Nationwide Children's Hospital, The Heart Center, Columbus-United States

Background: Readmissions during the interstage period are common in infants with single ventricle congenital heart disease

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

undergoing staged surgical palliation (S1P). We retrospectively examined readmissions during the interstage period.
Methods: Newborns undergoing S1P from January 2012-May 2015 who survived to hospital discharge were reviewed (n = 72). Patients followed elsewhere were excluded (n = 7). All of the patients undergoing S1P were home monitored.
Results: Study group comprised 65 patients. Surgeries included stage 1 hybrid palliation (44), Blalock-Taussig shunt (14), pulmonary artery band (7). Forty-nine patients had a total of 91 interstage readmissions; 86% were unscheduled. There were 19 major interstage adverse events (21%) - arrest/acute life threatening event (5); stroke (1); sepsis (1); cardiac catheterization requiring intervention - enlargement of atrial septal defect (3), retrograde aortic arch stenosis (2); evaluation for mesenteric ischemia (1); pneumonia/aspiration (2); shock (2); pericardial effusion requiring drainage (1); volvulous requiring bowel resection (1). Twenty-five readmissions (27%) were secondary to cardiac reasons defined as changes on echocardiogram - decreased function, restrictive atrial septal defect, retrograde aortic arch stenosis, stenotic BTS, or scheduled cardiac catheterization. Six patients suffered interstage deaths (9%). Nine patients (14%) spent >30 days in the hospital during the interstage period. Of the 55 newborns (85%) discharged following S1P 100% orally feeding; 73% remained 100% orally feeding throughout interstage period. No patient discharged with NGT/GT feedings learned to eat during the interstage period.
Conclusion: Interstage readmissions are common, with the majority being unscheduled. Interstage mortality was <10%. Majority of patients discharged 100% orally feeding following S1P remained 100% orally feeding throughout the interstage period. However, patients did not "learn to eat" during the interstage period.

P1130 - CAN ACUTE PHASE RESPONSE BIOMARKERS DIFFERENTIATE INFECTION FROM INFLAMMATION POST PEDIATRIC CARDIAC SURGERY

Bana Nasser[1], Abdulrahman Almesned[2], Tajalldin Mohmad[3], Mohammad Khabani[4]
PSCCQ, Pediatric Cardiac Intensive Care, Buridha-Saudi Arabia[1]; PSCCQ, Pediatric Cardiology, Buridha-Saudi Arabia[2]; PSCCQ, Pediatric Cardiac Surgery, Buridha-Saudi Arabia[3]; National Guard Hospital, Pediatric Cardiac Intensive Care, Alryadh-Saudi Arabia[4]

Infection is common serious complication post pediatric cardiac surgery, diagnosis of infection is difficult in presence of surgical stress and inflammatory reaction after cardiopulmonary bypass.
Aim: The purpose of this study is to investigate the value of available inflammatory biomarkers and its validity in differentiate infection from inflammation post pediatric cardiac surgery. And find out the trend and the figures of these biomarkers after cardiac surgery.
Methods: We conducted a prospective study included all pediatric patient underwent cardiac surgery Erythrocyte Sedimentation Rate , White Cell Count with Neutrophile count pre surgery and for 4 consequence days post surgery and pre discharge were collected for all patients. Patients were divided into two groups infected and non infected group and off- on pump group then group who received corticosteroid pre surgery and others who didn't receive. Data were reviewed and analyzed.
Results: During study period 134 pediatric cardiac patients were collected . non infected group was 125 cases and infected group was 9 cases. We found No statistical difference in inflammatory biomarkers elevation between the groups the infected group had higher RACSH score and more days on ventilator and they had more drop in platelet count comparing with non infected group in day 2 and 3 post surgery. Both patients in on and off pump had same level of inflammatory biomarkers. Giving corticosteroid didn't change the trend of serum elevation of biomarkers.
Conclusion: Available inflammatory biomarkers cant differentiate between infection and inflammation during 5 days post cardiac surgery.

P1134 - EARLY VASCULAR AGING AND MALADAPTIVE ARTERIAL VENTRICULAR INTERACTIONS IN PRETERM INFANTS WITH FETAL GROWTH RESTRICTION

Arvind Sehgal[1], Beth Allison[2], Stella Gwini[3], Samuel Menahem[4], Suzanne Miller[2], Graeme Polglase[2]
Monash Children's Hospital, Monash Newborn, Melbourne-Australia[1]; Hudson Institute of Medical Research, The Ritchie Centre, Melbourne-Australia[2]; Monash University, Department of Epidemiology & Preventive Medicine, Melbourne-Australia[3]; Monash Health, Fetal Cardiac Unit, Melbourne-Australia[4]

Background: The cardiac adaptations already present in preterm FGR infants soon after birth are not known. The objectives of the study were to assess vascular and cardiac morphology and biomechanics in preterm infants with FGR compared to an appropriate for gestational age (AGA) cohort.
Methods: 20 preterm infants (28-32 weeks) GA and birthweight (BW) <10th centile were compared with 20 preterm AGA infants. The total duration of respiratory support was recorded. Along with standard ECHO views, the abdominal aorta was imaged.
Results: The GA and BW of FGR and AGA infants were 29.8 ± 1.3 vs. 30 ± 0.9 weeks ($p = 0.78$) and 923.4 ± 168 vs. 1403 ± 237 g ($p < 0.001$). At 10.5 ± 1.3 days after birth, BP was significantly higher in the FGR infants. The aorta intima media thickness (aIMT) was higher in FGR infants (621 ± 76 vs 479 ± 54 μm, $p < 0.001$). The aorta was significantly stiffer in FGR infants. FGR infants also had significantly greater ventricular septal hypertrophy and a lower sphericity index (1.53 ± 0.15 vs 1.88 ± 0.2, $p < 0.001$). Diastolic dysfunction was noted (↑Transmitral E/A ratio, ↑Tei index, and ↑End systolic wall stress [0.84 ± 0.05 vs. 0.78 ± 0.03, $p < 0.001$, 0.34 ± 0.04 vs 0.25 ± 0.03, $p < 0.001$ and 45.9 ± 6.9 vs. 33.7 ± 4.2 g/cm2, $p < 0.001$]). The mean velocity of circumferential fibre shortening (mVCFc) was reduced in FGR infants (1.93 ± 0.4 vs 2.77 ± 0.5 circ/s, $p < 0.001$). Total duration of respiratory support was significantly longer in FGR infants and correlated with ECHO parameters; E/E' ($r = 0.65$, $p = 0.001$) and mVCFc ($r = -0.64$, $p = 0.001$). Significant correlations between vascular biomechanics and cardiac function were noted (Resistance vs E/E' = 0.7 & Tei index = 0.79).
Conclusions: Preterm FGR infants have impaired cardiac function which is associated with respiratory sequelae.

P1157 - CONGENITAL HEART DISEASE DOES NOT INCREASE THE RISK OF DEATH IN LOW BIRTH WEIGHT INFANTS

Yoshihiro Takahashi[1], Yuichi Nomura[1], Kiminori Masuda[1], Ryo Kusubae[1], Satoshi Ibara[2], Koji Sameshima[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Kagoshima City Hospital, Pediatrics, Kagoshima-Shi, Kagoshima-Japan[1]; Kagoshima City Hospital, Neonatology, Kagoshima-Shi, Kagoshima-Japan[2]

Congenital heart disease (CHD) is recognized as a risk factor for poor outcome in low birth weight infants, but its characteristics have not been fully understood.
Methods: To characterize the incidence and outcomes of CHD in low birth weight infants, we retrospectively reviewed the clinical data of infants weighing less than 2,500 g, who were born and admitted in our NICU between 2010 and 2014. We compared the data between infants with CHD and those without CHD (non-CHD).
Results: We excluded 21 infants with PDA alone, and analyzed the data for 1,825 infants. Of these, we diagnosed 86 infants as having CHDs (4.7%) and identified 52 infants with VSD (60%), 14 with TOF (16%), and 12 with ASD (14%). One infant each with HLHS, TGA, TA, TAPVR, and truncus arteriosus was also included. Chromosomal abnormalities were found in 32 infants (1.8%), and the incidence in the CHD group (30%) was significantly higher than that in the non-CHD group (0.3%) ($P < 0.0001$). Six infants in the CHD group (7.0%) and 45 infants in the non-CHD group (2.7%) died during their hospital stay. The CHD group showed a significantly higher mortality rate than the non-CHD group ($P = 0.047$), and infants with chromosomal abnormality also showed a significantly higher mortality rate than those without chromosomal abnormality (19.4% vs. 2.5%, $P < 0.0001$). A logistic regression analysis revealed that CHD alone was not a risk factor for death (odds ratio [OR]: 0.80; 95% confidence interval [95% CI]: 0.20-3.21) but chromosomal abnormality introduced a significantly high risk (OR: 28.0; 95% CI: 6.2-127, $P < 0.0001$).
Conclusion: Mortality in low birth weight infants with CHD was higher than in those without CHD. This difference was due to the higher incidence of chromosomal abnormalities and not due to the presence of CHD alone.

P1181 - EFFECTS OF PERCEIVED KNOWLEDGE GAIN FROM A NURSE RESIDENCY PROGRAM IN SOUTHERN INDIA

Hailey Miller[1], Adriana Dobrzycka[2], Rohini Paul[3], Sandra Staveski[4]
Cincinnati Children's Hospital Medical Center, Research in Patient Services, Cincinnati-United States[1]; Children's Heartlink, Minneapolis-United States[2]; Narayana Health, Bangalore-India[3]; Cincinnati Children's Hospital Medical Center, Cincinnati-United States[4]

Background/Hypothesis: There was a gap identified between the nurses' training and clinical expectations in a Pediatric Cardiac Intensive Care Unit (PCICU) in Bangalore, India. To address the identified gap, interventions were implemented through a nurse residency program (NRP) with the aim to enhance nurses' knowledge and patients' outcomes following cardiac surgery. Our study examined the feelings and perceptions of nurses' transitioning into clinical educator roles.
Materials and Methods: The five clinical educators participating in the NRP were chosen via purposeful sampling to participate in focus groups. Structured interviews were recorded and transcribed, and later analyzed by two researchers. One of the researchers was a disinterested member to remove bias from the analysis. Thematic analysis, a rigorous process of analyzing data, establishing codes, and identifying themes, was used to analyze content (Braun & Clarke, 2006). The researchers compared interpretations and common patterns to generate conclusions.
Results: Analysis showed common themes in the clinical educators' perceptions regarding their experience with the NRP. We found the clinical educators perceived the NRP led to an overall knowledge gain among participants, leading to increased confidence level, clinical competence, ability to use voice, ability to guide and teach others, happiness, and clinical care improvement. In addition, the clinical educators felt the knowledge enhancement led to greater recognition and respect from others. We found that these results ran parallel to previous publications and current literature.
Conclusions: Clinical educators felt the NRP had a positive impact on nursing practice and relationships in the PCICU, and the continuation of the program would be beneficial to their future careers.

P1182 - PEDIATRIC CARDIAC INTENSIVE CARE NURSE RESIDENCY PROGRAM'S EFFECT ON NURSING PERFORMANCE BEHAVIORS IN SOUTHERN INDIA

Sandra Staveski[1], Adriana Dobrzycka[2], Li Lin[3], E. Marsha Elixson[4], Jeff Paurus[5], Leela K[6], Margo Moore[3], Christine Alvarez[3], Rohini Paul[7]
Cincinnati Children's Hospital Medical Center, Research in Patient Services, Cincinnati-United States[1]; Children's Heartlink, Minneapolis-United States[2]; Cincinnati Children's Hospital Medical Center, Cincinnati-United States[3]; Pediatric Clinical Concepts, Inc., Atlanta-[4]; Normandale Community College, Bloomington-United States[5]; Narayana Institute of Cardiacs, Bangalore-India[6]; Narayana Health, Bangalore-India[7]

Background/Hypothesis: We identified a gap between nurses' academic training and Pediatric Cardiac Intensive Care Unit (PCICU) nursing care requirements. A nurse residency program (NRP) was created to improve nursing performance behaviors (i.e., knowledge, skills, competence). The aim of this study was to evaluate the NRP's effect on nursing performance behaviors.
Materials and Methods: The NRP consisted of three one-week training sessions and structured mentoring by on-site clinical educators. Our study was a pre-post cohort investigation which explored the NRP's effects on: 1) knowledge, 2) the mentors' and the NRP participants' perception of their nursing skill, and 3) the PCICU medical director perception of participants' competence. 40 PCICU nurses participated in this investigation (NRP $n = 20$; Controls $n = 20$). NRP participants and controls were asked to complete knowledge tests and skill assessments prior to the initiation of the NRP (T1), upon completion of the NRP (T2), and 6 months after completion of the NRP (T3). The mentors evaluated NRP participants and controls' skill at T1, T2, and T3. The medical director evaluated competency of all participants at T1 and T3. A mixed effect model with repeated measures was used to study differences between cohorts.
Results: There were no significant differences between NRP participants and controls' age, gender, birth state, and professional qualification. Mean NRP knowledge scores were higher than controls at T2 ($p < 0.0001$) and at T3 ($p = 0.01$). The NRP cohort mean knowledge scores were higher at T2 ($p < 0.0001$) and T3 ($p = 0.002$) than T1. NRP participants' perception of skill level were higher than controls at T2 ($p = 0.011$) and T3 ($p < 0.0001$). Mentors' perception of NRP participants' skill were higher

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

than controls at T2 ($p < 0.0001$) and T3 ($p < 0.0001$). Physician perception of the NRP participants' clinical competency was higher than controls at T3 ($p < 0.0001$).
Conclusions: There were sustained improvement in nursing performance behaviors for participants in the NRP cohort.

Table 1. Outcomes by intervention group and time.

	T1 Mean (SD)	T2 Mean (SD)	T3 Mean (SD)
Mean knowledge scores (0-100%)	60.82 (10.33)	78.32 (5.71)	72.70 (11.26)
Self-rated skill level (1-novice to 4-trainer)	1.93 (0.53)	2.78 (0.73)	3.04 (0.57)
Mentor-rated skill level (1-novice to 4-trainer)	1.69 (0.38)	2.81 (0.53)	2.72 (0.42)
Physician-rated competency (1-strongly negative to 7-strongly positive)	5.92 (0.34)		6.42 (0.49)

Table 2. Outcomes by control group and time.

	T1 Mean (SD)	T2 Mean (SD)	T3 Mean (SD)
Mean knowledge scores (0 to 100%)	57.55 (9.48)	57.95 (7.25)	61.20 (12.20)
Self-rated skill level (1-novice to 4-trainer)	2.09 (0.74)	2.15 (0.75)	1.78 (0.63)
Mentor-rated skill level (1-novice to 4-trainer)	1.52 (0.25)	1.84 (0.66)	1.78 (0.63)
Physician-rated competency (1-strongly negative to 7-strongly positive)	5.30 (0.59)		5.29 (0.81)

P1183 - OUTCOMES ASSOCIATED WITH IMPLEMENTATION OF A PEDIATRIC CARDIAC INTENSIVE CARE NURSES RESIDENCY PROGRAM IN SOUTHERN INDIA

Sandra Staveski[1], Adriana Dobrzycka[2], Li Lin[3], E. Marsha Elixson[4], Jeff Paurus[5], Leela K[6], Margo Moore[3], Christine Alvarez[3], Rohini Paul[7]
Cincinnati Children's Hospital Medical Center, Research in Patient Services, Cincinnati-United States[1]; Children's Heartlink, Minneapolis-United States[2]; Cincinnati Children's Hospital Medical Center, Cincinnati-United States[3]; Pediatric Clinical Concepts, Inc., Atlanta-United States[4]; Normandale Community College, Bloomington-United States[5]; Narayana Institute of Cardiacs, Bangalore-India[6]; Narayana Health, Bangalore-India[7]

Background/Hypothesis: We identified a gap between nurses' academic training and Pediatric Cardiac Intensive Care Unit (PCICU) nursing care requirements. A hospital-based nurse residency program (NRP) was created to improve nursing care delivery to children with structural heart disease in a Southern Indian PCICU. Our study examined NRP participants' satisfaction with the NRP and organizational outcomes associated with implementation of a NRP.
Materials and Methods: An international focus group was formed to create the NRP. The NRP consisted of three one-week training sessions and structured mentoring by on-site clinical educators. Twenty PCICU nurses participated in the NRP. Along with education on nursing care for children with structural heart disease each participant was educated on role-modeling adherence with hospital acquired infection reduction bundles and best ways to support bundle adherence in the PCICU. Nursing turnover rates, surgical volume, mortality rates, central-line associated bloodstream infections (CLASBI), ventilator associated pneumonia (VAP), catheter-associated urinary tract infections (CAUTI), and surgical site infection (SSI) rates were compared seven months prior to implementation of the NRP and seven months after initial NRP implementation. Descriptive statistics and Student t-test were used to evaluate outcome changes after the implementation of a NRP in a resource-constrained environment.
Results: Upon completion of the NRP, participants' mean NRP satisfaction score was 1.4 (SD = 0.41) on a Likert Scale ranging from strongly positive (1) to strongly negative (4). There were positive trends in a number of organizational and child outcomes during and after NRP implementation. The most significant was a reduction in mortality rate ($p = 0.007$). In addition, the PCICU CLASBSI rate was marginally lower after implementation of the NRP ($p = 0.056$).
Conclusion: Participants were satisfied with the NRP and there may have been positive effects on organizational and child outcomes. Further study is warranted.

Table 1. Organization and Child outcomes.

Outcome	Pre-education 7 months Mean (SD)	During and After education 15 months Mean (SD)	t, p
Mortality Rate	4.29 (.58)	3.39 (0.70)	t(20) = 3.14, 0.007*
CLASBSI Rate	6.09 (3.42)	3.0 (1.65)	t(20) = 2.26, 0.056*
Nursing Turnove Rate	11.86 (6.31)	6.93 (3.99)	t(20) = 1.89, 0.093
Pediatric Surgical Volume	203.14 (15.92)	223.67 (9.81)	t(20) = 1.60, 0.12
VAP Rate	2.6 (5.6)	0 (2.5)	t(20) = 1.67, 0.14
CAUTI Rate	0 (0)	0.1 (0.38)	t(20) = -1.0, 0.33
SSI Rate	1.35 (0.99)	2.15 (1.52)	t(20) = -1.47, 0.16

P1184 - DEVELOPMENT AND IMPLEMENTATION OF A PEDIATRIC CARDIAC CRITICAL CARE NURSE RESIDENCY PROGRAM IN BANGALORE INDIA

E. Marsha Elixson[1], Jeff Paurus[2], Adriana Dobrzycka[3], Rohini Paul[4], Sandra Staveski[5]
Pediatric Clinical Concepts, Inc., N/a, Atlanta-United States[1]; Normandale Community College, Bloomington-United States[2]; Children's Heartlink, Minneapolis-United States[3]; Narayana Health, Bangalore-India[4]; Cincinnati Children's Hospital Medical Center, Cincinnati-United States[5]

Background/Hypothesis: Many nurses in resource constrained environments do not receive subspecialty pediatric cardiac

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

intensive care (PCICU) training. Developing a sustainable, reproducible Nurse Residency Program (NRP) may address the gap between academic preparation and clinical practice in the Pediatric Cardiac Intensive Care Unit (PCICU) and improve nursing care of children requiring cardiac surgery.
Materials and Methods: A international focus group of pediatric cardiac nursing experts, in collaboration with Children's HeartLink, developed three peer-reviewed one-week PCICU nurse training sessions. The sessions focused on nursing management of post-operative pediatric cardiac surgical patients, implementation of hospital acquired infection reduction bundles, and methods to foster improved communication skills amongst healthcare team members. The NRP contained didactic, low-fidelity simulation, and mentored clinical care training components. NRP presentations encompassed a variety of topics included but limited to cardiac anatomy and physiology, review of critical organ systems, electrophysiology, and congenital heart defect specific nursing care. In addition, we developed a peer-reviewed structured mentor training program for expert local nursing staff. The NRP was implemented in an 81 bed PCICU in Bangalore, India during May-July 2015. Mentors received in depth coaching for our focus group weekly in order to prepare the mentors for future independent implementation of the NRP at our local site.
Results: Twenty-two nurses participated in the initial NRP. Six nurses were trained to become mentors and/or NRP coordinators. Subsequently, a second cohort was successfully led by the mentors January-March 2016.
Conclusions: A NPR can be implemented in resource constrained environments by local teams with the support a nongovernmental organization and expert nurse volunteers. A sustainable, reproducible model of PCICU may be a viable option for improving nursing care.

P1185 - UTILIZATION OF A REDCAP DATABASE AS A NOVEL TEACHING TOOL IN NURSE RESIDENCY PROGRAM

Christine Alvarez[1], Margo Moore[1], Rohini Paul[2], Sandra Staveski[3]
Cincinnati Children's Hospital Medical Center, Research in Patient Services, Cincinnati-United States[1]; Narayana Health, Bangalore-India[2] Cincinnati Children's Hospital Medical Center, Cincinnati-United States[3]

Background/Hypothesis: We discovered an educational gap between nurses' academic training and their clinical practice requirements for caring for critically ill children with congenital heart defects. Cincinnati Children's Hospital Medical Center, Children's HeartLink, and Narayana Institute of Cardiac Sciences (NICS) in Bangalore, India developed an intervention to improve Indian child outcomes after cardiac surgery through development of nursing expertise in a pediatric cardiac intensive care unit (PCICU).
Materials and Methods: Our team addressed this gap through development and implementation of a hospital-based PCICU nurse residency program. In addition, Children's HeartLink clinicians developed a comprehensive 75 question cardiac nursing examination in a REDCap database to assess the PCICU nurses' knowledge pre- and post-residency program. The multiple choice examination was emailed to each nurse participant utilizing the survey function in REDCap and was scored for commonly missed responses. Subsequently, respondents and mentors were notified of areas for further teaching.
Results: The REDCap database has proven to be an excellent teaching tool with the ability to improve nursing expertise. Median testing scores increased from 62.66% to 77.33%, showing an overall increase in scores of greater than 23%. The REDCap database provided a robust dataset and offered immediate feedback for the investigator that allowed for real-time assessment of the participating nurse's learning and adjustment of teaching strategies in order to promote participant learning.
Conclusions: The REDCap database has proven to be a novel tool in fostering nursing expertise that in turn may positively affect child outcomes at NICS.

P1226 - QUALITY IMPROVEMENT MINIMIZING UNPLANNED EXTUBATION IN PEDIATRIC INTENSIVE CARE UNIT

Khairul Faizah Mohd Khalid[1], Yogeswary Muniandy[2], Cw Azlawati Cw Ibrahim[2], Aida Sazwani Zamri[2]
National Heart Institute, PCHC Cardiology, Kuala Lumpur-Malaysia[1]; National Heart Institute, Pediatric Congenital Heart Centre, Intensive Care Unit (PCHC ICU), Kuala Lumpur-Malaysia[2]

Background: Unplanned extubation (UE) is a removal of the endotracheal tube by action of patient (self- extubation) or dislodge during care and manipulation of the patient. UE can cause serious complications for mechanical ventilation patient and it is one of the indicator in determining the quality of care in Pediatric Congenital Heart Centre, Intensive Care Unit (PCHC ICU) of National Heart Institute, Malaysia.
Objectives: To identify the risk factors of the incidence with the unplanned extubation and to evaluate the effectiveness of the targeted interventions with a reduced rate of the unplanned extubation.
Materials and Methods: Clinical information, incidence reports and demographic data of the patients were collected retrospectively over a 3-year period from January 2014 until October 2016 related to the unplanned extubations. Key performance indicator, continuous nursing educational programs, new securing techniques of ETT and protocols on care management were intervened and implemented to reduce the rate of unplanned extubations. Results: In year 2014 total number of 31 incident has occurred. After implementations of few targeted intervention, there were reduction to 10 incidences in the year 2015. From January 2016 till October 2016 the number of events was 11. Out of total incident for past 2 years till October 2016, the major factors that identified were due to patient factor about 51.6%.
Conclusion: Risk factors of unplanned extubation are varies. Based on identified risk factors, it contributes in implementing preventive measures to ensure the reduction of events in promoting patients safety. Good practice and the targeted interventions support in reduction of these potentially adverse events.

P1235 - DIRECT ECHOCARDIOGRAPHIC IMAGING OF THE BERLIN HEART VALVES CAN AID IN DIAGNOSING VALVE DYSFUNCTION

Gary Beasley[1], Kristen Nelson-Mcmillan[2], Luca Vricella[3], Reid Thompson[1], William Ravekes[1]
Johns Hopkins Children's Center, Pediatric Cardiology, Baltimore-United States[1]; Johns Hopkins Children's Center, Anesthesiology and Critical Care Medicine and Pediatrics, Baltimore-United States[2]; Johns Hopkins Children's Center, Pediatric Cardiac Surgery and Heart Transplantation, Baltimore-United States[3]

Introduction: Berlin Excor is a VAD that has been approved by the FDA for use in pediatric patients. The Berlin Heart (BH) differs

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

from many mechanical circulatory support (MCS) devices in that it is a pulsatile pump with two sets of artificial valves within the pumping mechanism. The primary drawback of the BH is a 20-30% stroke risk. This high rate comes in large part from thrombus formation on the valves. The BH valves are polyurethane (PU) tri-leaflet valves that significantly reduce backflow compared to mechanical valves. We report a novel way of directly imaging the BH valves that can lead to early thrombus detection and potentially decrease the risk of stroke. Imaging for valve regurgitation can also help detect loading conditions.
Method: Accurate images of inflow and outflow valves can be obtained bedside using a standard echocardiogram machine. Ultrasound gel is applied to the transducer and the transducer is placed directly onto the BH valve casing. The valve leaflets can be seen in 2D imaging and with color flow. Thrombi are difficult to visualize by 2D imaging alone but changes in color flow pattern representing increased valve regurgitation from thrombus formation can easily be seen.
Discussion: BH remains one of few options for infants and young children who require MCS. Unfortunately it carries a high risk of ischemic stroke. We present a new technique to monitor for the development of thrombus before it is visible. We have utilized this technique on several patients and believe there is an association between increasing valve regurgitation and need for pump exchange secondary to thrombus formation. Echocardiography can detect changes in valve regurgitation which should increase suspicion for early thrombus formation, which could lead to a decrease incidence in strokes. Direct imaging of BH valves can also detect changes in the afterload leading to regurgitation.

P1257 - CARDIAC RECOVERY AND OUTCOME OF NEONATES AND INFANTS PRESENTING WITH SEVERE AORTIC COARCTATION AND DEPRESSED CARDIAC FUNCTION

Maria Bello[1], Hiba Salih[1], Osama Eldadah[1], Fahad Alhabshan[1], Abdullah Alghamdi[2], Talat Yelbuz[1], Mohammed Kabbani[3]
King Abdulaziz Cardiac Center, Pediatric Cardiology, Riyadh-Saudi Arabia[1]; King Abdulaziz Cardiac Center, Cardiac Surgery, Riyadh-Saudi Arabia[2]; King Abulaziz Cardiac Center, Pediatric Cardiology Intensive Care Unit, Riyadh-Saudi Arabia[3]

Coarctation of the aorta (CoA) accounts for 5-8% of all congenital heart defects. Children with severe CoA may present with significant myocardial depression and shock. The aim of this study to identify short and midterm outcome of neonates and infants diagnosed with isolated Coarctation and depressed cardiac function (CoA-DF) looking for their cardiac recovery and overall outcome after repair.
Methods: All cases of isolated coarctation who had surgical repair between December 2002 and December 2015 were reviewed retrospectively. A case control study was performed comparing CoA-DF cases defined as shortening fraction (SF) < 25%) and ejection Fraction (EF) < 55% with cases of CoA and normal cardiac function (CoA-DF V.S control groups). Indices of cardiac function before and after repair were reviewed and statistically compared as well as outcome in both groups.
Results: 58 cases fulfilled inclusion criteria with 25 subjects in CoA-DF group and 33 in control group. There were statistically significant difference in EF (42 ± 14.6 v.s 66 ± 8.7) and SF (20 ± 7.6, 36 ± 6.7) pre surgery between both CoA-DF and control groups respectively ($P < 0.05$). Cardiac indices and ventricular function showed improvement in cases of CoA-DF within six months post repair to become comparable to control group. There was no difference in term of complication between both groups.
Conclusion: Majority of the patients with isolated CoA-DF showed improvement of function within 4 weeks after surgery. Patients with residual CoA or complications such as pulmonary hypertension (PHT) has longer recovery extending up to 6 month after surgery. Delayed recovery may hint to the presence of residual lesion or complications that may affect the myocardial ability to recover normally.

P1263 - MANAGEMENT OF CHYLOTHORAX IN CHILDREN AFTER CONGENITAL HEART SURGERY

Constanza Jimenez, Bernardita Lopetegui, Mercedes Guevara
Hospital Calvo Mackenna, Pcicu, Santiago-Chile

Background: Chylothorax is one of the serious complications after cardiothoracic surgery in children and usually manifests during the first postoperative week. Its appearance prolongs hospital stay and increases morbidity. A large number of endogenous proteins are lost, including those involved in the coagulation cascade, increasing the risk of venous thrombosis, malnutrition, infections and other complications.
Method: The study included 19 patients, with a median age of 2,7 months (SD +-1,6) between April 2013 and May 2015. All patients were treated according to our local protocol. The responses of patients to nutritional modifications, octreotide therapy, anticoagulant management and surgical interventions were reviewed.
Results: The prevalence of postoperative chylothorax, which developed at a median of 8 days after operation (3 to 26 days), was 6,1%. Surgical procedures included: repair of atrioventricular septal defects in 5 (26%), Jatene surgery in 4 (21%), single ventricle staging in 5, correction of Fallot in 3, double switch 1 and correction of total anomalous pulmonary venous drainage 1. The median duration and total volume of chylous drainage was 15 days (5 to 26 days) and 6,4 to 68 mL/kg/day. All patients received heparin prophylaxis and only one developed venous thrombosis. 16 patients responded to conservative therapy (84%). Octreotide was used in 14 patients (73%). Only three (15%) had to undergo surgery (thoracic duct ligation and pleurodesis). No patient died due to chylothorax. Only one patient developed venous thrombosis.
Conclusions: Conservative therapy has proven to be effective in most cases, reserving surgical treatment only for refractory cases. The use of octreotide decreases days of pleural effusion in half (13 vs 27 days), if it is used early (before 15 days of surgery), and Heparin prophylaxis proved to be effective in reducing the rate of associated thrombosis.

P1272 - PACKED RED BLOOD CELLS DILUTED WITH 0.9% NACL INFLUENCE ON OSMOLALITY TOTAL HEMOGLOBIN AND MARKERS OF HEMOLYSIS LEVELS

Marina Peres Gomes[1], Larissa Peres Pardo[1], Élen Francini Jardini[1], Maria Paula O. Pires[1], Fernado L. A. Fonseca[2], Paulo C. P. Rosa[3], Maria Angélica S. Peterlini[1], Mavilde L. G. Pedreira[1];
Federal University of Sao Paulo, Pediatric Nursing, Sao Paulo-Brazil[1]; Federal University of Sao Paulo, Biological Sciences, Diadema-Brazil[2]; University of Campinas, Pharmaceutical Sciences, Campinas-Brazil[3]

Background: Dilution of packed red blood cells (RBC) with 0.9% NaCl is performed in order to reduce blood viscosity and increase infusion rate. Despite contraindications, nurses and physicians analyze the risks and benefits in critical situations before deciding to manipulate the RBC, but the effects of this procedure on RBC

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

characteristics is indefinite. The objective of this study was to describe the osmolality of RBC diluted in 0.9% NaCl and to verify the effects on total hemoglobin, hematocrit, free hemoglobin, and hemolysis levels.
Materials and Methods: An experimental study approved by the ethical committee was developed with nine packed RBC (08 A+ and 01 AB+), storage time of 17 ± 8.9 days. The proportions of 0.9% NaCl dilution studied were 25% and 50%. Samples were collected directly of the packed RBC and after dilutions. Osmolality(mOsm/Kg) was measure by an osmometer; total hemoglobin(g/dl) and free hemoglobin (g/dl) were determined through spectrophotometry, hematocrit (%) and hemolysis degree (%) (free hemoglobin × 100-hematocrit/total hemoglobin) were calculated. Data were analyzed according to mean ± SD and ANOVA test ($p \leq 0.05$).
Results: Osmolality in the packed RBC was 350 ± 7.95; 336 ± 7.87 after dilution at 25% and 313 ± 3.52 at 50% ($p < 0.0001$). The initial level of total hemoglobin was 30.05 ± 5.59, with 25% 0.9% NaCl dilution decreased to 22.37 ± 4.93 and 14.06 ± 3.33 at 50% ($p < 0.0001$). Hematocrit values ranged from 73.6 ± 3.26, to 59.5 ± 3.23 at 25% dilution and 39 ± 2.35 at 50% ($p < 0.0001$). The levels of free hemoglobin was 0.06 ± 0.03; 0.11 ± 0.16 after dilution at 25% and 0.10 ± 0.15 at 50% ($p = 0.7025$). The initial degree of hemolysis was 0.06 ± 0.04; 0.25 ± 0.48 after dilution at 25% and 0.46 ± 0.66 ($p = 0.2324$).
Conclusion: There was a significant decrease on the osmolality, total hemoglobin and hematocrit levels, as expected. Hemolysis markers showed increased levels with no statistically significant variations.

P1276 - PULSE WAVE TRANSIT TIME USED IN THE PERIOPERATIVE PERIOD OF CONGENITAL HEART DISEASE

Yuzo Katayama[1], Tsukasa Ozawa[1], Satoshi Ikehara[2], Shinichi Takatsuki[2], Tomotaka Nakayama[2], Hiroyuki Matsuura[2], Ben Tsutomu Saji[2], Hitoshi Yoda[3], Noritsugu Shiono[1], Yoshinori Watanabe[1]
Toho University Omori Medical Center, Department of Cadiovascular Surgery, Tokyo-Japan[1]; Toho University Omori Medical Center, Department of Pediatrics, Tokyo-Japan[2]; Toho University Omori Medical Center, Department of Neonatology, Tokyo-Japan[3]

Back ground: The aim of this study is to assess whether pulse wave transit time (PWTT) is able to assess stroke volume in the children with congenital heart disease.
Method: This is a retrospective study of 56 consecutive patients with congenital heart disease who underwent definitive repair between July 2013 and March 2016. Exclusion criterions are palliative procedure and sustained arrhythmia. Pulse wave transit time and echocardiography were measured at perioperative day, postoperative day 1, and day 7. PWTT was measured and corrected data by body surface area was defined as PWTT index. Stroke volume was measured in the short axis view by transthoracic echocardiography. Patients were divided into two groups (group A: age ≧ 1 year, group B: age < 1 year).
Results: The median age and body surface area at surgery was 12 months (range; 13 days - 16years) and 0.44 m2 (minimum; 0.16 m^2 -1.52 m^2). The correction coefficient between PWTT index and stroke volume was $r = -0.427$ ($p < 0.01$) in a total of 140 data sets for 56 cases. In group A, the correction coefficient was $r = -0.488$ ($p < 0.01$) in a total of 95 data sets for 32 cases. Whereas, the correction coefficient was $r = -0.065$ ($p = 0.67$) in a total of 45 data sets for 24 cases in group B.
Conclusions: PWTT index as a non-invasive parameter was associated with stroke volume with children in the perioperative period of congenital heart disease. Although, it was still not be enough for the the parameter in neonates and infants.

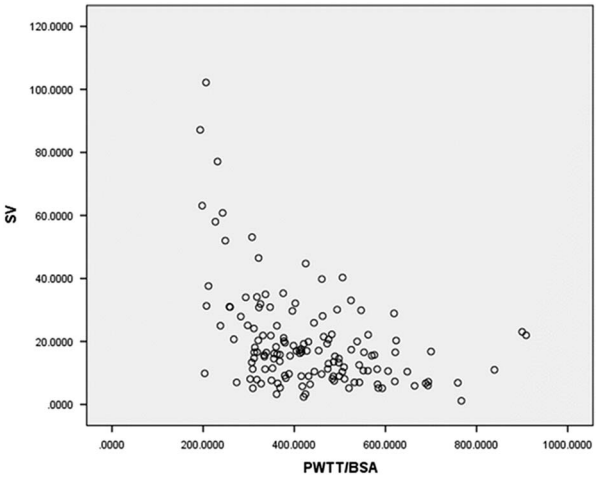

Figure.

P1283 - REDUCING OPIOID USE IN THE PEDIATRIC CARDIAC INTENSIVE CARE UNIT A QUALITY IMPROVEMENT PROJECT

Nick Pratap[1], Amy Donnellan[2], Jaclyn Sawyer[2], Anne Peach[2], Sandra Staveski[2]
Cincinnati Children, Anesthesia, Cincinnati-United States[1]; Cincinnati Children, Heart Institute, Cincinnati-United States[2]

Background: Sedation and analgesia reduce distress, ease mechanical ventilation, reduce metabolic needs, and facilitate stable hemodynamics. Excessive sedation can lead to longer stays, significant morbidities/mortality, withdrawal syndromes, and long-term neurological/behavioral difficulties. Protocolized sedation for ventilated adult patients has been shown to improve outcomes like morbidity, length of stay, and duration of ventilation, but pediatric data is limited. We designed and implemented a standardized comfort algorithm for a 25-bed CICU at Cincinnati Children's Hospital to ensure adequate comfort while minimizing use of opioids.
Materials and Methods: We adapted a PICU sedation protocol (Deeter et al., 2011) for children after elective cardiac surgery. We selected dexmedetomidine as a first-line sedative/anxiolytic agent rather than midazolam. We employed a dedicated opioid infusion line (separate from vasoactives) to facilitate delivery of as-needed morphine bolus doses from the infusion pump, obviating the need for the bedside nurse to leave the bedside of a distressed child to obtain medications and find a second nurse for double checking. A multidisciplinary team employed the Model for Improvement to refine the algorithm over nine months based upon detailed review of successes and failures, local cultural concerns, practice-related barriers and multidisciplinary feedback. Process, balancing and outcome measures were studied using statistical process control methodology.
Results: Over 12 months following implementation, the morphine infusion rate for all ventilated children was reduced from a baseline

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

monthly rate of 120 to 51 mcg/kg/hour (58% overall reduction). Unplanned tracheal extubation, duration of mechanical ventilation and length of CICU stay were unaffected.
Conclusions: Use of a comfort algorithm reduced infusion doses of opioid medications in our CICU. Duration of mechanical ventilation and length of ICU stay did not change, which may reflect CICU cultural factors and stepdown unit bed availability. Reducing opioid usage did not affect safety as judged by a stable rate of unplanned extubation.

P1286 - UNUSUAL CASE OF INTERVENTRICULAR SEPTAL HAEMATOMA AFTER SURGICAL REPAIR OF FALLOT TYPE DOUBLE OUTLET RIGHT VENTRICLE

Dimitar Pechilkov[1], Viliana Dragneva[1], Vetsislav Raykov[1], Marin Pavlov[2], Maxim Denev[2], Plamen Mitev[3], Stoyan Lazarov[3], Anna Kaneva[1]
National Heart Hospital, Department of Paediatric Cardiology, Sofia-Bulgaria[1]; National Heart Hospital, Department of Pathology, Sofia-Bulgaria[2]; National Heart Hospital, Department of Congenital Heart Surgery, Sofia-Bulgaria[3]

Background: Interventricular septal haematoma (IVSH) is a very rare complication after congenital heart surgery in childhood. Since 2005 there are 11 cases reported in the literature. In all of these cases with two exceptions, the surgical correction includes ventricular septal defect (VSD) closure and IVSH probably results from damage of the perforating branches of the coronary arteries near the suture lines of the VSD patch. IVSH manifestations may vary from mild heart failure to low cardiac output states (LCOS) and disturbances of the heart rhythm. The diagnosis is set by an echocardiography. There is no single treatment strategy. It is considered that secondary obstruction of ventricular inflow or outflow and severe systolic dysfunction are indicators for surgical treatment.
Aim: To present an unusual case of IVSH after congenital heart surgery, in which the IVSH is not related to the VSD patch closure.
Methods: Retrospective analysis of the medical files of the patient.
Results: We present a 6 months old boy after surgical repair of Fallot-type DORV with augemtation of right ventricular outflow tract (RVOT) with transannular patch (TAP). Early postoperative period was complicated by LCOS and third-degree AV block. Transesophageal echocardiography showed a thickening of the ventricular septum, moderate depression of the LV systolic function, no obstruction of both ventricular inflows and outflows. No surgical treatment was considered. Patient died at the end of first week with severe respiratory distress syndrome (RDS) on ventilator. Autopsy data showed RDS associated with respiratory syncytial virus (RSV) infection, large 10/12mm fusiform IVSH, originating near the proximal sutures of the transannular patch and not connected to the VSD patch.
Conclusion: IVSH is a rare complication after congenital heart surgery and in most cases is associated with VSD closure, but could be a result of TAP augmentation of RVOT.

P1298 - POSTOPERATIVE COMPLICATIONS IN PEDIATRIC CARDIAC SURGERY PROGRAM WITH LIMITED SYSTEMIC RESOURCES

Igor Polivenok[1], Alexander Petkov[2], Marcelo Cardarelli[3]
Institute For General and Urgent Surgery Namsu, Chief Department of Interventional Cardiology and Cardiac Intensive Care, Kharkiv-Ukraine[1]; Medical Academy of Postgraduate Education, Department of Cardiac Surgery, Kharkiv-Ukraine[2]; William Novick Global Cardiac Alliance, Pediatric Cardiac Surgeon, Memphis-United States[3]

Background: The complication rate after pediatric heart surgery, as well as the failure-to-rescue rate are less known in countries with limited systemic resources.
Methods: The postoperative complication (POC) rate, mortality related to complications, 25 patient and procedure variables as risk factors for developing POC or death and 27 POCs as predictors of mortality were evaluated.
Results: This retrospective, single-center observational study constituted 296 consecutive patients under 18 years of age, who underwent surgical interventions for congenital heart disease in Kharkiv cardiac center (Ukraine) between January 2014 and December 2015. Overall mortality was 5.7%. There were no deaths among 223 patients without POCs. The remaining 73 patients (24.7%) developed POCs and had 17 mortalities (23.3%). There was a strong association between number of POCs and mortality - from 8.1% among patients with only one POC to 35.3% with two POC to 42.1% with three and more POCs ($p = 0.007$). Risk factors for developing POC were younger age, previous cardiac surgery, extracardiac structural anomalies, concomitant diseases and cardio-pulmonary bypass, whereas total number of complications per patients was the only predictor of death. Among POCs a postoperative low cardiac output and acute renal failure requiring replacement therapy were independent predictors of mortality.
Conclusions: Rate of POCs after pediatric cardiac surgery in program with limited resources was less than in high-income countries, due to less complex patients. Despite the comparable crude mortality, the mortality among patients with POC (failure-to-rescue) in our series was significantly higher than in developed world. A number of initiatives are needed in order to improve failure-to-rescue rates after pediatric cardiac surgery in developing countries.

P1306 - VASOACTIVE INOTROPIC SCORE AND OUTCOME ASSESSMENT IN CYANOTIC INFANTS AFTER CARDIOVASCULAR SURGERY

Sachin Talwar[1], Ashwani Bansal[2], Manoj Sahu[2], Palleti Rajashekar[2]
All India Institue of Medical Sciencess, CTVS, New Delhi-India[1]; All India Institue of Medical Sciences, CTVS, New Delhi-India[2]

Background: Infantile cardiac surgery has made significant progress in last few decades but to compare various surgical modalities and treatment protocols, we lack one objective prognosticating criteria. This prospective clinical assessment of Vasoactive inotropic score (VIS) was undertaken to predict post operative outcomes in cyanotic infants after cardiopulmonary bypass surgery.
Methods: Post operative outcomes were analyzed in 100 cyanotic infants (less than 1 yr age) operated between September 2014 to April 2016. Inotropic score (IS) and Vasoactive inotropic score (VIS) were calculated for all patients at 1 hr, 24 hr and 48 hr after surgery.
Results: Mean surgical age was 7.39 months (3 days to 12 months) with 85% infants being male (85/100). In 81% patients intracardiac repair was performed (TAPVC 40, TOF 24, DORV VSD PS 4 and others 13) while rest 19% patients had single ventricular physiology requiring bidirectional Glenn operation. On regression analysis, prolonged ICU and hospital stay correlated best with VIS score at 48 hr interval ($R2 = 0.67$ and 0.50 respectively). Low birth weight (<2.5 kg), requirement of pre operative ventilation and high 1st hr VIS score (>25) were found predictive of higher post operative mortality. Maximum VIS score at 24 hr and 48 hr, on Spearman analysis were shown positively correlated with adverse post operative outcome.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: In cyanotic infants undergoing cardiac surgery, higher VIS score at 48 hrs was strongly associated with poor post operative outcome and is a good assessment tool for requirement of resources in post operative care.

P1317 - ARTERIAL UMBILICAL CATHETER FRAGMENT EMBOLIZATION IN AN INFANT

Lúcia M. V. O. Salerno[1], Juliana V. O. Salerno [2], Carolina V. O. Salerno[3], Pedro Rafael Salerno[4], Marcos Rivera[5], Carlos Eduardo Golveia Da Cunha[5]
HC-UFPE, Cardiology, Recife-Brazil[1]; FCMPB, Student, João Pessoa-Brazil[2]; UFPE, Student, Recife-Brazil[3]; UPE, Cardiovascular Surgery, Recife-Brazil[4]; Esperança Hospital, Vascular Surgery, Recife-Brazil[5]

Background: Catheterization of the umbilical vessel is a standard procedure in neonatal ICU, especially in premature infants. Rarely, the umbilical arterial catheter (UAC) may break leaving fragments that can provoke thrombosis, vasospasm, infection, distal embolization and even death.
Methods: Premature male infant, 24 weeks, 800 g, remained hospitalized for three months during which he was submitted to surgical procedures for the ductus arteriosus closure and necrotizing enterocolitis. Readmitted three days after discharge with hypoactivity and apnea, suggestive of sepsis, progressed with temperature decrease and distal cyanosis of left lower extremity (LLE). Doppler ultrasound confirmed emboli of left internal iliac artery. A 6-hour/day intravenous infusion of rTPA (0,2 mg/kg/h) was performed but suspended on day four due to nosebleed. Abdominal ultrasound detected catheter fragments in the iliac artery, which were removed by a transumbilical approach. Due to progressive distal necrosis of LLE 15 sessions of hyperbaric oxygen therapy (HBOT) were implemented, and enoxaparin (1,5 mg/kg/dose 12/12 h) was administered for a month, then substituted by acetylsalicylic acid (5 mg/kg/day). Later, the patient was submitted to debriding of LLE toes' necrotic tissue, and a heel culture was positive for Pseudomonas.
Results: Despite all efforts, resection of the LLE toes up to metatarsus was necessary, but below-knee amputation, initially recommended, was avoided. The preservation of the heel allowed physical rehabilitation and future prosthetic use.
Conclusion: Although UAC transection is rare, it can be lethal. Even after removal of the fragments the risk of limb ischemia remains; also, thrombolytics and anticoagulants can cause intracranial hemorrhaging. The rTPA and enoxaparin associated with HBOT proved to be efficient in this case. It is recommended that the removed catheter be always measured to avoid, in the event of a fracture, the serious complications caused by remaining fragments in the child's body.

P1336 - FUNCTIONAL ECHOCARDIOGRAMS IN PEDIATRIC INTENSIVE CARE UNIT

Shakuntala Prabhu[1], Sumitra Venkatesh[1], Ajitsingh Baghela[2], Uma Ali[3], Lakshmilakshmi Shobhavat[3]
B.J.Wadia Hospital for Children, Div. of Pediatric Cardiology,Dept. of Pediatrics, Mumbai-India[1]; B.J.Wadia Hospital For Children, Div. Dept. of Pediatrics, Mumbai-India[2]; B.J.Wadia Hospital For Children, Pediatric Intensive Care Unit, Mumbai-India[3]

Introduction: Functional Echocardiography has shown to impact medical decision by detecting cardiac dysfunction early in recent adult studies. The purpose of this study was to evaluate the cardiac functions by bedside 2D Echocardiogram/ Color Doppler in critically ill children in pediatric Intensive care Unit (PICU).
Methods: It is a descriptive, observational, prospective case control study in a tertiary care Children's Hospital. 83/100 critically ill PICU children who fulfilled the study criteria were included. Initial Echocardiogram was done within 48 hrs of admission and repeat echocardiograms if necessary. Cardiac dimensions, functions and cardiac output were assessed by standard methods and compared to pediatric norms for age and Body Surface area (BSA). Volume status was assessed by inferior venacaval (IVC) collapsing index (IVC-CI) and IVC distensibility index (IVC-DI).
Results: Left ventricular hypertrophy (LVH) was noted in 22.9% and high LVMI was noted in children with abnormal renal profile, hypertension and hypocalcaemia [$p < 0.05$]. LV systolic dysfunction was significant in sepsis group patients (32.5%) [$p = 0.0063$] and those who had a PICU stay more than 10 days duration. [$p = 0.013$]. Isolated LV diastolic dysfunction was found in 88.7% with (61.9%), having preserved LV systolic function [$p = 0.0058$]. Abnormal RV function was noted in (68.7%). Low LVCO-index was noted in (45.0%) and high in (21.7%). The IVC-CI more than 55% was found in (26.5%) and IVC-DI more than 18% (91.6%) suggestive of fluid responsive states. During PICU course ,after a 2D Echocardiography evaluation 69.9% patients ($n = 58/83$) required medical interventions. Ten (12%) children expired during study period.
Conclusion: Evaluation of Cardiac functions and volume status by functional echocardiography helps to tailor fluids and inotropes and support hemodynamics in critically ill children in PICU.

P1345 - THE ASSESSMENT OF THE ORAL FEEDING BEHAVIORAL INTERVENTION PROTOCOL IN THE NEONATES AFTER ARTERIAL SWITCH PROCEDURE

Wen-Yi Luo
Shanghai Children, Cicu, Shanghai-China

Objective: To improve newborns' feeding ability and maternal feeding skills after arterial switch procedure through the feeding behavioral intervention protocol.
Methods: A before-after study was conducted on 140 newborns and their mothers who were divided into experimental group and control group. Outcomes including newborns' feeding behavior and mothers' satisfaction, self-efficacy and depression were be Compared and analyzed.
Results The oral motor score was improved ($p < 0.05$) and the length of gastric usage was shortened ($P < 0.01$) in the experimental group; the maternal satisfaction score, self-efficacy score and the depression score was improved ($p < 0.01$)in the experimental group compared to those in the control group.
Conclusion: The reasonable and scientific intervention protocol improves patients' feeding ability and the quality of life after arterial switch procedure and it also improves maternal feeding skill and comfort their emotion.

P1357 - ENHANCED HANDOFF PROCESS IMPROVES COMMUNICATION LEADING TO IMPROVED PATIENT SAFETY AND OUTCOMES

Alistair Phillips[1], Nicole Berndsen[1], Pooja Nawathe[2], Maureen Davis[3], Courtnay Caufield[3], Ken Catchpole[4], Vincent Olshove[1], Bruce Gewertz[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Congenital heart surgery patients, who can deteriorate quickly, moving from the operating room to the intensive care unit requires co-ordination of people, devices, information, and patient knowledge, under time pressure,. We employed a range fo strategies (task design, task allocation, task sequence, teamwork, communication, checklists, protocols, environment and workspace considerations) to improve teamwork, reduce risk and improve safety.
Hypothesis: A theoretically robust handoff process would create a faster, smoother process with reduced subsequent treatment problems
Patients and Methods: Two distinct phases of care, GROUP 1 were cared for prior to starting the CHPICU prior to establishing the handoff process, and GROUP 2 were cared for in the CHPICU after robust handoff process was developed. 29 patients were included in the study, GROUP 1 n = 16, and GROUP 2 n = 13. Through direct observation, flow disruptions in 5 categories (organization, team, patient, equipment, communication), and clincal care concerns after 6 hours in 5 categories (vitals, bleeding, general clinical, respiratory, and drugs), were evaluated. Results: A proceduralized team handoff was used in 21 patients (72%), 8 did not follow a recognised procedure.Time (min) to complete the handoff was significantly less in Gp 2 (mean = 23.5 ± 7.5, median = 20), compared to Gp 1 (mean = 35 ± 14.6, median = 35), p = 0.029. Flow disruptions (Mean Gp1 = 1.5, mean Gp2 = 0.8, p = 0.19) and treatment problems (Mean Gp1 = 0.9, mean Gp2 = 0.2, p = 0.04) were reduced after implemtation of the process. Vitals and respiratory problems were substantially reduced in Gp 2(36% vs 7%; 21% vs 0%). Equipment problems during the handoff remained a problem in both groups.
Conclusion: A structured handoff process improves detection of missing information, reduces handoff duration, flow disruptions and clinical disruption. Developing a team handoff process will be important in reducing the variablity of care and responding to deterioration and other patient treatment demands.

P1362 - TARGETED PROPHYLACTIC HEPARIN INFUSIONS SIGNIFICANTLY REDUCE CATHETER ASSOCIATED THROMBOSES IN INFANTS AFTER CARDIAC SURGERY

Christa Cj Kirk[1], Monique Radman[2], Jane Di Gennaro[2], Robert Mazor[2], Titus Chan[2]
Seattle Children's Hospital, Pharmacy, Seattle-United States[1]; Seattle Children's Hospital, Division of Pediatric Critical Care, Seattle-United States[2]

Background: Infants with central venous catheters (CVC) after cardiac surgery are at an increased risk of venous thrombosis. Previous studies of fixed untargeted heparin infusions (10units/kg/hr) or other anticoagulants have not decreased the incidence of thromboses. We hypothesized that a targeted prophylactic heparin infusion (TPHI) protocol would reduce the incidence of catheter-associated thromboses in infants after cardiac surgery.
Materials and Methods: Beginning in September of 2010, all infants (age less than 6 months or weight less than 5 kg) with an upper extremity CVC received a TPHI for the duration of CVC usage. Heparin infusions were titrated to achieve slightly subtherapeutic unfractionated heparin levels between 0.2-0.3units/mL. All venous ultrasounds obtained between CVC insertion and one week after CVC removal were reviewed for presence of thromboses. Rates of venous thromboses were compared to historical controls receiving untargeted heparin infusions or no anticoagulation.
Results: Of 526 patients (TPHI: n = 397, control: n = 129), 544 CVC were analyzed. The median duration of CVC usage (TPHI = 4.9 days vs. control = 4.0 days, p = 0.06) was similar between cohorts; however, there were fewer venous ultrasounds (22% vs. 33%) in the TPHI cohort. TPHI was associated with a significantly decreased incidence of thromboses per CVC (8.6% vs. 19.1%, $p < 0.01$) as well as a significant reduction in thromboses per 1000 line days (8.0 vs. 19.2). Further analysis of ultrasound data also showed that, among identified thrombotic events, there were fewer occlusive thrombi after implementation of the TPHI protocol (3.5% vs. 12.2%, $p < 0.01$).
Conclusions: Targeted prophylactic heparin infusions significantly decreased catheter-associated thromboses in infants with congenital heart disease.

P1392 - QUALITY IMPROVEMENT INITIATIVE TO REDUCE CENTRAL LINE ASSOCIATED BLOOD STREAM INFECTION IN CARDIAC PEDIATRIC INTENSIVE CARE UNIT

Rusmawati Khosim[1], Nor Azura Yaacob[1], Nur Haslinda Abdullah[1], Subhashini Balakrishnan[1], Emisyelliza Harun [2], Siti Noorliza Sabudin[2], Nur Hafizah Muda[2]
Institut Jantung Negara, Infection Control, Kuala Lumpur-Malaysia[1]; Institut Jantung Negara, Pediatric ICU, Kuala Lumpur-Malaysia[2]

Background: Central line associated blood stream infections (CLABSI)are among top 10 of death caused by healthcare associated infections. CLABSI resulted in prolonged hospital stays, increased hospital cost, significant morbidity and mortality. The objective of this study is to reduce CLABSI in Pediatric Intensive Care Unit (ICU).
Methods: All patients in pediatric ICU with central line up to 18 years old were included in this study from January to November 2016. CLABSI was defined as per Centers fro Disease Control and Prevention guidelines. Pre intervention rate used as baseline rate.
Interventions were implemented as below: a) Infection Control Link Nurses (ICLN) conducted an observational audit of the nurses on their compliance to the bundle. This allowed ICLN to immediately educate the staff. b) Emphasized on scrub the hub for 15 seconds before give injection was incorporated. c) Empowering nurses to stop the central line insertion procedure if the doctor breaches aseptic technique. d) Introduction of a central line checklist to ensure proper aseptic technique were performed and documented. e) Easy access and availability of a fully equipped central line cart with appropriate consumable needed for central line insertion. f) Increased education by bedside teaching, visual aide at the bedside such as central line bundle poster and line care. g) Daily bath with Chlorohexidine.
Results: CLABSI rates from January to November 2016 was reduced to 1.3/1000 line days compared to 1.7 in 2015 and 5.1 in 2010. We also achieved zero CLABSI in month of May, June, July, October and November.
Conclusions: Multiple interventions were required to reduced CLABSI and it can be achieved with high compliance and commitment. Continuous audit, bedside teaching, education and awareness is very important to ensure sustainability. Interventions such as introducing the checklist, central line cart and empowerment were able to reduce CLABSI in pediatric ICU.

P1403 - PROLONGED MECHANICAL VENTILATION AFTER UNIFOCALIZATION SURGERY IN CHILDREN WITH TETRALOGY OF FALLOT PULMONARY ATRESIA AND MAJOR AORTOPULMONARY COLLATERALS (TOF PA MAPCAS) IS ASSOCIATED WITH NEED FOR FEEDING TUBE AT HOSPITAL DISCHARGE

Ritu Asija[1], Andrew M. Koth[1], Charlotte Sakarovitch[2], Douglas R. Sidell[3], Holly Bauser-heaton[4], Lisa Wise-Faberowski[5], Laura Presnell[1], Frank L. Hanley[6], Doff B. Mcelhinney[6]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Stanford University, Pediatrics, Palo Alto-United States[1]; Stanford University, Medicine, Palo Alto-United States[2]; Stanford University, Otolaryngology and Head And Neck Surgery, Palo Alto-United States[3]; Children, Pediatrics, Atlanta-United States[4]; Stanford University, Anesthesia, Palo Alto-United States[5]; Stanford University, Cardiothoracic Surgery, Palo Alto-United States[6]

Background: Children with Tetralogy of Fallot, Pulmonary Atresia and Major Aortopulmonary Collaterals (TOF/PA/MAPCAs) are at risk for prolonged hospitalization after unifocalization surgery. Feeding problems after congenital heart surgery are associated with longer hospital stay. We sought to determine the impact of baseline and intraoperative factors and duration of mechanical ventilation (VENT) on the need for a feeding tube (FT) at the time of hospital discharge.
Methods: We included children with TOF/PA/MAPCAs undergoing primary or revision unifocalization + /-VSD closure from age 3 months to 4 years from 2010-2016. We excluded patients requiring FT prior to surgery. Children discharged with an enteric tube for supplemental or primary nutrition were included in the FT group. VENT beyond postoperative day 5 was considered prolonged. We compared the FT to non-FT group by uni- and multivariable logistic regression.
Results: Of 56 patients studied, 41% required FT. Median age (7.1 months (Q1-Q3 5.6-16.0) vs 8.8 (6.5-21.5), P = 0.4) and weight z-score (-2 vs -1.5, P = 0.92) were similar in the two groups. A chromosome 22q11 deletion was associated with FT (41% vs 17%, P = 0.05), but surgical type was not (P = 0.26). Right ventricle to left ventricle pressure ratio (RV/LV) was similar in both groups (0.36 vs 0.35, P = 0.33). Median cardiopulmonary bypass (CPB) time in the FT group was longer (335 vs 244 minutes, P = 0.04). Median VENT duration was 4 days (Q1-Q3 2-5.5), and prolonged VENT was associated with FT (48% vs. 9%, P = 0.001). On multivariable analysis, prolonged VENT was the only variable associated with FT (9.2, 95% CI (1.5-56.1)).
Conclusion: Among children with TOF/PA/MAPCAs who were feeding by mouth prior to surgery, prolonged mechanical ventilation after unifocalization surgery was associated with need for FT at discharge. Anticipation of feeding problems in this population and earlier FT placement may help reduce hospital stay.

P1404 - CHILDREN WITH 22Q11 CHROMOSOME DELETION HAVE WORSE EARLY POSTOPERATIVE OUTCOMES AFTER UNIFOCALIZATION SURGERY COMPARED TO THOSE WITH NORMAL GENOTYPE

Ritu Asija[1], Douglas R. Sidell[2], Andrew M. Koth[1], Holly Bauser-Heaton[3], Laura Presnell[1], Lisa Wise-Faberowski[4], Frank L. Hanley[5], Doff B. Mcelhinney[1]
Stanford University, Pediatrics, Palo Alto-United States[1]; Stanford University, Otolaryngology and Head and Neck Surgery, Palo Alto-United States[2]; Children's Healthcare of Atlanta, Pediatrics, Atlanta-United States[3]; Stanford University, Anesthesia, Palo Alto-United States[4]; Stanford University, Cardiothoracic Surgery, Palo Alto-United States[5]

Background: A 22q11 chromosome deletion (DEL) is common in children with Tetralogy of Fallot, pulmonary atresia and multiple aortopulmonary collaterals (TOF/PA/MAPCAs). We sought to determine whether patients with TOF/PA/MAPCAs and DEL are at risk for worse early postoperative outcomes including duration of mechanical ventilation (VENT), duration of intensive care unit (ICU) and hospital stay (LOS) following unifocalization surgery.
Methods: We included all patients with TOF/PA/MAPCAs undergoing primary or revision unifocalization + /- ventriculoseptal defect (VSD) closure at our institution from 2008-2016 and excluded patients with unknown DEL. We compared perioperative outcomes using uni- and multivariable regression adjusting for VSD closure and delayed sternal closure (DSC).
Results: Of 180 patients included, 41% had DEL. Need for neonatal surgery (age < 3 months) was similar in children with DEL (P = 0.44). VSD closure was performed concomitantly with unifocalization in 74% of all patients, 67% with DEL (P = 0.06), and cardiopulmonary bypass time (CPB) was similar (P = 0.85). Right to left ventricle pressure ratio (RV/LV) was higher in patients with DEL, 0.37 vs. 0.33 (P = 0.02). DSC was more common in children with DEL, 43% vs. 17% (P = 0.001). Duration of mechanical ventilation was longer in DEL, median of 7 (1-71) vs. 4 (1-40) days (P = 0.001 on unadjusted and adjusted analysis). Duration of ICU stay was also longer in DEL, median of 16 (4-120) vs. 8.5 (2-171) days (P < 0.001 on univariable analysis, P = 0.04 when adjusted for DSC and VSD closure). LOS was not significantly longer in DEL with median of 21 (7-120) vs. 15 (5-174) days (P = 0.07).
Conclusion: Children with TOF/PA/MAPCAs and DEL are at risk for longer duration of mechanical ventilation and ICU stay and higher RV/LV pressures following unifocalization surgery. These data suggest patients with DEL may have less favorable pulmonary arterial anatomy and more postoperative complications.

P1407 - STUDY OF CLINICAL OUTCOMES OF CARDIORESPIRATORY RESUSCITATION IN CHILDREN

Shakuntala Prabhu[1], Sumitra Venkatesh[5], Atul Rane[5], Uma Ali[2], Lakshmi Shobhavat[2]
B.J.Wadia Hospital For Children, Div. of Pediatric Cardiology, Dept. of Pediatrics, Mumbai-India[1]; Pediatric Intensive Care Unit, Mumbai-India[2]

Introduction: Pediatric cardiopulmonary arrest is distinct from adult cardiac arrest. This study aimed at detecting prognostic factors for post CPR outcomes in children.
Methods: Demographic profile, clinical features, laboratory findings, treatment , resuscitation and survival outcome details of 40 children who required in-hospital CPR were analyzed. The outcomes were grouped as long-term survivors (survived to discharge); short-term survivors (survived >24 hours after CPR but not until discharge) and non-survivors (died within 24 hours of CPA). At discharge, patient's neurological functional status was classified as neurologically intact, impaired or dependent.
Results: 82.5% children survived CPR with 68% survivors having normal neurological functional status at discharge. Neither the level of expertise of resuscitator nor the site of CPR affected the outcome. 17(42.5%) required 2 or more CPR efforts during their hospital stay (p = 0.00002). No significant correlation was noted between presenting symptoms or signs to post-CPR survival outcomes (p > 0.05). Those children with oliguria post CPR (25%) and who required volume resuscitation had a poor survival (p = 0.024). Higher motor response post CPR shorter duration of resuscitation, fewer attempts of CPR and early return of spontaneous circulation(ROSC) (87.5%) had a favorable impact for survival (P <0.05). Early enteral feeds within 5 days post CPR in 32(80%) subjects had higher survival rates. (P = 0.0003).
Conclusion: Shorter duration of resuscitation, fewer attempts of CPR, early return of spontaneous circulation, higher motor response and early institution of enteral feeds post CPR had a favorable impact on survival outcomes. Oliguria, increased fluid requirement, hyponatremia, hyperglycemia, hypoxia and hypocarbia in the peri resuscitation period were unfavorable factors for survival. Prolonged ventilator support also correlated with poorer neurological outcome at discharge.

P1418 - NOVEL STRATEGY FOR PERIOPERATIVE MANAGEMENT OF MODIFIED BLALOCK TAUSSIG SHUNT ON PATENT DUCTUS ARTERIOSUS DEPENDENT CIRCULATION

Satoshi Matsuo[1], Sadahiro Sai[1], Akinobu Konishi[1], Ko Sakatsume[1], Takashi Tanaka[2], Akira Ozawa[2], Eiichiro Kawai[2], Takehiko Onoki[2], Ryo Takahashi[2]
Miyagi Children's Hospital, Cardiovascular Surgery, Sendai-Japan[1]; Miyagi Children's Hospital, Pediatric Cardiology, Sendai-Japan[2]

Background: Blalock-Taussig shunt (BT shunt) for pulmonary atresia (PA) or severe stenosis (PS) which depends on patent ductus arteriosus (PDA) has still had higher mortality because of post-operative excessive pulmonary flow.
Purpose: Two perioperative strategies for BT shunt of these patients have been employed since 2013. The first strategy was prophylactic decrease or withdrawal of Lipo-prostaglandin E1 (LipoPGE) one week before operation to avoid cardiac failure by reducing preload (low pulmonary flow strategy) and controlled SpO2 level as less than 80%. The other was administration of PDEIII inhibitor from anesthetic induction to control Qp/Qs by reducing afterload (low vascular resistance strategy). The aim of this study was to seek the efficacy of these strategies.
Methods: Forty two patients with PA (n = 34) or PS (n = 8) associated with PDA dependent circulation underwent BT shunt without extracorporeal circulatory support from July 2008 to November 2016. Patients were devided into two groups; No strategy group (N group, n = 20) and Strategy group (S group, n = 22). Primary end point was postoperative excessive pulmonary flow events (PEPF events) which refers to requirement of cardiopulmonary resuscitation or PDA ligation and/or shunt clipping.
Results: In term of change of preoperative cardiac function by low pulmonary flow strategy, BNP level at operation (213.8 ± 202.8 pg/ml) was significantly reduced compared with that one week before operation (467.5 ± 450.6 pg/ml) (P = 0.005) in S group. Characteristics and perioperative data in detail were shown in table. PEPF events were significantly less frequent in S group. Furthermore, preoperative SpO2, postoperative catecholamine index in S group were significantly lower than that in N group. Preoperative BNP, postoperative maximum lactate level and duration of ICU stay in S group tend to be lower than that in N group.
Conclusions: It is suggested that these strategies contribute to lower postoperative mortality and morbidity of BT shunt for PA or severe PS with PDA-dependent circulation.

Table.

	N group (n = 20)	S group (n = 19)	P value
Body weight (BW) at operation (kg)	3.6 ± 1.5	3.2 ± 0.3	0.18
Age at operation (days)	33.8 ± 11.2	34.5 ± 40.8	0.14
Preoperative SpO_2 (%)	84.8 ± 5.3	80.2 ± 5.8	0.02
Preoperative BNP (pg/ml)	344.1 ± 617.0	213.8 ± 202.8	0.44
Dose of preoperative PD EIII inhibitor at anesthetic induction (μg/Ag/min)	0.02 ± 0.12	0.47 ± 0.13	<0.01
BT shunt graft size/BW (mm/kg)	1.1 ± 0.2	1.1 ± 0.1	0.24
Postoperative excessive pulmonary flow events	6 (30%)	0	<0.01
Hospital death	1 (5.0%)	0	1.0
Postoperative catecholamine index	14.2 ± 7.8	7.8 ± 4.3	<0.01
Postoperative maximum lactate (mmol/L)	6.1 ± 7.6	2.7 ± 1.0	0.06
Duration of intubation time (day)	4.3 ± 14.8	3.1 ± 4.6	0.39
Duration of ICU stay (day)	6.6 ± 5.7	3.9 ± 3.6	0.08

P1423 - NATURAL HISTORY OF PULMONARY TRANSITION IN EXTREMELY PREMATURE INFANTS

Hussnain Mirza[1], Jorge Garcia[2], Elizabeth Crawford[3], Julie Pepe[4], Matthew Zussman[5], Rajan Wadhawan[6]
UCF College of Medicine, Neonatal Medicine, Orlando-United States[1]; Florida Hospital for Children, Pediatric Cardiology, Orlando-United States[2]; Florida Hospital Cardiovascular Institute, Peds Cardiac Imaging, Orlando-United States[3]; Florida Hospital, Office of Research Advancement & Support, Orlando-United States[4]; Florida Hospital, Pediatric Cardiology, Orlando-United States[5]; UCF College of Medicine, Pediatrics, Orlando-United States[6]

Background/ Hypothesis: Preterm infants are at risk for bronchopulmonary dysplasia (BPD)/death due to pulmonary hypertension (PH). However, normal physiology of pulmonary vascular transition (PVT) after delivery was not studied before. Hence the incidence of PH among extremely preterm infants during the first few days of life is unknown. Our primary objective was to report the temporal profile of PVT in preterm infants. We also hypothesized that infants with delayed PVT will be at higher risk for BPD/death.
Materials & Methods: Prospective cohort study of infants born at <29weeks. Initial echocardiogram was at <48 h of life and repeated every 24-48 h for 14 days. Infants were divided in normal and delayed PVT groups. Resolution of PH at <72 hours of life was considered normal. Delayed PVT was defined as evidence of PH at >72 hours. Recurrent PH after documenting normal pulmonary artery pressure was called early PH. Persistent PH (PPHN) was diagnosed if PH continued till 14 days of life. Incidence of PH was calculated at 0-2, 3-6, 7-10 and 11-14days of life. Multivariable analysis was performed to estimate the risk of BPD/death among infants with delayed PT.
Results: March, 2015-April, 2016, 60 infants were enrolled. The incidence of PH decreased from 71% at 0-2d to 30% at 11-14d of life. Five distinct patterns of PT were recognized i.e. normal PT, normal PT with early PH, delayed PT, delayed PT with early PH and PPHN. Two infants (3%) died before 72 hours. Normal and delayed PT was noted in 26(44%) and 32(53%) infants respectively. Infants with delayed PT were of smaller gestation, lower birth weight and at higher risk for BPD/death (p < 0.005).
Conclusion: Incidence of PH decreases over the 14 days of life. PH can reoccur after normal or delayed PT. Delayed PVT increases the risk for BPD/death in preterm infants.

P1432 - MALNUTRITION IS ASSOCIATED WITH POOR OUTCOMES IN CHILDREN UNDERGOING CONGENITAL HEART SURGERY IN BRAZIL

Candice Torres De Melo Bezerra Cavalcante[1], Titus Chang[2], Andrea Consuelo De Oliveira Teles[1], Jeanne Araújo Bandeira[1], Heloisa Maria De Castro Barbosa[1], Klebia Magalhães Pereira Castello Branco[1], Isabel Cristina Leite Maia[1], Ronald Guedes Pompeu[1], Kiarelle Lourenço Penaforte[1], Giselle Vianna De Andrade[1]
Messejana's Hospital, Pediatric Cardiology, Fortaleza-Brazil[1]; Seattle Children's Hospital, Pediatric Cardiology, Seattle-United States[2]

Background: Poor nutritional status is associated with adverse outcomes in patients undergoing congenital heart surgery in developed countries. In developing countries, interventions for congenital heart disease are performed late, resulting in a high prevalence of pre-operative malnutrition. Therefore, nutritional status may be an alterable peri-operative factor that may improve surgical outcomes.
Objectives: To assess the nutritional status of children undergoing pediatric congenital heart surgery and its association with clinical outcomes.
Methods: Retrospective review of children undergoing congenital heart surgery at a regional referral center in Brazil. Patients were assessed for nutritional status at admission using World Health Organization weight-for-age standards. The association between nutritional status and clinical outcomes (in-hospital mortality, ICU and hospital length of stay and length of mechanical ventilation) were examined in univariate and multivariate regression models.
Results: Over a two year period, 562 patients underwent corrective or palliative congenital heart surgery. Of these, 217 patients (38.6%) were malnourished. In-hospital mortality was 13.2% (n = 74) with a significantly higher mortality rate among malnourished patients (n = 38, 17.5%) than the non-malnourished patients (n = 36, 10.8%, p = 0.036). Malnourished patients had higher rates of non-cardiac structural anomalies, prematurity, and lower hematocrits. Malnutrition status was also associated with longer post-operative mechanical ventilation times, longer intensive care unit length of stay, and longer post-operative length of stay. In multivariate analyses, malnutrition status was associated with prolonged post-operative mechanical ventilation (additional 36.9 hours, 95% Confidence Interval (CI): 7.1-66.7 hours), increased ICU length of stay (75.7 hours, 95% CI: 28.9-124.1 hours) and increased odds of mortality (Odds ratio: 1.9, 95% CI: 1.06-3.48).
Conclusion: Malnutrition in children with congenital heart disease is associated with poor short-term outcomes after congenital heart surgery. Improvements in nutritional status may improve outcomes.

P1437 - INCOMPLETE AND ATYPICAL KAWASAKI DISEASE IS IT TIME FOR MODIFIED CRITERIA

Baher Hanna[1], Mourad Tadros[2]
Cairo University, Pediatric, Cairo-Egypt[1]; Galaa Military Specialized Women & Children, Pediatric, Cairo-Egypt[2]

Kawasaki disease (KD) lacking full classical criteria is a big diagnostic challenge especially that features are non-specific. We analyzed the data of 4 patients not fulfilling criteria for incomplete KD during same winter season: The first was a 4 months-old boy presenting with generalized mucopapular rash, purulent conjunctivitis, lip fissuring and 1-day of fever. Left coronary system was ectatic initially, progressed to left anterior descending (LAD) aneurysmal dilatation. Symptoms responded to IVIG after an episode of severe anaphylaxis. He continues to have CA aneurysm and is on anticoagulation. Second was a 5 year-old boy manifesting only with 20-days of fever, LAD had fusiform dilatation at its midportion. Fever resolved with IVIG and CA dilatation regressed in 2 months. Third was a 4 year-old boy presenting with 7 days of fever associated with nonpurulant conjunctivitis, follicular tonsillitis, and no other criteria of KD. Both coronary systems were dilated. Responded to IVIG and coronary dilatation regressed within 1 month. Fourth was a 2 year-old boy presenting with 5 days of fever and generalized lymphadenopathy, hepatomegaly, and marked elevation of transaminases. Pericardial effusion was discovered on work-up; on follow-up LAD became ectatic and finger-pealing appeared. Fever responded to IVIG, effusion resolved in 3 days and coronary dilatation regressed in 2 weeks. We report 4 cases diagnosed with KD despite insufficient criteria: typical fever being absent in one, fever was the only manifestation in another, a third with only 2 criteria in addition to fever and a fourth with generalized lymphadenopathy as the predominant feature beside fever. All of which had CA dilatation and responded clinically to IVIG, with the persistence of large coronary aneurysm in one case. We suggest that KD diagnostic criteria be modified to a scoring system including major and minor criteria; incorporating inflammatory markers as a minor criterion.

P1447 - A NOVEL POSTOPERATIVE PAIN CONTROL PROTOCOL TO MANAGE PAIN AND IRRITABILITY IN INFANTS UNDERGOING SUPERIOR CAVOPULMONARY ANASTOMOSIS

Casey Naughton, Melanie Muller, Ana Lia Graciano
University of Maryland Children's Hospital, Children's Heart Center-Critical Care, Baltimore, Maryland-United States

Background: Infants undergoing superior cavopulmonary anastomosis (SCPA) are at risk for immediate post-operative pain. In particular, post-operative headache can be difficult to manage, frequently requiring increasing doses of narcotics to achieve comfort. We describe a novel protocol using a clonidine transdermal patch as an adjunct for pain control after SCPA and its relation to narcotic needs and outcomes.
Methods: Retrospective chart review was performed for all patients who underwent SCPA between 2011 and 2016. Patients were divided into two groups, Group A (no clonidine) and Group B (clonidine). Both groups received acetaminophen and non-steroidal inflammatory drugs every 6 hours as well as narcotics as needed for breakthrough pain. In addition, patients in group B received a 0.05 mg clonidine transdermal patch which was placed immediately after surgery. Timing of extubation, narcotic use within 72 hours of surgery and hospital length of stay were compared between the two groups.
Results: There were a total of 19 cases (Group A n = 9, Group B n = 10). Mean age was 152 days (range 131-1018), mean weight 7.09 kg (range 5.54-11.8). When comparing both groups, patients receiving clonidine (Group B) were extubated earlier (19.9 vs. 59.9 hours, $p < 0.05$). Narcotic administration during the first 72 hours was significantly decreased in patients on the clonidine protocol (3.14 mcg/kg vs. 17.6 mcg/kg of fentanyl, $p = 0.02$) and hospital length of stay was significantly shorter in this group (6.9 vs. 19 days, $p < 0.05$).
Conclusions: Clonidine was a useful adjunct to manage postoperative pain and irritability in this patient population. Narcotic administration was markedly decreased in patients who were on a clonidine patch. Further evaluation of the protocol in a larger patient population is needed. It may prove to be effective in managing post-operative pain and irritability in this patient population.

P1454 - POSTOPERATIVE SECONDARY CHYLOTHORACES ARE ASSOCIATED WITH LYMPHATIC ENDOTHELIAL CELL DEFECTS AND MISEXPRESSION OF BETA ADRENERGIC RECEPTORS

Rozelle Corda[1], Sophia Chrisomalis-dring[2], Aqsa Shakoor[3], Christopher Kitajewski[4], Julie Monteagudo[5], Maia Reiley[4], June Wu[5], Carrie Shawber[6], Paul Chai[5]
Columbia University Medical Center, Surgery/Nursing, New York-United States[1]; Columbia University Medical Center, Cardiology/Pediatrics, New York-United States[2]; Columbia University Medical Center, Surgey, New York-United States[3]; Columbia University Medical Center, OB GYN, New York-United States[4]; Columbia University Medical Center, Surgery, New York-United States[5]; Columbia University Medical Center, OB GYN/Surgery, New York-United States[6]

Background/Hypothesis: Post-operative chylothorax continues to be a significant complication affecting 2-9% pediatric post-cardiac surgery patients. We have shown that lymphatic endothelial cells (LECs) isolated from congenital chylothorax form abnormal lymphatic vessels in a mouse model, overexpress beta-adrenergic receptors (βARs) and respond to propranolol, a βAR inhibitor. As several of the genes necessary for heart development are also required in lymphatic development, we hypothesized that pediatric cardiac patients with postoperative chylous effusion have underlying lymphatic abnormalities predisposing them to the pathology, and that propranolol would improve patient morbidities.
Materials and Methods: Eleven patients with postoperative chylothorax fluid having ≥ 80% lymphocyte count, triglycerides ≥ than serum level, and/or chylomicron positivity were included. LECs isolated from post-operative chylous fluid (n = 8) were subjected to quantitative reverse transcription-polymerase chain reaction to determine expression of endothelial progenitor, LEC and βAR. Human dermal LECs (HdLECs) served as a normal control. Seven patients who failed conservative management consisting of diet modification and diuretics and continued to drain greater than 10cc/kg/day were offered propranolol at 0.5-2.0 mg/kg/day. Fluid output was monitored daily.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: Pleural effusion contained LECs that expressed significantly lower level of LEC genes and high levels of progenitor genes, compared to HdLECs (Table 1). LECs from post-operative chylous effusions significantly overexpressed either β1AR (n = 4/8) or β2AR (n = 4/8). Six of seven patient's fluid volume did not worsen on propranolol, and reduced drainage was observed (Table 2).
Conclusions: Our results suggest that LECs from secondary chylothorax are improperly differentiated and have abnormal beta-adrenergic signaling. Consistent with abnormal beta-adrenergic receptor expression, propranolol treatment correlated with reduced chylous effusions. Thus, propranolol may be efficacious in inhibiting abnormal LEC function and reduce postoperative chylothorax volume, duration, and associated morbidity and mortality.

Table 1. Expression of endothelial progenitor and lymphatic endothelial genes in LECs isolated from lymphatic malformations, postoperative chylothorax and congenital chylothorax relative to HdLECs.

P1457 - VARIABILITY IN PERIOPERATIVE INOTROPIC USE IN CONGENITAL CARDIAC SURGERY

Pirouz Shamszad[1], Christopher Almond[2], Timothy M. Hoffman[3], Joseph Rossano[1]
Children, Cardiology, Philadelphia-United States[1]; Lucile Packard Children, Cardiology, Palo Alto-United States[2]; Unc Children, Cardiology, Chapel Hill-United States[3]

Background: Although inotropic support is instrumental in the perioperative care of children undergoing cardiac surgery, there is limited data describing hospital practices and trends.
Objective: We sought to describe perioperative inotrope use, including institutional variability, among US children's hospitals in children undergoing cardiac surgery.
Methods: A multi-institutional, retrospective review of the Pediatric Health Information System (PHIS) identified all hospitalizations involving patients <18y who underwent cardiac surgery and received inotropic support between 2004 and 2015. Inotropic support was defined as preoperative (starting before surgery) or operative (starting on the day of surgery) use of dobutamine, dopamine, epinephrine, or milrinone at the index cardiac surgery. Calcium was not included.
Results: There were a total of 106,921 hospitalizations (median age 0.5y [IQR 0.1-3.2], 55% male, 83% cardiopulmonary bypass [CPB]) across 46 hospitals. Preoperative inotropes were used in 22,301 (21%) hospitalizations, significantly associated with neonatal age (OR 5.6, 95% CI 5.4-5.7), and commonly involved epinephrine (68%) and milrinone (51%). Operative inotropes were utilized in 74,947 (70%) hospitalizations and involved milrinone (68%), epinephrine (66%), dopamine (39%), and dobutamine (24%). Among CPB cases, milrinone was utilized in 74%, followed by epinephrine (69%), dopamine (39%) and dobutamine (25%). Center variability among operative inotropes was wide (milrinone 42-99%, epinephrine 41-100%, dopamine 8-77%, and dobutamine 4-70%). Operative single-drug regimens were used in 25% while 2-drug and 3-drug regimens were used in 40% and 56%, respectively. Common multi-drug regimens were dopamine-epinephrine-milrinone (33%), epinephrine-milrinone (20%) and dobutamine-epinephrine-milrinone (18%). There was significant decline in usage of dobutamine (2%/yr; $r = 0.96$; $p < 0.001$) and dopamine (2%/yr, $r = 0.97$; $p < 0.001$) throughout the study period.
Conclusions: The use of inotropes in children undergoing cardiac surgery widely varies by center. It is unclear if this variation plays any role in differences in outcomes. Further study examining the details of drug administration and association with outcomes may help further improve care.

P1474 - EARLY TREATMENT OF INTRA PERICARDIAL TERATOMA IN A NEWBORN

Andréa Consuelo De Oliveira Teles[1], Candice Torres De Melo Bezerra Cavalcante[1], Klebia Magalhães Pereira Castello Branco[1], Ronald Guedes Pompeu[1], Maria Márcia Souto Maior[1], Valdester Cavalcante Pinto Júnior[2], Deborah Mont'alverne Dias[1], Rafael Lima Oliveira[1], Anna Karina Martins Brito[1], Márcia De Souza Degobi[1] Messejana's Hospital, Pediatric Cardiology, Fortaleza-Brazil[1]; Messejana's Hospital, Pediatric Cardiovascular Surgery, Fortaleza-Brazil[2]

Background: Intra-pericardial teratoma (IPT) is a rare congenital condition and well-recognized cause of pericardical effusion (PE), cardiac compression, severe cardio-respiratory distress and hydrops fetalis (HF). Usually, it presents as an intra-thoracic, well-delimited, heterogeneous mass with cystic areas. Most tumors are generally benign, but without an adequate prenatal and postnatal treatment, they can be potentially fatal.
Objective: To presente a case report of successful management of a newborn with an IPT and a large PE diagnosed in the pre-natal period.
Case presentation: A woman was referred at 38 weeks of gestational age (GA) to our service for a large fetal PE and a intrapericardial cystic mass diagnosed at 36 weeks GA by ultrasound (US), with no evidence of HF. Fetal echocardiography showed well-defined intrapericardial tumor, made up by soft tissue mass with cystic components above the root of the great vessels, no structural heart abnormalities and an important PE. There were no other abnormal US findings. An elective cesarean delivery was performed.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

A 3 kg baby girl evolved with important respiratory distress associated with cyanosis soon after birth, requiring tracheal intubation. Postnatal echocardiogram revealed a heterogeneous cystic mass arising from the base of the heart and a massive PE. The child was sent to the operating room for surgical removal of the tumor three hours after birth. Surgical finding showed a mass attached to the lateral wall of the ascending aorta. There was no extension of the tumor into the surrounding structures. The gross specimen was a 5 × 5 cm mass and histopathological exam confirmed the diagnosis. The postoperative course was uneventful and she was discharged from the hospital one week later.
Conclusion: Early surgery may be a successful option for newborn who present with important pericardial effusion and respiratory distress, with an excellent result.

P1492 - EARLY OUTCOME AFTER REPAIR OF TETRALOGY OF FALLOT IN ADULTHOOD IN THE CURRENT ERA

Ahmed Elsharkawy[1], Hossam Helmy[1], Amr Farrag[1], Islam Elbanna[1], Ahmed Abdelhaleem[1], Ahmed Eldowaik[1], Omar Aladdin[1], Hatem Hosny[2], Carin Van Doorn[3], Soha Romeih[4]
Aswan Heart Centre, Adult ICU, Aswan-Egypt[1]; Aswan Heart Centre, Cardiac Surgery, Aswan-Egypt[2]; Leeds Teaching Hospital, Cardaic Surgery, UK-Egypt[3]; Aswan Heart Centre, Cardiology, Aswan-Egypt[4]

Background: Tetralogy of Fallot (TOF) is the most common cyanotic congenital heart disease. Primary surgical repair is usually performed in early childhood with excellent results. However, in developing countries we still encounter adults with uncorrected TOF or whom only had a palliative procedure in early childhood. Repair of TOF in adulthood has been associated with prolonged intensive care stay related to myocardial dysfunction,arrhythmia and end-organ injury.
Methods and Patients: Retrospective study of all patients >16 years who underwent primary repair of TOF in our Centre since 2013. There were 29 patients (18 males) including 4 with a palliative shunt. Median age was 21 years (16 to 41 years) and percutaneous oxygen saturation 80% (45 to 98%) with saturation <75% in 13 patients. Median haematocrit value was 56% (33 to 73%). Surgical technique involved transatrial/transpulmonary repair with patch augmentation of right ventricular (RV) infundibulum in cases where the pulmonary valve remained functional (16 patients) or placement of a valved RV to pulmonary artery conduit if the valve was inadequate (13 patients). Milrinone and Norepinephrine were routinely used for post-operative inotropic support.
Results: There were no operative deaths. twenty seven patients were extubated within 36 hours, 2 required re-ventilation due to lung reperfusion injury and a further 2 were ventilated for 5 days due mediastinal bleeding and aspiration, respectively. Four Patients developed pleural effusion necessitating drainage, and 2 suffered a neurological complication (stroke and seizures) with full recovery. Four patients had 2nd degree heart block with no need for pacemaker, and none suffered junctional ectopic tachycardia. No patient required renal dialysis. Median hospital stay was 8 days (5 to 61 days).
Conclusion: In this contemporary series, repair of TOF in adulthood was associated with excellent early post-operative survival and acceptable morbidity.

P1498 - PERIPHERALLY INSERTED CENTRAL VENOUS CATHETERS IN CHILDREN WITH HEART DISEASE FIRST EXPERIENCE

Zuzana Hrubsova, Lubica Kovacikova, Miroslava Hargasova
Pediatric Cardiac Centre, Cicu, Bratislava-Slovakia

Background: In recent years the use of peripherally inserted central venous catheter (PICC) is significantly increasing and this increase has led to the expansion of indications such as pediatric intensive care. Children with congenital heart disease are a specific patient population in which the venous system thrombosis and its sequelae significantly contribute to morbidity and mortality. Prevalence and severity of thrombosis is associated with unique factors such as developmental and acquired bleeding disorders, complex perioperative care requiring central venous access and catheterization procedures.
Material and Methods: The aim of this study was to evaluate the initial experiences with the PICC at CICU in Pediatric Cardiac Centre in Bratislava from December 2015 to November 2016. Data collection was performed prospectively in patients who have undergone the PICC placement procedure.
Results: During the review period 42 lines were inserted in 34 patients. The median age at the time of insertion was 6.3 months (1 day - 21 years), median weight was 5 kg (2.4-90 kg). The PICC insertion was ultrasound guided through the basilic, cephalic, axillary, and femoral vein in 13 (31%), 4 (9.5%), 6(14.3%), 29 (45.2%) cases respectively. The PICC lines used were 1.9 Fr single lumen, 2.6 Fr double lumen and 4Fr single and double lumen used in 2, 35, and 3 patients respectively. The main indications were intensive complex therapy, parenteral nutrition and antibiotics therapy in 31 (73.8%), 4 (9.5%), and 7 (16.7%) patients respectively. The median duration of PICC was 22 days (14-98days). The complication rate was 9.5% including 3 line fractures, 1 infection at the insertion site and 1 venous thrombosis.
Conclusion: We believe based on our initial experience that the use of PICC in pediatric patients with heart diseases in the intensive care settings is a possible solution for central venous access.

P1503 - DECREASED OPIATE USAGE BY INCORPORATING OFIRIMEV IN POST OPERATIVE PAIN MANAGEMENT IN CONGENITAL HEART SURGERY

Alistair Phillips[1], Nicole Berndsen[1], Richard Hartmann[2], Rita Shane[2], Lorraine Lubin[3], Robert Wong[3], Pooja Nawathe[4], Vince Olshove[1]
Cedars-Sinai Medical Center, Surgery, Los Angeles-United States[1]; Cedars-Sinai Medical Center, Pharmacy, Los Angeles-United States[2]; Cedars-sinai Medical Center, Anesthesia, Los Angeles-United States[3]; Cedars-Sinai Medical Center, Pediatrics, Los Angeles-United States[4]

Background: Opioids and benzodiazepines are frequently used to manage post-operative pain and sedation in patients undergoing congenital heart surgery. In recent years, Ofirmev has been incorporated into the post-operative pain management plan.
Methods: We reviewed the use of opioids and benzodiazepines in two cohorts from our congenital cardiac surgery program. Group 1 consisted of congenital heart cases performed between 2012-2014. Group 2 were cases performed between 2014-2016. Data was extracted from Vizient, which comes from UHC institutions, and specifically looked at the type of medication used, percent of cases requiring the use of opiates, benzodiazepines and Ofirimev and number of treatment days each case required. A comparison of overall opiate, benzodiazepine and Ofirimev utilization between the two cohorts was completed.
Results: 37 congenital heart surgeries occurred between 2012-2014. Between 2014-2016, 173 heart surgeries were performed. 92% of cases from both cohorts received opiates post-operatively while 68% of Group 1 received benzodiazepines, compared to 69% of Group 2. Ofirimev was not used in post-operative management for cases performed between 2012-2014, whereas, 51% of cases from 2014-2016 received Ofirimev. With the addition of

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Ofirimev in post-operative pain management, there was an overall decrease in length of opiate treatment with the current cohort receiving 3.8 days of opiates compared to the historical group at 7.7 days. Benzodiazepine use was 3.2 days in the recent cohort compared to 3.8 days in the previous cohort.
Conclusions: When compared to the historical cohort, patients undergoing heart surgery between 2014-2016 received fewer days of opiates and more Ofirimev. Overall use of benzodiazepines was similar for each group. Although early results suggest that Ofirimev decreases opiate and benzodiazepine usage in post-operative pain management, further studies are needed.

P1506 - SIGNIFICANTLY REDUCING BLOOD DRAWS IN THE CONGENITAL CARDIAC INTENSIVE CARE UNIT BY MULTI DISCIPLINARY TEAM APPROACH AND GOAL ALIGNMENT

Alistair Phillips[1], *Nicole Berndsen*[1], *Maureen Davis*[2], *Courtnay Caufield*[2], *Pooja Nawathe*[3], *Vincent Olshove*[1]
Cedars-Sinai Medical Center, Surgery, Los Angeles-United States[1]; *Cedars-Sinai Medical Center, Nursing, Los Angeles-United States*[2]; *Cedars-Sinai Medical Center, Pediatrics, Los Angeles-United States*[3]

Background: Communication is critical and is important the entire team understands the goals for the patient. Blood draws are a leading cause of unnecessary harm to the patient from (1) requirement for being stuck for the blood draw, (2) cost, and (3) iatrogenic blood loss. Volume of blood per test is >5 ml, traditional, >2 ml, micro-tubes, and 100 microliters, point of care testing (POC).
Methods: We looked at all procedures that required cardiopulmonary bypass from November 2013 to November 2016 program, after establishing a new congenital heart program, with the crucial goal of decreasing the overall impact to our patients. We developed a multi-disciplinary team to (1) reduce blood draws, (2) use POC as the primary lab, (3) reduce waste of blood, and (4) develop standard protocols for blood draws.
Results: We performed eighty surgeries. In the traditional ICU there was a median POC of 15 tests, median CBCs of 7 tests and median chemistries of 9 tests, and for the new congenital cardiac ICU there was a median POC tests of 7, median CBCs of 1 test, and median chemistries of 1 test. In attributed blood loss for tests in the traditional ICU on average was 267 ml in FY14, 124 ml in FY15 and 92 ml in FY 16, for the congenital cardiac ICU was 7.3 ml in FY 14, 3.6 ml in FY 15, and 2.4 ml in FY 16, all significantly less, $p < 0.05$.
Conclusions: We developed a multi-disciplinary team to reduce the blood draws, and developed a method to reduce blood waste during the blood tests. Using a 2-stopcock technique, with the waste blood remaining inline and be given back immediately without disconnecting. We could move to a POC primary blood draw system that significantly reduced blood draws and blood loss.

P1507 - SIMULATION TRAINING ENGENDERS HIGHER COMFORT LEVELS AMONG CAREGIVERS AND LOWERS TIME TO RESPONSE IN LOW RESOURCE INTENSIVE CARE UNIT

Sivaram Emani[1], *Catherine Allan*[2], *Anna Fisk*[3], *Christine Lagrasta*[3], *Bistra Zheleva*[4], *Peter Weinstock*[5], *Ravi Thiagarajan*[2]
Boston Children, Boston Children, Boston-United States[1]; *Boston Children, Department of Cardiology, Boston-United States*[2]; *Boston Children, Department of Nursing, Boston-United States*[3]; *Children, International Programs, Minneapolis-United States*[4]; *Boston Children, Department of Anesthesia, Boston-United States*[5]

Background/Hypothesis: Although simulation-based Crisis Resource Management (CRM) training has demonstrated improvement in team performance in many high-resource cardiac intensive care (CICU) environments, its impact in low resource CICUs has not been studied. Endemic to such environments are multifactorial barriers that inhibit effective nurse-physician communication in crisis situations. We hypothesize that CRM training leads to improvements in team dynamics and time to appropriate medical response in such settings.
Materials and Methods: In this prospective observational study, the effects of CRM training on team dynamics and performance were assessed in 23 healthcare providers at a single CICU in South-East Asia. A 5-day training program was utilized consisting of didactic sessions and CRM training exercises. Improvements in team dynamic (effective and closed-loop communication, role delegation, idea acceptance) were assessed using participant questionnaires, expert evaluations, and video analysis. The time to appropriate medical intervention following a simulated perturbation in vital signs (fluid bolus, inotropic support, bag-mask ventilation) was measured over the training period.
Results: Through questionnaires, participants noted significant ($P < 0.05$) improvement in team dynamics and performance over the training period (Table 1). Independent external observers also reported improvements in team performance. Blinded video analysis of training exercises revealed significant increase in frequency of closed-loop communication between caregivers (2.2/min ± 0.02 vs. 4.4/min ± 0.6, $P < 0.05$), and a trend towards decrease in times to appropriate clinical intervention (Table 1). Through questionnaires sent 30 days following CRM training, caregivers expressed improved communication within their native clinical environment as a result of CRM training.
Conclusions: The study demonstrates the feasibility and effectiveness of CRM training at improving team dynamics, particularly between nurses and physicians, in global health environments, indicating its potential role as a training tool in such settings.

P1510 - ACUTE KIDNEY INJURY SCORING SYSTEM IS A BETTER PREDICTOR OF INCREASED LENGTH COMPARED TO INOTROPE SCORE

Vincent Olshove[1], Nicole Berndsen[1], Pooja Nawathe[2], Stephen Robert[2], Alistair Phillips[1]
Cedars-Sinai Medical Center, Surgery, Los Angeles-United States[1]; Cedars-sinai Medical Center, Pediatrics, Los Angeles-United States[2]

Background: Acute Kidney Injury (AKI) and increased inotrope score have been shown to be associated with increased morbidity and mortality in pediatric congenital cardiac surgery. AKI has been shown to occur in adult and pediatric post-operative cardiac surgical patients between 18 and 60%. The purpose of this study was to evaluate the incidence of AKI comparing the pediatric risk, injury, failure, loss, end (pRIFLE) and the acute kidney injury network (AKIN) scoring systems to inotrope score and post-operative lactate.
Methods: Retrospective analysis of all congenital heart surgeries requiring cardiopulmonary bypass between 2014 and 2016. All patients received aggressive dilutional ultrafiltration on cardiopulmonary bypass. All neonates received a peritoneal catheter for fluid removal only, no dialysis was used. Values for serum creatinine measured pre-operative (baseline), first on arrival to the intensive care unit (ICU), twenty-four, and forty-eight hours, urine output for the first 24 hours, lactate, bypass time, ventilation time, inotrope scores, and length of stay (LOS) were pulled from the quality database.
Results: Eighty cardiopulmonary bypass cases were performed, but 4 cases were excluded for pre-operative renal failure leaving seventy-six bypass cases. AKI was associated with significantly increased CPB time (No AKI at 134 min AKIN and 130 min pRIFLE vs any AKI 191 min AKIN and 198 min pRIFLE), increased creatinine (AKIN 270%, pRIFLE 235% over baseline), greater reintubation rate(2-5% versus 25-36%), and LOS (No AKI 10 days versus AKI 36 days AKIN and 25 days pRIFLE). There was not a significant difference in peak inotrope score over 48 hours post-op or peak lactate post-op.
Conclusion: The incidence of AKI significantly increases post-operative length of stay. Inotrope score, while important, does not necessarily lead to improvement in length of stay. Focus on fluid management peri-operatively, and specifically fluid overload, may lead to decreased length of stay.

P1514 - FONTAN COMPLETION DURING WINTER SEASON IS NOT ASSOCIATED WITH SIGNIFICANTLY HIGHER MORTALITY OR SEVERE MORBIDITY IN THE EARLY POSTOPERATIVE PERIOD

Sarah Nordmeyer[1], Sabeth Krettek[1], Johannes Nordmeyer[1], Oliver Miera[1], Mi-young Cho[2], Joachim Photiadis[2], Felix Berger[1], Stanislav Ovroutski[1]
Deutsches Herzzentrum Berlin, Paediatric Cardiology, Berlin-Germany[1]; Deutsches Herzzentrum Berlin, Paediatric Cardiac Surgery, Berlin-Germany[2]

Objectives: The aim of our study was to compare postoperative outcomes after total cavopulmonary connection (TCPC) between patients who were operated during winter and summer season.
Methods: We retrospectively studied 193 patients who underwent extracardiac TCPC completion at our institution between 1995 and 2015. 63 (33%) patients were operated during winter (november-to-march) and 130 (67%) patients during summer season (april-to-october). We compared the following post-operative outcomes: early mortality (i.e. within 30 days postoperatively), need for Fontan takedown, intubation time (hours), incidence of fast track extubation (extubation within 6 hours postoperatively), incidence of pleural effusions longer than 10 days, incidence of low cardiac output (i.e. need for intravenous catecholamine therapy longer than 72 hours), need for dialysis, intensive care unit (ICU) and hospital stay (days). Data are presented as percentage or median values, respectively.
Results: Intubation time (13 vs. 11.5 hours, $p = 0.047$) was slightly longer in patients operated during winter season, however, early mortality (8% vs. 5%, $p = 0.53$), need for Fontan takedown (2% vs. 1%, $p = 0.55$), low cardiac output (19% vs. 9%, $p = 0.09$), dialysis (13% vs. 8%, $p = 0.4$), fast track extubation (13% vs 18%, $p = 0.5$), prolonged pleural effusions (36% vs. 29%, $p = 0.4$), ICU (4 vs. 3 days, $p = 0.2$) and hospital stay (15 vs. 14, $p = 0.05$) were not significantly different between both groups.
Conclusion: TCPC completion during winter season was not associated with higher mortality or severe morbidity in the early postoperative period. These results suggest that TCPC completion during winter season might be performed at no significant additional risk for patients.

P1529 - ASSESSMENT OF SERUM VITAMIN A LEVELS IN INFANTS WITH CONGENITAL HEART DISEASE

Saeed Abtahi[1], Zahra Mostafavian[2]
Mashhad Branch, Islamic Azad University, Mashhad, Iran, Department of Pediatric Cardiology, Mashhad-Iran[1]; Mashhad Branch, Islamic Azad University, Mashhad, Iran, Departments of Community Medicine, Mashhad-Iran[2]

Background: Prevention of congenital heart disease (CHD) has been hampered by a lack of information about modifiable risk factors for abnormalities in cardiac development. Vitamin A plays an important role in the periods of rapid cellular growth and differentiation, especially during pregnancy. The aim of this study is evaluation of vitamin A serum levels in children with CHD and compare to children without CHD.
Materials and Methods: In a case-control study that was conducted in 2015 in Mashhad /Iran, serum levels of vitamin A in 30 children with CHD were compared to 30 controls. Cases of congenital heart disease diagnosed by echocardiography and were recruited by convenience sampling. The control group was selected from infants who referred to health centers for routine care. Exclusion criteria for both groups were concurrent systemic diseases and malnutrition. Data analysis was done in SPSS V 20 software and descriptive statistics, t-test was used.
Results: The mean age in cases was 10.25 ± 6.5 days and in controls was 18 ± 6 days. In both groups, 18 patients (60%) were male and 12 patients (40%) were female. In CHD patients, 10 cases (33.3%) had cyanotic heart disease and 20 cases (66.7%) had acyanotic heart disease. The mean serum vitamin A values in subjects 11.66 ± 13.58 ng/dl and controls 22.54 ± 16.3 ng/dl was significantly different, ($P < 0.05$).
Conclusions: There was a significant difference in serum vitamin A values in subjects and controls. Therefore, we suggest that the serum levels of vitamin A in children with CHD should be checked routinely.

P1544 - THE CURRENT STATE OF SURGICAL INTERVENTION FOR CONGENITAL HEART DISEASE IN TRISOMY 13 AND TRISOMY 18

Yoshimitsu Tsuzuki, Masanori Mizuno, Yousuke Osada, Marie Nakano, Kenzo Sakurai, Kenziro Goto, Kentaro Aso, Hitoshi Yamamoto
St. Marianna University School of Medicine. Kanagawa, Japan, Pediatrics, Kawasaki-Japan

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Introduction: Trisomy 13 (T13) and Trisomy 18 (T18) are relatively common chromosomal disorders often observed in pediatrics practice. Both T13 and T18 are highly associated with congenital heart disease (CHD). For a long-time, aggressive surgical intervention to CHD accompanied with 13 T and 18 T were refrained due to its extremely poor track records, however, in some advanced hospitals, owing to recent advancements, surgical intervention is being considered and has resulted in stabilizing general conditions. Having said, it is yet uncertain whether aggressive surgical interventions have brought about a truly positive impact. Under such circumstances, we have reviewed our experience of surgical interventions for CHD in T13, T18 retrospectively to clarify its effectiveness.
Subjects and Results: Thirty consecutive patients of T13 and T18 were enrolled. Twenty-eight of the patients had CHD, and 7 of those underwent surgical intervention. Performed procedures were palliative operation for all cases. During the study period, only 2 patients survived; of these, 1 underwent surgery and the other did not. Of those 28 patients, median survival days of patients who underwent surgery was 443 days while median survival days of those who did not had surgical intervention was 94 days. However, only 2 of 7 patients (28.5%) who underwent surgery were able to discharge from the Neonatal Intensive Care Unit (NICU) while 9 of the 23 patients (39.0%) who did not undergo surgery were able to discharge from the NICU.
Discussion: Judging from our experiences, it seems that surgical intervention to CHD either T13 or T18 prolongs lifespan. However, even if we did surgical interventions, few of those patients were discharged from NICU and most of those forced to continue intensive care. Considering our results, even if we could prolong lifespan by surgical intervention, we are not sure if it is truly beneficial.

P1546 - EFFECTIVENESS OF INFLIXIMAB IN REFRACTORY KAWASAKI DISEASE

Masanori Mizuno, Yoshimitsu Tsuduki, Yosuke Osada, Chikako Masumori, Marie Nakano, Kenzo Sakurai, Kenjiro Goto, Kentaro Aso, Hitoshi Yamamoto
St.Marianna University School of Medicine, Pediatrics, Kawasaki-Japan

Background: Infliximab (IFX) is recognized as an additional therapy for Kawasaki disease (KD). We examined the effectiveness of IFX therapy in refractory KD.
Materials and Methods: Between 2013 and 2016, 11 patients with refractory KD including 1 recurrent case were enrolled. All patients were primary treated with intravenous immunoglobulin (IVIG) at single dose of 2 g/kg. Refractory to IVIG was defined as persistent fever over 37.5 degrees Celsius 48 hours after IVIG. IFX was administered as a second or third line treatment at 5 mg/kg intravenous infusion. IFX was considered to be effective when body temperature remained under 37.5 degrees Celsius 48 hours after administration.
Results: IFX was administered as second line treatment in 4 patients, and third in 7 patients. Median age was 33 months (range: 9-85 months), median interval from the onset to initial IVIG was 4 days (range: 3-5 days), median interval from the onset to IFX administration was 9 days (range: 6-20 days), median interval from the onset to removal of fever was 12 days (range: 8-21 days), and median hospitalization was 20 days (range: 10-59 days). Initial laboratory examinations showed elevated C-reactive protein (median 9.3 mg/dL: range 4.25-20.8 mg/dL) and neutrophil counts (median 11.0 ×109/L: range 5.5-20.5 ×109/L). At 48 hours after IFX infusion, C-reactive protein decreased in 9 patients, whereas neutrophil counts decreased in 6 patients. IFX was effective in 8 patients, 6 of them brought a high temperature down within 24 hours after IFX infusion. Three non-responders were treated with plasma exchange. Coronary aneurysms at discharge from the hospital were detected in 3 patients. No severe adverse effect was attributable to IFX.
Conclusions: IFX would be provided safely in pediatric patients with KD. Our results suggest that the further evaluation and accumulation of evidence in refractory KD regarding IFX treatment is necessary.

P1551 - COMPLICATIONS OF TAKEUCHI'S SURGERY ANEURISM OF PULMONARY TRUNK CASE REPORT

Felipe Caino[1], Paloma Castro[2], Anabel Goes Costa[2], Adriano Dourado Oliveira[3], Daniela Barauna[1]
Santa Izabel, Cardio Picu, Salvador-Brazil[1]; Santa Izabel, Ped Cardiology, Salvador-Brazil[2]; Santa Izabel, Interventional Cardiology, Salvador-Brazil[3]

Introduction: The anomalous origin of the left coronary artery of the pulmonary trunk (ALCAPA) is the most frequent congenital coronary anomaly and represents one of the most common causes of ischemia and myocardial infarction in children Echocardiography is the most commonly used method for the diagnosis of ALCAPA, Cardiac catheterization with coronary angiography is the exam of choice to confirm the diagnosis and should be used whenever echocardiography leaves doubts. The treatment of ALCAPA is always surgical. One of the most commonly used techniques is the Takeuchi procedure. The complications most associated with this technique are pulmonary supravalvular stenosis, coronary-pulmonary fistula and aortic valve insufficiency.
Case Description: ESS, 5 years and 6 months, male, diagnosed at 3 months of age, of anomalous left pulmonary trunk coronary artery (ALCAPA), complicated with significant mitral regurgitation (IM) and significant left ventricular systolic dysfunction, submitted to Takeuchi's procedure. After surgery, he had a progressive improvement in the left ventricular ejection fraction (LVEF). It evolved with turbulent flow in the pulmonary artery and progressive increase of the supravalvular pulmonary gradient (Gd) on subsequent echocardiograms and decrease of LVEF as times go on. He underwent thoracic angiotomography 1 year and 11 months after surgery, showing pulmonary trunk stenosis and left coronary redirect tunnel obstruction, as well as an image suggestive of myocardial infarction in the anterior and mid-apical segments of the LV.He performed a new cardiac catheterization 5 years after the surgical procedure with a description of normal LVEF, important pulmonary supravalvular stenosis near the

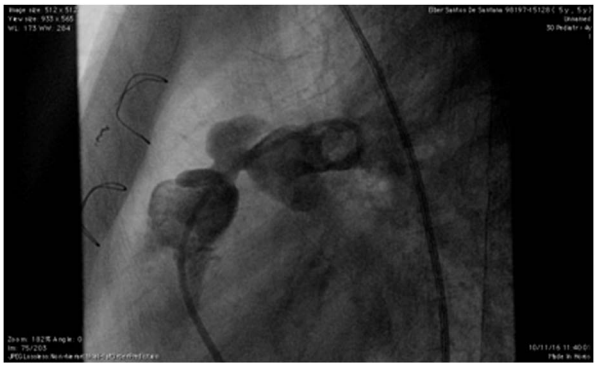

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

pulmonary artery bifurcation with Gd 80 mmHg to the method (Figure 1). Additionally, visualized in profile image suggestive of aneurysm of the pulmonary trunk at the stenosis level (Figure 2).
Discussion: ALCAPA is a pathology with high mortality and morbidity,The case in question brings pulmonary trunk aneurysm as a possible complication associated with the technique.

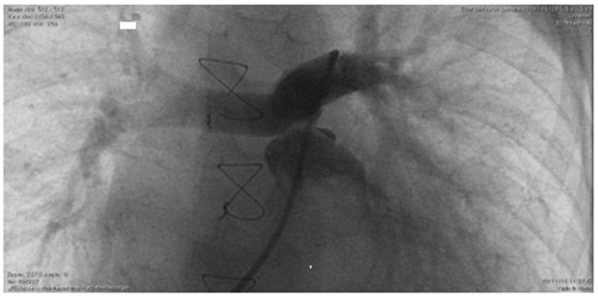

Figure 2.

P1554 - THE MULTIDISIPLINARY EXPERIENCE OF MOVING FROM A TRAINEE NURSE PRACTITIONER ROLE TO ADVANCED NURSE PRACTITIONER ROLE ON PAEDIATRIC CARDIAC INTENSIVE CARE

Grace Banks
GOSH, CICU, London-United Kingdom

Background: Advanced nurse practitioner roles have developed from a perceived need within the NHS and worldwide. The success of Advanced nurse practitioners is widely documented in primary care and adult services while there is only a small amount of literature within paediatrics and less again within specialty services, such as paediatric intensive care. The study aim was to improve the trainee role as it moves into an advanced nurse practitioner role through evaluation of the current trainee nurse practitioners on paediatric cardiac intensive care and a comparison to the established advanced nurse practitioners within children's acute transport service.
Methods: The research was a pilot study which utilized qualitative questionnaire. Questionnaires were distributed within the multidisciplinary teams on cardiac intensive care and the children's acute transport service using an online application. Sampling was purposeful to include a representative sample of the multidisciplinary teams. Findings: Content analysis was used to identify themes from the research. Six themes emerged; positive impact on patient and staff experience, provision of expert care, recognition of blurring of boundaries and unclear role definition, difference in working across the two studied specialties, development suggestions for a more effective advanced nurse practitioner role on cardiac intensive care and perceived impact of an advanced nurse practitioner program on nursing.
Conclusions: Having a trainee nurse practitioner role on cardiac intensive care has been identified by the multidisciplinary team as a positive experience for staff, patient and families. There is an opportunity to develop and grow the advanced nurse practitioner program on cardiac intensive care. It is important further research is undertaken into the scope and practice of advanced nurse practitioners to allow greater understanding of their impact in paediatric intensive care.

P1576 - TRANSCIENT ISOLATED SEPTAL AND RIGHT VENTRICULAR HYPERTROPHIC CARDIOMYOPATHY IN A NEONATE

Cecilia Britton[1], Jesus Yanez[1], Bronson Onorio[2], Ximena García[3], Mario Vázquez[2]
Zambrano Hellion, Pediatric Cardiology, Monterrey-Mexico[1]; Zambrano Hellion, Neonatology, Monterrey-Mexico[2]; Zambrano Hellion, Pediatrics, Monterrey-Mexico[3]

Hypertrophic cardiomyopathy usually involves left ventricle. Isolated involvement of the septum and right ventricle without involvement of left ventricle in the neonatal period is a very rare condition. Clinical manifestations can be serious and 25% can develop signs of heart failure usually secondary to obstruction of the right outflow tract. Early diagnosis is vital since this condition may be reversible with appropriate treatment. We report the case of a male newborn who develop cyanosis in his first hour of life. He was born via cesarean section due to perinatal stress. There was no history of maternal or fetal metabolic disease, no gestational diabetes mellitus. Pregnancy was eventful due to a maternal left mastoiditis which required mastoidectomy and antibiotic and analgesic therapy (NSAID) at 34 gestational week. Normal birth weight (3.3 kilogram), APGAR score at 1 and 5 minute was 7 and 9 respectively. Oxygen saturation on room air was 65%, and was rised to 85% with oxygen supplement. A grade II systolic murmur was present in the tricuspid focus. ANP values were high. Echocardiogram revealed massive hypertrophy in the right ventricle with septal and right ventricular hypertrophic cardiomyopathy, with a very restricted diastolic cavity and a right to left shunt across de patent foramen ovale, grade II tricuspid regurgitation which estimated a right ventricular pressure of 50 mmHg. Patient was admitted to neonatal intensive care unit and put on phosphodiesterase 3 inhibitor and sildenafil to decrease pulmonary vascular resistance. An oxygen saturation of 90% was achieved with the supplementation of 40% oxygen. Saturation values rose up to 95% as of day three and oxygen supplement weaned. The patient was discharged oxygen-free and breastfed on the 10th day. With clinical and echocardiographic follow up patient continuos with normal right ventricular and saturation values.

P1594 - URINARY SYNDECAN 1 IMPROVES SEVERE ACUTE KIDNEY INJURY PREDICTION AFTER PEDIATRIC CARDIAC SURGERY

Candice Torres De Melo Bezerra Cavalcante[1], Alexandre Braga Libório[2], Klebia Magalhães Pereira Castello Branco[1], Andréa Consuelo De Oliveira Teles[1], Valdester Cavalcante Pinto Júnior[3], Ronald Guedes Pompeu[1], Anna Karina Martins Brito[1], Isabel Cristina Leite Maia[1], Jeanne Araújo Bandeira[1], Simone Michiles[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Messejana's Hospital, Pediatric Cardiology, Fortaleza-Brazil[1]; General Hospital, Nephorlogy, Fortaleza-Brazil[2]; Messejana's Hospital, Pediatric Cardiovascular Surgery, Fortaleza-Brazil[3]

Introduction: Acute kidney injury (AKI) is a common occurrence after pediatric cardiac surgery and is associated with adverse patient outcomes. Previous we have demonstrated plasma syndecan-1 (a biomarker of endothelial glycocalyx damage) is associated with cardiac surgery-associated AKI. Here, we evaluated the value of urinary syndecan-1 in predicting AKI in this population.
Methods: Prospective cohort study with 83 patients under 18 years old submitted to cardiac surgery at one reference institution. Postoperative urinary syndecan-1 within the first 2 hours after cardiac surgery was collected and normalized to urinary creatinine. Severe AKI - defined according KDIGO stage 2 or 3 was the main outcome. We evaluated if urinary syndecan-1 was independently associated with severe AKI and if it adds prognostic value when added to a clinical model (including age, sex, CPB use, CPB time more than 120 minutes, RACHS-1 3 or more, pre- operative eGFR percentile, percentile of systolic blood pressure at ICU admission, maximum vasoactive inotropic score in the first 48 hours and lactate at ICU admission) performance to predict severe AKI.
Results: Urinary syndecan-1 levels in the postoperative period was higher in patients developing severe AKI (1,062 vs 272 ng/mg-Cr, $p < 0.001$). After adjusting for several confounders, urinary syndecan-1 remained independently associated with severe AKI (OR 1.02 95% CI 1.01-1.04 for each 10ng/mg-Cr increment). The accuracy of postoperative syndecan-1 for diagnosis of severe AKI was moderate (AUC-ROC of 0.78 95% CI 0.58-0.98). The addition of urinary syndecan-1 improved the discrimination capacity of a clinical model (from 0.81 to 0.89, $p = 0.008$).
Conclusions: Postoperative urinary syndecan-1 is associated with subsequent severe AKI and adds predictor value to a clinical model in predicting severe AKI after pediatric cardiac surgery. It may be useful for risk stratifying patients undergoing cardiac surgery.

P1597 - CLINICAL PROFILE AND TREATMENT OUTCOME OF BLOOD CULTURE NEGATIVE (BCN IE) INFECTIVE ENDOCARDITIS IN CHILDREN A TEN YEAR RETROSPECTIVE STUDY

Mylah Alfeche, Maria Concepcion Sison
University of the Philippines College of Medicine- Philippine General Hospital, Pediatrics, Manila-Philippines

Background: Infective endocarditis (IE) remains to be a dreaded complication of congenital and rheumatic heart disease in a third world country where corrective surgical intervention is not readily accessible and affordable. The higher incidence of BCN-IE, whether due to fastidious organisms or technical inadequacies in a government tertiary center, makes it more challenging to manage these cases. Evaluation of clinical practice and outcomes amidst international guidelines on BCN-IE is necessary We conducted a ten-year retrospective study of BCN-IE in children admitted at the University of the Philippines-Philippine General Hospital (UP-PGH) to describe their clinical profile, echocardiographic findings, and antibiotic treatment; and correlate with clinical outcome.
Materials and Methods: Demographic data, clinical presentation, previous antibiotic use, echocardiographic findings, and antibiotic treatment of children with BCN-IE admitted at UP-PGH from 2004-2013 were recorded and analyzed. The clinical outcome of patients, whether favorable (discharged) or unfavorable (died, went home against medical advice, re-admitted one month after discharge) were likewise noted. The Fischer's exact test was used to evaluate association of outcome and clinical features, echocardiographic findings and antibiotic regimen.
Results: Among 91 patients diagnosed with infective endocarditis, 61.54% had BCN-IE. Age ranged from 2 weeks to 18 years old (mean = 10.15 years). Thirty four (52.86%) patients had congenital heart disease in which VSD (25%) was the most common. Nineteen (33.93%) had Rheumatic Heart Disease. Clinical presentation and echocardiographic findings were not associated with outcome. The use of penicillin G and amikacin is associated with unfavorable outcome (11 out of 38, with 5 deaths) ($p = 0.007$, $\alpha = 0.05$).
Conclusion: The trend to unfavorable outcome with use of penicillin suggests adhering to international guidelines for antibiotics of choice for BCN-IE with need for re-evaluation.

P1603 - FUTILITY OF ROUTINE METHEMOGLOBIN LABORATORY ASSAYS IN CRITICALLY ILL PEDIATRIC PATIENTS RECEIVING INHALED NITRIC OXIDE

Christopher A. Thomas[1], Kevin Valentine[2]
Riley Hospital for Children At Indiana University Health, Pharmacy, Indianapolis-United States[1]; Riley Hospital for Children at Indiana University Health, Section of Cardiac Critical Care, Indianapolis-United States[2]

Background: Inhaled nitric oxide (iNO) is metabolized to methemoglobin and has historically resulted in methemoglobin levels of up to 10.4% in neonates. Methemoglobinemia above 3% related to iNO administration has been linked to increased mortality in some patient populations. It is a standard of care at our institution to measure methemoglobin concentrations every 24 hours while receiving iNO therapy. We aimed to determine the incidence of methemoglobinemia in pediatric patients receiving inhaled nitric oxide.
Methods: A retrospective chart review was performed from 10/18/2014 to 11/18/2016 at our institution for all pediatric patients less than 18 years of age receiving iNO therapy. Patients receiving iNO with at least one methemoglobin concentration were included in the analysis. Patients with methemoglobinemia on admission as well as those with an underlying risk factor for methemoglobinemia were excluded from the analysis. Data are represented as mean (standard deviation), median (interquartile range), or absolute counts (%) as appropriate.
Results: During the study period 1702 methemoglobin concentrations were collected in 248 patients. Median age and weight were 0.33 years (0.04–0.83) and 4.6 kg (3.38–8.00), respectively. Fifty percent of patients were admitted to the cardiac intensive care unit followed by 25% admitted to both the pediatric and neonatal intensive care units. The mean methemoglobin concentration was 1.33% (+/-0.42) while receiving a mean iNO dose of 11.71 ppm (+/-7.97). Twenty-nine patients had a total of 131 methemoglobin concentrations analyzed while receiving iNO doses greater than 20 ppm. The mean methemoglobin concentration in these patients was the same as the entire cohort at 1.33% (+/-0.42).
Conclusions: Pediatric patients receiving inhaled nitric oxide at doses less than 40 ppm have a low risk of developing methemoglobinemia. Methemoglobin monitoring in pediatric patients receiving iNO therapy should be based upon clinical evidence. Routine monitoring is unnecessary and should be avoided.

P1632 - EARLY LONGITUDINAL NEURODEVELOPMENTAL QUALITY OF LIFE AND FAMILY IMPACT OUTCOMES FOR INFANT SURVIVORS OF EXTRACORPOREAL LIFE SUPPORT

Bronagh Mcalinden[1], Christian Stocker[2], Karen Eagleson[3], Nelson Alfonso[4], Susan Johnson[5]
Lady Cilento Children, Physiotherapy, Brisbane-Australia[1]; Lady Cilento Children, Critical Care, Brisbane-Australia[2]; Lady Cilento Children, Cardiology, Brisbane-Australia[3]; Lady Cilento Children, Cardiac Surgery, Brisbane-Australia[4]; Lady Cilento Children, Psychology, Brisbane-Australia[5]

Background: Extracorporeal Life Support (ECLS) treatment is well-established in neonatal and paediatric intensive care. International data pooling and analysis has significantly contributed to improved outcomes and understanding of co-morbidities, including brain injury, following ECLS. However, there is little longitudinal data describing functional health and family impact of infant survivors.
Methods: Infants receiving ECLS from 2013 to 2015 underwent sequential assessments. Demographic, clinical data, Bayley Scales of Infant Development, Health-Related Quality of Life (HRQoL) scores, and Parenting Stress (PS) indices were collected longitudinally. Enrolment and assessment of infants is ongoing.
Results: Infants were assessed at 4-6 (N = 17), 12 (N = 13), and 24 months (N = 3) of age. Median age at cannulation was 17 days (IQR = 49), weight 3.9 kg (IQR = 0.86), and duration of ECLS 51 hours (IQR = 136). Reasons for cannulation were cardiac failure (N = 7), respiratory failure (N = 6) and Extra-Corporeal Cardiopulmonary Resuscitation (ECPR) (N = 4). Veno-arterial cannulation occurred centrally (N = 8) and peripherally (N = 9). Average range (±1 SD) for language and cognitive domains were observed at 6 (92.7 ± 12.0; 90.3 ± 9.9) and 12 (92.9 ± 12.9; 93.8 ± 15.0), but low average range (1-2 SD) at 24 months (84.3 ± 22.7; 85.0 ± 13.2), as were motor scores at all age points (82.5 ± 18.7; 83.6 ± 13.4; 88.3 ± 28.9). Average range for social-emotional and adaptive behaviour domains were recorded at 6 (94.0 ± 28.8; 79.3 ± 33.9) and 12 (101.1 ± 16.2; 86.8 ± 13.1), but well below normal (<2 SD) at 24 months (61.7 ± 54.0; 47.0 ± 42.0). Scores in ECPR were generally higher compared to non-ECPR, but in average range across all domains at 6 and 12 months (see Table). Parent-reported HRQoL was significantly impaired (<2 SD) at 6 and 12 months, though normal at 2 years. PS was normal at all time points.
Conclusions: Early results and small numbers indicate that infant survivors bear functional health and family impact deficits over the 2 years following ECLS, particularly in motor, social-emotional, behaviour and HRQoL domains, and that ECPR may not make them worse.

Table.

	ECPR		Non-ECPR	
Bayley Scales of Infant Development 3rd Edition	**6 Months N = 4**	**12 Months N = 2**	**6 Months N = 13**	**12 Months N = 11**

P1654 - SAFETY OF SILDENAFIL IN HEMODYNAMICALLY UNSTABLE CHILDREN

Emily N. Israel[1], Elizabeth Beckman[1], Alexandra M. Bednarz[2], Austin M. Kurkowski[2], Michael Johansen[3], Christopher A. Thomas[1]
Riley Hospital for Children at Indiana University Health, Pharmacy, Indianapolis-United States[1]; Purdue University College of Pharmacy, Pharmacy, West Lafayette-United States[2]; Riley Hospital For Children at Indiana University Health, Section of Pediatric Cardiology, Indianapolis-United States[3]

Background: Sildenafil is a first-line agent used to treat pulmonary hypertension in pediatric patients. While it is often initiated in critically ill children, it is unknown whether sildenafil worsens hemodynamic instability in patients receiving continuous inotropic or vasopressor medications. We hypothesize that hemodynamic instability occurs frequently in children receiving concurrent vasoactive infusions after sildenafil initiation and that current sildenafil dosing recommendations may be inappropriate for this population.
Methods: Children younger than 2 years were included in this retrospective chart review if sildenafil was initiated during receipt of a vasoactive infusion between January 1, 2010 and September 30, 2016. Demographics, sildenafil dose, and vasoactive infusion data were collected. Patients receiving mechanical circulatory support or renal replacement therapy during the study period were excluded. The primary outcome was a composite endpoint of the incidence of sildenafil discontinuation and/or increased vasoactive support within 24 hours of sildenafil initiation.
Results: A total of 82 patients were included. The median age was 5 months (IQR 0.89-8.71) and 22% had a diagnosis of Trisomy 21. The median initial sildenafil dose for all patients was 1.29 mg/kg/day (IQR 0.86-2 mg/kg/day) with a median vasoactive inotrope score (VIS) of 5.28 (IQR 3.58-7.49) at sildenafil initiation. Twenty patients (24%) met the primary endpoint, 19 of which had inotropic support increased during the study period. Patients that met the primary endpoint tended to be younger (median 3.38 versus 5.5 months) with similar median total daily sildenafil dosing (1.13 mg/kg/day versus 1.33 mg/kg/day) as well as initial VIS (5 versus 5.5) between groups.
Conclusion: Critically ill children initiated on sildenafil while receiving concurrent inotropic infusions may be at risk for further hemodynamic instability. Lower empiric sildenafil dosing may be appropriate for this patient population to avoid the need for escalation of inotropic support.

P1680 - RISK FACTORS FOR MECHANICAL VENTILATION TIME AFTER CONGENITAL HEART SURGERY

Paulo Manso[1], Mariana Ferreira[1], Tarcisio Silva Jr[1], Aida Turquetto[2], Luiz Caneo[2], Johnny Santos[2], Luciana Amato[2], Fabio Carmona[1]
Ribeirao Preto Medical School, Pediatrics, Ribeirao Preto-Brazil[1]; Heart Institute, Cardiology, Sao Paulo-Brazil[2]

Background: Risk factors for prolonged mechanical ventilation time are not well defined and may lead to increased mortality, morbidity, and costs.
Objectives: To verify risk factors that affect mechanical ventilation time after congenital heart surgery by using the ASSSIST/PPSUSP databank of the state of São Paulo, Brazil.
Methods: Patients were prospectively included in the ASSIST/PPSUSP electronic databank, which gathers information from two tertiary hospitals where congenital heart disease surgeries. We retrospectively analyzed the data recorded from September 2014 to December 2015. We examined the following variables: weight

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

at surgery, Prematurity, previous admission to intensive care unit (ICU), cardiopulmonary bypass (CPB) duration, procedure type, lactate levels after 12 hours at ICU, diagnosis of infection, and Rachs-1 classification. A Cox multiple regression model was used to correlate these risk factors and mechanical ventilation time.
Variables B p HR IC95%
Inferior Superior
Weight 0.014 0.000 1.014 1.009 1.018
Prematurity -0.156 0.403 0.856 0.593 1.234

Rachs-1: 3-6 -0.620 0.000 0.538 0.396 0.730
Conclusion: Previous ICU admission, CPB duration, UCI lactate, infection, and Rachs-1 higher than 3 affected mechanical ventilation time negatively in patients submitted to congenital heart disease surgery.

P1682 - PERINATAL ARRHYTHMIAS 10 YEARS EXPERIENCE

Joana Pimenta[1], *Cláudia Mota*[1], *Paulo Soares*[2], *Cláudia Moura*[1], *António Vieira*[1], *José Carlos Areias*[1]
Centro Hospitalar De São João, Pediatric Cardiology, Porto-Portugal[1]; *Centro Hospitalar De São João, Neonatology, Porto-Portugal*[2]

Perinatal arrhythmias are frequent and usually benign. The aim of this study is to evaluate newborns with perinatal arrhythmia.
Material and Methods: Retrospective analysis of the clinical data of newborns admitted to neonatology due to cardiac arrhythmia, over a 10-years period.
Results: During study period, 113 newborns were admitted, 109 as primary arrhythmias and 4 as post-procedure complication. Of the 109 with primary arrhythmia, 62.4% were male, 12.8% (14) had congenital heart disease and 7.3% (8) other organs anomalies. Fetal diagnosis was made in 64.2% (70): 57.1% (40) tachycardia, 27.2% (19) premature contractions, 14.3% (10) bradycardia and 1.4% (1) tachy-brady syndrome. In complete AVB group, 7 mothers had autoimmune disease. Fetal hydrops was observed in 12. Prenatally drugs were prescribed in 22: 18 (45%)tachycardia (all digoxin;9 flecainide; 3 sotalol) and 4 (40%) bradycardia (4corticoid; 2salbutamol). Tachycardia termination was achieved in 11 on average 1.2 weeks after drug onset. Postnatal arrhythmia wasn´t observed in 10.
Thus, neonatal arrhythmia occurred in 99 (90.8%). Tachycardia in 65.6% (65) (28 AVRT – 11 WPW, 5 focal atrial tachycardia, 5 atrial flutter, 3 PJRT, 3 VT and 1 left fascicular), premature contractions in 22.3% (22) (15atrial and 6ventricular) and bradycardia in 12.1% (12) (10 cAVB, 1 2:1 AVB and 1 1° and 2° degree AVB). 12 (11%) had ventricular dysfunction. Within tachycardia group, anti-arrhythmic was given to 90.7% (59): 55 propranolol, 39 flecainide, 6 digoxin and 14 amiodarone iv. Electric cardioversion was performed in 10. Discharged antiarrhythmic therapy were maintained in 56. Follow-up time was 3 years and recurrences observed in 9 (13.8%). Within bradycardia group, 3 received isoprenaline, 6 temporary pacemaker and 7 definitive pacemaker. Mean follow-up time was 2.7 years (1 generator change and 1 remained without pacemaker). Seven (6%) children died, 3 related to arrhythmia.
Conclusion: Like other studies we conclude that perinatal arrhythmias are usually a a benign event,with low mortality and good long-term prognosis.

P1719 - IMPACT OF THE COMBINATION OF HIGH FLOW NASAL OXYGEN THERAPY AND INHALED NITRIC OXIDE ON THE POSTOPERATIVE MANAGEMENT OF THE FONTAN PROCEDURE

Yuji Tominaga[1], *Shigemitsu Iwai*[1], *Sanae Yamauchi*[1], *Yosuke Kugo*[1], *Hutoshi Kayatani*[2], *Kunihiko Takahashi*[2], *Hisaaki Aoki*[2], *Muneyuki Takeuchi*[3], *Miyako Kyogoku*[3], *Hiroaki Kawata*[1]
Osaka Medical Center and Research Institute for Maternal and Child Health, Cardiovascular Surgery, Izumi-Japan[1]; *Osaka Medical Center and Research Institute for Maternal and Child Health, Pediatric Cardiology, Izumi-Japan*[2]; *Osaka Medical Center and Research Institute For Maternal and Child Health, Intensive Care Medicine, Izumi-Japan*[3]

Background: Since 2014, we have applied the combination of high-flow nasal oxygen therapy and inhaled nitric oxide after extubation to high-risk patients after the Fontan procedure. We investigated its benefits.
Materials and Methods: This was a single-center, retrospective review of 57 patients who underwent the Fontan procedure and needed nitric oxide inhalation therapy before extubation. Forty-nine patients were selected: patients who were ≧15 years old, or had preoperative tracheostomy, or postoperative brain complications, or postoperative phrenic paralysis were excluded. They were divided into two groups for comparison: early (January 2010 to December 2013, n = 28) and late (addition of high-flow nasal oxygen/ inhaled nitric oxide after extubation, January 2014 to June 2016, n = 21). There were no significant differences between the 2 groups in preoperative cardiac function and body weight, and they were similar for types of initial cardiac diagnosis: hypoplastic left heart syndrome (n = 6, 3), heterotaxy (n = 8, 11), and total anomalous pulmonary venous return (n = 6, 4). One patient in the late group had a single lung.
Results: There were no significant differences between the groups in intraoperative fluid balance, and central venous pressure at admission to the ICU. There were significant decreases in the late group in postoperative intubation time (53.1 ± 98.8, 5.9 ± 5.6 hours, p = 0.01), drainage time (24 ± 14, 15 ± 12 days, p = 0.01), and duration of the postoperative hospital stay (42 ± 22, 30 ± 16 days, p = 0.028), while urinary output per body weight at 6 hours post-surgery was significantly greater (p = 0.036). Three patients in the early group (10.3%) required re-intubation, but none was required in the late group.
Conclusions: Our results suggest that high-flow nasal oxygen therapy with inhaled nitric oxide contributes to a decreased requirement for re-intubation, and decreases the time required for postoperative intubation, drainage, and hospitalization.

P1729 - PREDICTION OF POST OPERATIVE INFECTION AFTER CONGENITAL CARDIAC SURGERY ROLE OF LAB PARAMETERS AND LOW CARDIAC OUTPUT STATE

Venkata Krishna Kishore Jayanthi[1], *Ramkinkar Shastri*[2], *Jagannath Byalal*[3], *Pavan Prasad Kapavarapu*[4], *Gopichand Mannam*[3], *Ramesh Dasari*[5], *Ravi Komalla*[6], *Anitha Maddarala*[1], *Snehalatha Meruga*[6]

Aims and Objectives: To differentiate between infection and inflammation in post cardiac surgery. To predict the probability of infection in post operative Congenital cardiac condition based on clinical and lab parameters and low cardiac output (LCOS) state

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Methods: 210 patients who underwent cardiac surgery from October, 2015 till June, 2016 were enrolled in a prospective observational study. TLC, Platelet count, Procalcitonin, CXR, CRP done on day 1 and day 3 postoperatively along with cultures when indicated. Patients were classified into three groups. Patients with three or more abnormal values were included into group 3 (infection, n = 48), one or two criteria which normalized over next 48 hours into group 1(non infected, n = 111), all others into group 2(suspected infection, n = 51). Appropriate statistical analysis performed using SBSS software.
Results: Pre-operative respiratory infection and hospitalization were associated with post-operative infection. Post-operative CRP values failed to suggest infection. procalcitonin >2ng/ml and persistently higher levels on D3 was seen in group 3 as compared to group 2(p-0.000). Multiple regression analysis using TLC, fever, platelets, procalcitonin on D1, predicted infection with only 45% accuracy (F value- 27.22) and this went up to 70% accuracy(F value-45.23) if day 3 was included. LCOS on D1 is significantly more in group 3 as compared to group 2 (p- < 0.014).
Conclusion: It is difficult to differentiate between sepsis and inflammation in the post-operative period especially if cultures are negative. A combination of fever, chest x ray findings along with deranged TLC, platelet count, procalcitonin >2ng/ml can suggest infection with an accuracy of 70% on D3 as suggested by regression analysis. LCOS on D1 is possibly the best predictor of possible infection. We believe that having covered BSI, VAP, and CAUTI, with appropriate strategy, the only other source of infection is transmigration of bacteria from relatively ischemic gut exacerbated by the LCOS.

P1743 - INCESSANT JUNCTIONAL ECTOPIC TACHYCARDIA AS INITIAL PRESENTATION OF ENTEROVIRAL MYOCARDITIS SUCCESSFUL BRIDGING TO RECOVERY WITH ECMO SUPPORT

Gilbert T Chau[1], Sit Yee Kwok [2], Kin Shing Lun[2], Tak Cheung Yung[2]
Queen Mary Hospital, Paediatric and Adolescent Medicine, Hong Kong-Hong Kong[1]; Queen Mary Hospital, Paediatric Cardiology, Hong Kong-Hong Kong[2]

Junctional Ectopic tachycardia (JET) is a rare presentation in neonatal myocarditis. We report a case of neonatal enteroviral myocarditis and encephalitis, who presented with fever and JET, and refractory to direct-current cardioversion and antiarrhythmic therapy, including amiodarone, esmolol and ivabradine. Subsequently the clinical course progressed to ventricular tachyarrhythmia and severe ventricular dysfunction, requiring emergency support using extracorporeal membrane oxygenation (ECMO). Intravenous immunoglobulin was given but resulted in significant platelet aggregation and fibrin formation, complicated with haemolysis and haemoglobinuria requiring exchange of circuit. Patient recovered after 15 days of ECMO support with full recovery of cardiac function and resumption of sinus rhythm, with satisfactory neurological outcome. A literature review of 16 cases of neonatal enterovirus myocarditis from year 2008-2016 was performed, showing a mortality of 31%, similar to previous literature review. JET is a rare presentation even in cases presented with arrhythmias. Role of IVIG remains controversial in viral myocarditis and risk of thromboembolic events has to be considered. ECMO support and heart transplantation are the ultimate management for neonatal viral myocarditis refractory to medical therapy.

P1745 - INCIDENCE AND RISK FACTORS FOR EARLY POST OPERATIVE ARRHYTHMIAS FOLLOWING PEDIATRIC CARDIAC SURGERY

Anupam Das[1], Manoj Kumar Sahu[2], Sachin Talwar[1], Atul Abraham[1], Shiv Kumar Choudhary[1], Balram Airan[1]
All India Institute of Medical Sciences, Cardiothoracic Vascular Surgery, New Delhi-India[1]; All India Institute of Medical Sciences, Cardiac Surgical Intensive Care, New Delhi-India[2]

Background: This prospective study was conducted to determine the age specific incidence and the risk factors for early post operative arrhythmias in the intensive care unit following pediatric cardiac surgery with special focus on the disease specific incidence and early outcome using a uniform strategy for management of the arrhythmias and a special reference to serum magnesium levels in the post operative period.
Methods: The study population included 370 consecutive pediatric patients undergoing open heart surgery using cardiopulmonary bypass, from September 2013 to July 2015 regardless of the diagnosis. Patients having pre operative arrhythmias were excluded from the study. Patients were continuously monitored, and hemodynamically significant arrhythmias were recorded.
Results: The incidence of post operative arrhythmias was 11.12% (n = 25). The predominant arrhythmias noted were junctional ectopic tachycardia (JET) (n = 15, 60%), ventricular premature ectopics/ ventricular tachycardia (n = 8, 32%), supraventricular

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

tachycardia (n = 2, 8%), ventricular fibrillation (n = 2, 8%) and atrial fibrillation (n = 1, 4%). 22 patients recovered and were discharged uneventfully and 3 deaths were reported in the study group. Factors that were found to be significantly related statistically to the occurrence of arrhythmias included surgical duration (p = 0.01), serum lactate (p = 0.04), systolic blood pressure (p = 0.02) and Wernowsky inotropic score (p = 0.02). Serum electrolyte levels (sodium, potassium, magnesium and calcium) were not significantly different in the two groups. Both atrioventricular septal defect repairs (n = 4) and arterial switch operations (n = 4) had equal incidence of the arrhythmias in the post operative period.
Conclusions: We found a low incidence of arrthymias particularly JET after pediatric open heart surgery. A management protocol consisting of amiodarone, digoxin, surface cooling and optimization of inotropes was uniformly used and found to be effective. Longer surgical duration, higher serum lactate levels, lower systolic blood pressure and higher Wernowsky inotropic score were found to be independent risk factors for the early post operative arrhythmias.

P1746 - NOSOCOMIAL INFECTION RELEVANCE AND OUTCOME IN INFANTS UNDERGOING OPEN HEART SURGERY IN THE PRESENT ERA

Bharat Siddharth Chigurupati[1], Manoj Kumar Sahu [2], Devagouru Velayudham[1], Sachin Talwar[1], Sarveshpal Singh[3], Shiv Choudhary[1], Balram Airan[1]
All India Institute of Medical Sciences, Cardiothoracic and Vascular Surgery, New Delhi-India[1]; All India Institute of Medical Sciences, Intensive Care, Dept of Cardiothoracic And Vascular Surgery, New Delhi-India[2]; All India Institute of Medical Sciences, Intensive Care, Cardiothoracic and Vascular Surgery, New Delhi-India[3]

Background: To evaluate the causal relation between nosocomial infection(NI) and clinical outcomes following cardiac surgery in neonates & infants and to identify risk factors for the development of NI in this subset of patients
Methods: After Ethics committee approval, one hundred consecutive infants undergoing open heart surgery (OHS) between June 2015 and June 2016 were included in this prospective observational study. Data were prospectively collected using a standardized data collection form. The incidence and distribution of NI, the microorganisms, their antibiotic resistance and patient outcome were determined. Centers for Disease Control and Prevention criteria were used for defining NIs.
Results: Sixteen infants (16%) developed microbiologically documented NI after cardiac surgery. Neonatal age group was found to be most susceptible. Lower respiratory tract infections accounted for majority of the infections (47.4%) followed by bloodstream infection (31.6%), urinary tract infection (10.5%) and surgical site infection (10.5%). Klebsiella (36.8%) and Acinetobacter (26.3%) were the most frequently isolated pathogens. Major risk factors for NI were neonatal age group ([odds ratio] OR = 6.4), preoperative hospital stay ≥3 days (OR = 3.7), duration of cardiopulmonary bypass >180 minutes (OR = 5), aortic cross clamp >99 minutes (OR = 2.8), open sternum ≥2 days(OR = 4.4) and surgical complexity score (P = 0.03).
Conclusion: NI still remains a dreaded complication in infants after OHS and contributing to morbidity and mortality. Strategies like decreasing preoperative hospital stay, early sternal closure, early extubation and rational antibiotic usage should be implemented to prevent NI.

P1781 - IS PRE OPERATIVE ENTERAL FEEDING SAFE IN INFANTS WITH DUCT DEPENDENT CONGENITAL HEART LESIONS

Thomas Day[1], Diana Dionision[2], Diana Zannino[3], Chrisitan Brizard[4], Michael Cheung[2]
Great Ormond Street Hospital for Children Nhs Foundation Trust, Cardiology, London-United Kingdom[1]; Royal Children's Hospital, Cardiology, Melbourne-Australia[2]; Murdoch Children's Research Centre, Heart Research Group, Melbourne-Australia[3]; Royal Children's Hospital, Cardiac Surgery, Melbourne-Australia[4]

Background: Infants with duct-dependent congenital heart lesions are treated pre-operatively with a continuous prostaglandin E1 infusion to maintain patency of the ductus arteriosus. The optimal feeding strategy of these patients remains controversial, and there is widespread variation in practice worldwide. Many units choose not to feed these patients enterally whilst on a prostaglandin infusion due to the theoretically increased risk of necrotising enterocolitis (NEC), although there is a lack of high-quality evidence to demonstrate this association. We aimed to describe the feeding strategies used at the Royal Children's Hospital in infants receiving prostaglandin, and to describe the incidence of gastrointestinal complications (including NEC) in this patient group, investigating whether enteral feeding is associated with a higher risk.
Methods: Using an institutional cardiology database, all patients diagnosed with hypoplastic left heart syndrome, coarctation of the aorta, pulmonary atresia, or transposition of the great arteries born between September 2013 and December 2014 were identified. Data were gathered from the hospital records. Premature infants, those with pre-existing gastrointestinal disease, and those who never received prostaglandin were excluded. Data were compared using the chi-squared, Fisher's exact, and Student's T test as appropriate.
Results: 89 infants were identified (11 hypoplastic left heart, 28 coarctation, 14 pulmonary atresia, 36 transposition). 7 patients received a clinical diagnosis of suspected or confirmed NEC (incidence 7.9%). 26 (29.2%) patients received some enteral feed whilst receiving prostaglandin. There was no association between the diagnosis of NEC and enteral feeding (P = 0.1), sex (P = 0.1), timing of diagnosis (P = 0.9), cardiac diagnosis (P = 0.3), or birthweight (P = 0.6). All NEC cases were managed conservatively.
Conclusions: Based on these retrospective non-randomised data, there does not appear to be an association between enteral feeding and NEC in infants receiving prostaglandin. Further prospective studies are required to confirm the safety of enteral feeding in this patient group.

P1791 - DILATED CARDIOMYOPATHY DUE TO SEVERE IRON DEFICIENCY ANEMIA

Peter Bride[1], Micheal Kaestner[1], Helmut Hummler[2], Christian Apitz[1]
University Hospital ULM, Pediatric Cardiology, ULM-Germany[1]; University Hospital ULM, Pediatric Intensive Care, ULM-Germany[2]

Background: Alimentary iron-deficiency is the most common cause of nutritional anemia in both developed and developing countries. Typical symptoms are fatigue, exercise limitation and tachycardia. We present a case of dilated cardiomyopathy due to severe iron deficiency anemia.
Results: A previously healthy 23 months old girl came to our emergency department with a recent history of peripheral edema, fatigue and dyspnea. During the last 12 Months she was fed exclusively with 1.5% cow's milk and fruit juice. Physical examination revealed hepatomegaly, pallor and a systolic murmur with

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

hyperdynamic precordium. Lab results showed a low hemoglobin level of 1.4 g/dl and a hematocrit level of 7.1%, the mean corpuscular volume was 66fl (normal range 73-101fl), mean corpuscular hemoglobin was 13 pg (normal range 23-31 pg). Ferritin was below detection limit, Vitamin B12, B1 and folic acid were within normal range. There were no signs of bleeding, hemolysis or inflammation. Initial NT-proBNP was 14258 pg/ml (normal range <320 pg/ml). Echocardiography revealed severe dilation of the left ventricle (LVIDd 46mm, Z-Score +4.4) and mild to moderate LV dysfunction with fractional shortening of 24% and ejection fraction of 48%, mild mitral regurgitation and a tricuspid regurgitation peak gradient of 40 mmHg. The patient received 2 units of packed red blood cells and was treated with oral iron sulfate, an initial short course of Furosemide followed by Lisinopril and Bisoprolol. Within 12 days cardiac function and LV-diameter improved markedly (LVIDd 38mm, Z-Score +2.5, fractional shortening 31%, ejection fraction 59%, peak tricuspid regurgitation gradient 25 mmHg).
Conclusion: Iron deficiency is the most common cause of nutritional anemia. A strict vegetarian/vegan lifestyle can be a contributing factor. The exact pathomechanism of anemia induced cardiomyopathy remains unclear, but might be explained by tissue hypoxia and chronic increased sympathetic nervous activity. Fortunately, blood transfusion, iron substitution and anticongestive medication usually result in complete restitution.

P1803 - CARDIAC THROMBI IN NEWBORN TREATMENT WITH RECOMBINANT TISSUE PLASMINOGEN ACTIVATOR TEN YEAR EXPERIENCE

Patricia Alvarez[1], Patricia Verdugo[2], Valeria Acevedo[1], Claudia Avila[3], Patricia Ríos[4], Vicente Montes[5]
Hospital Roberto Del Rio, Cardiology, Santiago-Chile[1]; Hospital Roberto Del Rio, Hematology, Santiago-Chile[2]; Hospital San José, Neonatology, Santiago-Chile[3]; Universidad De Chile, Cardiology, Santiago-Chile[4]; Universidad Del Desarrollo, Cardiology, Santiago-Chile[5]

The incidence of cardiac thrombi in newborns has increased with the use of central venous catheters. Preterm infants have high risk of catheter-related thrombus formation due to a combination of high prothrombotic activity, low levels of natural anticoagulants and an imbalance of the fibrinolytic system. Thrombolysis with recombinant tissue plasminogen activator (rTPA) has been used as an alternative to heparin in life threatening thrombus with risk of embolization. The objective was to study the response and complications of rTPA in the management of life threatening cardiac thrombi in newborns.
Materials and Methods: 10 year retrospective study, 11 medical records of newborns with intracardiac thrombi were analyzed.
Results: 10 patients were premature newborns, median age was 30 weeks, median weight was 1003 g (ranging 856-3430 g) and 6 weighed less than 1000 g. Diagnosis age was between 5 to 18 days. 10 subjects suffered from sepsis and all of them had central venous catheters. 10 thrombi were located in the right atrium and one in the left atrium. Three patients received low molecular weight heparin prior rTPA. 5 patients showed complete resolution of thrombus, 4 partial resolution and 2 did not respond to therapy. One of these last required thrombectomy and the other died from sepsis. Four patients had intracranial hemorrhage grade I without sequelae.
Conclusion: The use of rTPA is an effective therapy in newborn afflicted with cardiac thrombi. This therapy achieved the resolution or reduction of the thrombus and therefore, reduced the secondary life-threatening risk without serious side effects. The thrombolysis was effective even in newborn weighing less than 1000 g. New prospective studies are required to further validate the use of rTPA.

P1827 - PATIENT DEMOGRAPHICS AND EARLY OUTCOMES AFTER CARDIOPULMONARY RESUSCITATION IN PAEDIATRIC CARDIAC INTENSIVE CARE UNIT

Abhishek Narayanan[1], Troy Dominguez[1], Tain-Yen Hsia[2], Timothy Thiruchelvam[1], Bridget Leavey[1], Victoria Banks[3]
Great Ormond Street Hospital For Children, Paediatric Cardiac Intensive Care, London-United Kingdom[1]; Great Ormond Street Hospital for Children, Paediatric Cardiac Surgery, London-United Kingdom[2]; Great Ormond Street Hospital For Children, Critical Care and Cardiorespiratory Unit, London-United Kingdom[3]

Background: Children with underlying cardiac problems are at greater risk of experiencing cardiac arrest compared to general population with reported incidence of 2-6%.
Objective: Describe patient demographics, aetiology, and early outcomes after cardiopulmonary resuscitation (CPR) in a tertiary-care, Paediatric Cardiac Intensive Care Unit (PCICU).
Methods: A retrospective, cohort study of children (<16 years) admitted to the PCICU who underwent CPR between 31/5/13–12/31/15. Outcomes assessed were return of spontaneous circulation (ROSC), ECMO cannulation during CPR (ECPR), and in-hospital mortality.
Main Results: There were 39 CPR events in 2145 children (1.8%) during the study period. Patient demographics are given in Table 1. Successful resuscitation (ROSC or ECPR) was possible in 79.5% (ROSC-64.1% and ECPR-15.4%). In-hospital survival

Table.

Patient Demographics

Age	1.5 months (4 day-15 year)
Sex (Female)	24/39 (61.5%)
Weight (kg)	3.2 (2-88)
Unplanned Admission	20/39 (51.3%)
Night Shift (8pm-8am)	24/39 (61.5%)
Not Ventilated	5/39 (12.8%)
Difficult airway	3/39 (7.7%)
Surgery	24/39 (61.5%)
Risk adjusted congenital heart surgery score (RACHS) Category (n = 22)	
2	2 (9.1%)
3	11 (50.0%)
4	5 (22.7%)
6	4 (18.2%)
Systemic to PA shunt	10/39 (25.6%)
Preceding rhythm	
Bradycardia	30/39 (76.9%)
Ventricular Fibrillation/Tachycardia	6/39 (15.4%)
Paced-Complete Heart Block	2/39 (5.1%)
Junctional Ectopic Tachycardia	1/39 (2.6%)
Vasoactive Inotrope Score prior to event	8 (0-70)
Lactate prior to event (mmol/L)	7 (0.3-18)
Acute Kidney Injury- preceding	13/39 (33.3%)
Inhaled Nitric Oxide	9/39 (23.1%)

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

was 61.1% overall: 82% with ROSC and 50% requiring ECPR survived to hospital discharge. Survival was better in surgical compared to medical admissions (73.9% vs. 38.5%, p = 0.036). Approximately half of the CPR events occurred within 24 hours of PCICU admission. Comparing survivors to non-survivors, the duration of CPR (5.5 (0-45) minutes vs. 11(0-53) minutes, p = 0.15) and the occurrence of CPR at night (8 pm-8 am) (59.1% vs. 40.9%, p = 0.75) were not significantly different, respectively. Higher serum lactate and vasoactive-inotrope score (VIS) prior to CPR was associated with mortality. In surgical patients with CHD, all in-hospital deaths occurred in children with a systemic to PA (SPA) shunt.
Conclusion: We were able to identify patient factors in our unit associated with CPR events and poor outcomes: SPA shunts, higher VIS and lactate levels prior to CPR, and preceding end-organ dysfunction. Critical time periods: 24-48 hours post- surgery and after delayed sternal closure were also identified. A multi-disciplinary approach is being implemented to prevent need for CPR and improve outcomes after CPR based on these findings.

P1834 - THROMBOELASTOGRAPHY CAN PREDICT RISK OF BLEEDING IN PATIENTS ON EXTRACORPOREAL MEMBRANE OXYGENATION SUPPORT

Sirisha Emani[1], *Michelle Mulone*[1], *Viviane Nasr*[2], *Ravi Thiagarajan*[3], *Sitaram Emani*[1]
Boston Children, Cardiac Surgery, Boston-United States[1]; *Boston Children, Anesthesiology, Perioperative & Pain Medicine, Boston-United States*[2]; *Boston Children, Cardiology, Boston-United States*[3]

Background: Patients undergoing Extracorporeal Membrane Oxygenation (ECMO) are at high risk for complications of bleeding and thrombosis. Current methods of laboratory assessment of the coagulation system (PT/PTT, ACT) are imprecise and thereby complicate clinical decision-making. We hypothesize that assessment of physical properties of clot formation by thromboelastography (TEG) is more predictive of bleeding than PTT for patients on ECMO. In addition, thrombin –antithrombin (TAT) -complex, fibrinogen and plasminogen function coagulation tests maybe be useful in predicting bleeding in patients on ECMO.
Methods: In a prospective study at a single institution, TEG was performed in patients with congenital heart disease requiring ECMO support. Whole blood samples were collected 6-12hrs following ECMO initiation and daily for the duration of support. Platelet poor plasma was utilized for the functional and immunoassays. Bleeding during each 24hr period was defined as need for re-exploration and transfusion requirement. Associations between TEG parameters and bleeding over each 24hr period (bleeding vs. non-bleeding days) were assessed using logistic regression analysis.
Results: Twenty patients were enrolled, yielding a total of 116 patient-days of data for analysis. TEG MA, but not PTT, was associated with bleeding (p = 0.03 and p = 0.1 respectively). Fibrinogen levels were significantly lower in patients on bleeding days compared to non-bleeding days (320 mg/dl (IQR: 229-412) vs. 376 mg/dl (IQR: 306-510), p = 0.02). Abnormally elevated plasminogen function (>100%) and TAT levels (>10 micrograms/ml) were more frequently observed on bleeding days compared to non-bleeding days in patients on ECMO (Table 1).
Conclusions: In patients undergoing ECMO support, TEG MA and fibrinogen levels correlate better with bleeding than does PTT. Elevated TAT and plasminogen function suggests that hyperactive thrombin generation and fibrinolysis are present on bleeding days compared to non-bleeding days. TEG may be a useful diagnostic test in monitoring coagulation system in these patients.

Table 1. Abnormal coagulation markers comparing bleeding days verses Non-bleeding days in patients on ECMO.

Coagulation Markers	% Bleeding days	% Non-Bleeding days	p-value
Low TEG MA (<50 mm)	83	50	0.03*
Elevated PTT (>60 seconds)	65	47	0.1
Elevated Plasminogen Function (>100%)	27	10	0.04*
Elevated TAT- complex levels (>10 μg/ml)	86	65	0.02*

*p-value < 0.05 is considered significant.

P1869 - COARCTATION OF THE AORTA IN NEWBORN

Jihen Mathlouthi[1], *Houda Ajmi*[2], *Amina Wardeni*[1], *Hedia Ayech*[1], *Manel Bellaleh*[1], *Sonia Nouri*[1], *Nebiha Mahdhaoui*[1]
Farhat Hached Teaching Hospital, Neonatology, Susah-Tunisia[1]; *Sahloul Teaching Hospital, Pediatric, Susah-Tunisia*[2]

Background: Coarctation of the aorta represents 5-7% of all congenital heart diseases. Early, at best, prenatal diagnosis permits to improve prognosis. The objective of this study is to analyze epidemiological, clinical, therapeutic aspects as well as outcome of the constrictions of the aorta in neonatal period.
Methods: We conducted a descriptive study, enrolling all the patients with constriction of the aorta diagnosed and confirmed in prenatal or neonatal period, over 12 years, in the department of neonataology of Farhat Hached teaching hospital (Sousse).
Results: Twenty seven newborns had a constriction of the aorta representing 6.47% of congenital cardiac malformations with an incidence of 0.16% alive births. Diagnosis was suspected in prenatal period in only one case. Clinical features suggestive of a congenital heart disease were mainly circulatory insufficiency features or respiratory symptoms not explained by a pulmonary cause. Cardiac ultrasound allowed making the diagnosis of the constriction in 23 newborns. The preoperative mortality rate was of 35% and was in relation with the cardiac malformation in 71.4% of cases. Twenty neonates survived and underwent surgery. Post operative mortality rate was of 35% with a total mortality of 51.8%. The rate of coarctation relapse among survivors was 30.8%.
Conclusion: Prognosis of the constrictions of the aorta in neonatal period remains reserved in our department. It could be improved thanks to the progress of diagnostic and therapeutic means.

P1872 - PULSE OXIMETRY SCREENING FOR CRITICAL CONGENITAL HEART DISEASE IN NEWBORNS

Jihen Mathlouthi[1], *Houda Ajmi*[2], *Dhouha Zouari*[1], *Manel Bellalah*[1], *Hedia Ayech*[1], *Sonia Nouri*[1], *Nebiha Mahdhaoui*[1]
Farhat Hached Teaching Hospital, Neonatology, Susah-Tunisia[1]; *Sahloul Teaching Hospital, Pediatric, Susah-Tunisia*[2]

Introduction: Congenital heart disease (CHD) are the commonest type of congenital malformation, occurring in 6– 8 per 1000 live births. 25% of them are Critical (CCHD), needing surgery or other procedures in the first year of life. Screening is important; it provides significant opportunity to reduce infant mortality and morbidity. Considering that routine clinical examination and antenatal ultrasound still miss a significant proportion of cases. Based on the rationale that most newborn babies with CCHD have a degree of hypoxemia, the use of pulse oximetry to screen

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

asymptomatic babies for CCHD is Simple, painless, non-invasive. The aims of our study were to determine the CCHD's incidence, screened by pulse oximetry added to physical assessment and to compare it with the incidence evaluated before the introduction of this technique in the screening protocol.
Methods: Prospective screening study of all babies born in Susah's maternity hospital during 12 month (1er February 2014-31 January 2015).
Results: During the time of this study a total of 7992 live born were enrolled to the study. The incidence of CCHD were 3.25‰ (n = 26). This incidence is greater than that detected by the clinical assessment alone (p = 0.025). Screening was performed by pulse oximetry in 5 infant and by routine clinical examination in 21. Two infants have been positive POX screening without CCHD. They had pulmonary infection, so the specificity of this technique was 99.99% with positive predictive value 71.4%.
Conclusion: Pulse-oximetry screening offers an effective, accurate and reliable means for detecting CCHD in asymptomatic newborns. It should be used, added to clinical examination, in maternity hospitals as a screening method. Next step: multicenter study.

P1873 - SHORT AND LONG TERM OUTCOMES OF PRIMARY NEONATAL REPAIR FOR TETRALOGY OF FALLOT PULMONARY STENOSIS VS. PULMONARY ATRESIA

Martin Zahorec[1], Peter Skrak[1], Peter Olejnik[2], Zuzana Hrubsova[1], Lubica Kovacikova[1]
Pediatric Cardiac Centre, National Institute of Cardiovascular Diseases, Cardiac Intensive Care Unit, Bratislava-Slovakia[1]; Pediatric Cardiac Centre, National Institute of Cardiovascular Diseases, Department of Cardiology, Bratislava-Slovakia[2]

Background: The management of symptomatic neonates with tetralogy of Fallot and pulmonary stenosis (TOF/PS) or pulmonary atresia (TOF/PA) and well-developed native pulmonary arteries remains controversial. Since 1997, our institutional approach was to perform primary neonatal repair if the preoperative weight was over 2.5 kg. Right ventricular outflow tract (RVOT) was reconstructed without use of valved conduit except for cases of unfavourable coronary anatomy and complete absence of pulmonary artery trunk. We sought to determine short- and long-term results of this strategy and compared outcomes of TOF/PS and TOF/PA subgroups.
Methods: This is a retrospective review of 35 neonates undergoing primary repair at a single centre (1997-2016). Fourteen TOF/PS and 14 TOF/PA patients underwent transannular/transjunctional patch repair and 4 TOF/PS patients received valve-sparing RVOT reconstruction. In 2 neonates with TOF/PA and 1 TOF/PS, the primary conduit placement was needed.
Results: The median age at primary repair was 16 days for TOF/PS and 8.5 days for TOF/PA (p = 0.02). One patient with TOF/PS died early after surgery. Postoperative course was comparable for TOF/PS and TOF/PA subgroups according to duration of mechanical ventilation (96 vs. 111 hours; p = 0.86), maximum vasoactive-inotropic score (10 vs. 10.5; p = 0.27), incidence of junctional ectopic tachycardia (33.3% vs. 18.7%, p = 0.33) and hospital stay (19 vs.15 days; p = 0.72). One infant with TOF/PA died during follow-up. One third (33%) of patients underwent RVOT/pulmonary arteries reintervention during mean follow-up of 8.8 + /-6.2 years. Overall freedom from RVOT reintervention was 88.9% in TOF/PS and 64.3% in TOF/PA at 5 years and 79.0% in TOF/PS and 57.1% in TOF/PA at 10 years (p = 0.17).
Conclusions: Primary repair of TOF/PS and TOF/PA with present native pulmonary arteries can be safely accomplished without use of conduit placement in majority of normal weight neonates. Late reintervention rate is reasonable and tends to be higher for TOF/PA group.

P1876 - DUCTUS ARTERIOSUS IN PRETERM INFANTS DO WE REALLY NEED TO TREAT IT

Juan Pablo Miranda[1], Rodrigo Salas[2], Correa Patricia[2], Abraham Vallejos[2], Reyes Roberto[2]
Hospital Barros Luco/universidad De Chile, Neonatología, Santiago-Chile[1]; Hospital Barros Luco, Neonatología, Santiago-Chile[2]

Introduction: There is still controversy about the optimal treatment in management of the ductus arteriosus of the preterm infants.
Objective: to analyze the results of ductal closure in extreme preterm infants in a Neonatal Unit in a developing country.
Patients and Methods: Between December 2015 and December 2016, we had 104 patients younger than 32 weeks. All had an echocardiogram at 48-72 hrs. of life DAP > 3 mm, AI/Ao > 1.5, reverse diastolic flow in the descending Ao, estimated GC of VI > 300 ml/Kg / min.
Results: Of the 104 patients, only 48 had a PDA that fulfilled these criteria (46%). Of these 22 received pharmacological treatment (21%): 10 were treated with paracetamol (mean gestational age 26.6 wk, 24-29), 1 with ibuprofen (24 wk) and 11 with indomethacin (mean gestational age: 27.3 wk, 23-31), observing its closure by 90% cases. Only 2 patients of this group underwent surgical ductal closure (1,9%). The other 26 patients were followed until their spontaneous closure, considering that they did not use NSAIDs because there was an intercurrent infection, excess fluid supply or inadequate mechanical ventilation.
Conclusion: currently only a small percentage of patients require ductal pharmacological closure,even at extreme gestational ages, when they are individually selected and with specific echocardiographic criteria, reducing their cost of treatment and the potential complications of NSAID use.

P1887 - FREQUENCY AND OUTCOME OF ACUTE NEUROLOGIC COMPLICATIONS IN PATIENTS AFTER CONGENITAL HEART DISEASE SURGERY

Qalab Abbas, Sidra Kaleem, Anwar Ul Haque
Aga Khan University, Pediatrics and Child Health, Karachi-Pakistan

Objectives: To determine the frequency and immediate outcome of acute neurologic complications in children undergoing congenital heart surgery
Methods: This retrospective unmatched case control study was done at our 4 bedded pediatric cardiac intensive care unit. All patients from newborn upto 30 years who underwent congenital heart surgery from January 2010 to October 2016 and developed a neurologic complication (seizure, abnormal movements, altered sensorium, stroke) were included. Data collected included cardiac diagnosis, anatomical lesion, type of surgery, cardiopulmonary bypass time and aortic cross clamp time, GCS, neurophysiologic and radiologic investigations done and outcome. Data was entered and analyzed using SPSS v 20. Chi square test was used to determine the association of different factors associated with neurological problems. P value of <0.05 was taken as significant
Results: A total 35 patient's developed neurological complication during the study period (35/1300, 2.7%) for which 35 controls were chosen based on similar time of admission. Both the group were similar in age (Median age 18 and 21 months for cases and

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

controls), gender (males were 25 and 22 in cases and controls), cyanotic congenital heart disease (n = 23 and 24 in cases and controls), 12 had single ventricle physiology, and 29 patients surgery was done on cardiopulmonary bypass machine in cases and 30 in controls. 28 patients developed seizures postoperatively, 5 had altered sensorium and 2 patients developed stroke while 6 of these developed brain death and expired and 5 others had poor Glasgow coma outcome scale. Cardiopulmonary resuscitation, prolonged aortic cross clamp time were significantly ($p < 0.05$) associated with development of neurological complications.
Conclusion: Neurological morbidities after congenital heart surgery are uncommon but significant contributor to morbidity of these patients.

P1891 - SYSTEMATIC REVIEW AND META ANALYSIS ON MANAGEMENT OF PEDIATRIC STROKE

Juliana Pacheco[1], Simon Wizer[2], Jessica Barlinn[2], Heinz Reichmann[2], Volker Puetz[2], Timo Siepmann[2], Kristian Barlinn[2]
Dresden International University, Division of Health Care Sciences, Dresden-Germany[1]; Carl Gustav Carus University Hospital, Technische Universität Dresden, Department of Neurology, Dresden-Germany[2]

Although acute ischemic stroke (AIS) in children is rare, the disease poses a significant clinical problem due to its potentially devastating consequences and its complex pathophysiology. While treatment in adults is well established, evidence in children is limited to date. We reviewed the current literature and synthesized data on safety and efficacy of intravenous thrombolysis (IVT) and endovascular therapy (EVT) in pediatric AIS. We performed a systematic review and meta-analysis of all available case series and observational studies that evaluated safety of IVT and EVT in stroke patients aged <18 years, since there were not enough papers to be included only with children with congenital heart disease. We searched Medline/PubMed, Cochrane Library, Google Scholar for eligible studies. Safety outcomes included any intracerebral hemorrhage post-treatment and in-hospital mortality. A random-effects model was used to compute pooled effect estimates and the I2 statistic was used to assess heterogeneity. Our analysis complied with PRISMA statement. We identified 152 records, of which only 3 studies with a total of 16,335 pediatric patients with AIS met our eligibility criteria. Of these studies, two explored safety of sole IVT and one combinatory IVT/EVT. In-hospital mortality rates were similar between pediatric stroke patients treated with either IVT or IVT/EVT and controls (odds ratio = 0.85, 95% CI: 0.15-4.87; $p = 0.857$), with moderate evidence of heterogeneity (I2 = 64%). Risk of intracerebral hemorrhage was substantially increased in IVT (odds ratio = 3.60, 95% CI: 1.66-7.80; $p = 0.001$) compared with controls, with no evidence of heterogeneity (I2 = 0%). Efficacy of revascularization therapies could not be analyzed due to lack of uniform outcome data in the included studies. We revealed a substantial lack of evidence for acute revascularization treatment of pediatric AIS. While an increased risk of intracerebral hemorrhage related to IVT emerged in our analysis, further research is needed to elaborate these findings and identify the optimal treatment regimen for pediatric stroke.

P1905 - ECMO IN POST HEART SURGERY PEDIATRIC PATIENTS.A CASE REPORT.CHRISTUS MUGUERZA HOSPITAL MONTERREY N.L

María Verónica Contreras Cepeda, Rene Gómez Gutiérrez, Gerardo Vargas Camacho, Francisco González, Guillermo Quezada Valenzuela
Christus Muguerza Hospital, Ecmo, Monterrey-Mexico

Introduction: Extracorporeal Membrane Oxigenation (ECMO) is a life support procedure where cardiopulmonary function is substituted by a machine. ECMO is indicated in case of serious respiratory insufficiency, or cardio respiratory insufficiency without response to current treatment. Since 1980's, ECMO has been a therapeutic alternative in third level hospitals in America and Europe, but it hasn't been used in Mexico. In 2013 Neonatal ECMO Program was initiated in Christus Muguerza Hospital in Monterrey Mexico. Results are described.
Materials and Method: This is an statistical, retrospective, observational, and analytical study. ICU Patient's clinical files in Christus Muguerza Hospital Monterrey were analyzed since January 2013 up to date. Cardiac surgery immediate post operatory patients under ECMO were included. Patient's incomplete files were excluded. Data were collected in an Excel Database and were analyzed using SPSS Statistics Program.
Results: Most of the patients who entered into ICU were newborn (54.5%); most of them were male. The ICU admission diagnose was low cardiac load, with or without lung failure. The most common causes of cardiopathy were Great Vessels Transposition (GVT) and Tetralogy of Fallot (TOF). Co morbidity before ECMO was variable, and Dimorphic Syndromes were frequent, except in 3 patients who didn't have any co morbidity. The most common complications were acidosis, bleeding and infection. Respiratory acidosis was the most frequent. Pneumonia and sepsis were the most frequent type of infections. The current treatment was integrated by antibiotics (Meropenem), amines (Milrinone), anticoagulants (Heparine), and blood products.

P1906 - ECMO POSTCARDIOTOMY IN A NEWBORN WITH COMPLEX CONGENITAL CARDIAC DISEASE FIRST SUCCESSFUL CASE IN MEXICO AND NEUROLOGICAL OUTCOME AT 18 MONTHS

María Verónica Contreras Cepeda[1], Adriana Nieto Sanjuanero[1], Bárbara Cardenas Del Castillo[1], Rene Gómez Gutiérrez[1], Guillermo Quezada Valenzuela[1], Victor Quezada Elvira[1], Adrián Abrego Ambía[1], Arturo Saldivar[1], Jaime García[2], Teresa Medina[2]
Christus Muguerza Hospital, Ecmo, Monterrey-Mexico[1]; Christus Muguerza Hospital, IMSS, Monterrey-Mexico[2]

Introduction: Extracorporeal Membrane Oxygenation (ECMO) is a life support therapy that temporarily replaces cardiopulmonary function.
Clinical Case: Male neonate, 37 weeks, 2770 gr, Apgar 8-8, cyanosis at birth. Echocardiogram/Angio-CT: Taussig-Bing anomaly with Severe Aortic Arch Hypoplasia, large PCA and LV outflow tract obstruction by myxomatous mass in the mitral valve. On the 7th day of life, they performed corrective surgery, with a score of 4 in RACHS-1 Scale, performing aortic arch repair, IV closure, Jatenne type arterial swich, myxoma resection and IA closure with extracorporeal circulation time (CEC) 392 Minutes, Aortic Time-Clamping 198 minutes, Selective Time-Brain Perfusion 24 minutes, Temperature 25oC. In the attempt to exit extracorporeal circulation (ECC) presented complete AV block and severe ventricular dysfunction, started ECMO VA support with central cannulation providing ECMO pump flow 100 ml/kg/hour with immediate recovery of blood pressure and systemic perfusion. The thorax was covered with plastic and transported in ECMO to the NICU. Twenty-four hours post-ECMO-VA , the patient regain pulsatility and sinus rhythm with normal lactate values. Anticoagulation with UF heparin to maintain anti Xa levels 0.2 to 0.5 UI/mL., At 3rd day on ECMO support with 60% LVEF, weaning from ECMO-VA was successfully done. Hospital stay 22 days, follow-up by multidisciplinary team without complications after

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

discharge. At 18 months a Bayley III Development Scale was made with a score by areas: Cognitive 95, Language 106 and Motor 107.
Discussion: ECMO-VA is a valuable therapy in postoperative patients with complex congenital heart disease with prolonged CPB and failure to exit ECC.
Conclusions: ECMO programs in Congenital Heart Surgery Centers are necessary in Mexico , they increase survival. It is important to perform long-term neurological follow-up.

P1922 - USING SOCIAL MEDIA TO OBTAIN PARENTAL FEEDBACK ON COMPLICATIONS ASSOCIATED WITH PAEDIATRIC CARDIAC SURGERY A QUALITATIVE ANALYSIS OF DATA FROM A CHARITY MODERATED ONLINE FORUM

Veena Rajagopal[1], Katherine Brown[1], Christina Pagel[2], Jo Wray[1]
Great Ormond Street Hospital, Cardiac Unit, London-United Kingdom[1]; Univeristy College London, Clinical Operational Research Unit, London-United Kingdom[2]

Background: As mortality rates fall it becomes increasingly important to focus on morbidity associated with paediatric cardiac surgery, including how information about morbidity is communicated to parents. Our aim was to elicit parents' understanding and experience of complications following their child's cardiac surgery, using an online forum as a means of accessing viewpoints that may be missed in alternative data collection methods.
Methods: The Children's Heart Foundation (a national parent charity accessed by families at all UK paediatric cardiac centres) set up and moderated a closed, anonymous online discussion group via their Facebook page, which focused on complications, information needs and methods of providing families with information. The forum transcript was thematically analysed by the research team.
Results: The forum ran over 3 months and involved 72 participants (68 mothers, 1 father, 1 patient, 2 grandmothers; age range 15-59 years). Several themes were identified:

- Language used by clinicians about complications of surgery may be poorly understood by families.
- There can be a lack of consistency in how we explain complications.
- Parents often felt unprepared for complications when they arose.
- There is no 'right amount of information' that suits every family.
- Written and audio-visual material about surgery and expected complications, as well as access to a liaison staff member, would be helpful aids.

Conclusions: Our language is often misunderstood. There is wide variability in the way we describe complications, much of which is not absorbed or retained. Adjuncts and availability of a liaison staff member may help understanding and preparation for surgery, intensive care and beyond. The nature of the online forum promoted free debate and sharing of views, providing rich data that may not have been elicited in face to face groups or interviews. These data have helped us identify and understand areas for improvement.

P1926 - ASSOCIATION BETWEEN RACE AND ILLNESS SEVERITY IN CHILDREN UNDERGOING CARDIAC SURGERY

Yuen Lie Tjoeng[1], Titus Chan[2]
Seattle Children, Critical Care Medicine, Seattle-United States[1]; Seattle Children, Critical Care Medicine/Heart Center, Seattle-United States[2]

Background/Hypothesis: Prior studies have demonstrated that non-white race/ethnicity and insurance status are associated with mortality after congenital heart surgery. We hypothesize that non-white children undergoing congenital heart surgery have higher severity of illness and, in turn, have higher mortality and ICU lengths of stay than their white counterparts.
Materials and Methods: We performed a retrospective analysis of registry data from the Virtual Pediatric Systems dataset from 2009-2016. All children (less than 18 years of age) undergoing cardiac surgery and admitted to an ICU in one of the 82 participating institutions were included (n = 30, 814).
Results: In a univariate analysis, there was significant variation in severity of illness scores across race/ethnicity groups with black, Hispanic and other race/ethnicity patients having higher severity of illness scores than white patients. However, multivariate regression models did not demonstrate an association between race/ethnicity and severity of illness scores, after adjustment for insurance status and other covariates. In multivariate models that examined ICU mortality, black patients remained at increased odds of mortality (Odds Ratio: 1.38, 95% Confidence Interval: 1.09-1.75) when compared to white children, adjusting for illness severity, insurance, gender, complexity of cardiac surgery, weight, and age. In a multivariate regression model for ICU length of stay, black children (Estimate: 0.87, 95% Confidence Interval: 0.08-1.65) and children on government insurance (Estimate: 1.30, 95% Confidence Interval: 0.34-2.25) experienced longer lengths of stay when compared to white patients and patients with private insurance.
Conclusions: Black children undergoing cardiac surgery have higher odds of death compared to white children, despite adjustment for illness severity on admission to the ICU. These results suggest that severity of illness may not be the main driver of health disparities in children undergoing congenital heart surgery.

P1989 - LUNG ULTRASOUND (LUS) TO ASSESS PERSISTENT PULMONARY HYPERTENSION OF THE NEWBORN (PPHN) ETIOLOGY

Beatriz Del Rey Hurtado De Mendoza[1], Javier Rodiguez-fanjul[2], Julio Moreno Hernando[2], Joan Sánchez De Toledo[3]
Bcnatal. Hospital Sant Joan De Déu-hospital Clinic. University Of Barcelona, Neonatology Department, Barcelona-Spain[1]; Bcnatal. Hospital Sant Joan De Déu-hospital Clinic. University Of Barcelona, Neonatology Deparment, Barcelona-Spain[2]; Hospital Sant Joan De Déu-hospital Clinic. University Of Barcelona, Cardiology Deparment, Barcelona-Spain[3]

Background: PPHN is defined by the failure of post-natal reduction in pulmonary vascular resistance with significant morbidity and mortality associated. Patients may require Extracorporeal Membrane Oxygenation therapy (ECMO) although not having a causal diagnosis. LUS has proved to be extremely useful to diagnose pulmonary diseases. The aim of this study was to explore LUS pattern in newborns with PPHN requiring ECMO. We hypothesized that patients with a normal LUS had a non lung parenchimal disease and that LUS was as useful as CXR to reach the causal diagnosis.
Materials and Methods: This is a prospective study of LUS to assess PPHN etiology in patients admitted for ECMO, with patients recruited from 2014 to 2016 at Hospital Sant Joan de Déu at the NICU. LUS was performed by a neonatologist blinded to the perinatal history before the patient was placed in ECMO, scanning four lung areas in each hemithorax;

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

afterwards they were compared with CXR diagnosis. PPHN final diagnosis was made based on the patient's medical history, and complementary tests, without the information provided by LUS.
Results: Fifteen patients were recruited. Ten were male (66.7%) and the median gestational age was 38.3 weeks, with eleven term newborns (80%). Twelve were under veno arterial ECMO treatment and the median ECMO run was 122.7 hours. Eight survived (53.3%). LUS and CXR reached the same diagnosis in 26.6% cases. Patient with a normal LUS (A-lines) had a non lung parenchymal disease in 89% (3 Alveolar Capillary Displasia, 3 sepsis, 2 premature clousure of PDA). Comparing with the definitive diagnosis, LUS stablished the correct one in 93% cases, while CXR did in 46.6%.
Conclusions: LUS can provide additional information that helps to reach the causal diagnosis of PPHN in an early and more effective way compared to CXR being suitable for routine application in the NICU.

P1992 - SPONTANEOUS THROMBOSIS OF GREAT VESSELS IN NEONATES WITH VARIED PRESENTATION

Sudeep Verma[1], Gouthami V[1], Nagarajan R[1], Atul Bonde[2]
Kims Hospital, Department of Paediatric Cardiac Sciences, Hyderabad-India[1]; Kims Hospital, Department or Paediatrics, Secunderabad-India[2]

Spontaneous thrombosis of great vessels is well described entity even in absence of known risk factors of sepsis, polycythemia, dehydration or thrombophilic disorders. We are sharing our experience with three neonates having unstable haaemodynamics subsequently diagnosed to have large thrombus in aorta and main pulmonary artery (MPA). Two neonates were successfully treated thrombolytic therapy while one patient succumbed due to renal failure.
Description:
Case 1: Full term neonate presented on day two of life with respiratory distress and bluish discolouration of lower limb with working diagnosis of coarctation of aorta in view of radio femoral delay and unrecordable BP in lower limb. Subsequently diagnosed to have infrarenal aortic thrombus. Successfully treated with Urokinase infusion for 72 hours followed by 4 weeks of subcutaneous low molecular weight heparin (LMWH) injections with full re-canalisation of aorta on follow up.
Case 2: One day old term baby referred for onset of breathlessness from birth. Features of right heart failure was present with low saturation of 90%. Echocardiogram revealed large thrombus in MPA extending to right and left pulmonary artery. Successfully Treated with unfractionated heparin infusion for 96 hours followed by LMWH injection for 2 weeks with complete resolution of thrombus.
Case 3: 3 days old born to diabetic mother presented in shock with history of poor oral acceptance, breathing difficulty and anuria from last 24 hours. Echocardiographic evaluation revealed biventricular dysfunction and large ductal aneurysm with thrombus insitu extending into aorta and blocking bilateral renal arteries. Baby died within one hour of admission.
Conclusion: Spontaneous thrombus involving great vessels can present with varied clinical pictures ranging from renal failure, shock, right heart failure or coarctation. High index of suspicion and basic interrogation with echocardiogram is crucial in diagnosing such conditions. Thrombolytic therapy is possible with good results even in neonates with fragile haemodynamics.

P2013 - LONGITUDINAL CHANGES IN NEAR INFRARED SPECTROSCOPY DURING THE PERI OPERATIVE PERIOD IN CHILDREN UNDERGOING FULL CORRECTION OF CYANOTIC HEART DISEASE

Judith Ju-Ming Wong[1], Rajesh Babu Moorakonda[2], Ching Kit Chen[3], Masakasu Nakao[4], Tracy Yi Shuen Tan[5], Olivia Wijeweera[5], Tsee Foong Loh[6], John Allen Jr Carson[7], Jan Hau Lee[6]
KK Women, Pediatrics, Singapore-Singapore[1]; Singapore Clinical Research Institute, Quantitative Medicine, -Singapore[2]; KK Women, Cardiology, -Singapore[3]; KK Women, Cardiothoracic Surgery, -Singapore[4]; Kk Women, Pediatric Anesthesia, -Singapore[5]; KK Women, Children, -Singapore[6]; Duke-Nus Graduate Medical School, Quantitative Medicine, -Singapore[7]

Background: Changes in tissue oxygenation (rSO2) as measured by near infrared spectroscopy (NIRS) longitudinally after corrective surgery in children with cyanotic congenital heart disease (CHD) have not been previously described. We hypothesized that improvements in rSO2 occur over time as opposed to immediate

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

improvement in arterial oxygen saturations as measured by pulse oximetry (SpO2). We aimed to describe the rSO2 trend before, during and after surgery in children with cyanotic CHD.

Methods: This is a prospective cohort study of children with cyanotic CHD who underwent corrective surgery. Continuous cerebral and somatic NIRS measurements were taken pre-, intra, and post-operatively for 48 hours and before hospital discharge. The Wilcoxon rank-sum test was used to compare medians of rSO2 before and after surgery, and at hospital discharge. NIRS sensors were supplied by Medtronic.

Results: Fifteen consecutive patients were recruited (Table 1). The most common lesion in our cohort was Tetralogy of Fallot in 7/15 (47%) patients. Overall mortality was 1/15 (7%). Post-operative increases in SpO2 were immediate following corrective surgery and remained in the normal range through hospital discharge (Table 2). Following corrective surgery, median post-op somatic rSO2 (%) was 80.4 compared to pre-op 74.3 ($p = 0.004$); median post-op cerebral rSO2 was 68.7 compared to pre-op 63.7 ($p = 0.636$). Median discharge levels for both somatic and cerebral rSO2 fell below pre-surgery levels: median cerebral rSO2 pre-op was 63.7 vs 60.5 at discharge ($p = 0.101$), and median somatic rSO2 was 74.3 pre-op vs 66.9 at discharge ($p = 0.064$), although differences were not statistically significant for either.

Conclusion: This pilot study observed a lack of improvement from pre-surgery levels in rSO2 following corrective surgery and suggests that targeting higher than baseline rSO2 values after surgery may not be physiological. Further studies are required to validate our findings showing lack of improvement in rSO2 after corrective surgery in children with cyanotic CHD.

P2044 - SEVERE SEPTIC SHOCK SUCCESSFULLY MANAGED WITH ECMO IN A CHILD WITH HEMATOLOGIC MALIGNANCY

Hwa Jin Cho[1], Jihee Kwak[2], Hee Jo Baek[3], In Seok Jeong[4]
Chonnam National University Hospital, Department of Pediatrics, Gwangju-Korea, South[1]; Seonam University, Myoungji Hospital, Department of Pediatrics, Gwangju-Korea, South[2]; Chonnam National University Hospiral, Department of Pediatrics, Gwangju-Korea, South[3]; Chonnam National University Hospiral, Department of Thoracic and Cardiovascular Surgery, Gwangju-Korea, South[4]

This is a case of a 2 year-old male who was diagnosed of AML, M5 at his age of 11 months. He presented with leukocytosis and bicytopenia with atypical cells of inderminate nature about 72%. Fluorescence in situ hybridization revealed negative for MLL gene rearrangement with t(9:11)(p22:q23) on karyotypic analysis at the time of diagnosis. Under diagnosis of acute myelocytic leukemia (AML) M5, chemotherapy was started with AML 2012 protocol and achieved the complete remission (CR). However, CNS relapse occurred and at age of 16 months, unrelated peripheral blood stem cell transplantation (uPBSCT) was performed. At age of 21 months and 2 months ago, he had his 3rd relapse of AML and he underwent 2nd AML 2012 protocol of chemotherapy which also achieved complete remission. However, he had diarrhea continuously after the chemotherapy, perineal skin infection was appeared which was aggravated to abscess with necrosis of the skin and he underwent surgical debriment of the abscess. Two days after the debridment of the necrotic tissue, acute respiratory failure with hypotension developed. He underwent venoarterial extracorporeal membrane oxygenation to manage the septic shock with acute respiratory distress syndrome. After 8 days of ECMO support, he could wean off the ECMO and extubated next day. He completely recovered from septic shock and ARDS and he was discharged home after 3 months when his skin defect was completely recovered. For follow up of 5 months, he is under good condition with sustaining CR. Our case, a child with relapsed AML, previous uPBSCT with acute septic shock and acute respiratory failure, can also have many controversies, but physicians and statistics cannot always predict the outcomes of severely ill children with malignancy. ECMO should be considered in case-by-case.

P2046 - ECHOCARDIOGRAPHY IN PERSISTENT PULMONARY HYPERTENSION OF THE NEWBORN MANAGEMENT

Zoe Vetten[1], Dianne Bruce[1], Fiona Bailey[1], Luke Eckersley[1], Corrado Minutillo[2], James Ramsay[1]
Princess Margaret Hospital for Children, Cardiology, Subiaco-Australia[1]; Princess Margaret Hospital for Children, Neonatal Intensive Care, Subiaco-Australia[2]

Background: Persistent Pulmonary Hypertension of the Newborn (PPHN) is a common neonatal problem with significant morbidity and mortality. Echocardiography is used to rule out cyanotic congenital heart disease (CHD) and to measure pulmonary vascular resistance, cardiac function and intra-cardiac shunts. The aim of this audit was to assess the management and outcomes of PPHN

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

in a tertiary neonatal intensive care unit (NICU) to then develop a standard echocardiography protocol.
Materials and Methods: A retrospective chart review was conducted January 2010 - December 2015. All patients admitted to the NICU at a tertiary paediatric hospital in Perth, Australia, and requiring inhaled nitric oxide (iNO) were eligible for inclusion. Exclusion criteria included birth gestation <32 weeks and age >5 days on iNO commencement. Clinical information including cause for PPHN; ventilation type and duration; oxygenation index prior to iNO; duration of iNO; use of inotropes, Prostaglandin-E1, or Extracorporeal Membrane Oxygenation (ECMO); and mortality were recorded. The timing of the initial echocardiogram was reviewed, along with the number of subsequent studies.
Results: A total of 104 neonates were eligible for inclusion. Patient information is listed in Table 1. Full echocardiographic assessment was performed in 95/104 (91.3%), with 40/95 (42.1%) prior to iNO commencement. It was hypothesised that patients with expedient iNO commencement had severe PPHN, yet no significant difference between groups was identified (Table 2). Follow-up echocardiography was performed in 37/104 (35.6%) patients.
Conclusions: Over 90% of our cohort were assessed with echocardiography during PPHN management. Less than half of the cohort had an echo prior to iNO commencement, and only one third had a follow-up echo. Collaboration with the NICU is required to ensure a comprehensive echocardiogram is performed in hypoxic patients prior to iNO to rule out CHD. Subsequent echo assessment may be targeted to assess response to therapy.

Table 1. Clinical features and outcomes.

Median Gestational Age	38 + 6
Median Birth Weight	3260 g
Diagnoses	Meconium aspiration n = 36 Hyaline Membrane Disease n = 24 Hypoxic Ischaemic Encephalopathy n = 16
Mean ventilation hours	147 (range 7-622)
High frequency oscillation ventilation	46 (44.2%)
Oxygenation index >20	36 (34.6%)
Mean iNO hours	82 (range 1-289)
Inotropic agents	72 (69.2%)
Prostaglandin-E1	24 (23.1%)
ECMO	7 (6.7%)
Death	13 (12.5%)

Table 2. Clinical features and outcomes based on timing of echocardiogram.

	Echocardiogram pre-iNO (n = 40)	Echocardiogram post-iNO (n = 55)	p value
Mean ventilation hours	179 (range 29-579)	128 (range 7-622)	0.647

Death	3 (7.5%)	10 (18.2%)	0.2258

P2061 - TITLE SUDDEN CARDIAC DEATH IN CHILDREN UNDER 14 YEARS OF AGE IN OUR ZONE

Miren Eizmendi[1], Erika Rezola[1], Jon Igartua[2], Miren Alicia Apilanez[3], Maria Angeles Izquierdo[1]
Donostia University Hospital, Children´s Cardiology Unit, Donostia-Spain[1]; Donostia Universitiy Hospital, Pediatric Intensive Care, Donostia-Spain[2]; Donostia University Hospital, Neonatal Intensive Care, Donostia-Spain[3]

Matherial and Methods: We performed a retrospective study, collecting clinical and autopsy information on SCD cases with cardiac cause among children 0 to 14 years of age in Gipuzkoa (Spain) from 2005 through 2016. When no previous cardiac cause justifying cardiac death was known, autopsy and genetic testing was offered to relatives.
Results: 16 cases of SCD with cardiac cause were identified. The anual incidence was 1,1 cases per 100000 persons 1 to 14 years of age. 63% of the cases involved men. Median age of cardiac death event was 5,9 months (inter-quart rank of 58,3 months). The most common explained causes of cardiac sudden death were primary pulmonary hypertension in syndromic patients (3 cases; 18,7%), coronary artery anomalies (2 cases; 12,5%), long QT syndrome (2 cases; 12,5%), acute myocarditis (2 cases; 12,5%), bacterial endocarditis (1 case; 6,3%), ventricular fibrillation (1 case; 6,3%) and irreparable structural congenital heart disease (5 cases 31,3%; 2 term newbors: 1 with hypoplastic pulmonary veins and 1 massive systemic-to-pulmonary venous fistulae; and 3 extremely preterm infants: 1 abnormal pulmonary venous return, 1 aortic coarctation and 1 critical pulmonary stenosis). 10 cases (62,5%) had previous diagnosis of primary cardiac anomalies, 3 cases (18,7%) had autopsy findings of acquired cardiac anomalies and 3 cases (18,7%) were diagnosed after successful cardiopulmonary resuscitation (CPR) by cardiological studies and/or genetic testing. 3 cases (18,7%) recovered from SCD after resuscitation with no significant sequel. 7 cases (43,8%) were outpatient SCD, 5 of them (71,4%) were witnessed and received advanced CPR, but only 2 (28,6%) of them reverted (60% death risk even with early CPR onset (95% Confidence Interval: 0,29-1,23).
Conclusion: Autopsy and genetic investigation increases SCD cause identification. Witnessed SCD and early CPR is the key to its recovery.

P2082 - FETAL VERSUS POSTNATAL DIAGNOSIS OF INTERRUPTED AORTIC ARCH AND ITS IMPACT IN SHORT AND LONG TERM OUTCOMES

Guillermo Larios[1], Maria Jose Soto[2], Shi-Joon Yoo[1], Edgar Jaeggi[1], Varsha Thakur[1]
The Hospital for Sick Children, Division of Cardiology, Toronto-Canada[1]; The Hospital for Sick Children, Division of Critical Care, Toronto-Canada[2]

Background: Prenatal diagnosis of interrupted aortic arch (IAA) allows for comprehensive fetal and genetic counseling, but the impact on post-natal outcomes remains unknown. Our study aims to evaluate the impact of fetal (FD) versus post-natal (PND) diagnosis of IAA on pre and post-surgical outcomes.
Methods: A retrospective review of confirmed IAA patients, from 2004 to 2016 was performed. Patients with a lethal genetic disorder (i.e.: trisomy 13,18), severe extra-cardiac malformations, pre-term <34 weeks, birth weight less than 2.5 kg and patients to receive compassionate care were excluded. Patients were grouped as FD or PND based on timing of the initial suspicion of a

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

prostaglandin (PGE) dependent lesion. Patients were also grouped according to the presence of usual (i.e.: VSD) versus complex associated lesions (CAL; i.e.: truncus arteriosus) and if genetic disorders (GD) were present. Pre and post-surgery clinical data and long-term arch geometry were documented. Survival and outcome analysis were performed.

Results: Twenty-one fetal and 39 postnatal infants with IAA were analyzed. There were similar distributions of gender, gestational age at birth and IAA type in both groups (Table). There was a decreased frequency of 22q11 microdeletion in FD 9.5% vs PND 48.7%, p = 0.004. Fetal group was associated with more complex lesions (CAL: FD 57.1% vs PND 17.9%, p = 0.003). The FD group needed lower doses of PGE, shorter time of mechanical ventilation and ICU/hospital stay prior to surgical repair. Surgery occurred earlier in the FD group (FD at 3 (range 2-6) days, PND 7 (3-77) days, p = 0.001). There were no differences in post-operative mortality, hemodynamic or respiratory support or long-term arch geometry. Similar findings were observed after adjusting for the presence of GD or CAL.

Conclusions: Fetal diagnosis of IAA improves the pre-surgical outcomes; however has no impact on post-operative outcomes or on long-term aortic arch geometry.

Table 1. Demographic, clinical, pre-surgical, surgical, post-operative and long term data according to fetal or post-natal diagnosis of PGE dependent lesion. Data presented as: Mean ± standard deviation, median (range) or n (%) as appropriate.

P2086 - EFFECTIVENESS OF A PROGRAM TO REDUCE SURGICAL SITE INFECTION IN CONGENITAL HEART SURGERY IN A REFERAL PEDIATRIC HOSPITAL IN ARGENTINA

Norma Aquino[1], Maria Balestrini[2], Elena Andion[1], Ricardo Magliola[2], M Rodriguez[3], Miriam Lenz[2], Cristina Herrera[2]
Garrahan Hospital, Infectology, Capital Federal-Argentina[1]; Garrahan Hospital, Pcicu, Capitalfederal-Argentina[2]; Garahan Hospital, Infectology, Capital Federal-Argentina[3]

Introduction: Surgical site infections (SSI) in congenital heart surgery are an important cause of morbidity and mortality, and use of hospital resources. In the context of an increasing SSI rate we developed an intervention program to reduce SSI.
Objective: Describe the results of a multidimensional intervention program to reduce SSI in a congenital heart surgery program.
Setting: operating room and pediatric cardiac intensive care unit at Hospital de Pediatria "J.P. Garrahan" Intervention: Professional supervision of preoperative bath with 4% chlorhexidine soap, incorporation of 2% alcoholic chlorhexidine for skin antisepsis, educational workshops, and an infection control nurse present in the operating room area.
Patients and Methods: all patients undergoing cardiac surgery performed between 1/1/2015 to 12/31/2016 were included. SSI rates pre and post intervention were compared. A subgroup analysis was performed in patients with delayed sternal closure (STATA 9.0).
Results: 1145 surgeries were performed, 14% with delayed sternal closure. Adequate preoperative antibiotic prophylaxis was confirmed in at least 881 patients (77%). 58 infections were observed (5.06%), 60% superficial, and 40% deep/mediastinitis. Bacterial isolation was 64% gram + cocci, 21% gram -, and 16% enterobacteriaceae. After intervention we observed a reduction in the infection rate from 4.1% to 2.41% with RR 1.25 (95% CI 0.97-1.62, p 0.13) in patients with primary sternal closure. This reduction was observed for both superficial 16 (76.2%) vs 9 (81.8%) and deep infections 5 (23.8%) vs 2 (18.1%). In patients with delayed chest closure no SSI reduction was found 13.7% vs. 14.1%.
Conclusion: The program was useful, a reduction in the SSI rate was observed in patients with primary chest closure. Infection rate remained high in children with delayed sternal closure. The program and epidemiological surveillance should be continued to improve the quality of care for children undergoing cardiovascular surgery.

P2089 - WEBINARS' BASED COURSE IN PEDIATRIC CARDIAC INTENSIVE CARE UNIT A STRATEGY TO IMPROVE NURSES' CONTINUOUS EDUCATION

Raquel Quiroz[1], Barbara Cordisco[2], Eva Martinez[1], Maria Althabe[1], Maria Balestrini[1], Ricardo Magliola[1]
Garrahan Hospital, Pcicu, Capital Federal-Argentina[1]; Garahan Hospital, Pcicu, Capital Federal-Argentina[2]

Introduction: Quality Improvement Collaborative for Congenital Heart Surgery (IQIC) webinars are a valuable educational resource for staff involved in the care of patients with congenital heart disease. However in our environment there are barriers to optimum utilization. To promote continuous education we designed a virtual course for pediatric cardiac intensive care unit (PCICU) nurses.
Objective: to describe a continuous training course for the PCICU nursing staff.
Setting: Garrahan Pediatric Hospital. Buenos Aires. Argentina
Material and Methods: With IQIC authorization a continuous virtual training course was designed for the PCICU staff. This course was mandatory for new nurses, optional for rest of the staff and grants credits for institutional professional promotion. 10 translated webinars were selected considering staff training priorities, complemented with additional audiovisual material and suggested readings, 4 workshops and 3 in situ simulation scenarios. Partial assessments and final examination was required for approval. A satisfaction survey was completed at the end of the course.
Results: Fifty nurses (56% of the total staff) were enrolled: 80% with master degreeand 20% registered nurses. Most of them (60%) with more than 10 years working in the CICU, while 20% were recently hired. 48 nurses (96%) completed the course and approved exams. Satisfaction survey analysis showed 10% very satisfied, 80%satisfied, and only 10% unsatisfied.
Conclusions: The course was very successful, more than half of PCICU nursing staff enrolled, complete and approved the course. Ninety percent were satisfied or very satisfied with it. This new training tools are very useful in professional continuous education in our unit.

P2105 - NEONATAL DEATH ARISING FROM CONGENITAL HEART DISEASE IN A TERTIARY NICU

Ana Morillo[1], Jordi Clotet[1], Julio Moreno[1], Freddy Prada[2], María José Troyano[1], Ana Ropero[1], Ana Riverola[1]
Hospital Sant Joan De Deu, Nicu, Barcelona-Spain[1]; Hospital Sant Joan De Deu, Cardiology, Barcelona-Spain[2]

Introduction: Congenital heart disease (CHD) is responsible for more deaths in the first year than any other birth defects. The causes and circumstances of neonatal death have barely been studied in these patients.
Aim: To examine causes and manner of death, and characteristics of the dying process in patients with CHD, in our NICU.
Method: observational retrospective study. Study group: deceased patients with CHD from January 2009-December 2016. Medical histories were checked and epidemiological and characteristics of the dying process were registered.
Results: During the period of study there were 5331 admissions (716 patients with CHD) and 283 deceased patients. 61/283 (21.5%) of deceased patients had a CHD. Average gestational age in CHD was 37.4w, weight 2700 g, 52.4% were males. 31.1% were outside admissions. Age at the moment of death: 18.5 days. Causes of death : 1) somatic poor prognosis (not candidate for surgery)(21/61), 2) a context of multiple malformation syndrome and/or chromosome abnormalities (20/61) and 3) complications related to surgery (18/61). Some types of CHD: 20 SCIH or obstruction of the left heart outflow tract, 6 complex TGV, 2 total APVR, 6 complex CHD (right and left side affected). Treatment limitation (TL) was settled in 37/61(60.7)% and in 83% of the patients with CHD associated to multiple malformation syndromes and/or chromosome abnormalities . Types of TL: withdrawing life-support (73% of cases and withholding new treatments: 27%. All the patients that died after TL were accompanied by their parents. Autopsy was granted in 52.5%.
Conclusions: The most significant groups of newborns with CHD who die during admission to NICU are those that have a poor somatic prognosis and those that link multiple malformation syndromes and/or chromosome abnormalities. The majority die after TL, predominantly after life support is withdrawn.

P2106 - PROMOTING COLLABORATION BETWEEN NURSES AND PHYSICIANS IN PAEDIATRIC CARDIAC INTENSIVE CARE CHARACTERISING INTERPROFESSIONAL RELATIONSHIPS ATTITUDES AND BEHAVIOURS

James Ip[1], Konstantinos Dimitriades[2], Daryl Herring[3], Jo Wray[4], Sanjiv Sharma[2], Akane Iguchi[5]
Great Ormond Street Hospital, Anaesthetics, London-United Kingdom[1]; Great Ormond Street Hospital, Critical Care, London-United Kingdom[2]; Great Ormond Street Hospital, Nursing, Critical Care, London-United Kingdom[3]; Great Ormond Street Hospital, Psychology, London-United Kingdom[4]; Great Ormond Street Hospital, Anaesthetics and Critical Care, London-United Kingdom[5]

Background: The paediatric cardiac intensive care unit (CICU) is a 'high-stakes' environment in which inter-professional relationships may come under great pressure. Collaboration between nurses and physicians improves patient safety and job satisfaction whilst reducing burnout and staff turnover (1,2). The aims of this study were: to characterise the perceptions of nurse-physician relationships in our paediatric CICU (a 21-bed tertiary/quaternary centre); to identify strategies to promote collaboration; and to obtain 'benchmark' data for assessing the efficacy of these strategies going forward.
Methods: Anonymous electronic survey of medical and nursing staff working on CICU during May-November 2016.
Results: •90/168 (54%) surveys were completed; 71/124 (57%) from nurses and 19/44 (43%) from physicians. •90% rated the overall quality of nurse-physician relationships on CICU as 'somewhat', 'very' or 'extremely' positive. •85% reported positive interactions occurring daily; examples included shared decision making/learning and mutual respect. •Negative interactions occurred less frequently (5% daily; 33% 2-weekly; 19% monthly); examples included: not introducing oneself; dismissing clinical concerns; and comments perceived as patronising and/or disrespectful. • > 50% rated the following as 'absolutely critical' in influencing nurse-physician relationships: respect; communication/listening skills; and common goals. •Less influential, but still important factors included: consultant/nurse in charge and patient workload. • > 90% reported joint ownership of the patient with 70% agreeing that nurses and physicians shared decision making. •Respondents indicated that beneficial strategies for improving relationships might include: joint simulation/ teaching sessions (>90%); social functions (88%); and a nurse-physician 'buddy' system (72%).
Conclusions: This study suggested a predominance of positive inter-professional interactions/relationships on our unit; however, areas for improvement were identified. Several potential interventions for improving relationships emerged, including simply presenting these data to new starters to encourage reflection and improve awareness. The data could also be used as a benchmark for future interventions.

P2118 - PULMONARY LYMPHANGIECTASIA A RARE BUT SERIOUS OUTCOME PREDICTOR IN NEONATES WITH TOTAL ANOMALOUS PULMONARY VENOUS DRAINAGE

Sreekanthan Sundararaghavan, Jonathan Tlj Choo, Yi Peng Lim, Ching Kit Chen, Teng Hong Tan
KK Women and Children, Pediatric Cardiology, Singapore-Singapore

Background: Congenital Pulmonary Lymphangiectasia (CPL) is a very rare entity. Type 2 CPL has been noted to be associated with congenital heart diseases such as TAPVD. Most patients with CPL tend to have a poor prognosis with significant mortality being reported. There is very little information on the clinical characteristics including morbidity and mortality in this subset.
Methods: Review of all patients diagnosed with TAPVD between 2012 and 2016 in a tertiary care hospital in Singapore. Patients with complex heterotaxy syndromes were excluded. Patients with biopsy proven pulmonary lymphangiectasia were studied.
Results: 15 patients with TAPVD were identified. In all patients, the diagnosis was confirmed postnatally by echocardiogram. Five patients (33%) had obstruction to the pulmonary venous drainage in our series; 2 of 5 (40%) were identified with pulmonary lymphangiectasia through CT imaging and confirmed by histopathology. There were 7 patients (47%) with supracardiac TAPVD and 2 had obstructed drainage; 4 patients (27%) had a cardiac type TAPVD and none were obstructed; 2 patients (13%) had mixed type TAPVD and 2 patients (13%) had Infracardiac TAPVD. Both patients with Infracardiac TAPVDs and 1 patient in mixed type with partial infradiaphragmatic drainage were considered to be obstructed physiologically, even if Doppler studies were negative. One patient with lymphangiectasia with supracardiac obstructed TAPVD succumbed by postoperative day 82 despite correction of TAPVD on Day 1 of life. The other patient with pulmonary lymphangiectasia and Infracardiac TAPVD survived till date despite later repair (day 18 of life). Both required prolonged and difficult ventilation post surgery.
Conclusions: 1. Patients with TAPVD and pulmonary lymphangiectasia are complicated by prolonged ventilation even if corrective repair is done. 2. Presence of pulmonary lymphangiectasia may predict higher mortality but certainly portends significant morbidity compared to isolated TAPVD. 3. Pulmonary lymphangiectasia can occur irrespective of the type of TAPVD.

P2125 - PULMONARY ARTERY HYPERTENSION MANIFESTING AS SYNCOPE WITH CYANOSIS. A CASE REPORT

Vishal Singh[1], Smita Mishra[2], Rajesh Sharma[3]
Jaypee Hospital, Pediatric Cardiac Critical Care, Noida-India[1]; Jaypee Hospital, Pediatric Cardiology, Noida-India[2]; Jaypee Hospital, Pediatric Cardiac Surgery, Noida-India[3]

A 15 month old female child, weight 5.7 kg referred with a history of sudden loss of consciousness with intermittent cyanosis after episodes of excessive irritability, for previous 3 months. The patient was the second of twin preterm delivery (28 weeks gestation), small for gestational age (SGA) with birth weight 700 gms. The patient had prolonged NICU stay and underwent PDA ligation due to inability to wean off non invasive ventilation. The patient was referred to a neurophysician and was investigated for the same, but the imaging and electroencephalogram (EEG)were normal. A 2D echocardiography with color Doppler revealed the diagnosis as severe right upper pulmonary vein discrete stenosis with a mean gradient of 8 mm hg with bidirectionally shunting secundum atrial septal defect (ASD) with severe tricuspid regurgitation (TR) and severe pulmonary hypertension (PAH), confirmed with CT pulmonary angiography. The child was taken for a high risk surgical intervention (Sutureless neoatrium technique) with repair of pulmonary vein stenosis with extrapericardial cannulation and fenestrated ASD closure. The patient required prolonged ventilation due to recurrent desaturation with hemodynamic instability with systemic PAH postoperatively and required inodilators with oral pulmonary vasodilators at maximum

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

dosage including intravenous sildenafil infusion for reducing PAH. The patient could only be extubated by the 8th post operative day (POD) on nasal continuous positive airway pressure (CPAP), which was withdrawn on the 11th POD. The patient on discharge had half systemic PAH and maintained saturation greater than 90% on room air. On one month follow up the PAH had regressed to one third systemic and the patient had improved appetite with weight gain and no recurrence of syncope. To conclude syncope with cyanosis in younger children is a rare manifestation of PAH and warrants timely intervention.

P2126 - PREDICTORS OF PROLONGED MECHANICAL VENTILATION PROLONGED INTENSIVE CARE UNIT STAY AND MORTALITY IN PEDIATRIC CONGENITAL CARDIAC SURGERY PATIENTS IN INDIAN POPULATION

Srinath Damodaran, Rajarajan Ganesan, Unnikrishnan Vs, Sheenam Walia, Ganesh Munirathinam, Goverdhan Dutt Puri
Pgimer, Cardiac Anaesthesia, Chandigarh-India

Background: Knowledge of factors predicting prolonged mechanical ventilation (MV), ICU stay and mortality in children undergoing cardiac surgery can help in early treatment and targeted therapy. We aimed to determine such predictors in pediatric patients undergoing surgery for congenital heart disease in a tertiary hospital.
Methods: This ongoing prospective observational study has enrolled 34 patients till now. Perioperative data including hematological and biochemical parameters, cardiopulmonary bypass(CPB) time, CPB temperature, aortic cross clamp time, blood gas analysis, lactate level, drain output, transfusion data, Vasoactive-inotropic score (VIS), renal score, ventilation index (VI), Vasoactive-ventilation-renal (VVR) score are recorded pre-operatively, at the time of receiving in ICU and 6, 24 and 48 hours postoperatively.
Results: Median age and weight were 12 months (IQR: 3 -36) and 6.5 kg (IQR: 4-11) respectively. Median mechanical ventilation duration and ICU stay were 50 hours (IQR: 17-120) and 7 days (IQR: 4-10) respectively. Lower age, prolonged CPB time, Low platelet counts and high renal index on receiving in ICU, high renal index, high bilirubin and low pao2 at 6 hours, high creatinine, increased creatinine, high lactate, high ventilation index and high VVR score at 48 hours in ICU were all independently associated with prolonged mechanical ventilation. Similarly higher intraoperative base deficit, high VIS score at 30 minutes post CPB, lower venous CO2 on receiving in ICU, high VIS score and high VVR after 6, 24 and 48 hours in ICU, low arterial CO2 at 48 hour in ICU were independently associated with prolonged ICU stay. Low pH in the early postoperative period and increased 2 day drain output were significantly associated with high mortality.
Conclusion: While patients with abnormal renal parameters had prolonged mechanical ventilation, higher inotrope requirement patients had a longer ICU stay. Acidosis and mortality went together in this interim analysis.

P2129 - ASSOCIATION OF HIGH VASOACTIVE-INOTROPIC SCORE WITH POOR OUTCOMES AFTER PEDIATRIC CARDIAC SURGERY IN INDONESIA

Indah K. Murni[1], Rubiana Sukardi[2], Piprim B Yanuarso[3], Noormanto Normanto[1], Sasmito Nugroho[1], Mulyadi M. Djer[3]
Dr Sardjito Hospital/Universitas Gadjah Mada Department of Pediatrics Yogyakarta-Indonesia[1]; Integrated Cardiac Center, Dr Cipto Mangunkusumo Hospital Jakarta-Indonesia[2]; Dr Cipto Mangunkusumo Hospital/University of Indonesia Department of Pediatrics Jakarta-Indonesia[3]

Background: The use of high vasoactives on leaving operating room was associated with poor outcomes in children after cardiac surgery. The more severe the hemodynamic state, the lower the cardiac index, and therefore, a higher vasoactive inotropic support were needed. These might complicate to death.
Objective: To determine the association of high vasoactive-inotropic score with poor outcomes in children after cardiac surgery in Indonesia.
Methods: A prospective cohort study was conducted from April 2014 to March 2015 on all children undergoing cardiac surgery at Dr Cipto Mangunkusumo Hospital, Jakarta, Indonesia. The use of vasoactive agents at cardiac ICU was recorded for the first 24 hours after cardiac surgery. The use of vasoactive support and its association with poor outcomes including in-hospital mortality, cardiac arrest, and multi-organ failure were analyzed. Multivariable logistic regression analyses were used to quantify the association between high vasoactive-inotropic score and poor outcomes allowing for statistical control of age, sex, nutritional state, syndrome, cardio-pulmonary bypass, and complexity of surgery. High vasoactive-inotropic score was defined as more than or equal to 20. Formula of vasoactive-inotropic score was dopamine dose + dobutamine dose + (100 x epinephrine dose) + (10 × milrinone dose) + (100 × norepinephrine dose). Doses were in μg/kg/minutes.
Results: We recruited 257 patients with median age of 36 months. Of those, 32 (12.5%) were administered to a high vasoactive-inotropic score. Median vasoactive-inotropic score was 10 (3–42). After adjusting for patient characteristics and the complexity of surgery; there was a significant association between high vasoactive-inotropic score and poor outcomes in children after cardiac surgery including mortality (odds ratio 56.3; 95% CI 17.9–176.8), cardiac arrest (odds ratio 5.6; 95% CI 1.6–19.6), and multi-organ failure (odds ratio 17.8; 95% CI 5.6–56.3).
Conclusions: High vasoactive-inotropic score is significantly associated with in-hospital mortality and other poor outcomes in children after cardiac surgery.

P2163 - ARRHYTHMIA IN THE NEONATAL INTENSIVE CARE UNIT AT OSAKA MEDICAL COLLEGE HOSPITAL

Atsuko Ashida[1], Kanta Kishi[1], Hiroshi Katayama[1], Noriyasu Ozaki[1], Yutaka Odanaka[1], Shintaro Nemoto[2], Hayato Konishi[2], Ryo Shimada[2], Hiroshi Tamai[1]
Osaka Medical College, Department of Pediatrics, Takatsuki-Japan[1]; Osaka Medical College, Department of Pediatric Cardiovascular Surgery, Takatsuki-Japan[2]

Objective: The aim of the present study is to analyze non benign neonatal arrhythmias (NBNA) observed in a neonatal intensive care unit (NICU) at Osaka Medical College Hospital.
Materials and Methods: From January 2010 to December 2016, newborns admitted to our NICU due to NBNA were evaluated retrospectively. We defined the arrhythmias such as supraventricular tachycardia (SVT), sinoatrial node dysfunction, disorders of the atrioventricular (AV) conduction system, atrial flatter (AF), ventricular tachycardia (VT), long QT syndrome, and ventricular fibrillation (VF) which need treatment or long term follow up as NBNA.
Results: Fourteen cases were included in this study. The incidence of NBNA was 1.2% of total admission of NICU. The median age at diagnosis was 10 day ranging from 0 to 187 day. Twelve of 14 patients had congenital heart disease (CHD). The most common type of congenital heart disease was total anomalous of pulmonary venous connection (TAPVC) and heterotaxy syndrome,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

following tetralogy of Fallot. In eight cases with CHD, NBNA occurred postoperative period from 1 to 61 days (median 10 days) after surgical operation. The most frequent type of arrhythmia was SVT (57%). Other types of NBNA were advanced AV block (22%), sick sinus syndrome (14%) and VT (7%). All cases but three case with AV block underwent medical treatment. Propranolol was used to treat of 6 patients with SVT (42.9%). Overall mortality rate was 35.7% (n = 5). Three of 5 deaths were associated with NBNA. All three cases associated with NBNA had advanced AV block.
Conclusion: In this study, NBNA in our NICU were associated with cardiac surgery. The most common type of arrhythmia in this study was SVT after total repair for TAPVC. Advanced AV block had poor prognosis and occurred late after cardiac surgery.

P2165 - IMPACT OF MULTIPLE LOW FLOW INTRAVENOUS INFUSIONS ON VOLUME AND DRUG DELIVERY

Chane Choedamphai, Kanda Fanhjaksai, Chanika Kosarat, Suchaya Silvilairat, Rekwan Sittiwangkul, Krit Makonkawkeyoon
Chiang Mai University, Pediatrics, Chiang Mai-Thailand

Background: In practice of neonatal postoerative cardiac surgery, using low volume with multiple concurrent drug infusion via peripheral vein sometime is inevitable. These could be altered the accuracy of drug delivery. Data of accuracy for concurrent low rate fluid infusion should be demonstrated.
Objectives: To verified accuracy of infusion pumps under low infusion rate and to study accuracy of concurrent infusion at low rate.
Methods: Ten Infusion pumps and ten syringe pumps were tested for accuracy and precision of fluid delivery at multiple flow rate. The most accurate pumps type were used to deliver concurrent Copper sulfate solution rate 1 mL/h side tube, 1 mL/h of sterile water side tube and 3 mL/h main tube through a multiple stopcock connection. Samples were collected in two-minute interval over a 60 minute period to measure optical density of Copper sulfate. Then Copper sulfate concentration was calculated by using optical density-concentration curve.
Results: Mean actual rate of infusion pump at preset rate 0.1, 0.5, 1, 2, 5 mL/h are 0.1177, 0.4933, 0.9996, 1.9990, 4.9831 mL/h respectively. And mean actual rate of syringe pump at the same preset rate are 0.0114, 0.4986, 0.9811, 2.0063, 4.9948 mL/h respectively. Delivering of Copper Sulfate at main tube rate of 3 mL/h and side tube rate of 1 mL/h through the near patient port of multiple stopcock connection and far from patient port take 30 and 40 minutes respectively to reach the steady stage, and for spider triple lumen, 25 minutes is required to reach the steady stage.
Conclusions: At low flow rate of less than 2 mL/h. the infusion pump is more accurate than syringe pump. Using concurrent infusion has significant effect of early delivery precision and this should be avoid by using multiple lumen catheter for delivery of inotropic agents.

P2172 - VALUE OF NEAR INFRARED SPECTROSCOPY AS A PROXY FOR CARDIAC OUTPUT IN AN INFANT ON EXTRACORPOREAL MEMBRANE OXYGENATION A CASE REPORT

Francis Emperador[1], Marcelo Cardarelli[2], Frank Molloy[3], Bryan Forsberg[4], Fatima Rajah[5], Davinder Singh[6], Vesna Trpkovska[7], Vladimir Chadikovski[7], William Novick[8]
King Abdulaziz Medical City, And Volunteer in Willian Novick Global Cardiac Alliance, Cardiac, Jeddha-Saudi Arabia[1]; Inova Children Hospital, Surgery, Virginia-United States[2]; William Novick Global Cardiac Alliance., Education, Memphis-United States[3]; Jackson Memorial Health Hospital, Perfusion, Miami-United States[4]; Grid Leeds General Infirmary And Volunteer in William Novick Global Cardiac Alliance, Pediatric Intensive Care Unit, Leeds-United Kingdom[5]; Grid Leeds General Infirmary, Volunteer in William Novick Global Cardiac Alliance., Pediatric Intensive Care Unit, Leeds-United Kingdom[6]; University Clinic For Pediatric Surgery, Pediatric Intensive Unit, Skopje-Macedonia[7]; William Novick Global Cardiac Alliance, Surgery, Memphis-United States[8]

Background: Low cardiac output syndrome after cardiopulmonary bypass (CPB) in neonates occurs in 25% and extracorporeal membrane oxygenation (ECMO) is the treatment of choice in extreme cases. Actual cardiac output is difficult to measure in children, therefore proxies like peripheral perfusion, pulses, urine output, arterial blood pressure, metabolic acidosis, lactate levels must be followed. We observed the correlation between NIRS and other proxies in relationship to cardiac output.
Material and Methods: A neonate diagnosed with single ventricle, transposition of great arteries and restrictive atrial septal defect underwent a palliative procedure: atrial-septostomy and banding of the pulmonary artery. Cerebral oxygen saturation was monitored via NIRS (INVOS ™5100C) during surgery. Severe ventricular failure with low cardiac output when attempting to wean from CPB despite maximal inotropic therapy was managed with ECMO through central cannulation. Blood pressure, NIRS levels, base deficit and urine output were followed during 96 hrs of ECMO support as proxies for cardiac output (see figure 1). After ECMO was weaned off with an inotropic support and stable blood pressures the NIRS value dropped from 55 to 20 with a lactate rise (3,69). After 40' low blood pressures followed, with severe metabolic acidosis and ST changes. Unable to go back on ECMO due to technical issues, pediatric advanced life support was unsuccessful to reverse the situation.
Results: See Figure 1
Conclusion: Near infrared spectroscopy (NIRS) had the ability to monitor and predict low cardiac output in this patient. When confronted with patients lacking direct measure of cardiac output due to weight restrictions, the use of NIRS seems to be at least as effective as other proxies utilized to that end.

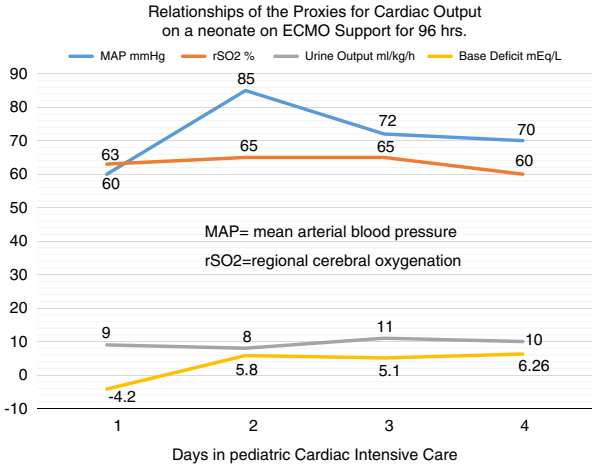

Figure.

P2192 - RESTRICTIVE RIGHT VENTRICLE PHYSIOLOGY IN TETRALOGY OF FALLOT DURING EARLY POSTOPERATIVE PERIOD

Gulhan Tunca Sahin[1], Serhat Bahadir Genc[2], Emre Yasar[2], Erkut Ozturk[1], Okan Yildiz[2], Hasan Candas Kafali[1], Alper Guzeltas[1], Sertac Haydin[2]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiovascular Surgery, Istanbul-Turkey[2]

Background: The mortality rate of tetralogy of Fallot (TOF) decreases as the surgical experience increases and the intensive care unit (ICU) follow-up improves. In this study, the effects of restrictive right ventricle in postoperative period were investigated in TOF patients undergone total correction.
Materials and Methods: Between January 2015 and November 2016, 112 cases that were undergone total correction were included in the study. Cases are identified as restrictive right ventricle (RRV +) and the ones with peritoneal dialysis were applied (Group 1), and the ones without the restrictive right ventricle (RRV-)(Group 2) according to their antegrade pulmonary flow using pulse wave in postoperative echocardiography. The demographical datas, preoperative echocardiographic and angiographic datas, type and duration of the operation, complications in the ICU were evaluated.
Results: Median age of the cases were 12 months (range 1 month-16 years), median weight was 8.7 kg (range 3.3-41). Group 1 included 17 cases and Group 2 included 95 cases.The McGoon index, z scores of the pulmonary annulus, the pulmonary artery, RPA and LPA were similar in both groups. Intraoperative datas (cardiopulmonary bypass (CPB) time, cross clamp (CC) time, right ventricular/left ventricular pressure ratio (pRV/pLV), usage of transannular patch) were also similar. In Group 1 the incidence of residual defect and pulmonary regurgitation were higher.Also in group 1, the inotrope score, duration of stay in the ICU and in the hospital were statistically significant ($p < 0.05$). One of the cases in Group 1 was passed away.
Results: Diagnosis of restrictive right ventricle physiology after the total correction of TOF has a negative effect on the morbidity and the mortality in early postoperative period. Early onset peritoneal dialysis in RRV + cases can prevent these negative effects.

P2194 - ENTERAL NUTRITIONAL THERAPY IN CHILDREN UNDERGOING EXTRACORPOREAL MEMBRANE OXYGENATION (ECMO) HOW TO DO IT

Denise Pasin[1], Maria Cristina Heron[2], Rosana Tumas[2], Beatriz Furlanetto[3], José Cicero Guilhen[3], Nelson Horigoshi[1], Larissa Gondim[1], Ecryd Elias[3], Grace Bichara[3]
Sabará Hospital, Pediatric Intensive Care, São Paulo-Brazil[1]; Sabará Hospital, Nutrology, São Paulo-Brazil[2]; Sabará Hospital, Cardiology, São Paulo-Brazil[3]

Background: ECMO is a therapeutic modality that has been increasing in Pediatric Intensive Care Units (PICU). The enteral nutrition sometimes is delayed and many of these children remain fasting, due to the severity of the disease.
Objective: The objective of this study is to describe the enteral nutrition therapy in critically ill children treated with ECMO.
Methods: This is a retrospective study of consecutive children who underwent ECMO from November 2015 to December 2016; patient demographic, diagnosis, time of fasting, tube type, diet used, initial volume, time to reach full enteral nutrition, presence of pathological residues, vomiting, diarrhea and abdominal distension.
Results: Nine children were treated with venoarterial ($n = 8$) and venovenous ($n = 1$) ECMO in the period of the studying the PICU of a tertiary and private children's hospital in São Paulo, Brazil. The underlying conditions were acute respiratory distress syndrome, refractory septic shock, respiratory and circulatory failure after left pneumectomy, acute lymphoblastic leukemia and cardiogenic shock after Tetralogy of Fallot repair. The age ranged from 5 months to 7 years, of these, 5 (55,56%) received enteral nutrition by gastric tube starting 24 hours after being on ECMO, 3 (33,33%) stayed with parenteral nutrition due vomiting, diarrhea and abdominal distension and one child (11.11%) stayed in fasting due to side effects of chemotherapy, poor intestinal perfusion and intestinal bleeding. The enteral nutrition diet used was oligomeric (extensively hydrolyzed or elemental), without difference of tolerance between them, with initial volume of 20 mL/kg/day, in continuous or intermittent form, with an increment up to 50 mL/kg/day. Full enteral nutrition was achieved in up to 6 days
Conclusion: Although children on ECMO are critically ill, enteral nutritional therapy should always be established through algorithms that prioritize this nutritional modality.

P2209 - PEDIATRIC INFECTIVE ENDOCARDITIS DURING A PERIOD OF TEN YEARS IN A SINGLE COLOMBIAN INSTITUTION

Ana Maria Eraso-Díaz Del Castillo[1], Adriana Castillo Rincon[2], Martha Isabel Alvarez Larrañaga[3], Victor Manuel Huertas Quiñones[4]
Fundacion Cardioinfantil Instituto De Cardiologia, Pediatric Cardiology, Bogota-Colombia[1]; Fundacion Cardioinfantil Instituto De Cardiologia, Pediatrics, Bogota-Colombia[2]; Fundacion Cardioinfantil Instituto De Cardiologia., Pediatric Infectious Diseases, Bogota-Colombia[3]; Fundacion Cardioinfantil Instituto De Cardiologia. Universidad Nacional De Colombia, Pediatric Cardiology, Bogota-Colombia[4]

Background: Infective endocarditis (IE) is an entity with a growing incidence worldwide with an important morbidity and mortality. The aim of this study was to describe the epidemiological and clinical characteristics of the pediatric population with IE in a single institution over a period of ten years.
Materials and Methods: A descriptive retrospective study was performed. All pediatric IE cases (according to Duke criteria) between January 2002 and December 2012 were retrospectively reviewed. Ethics board approval was obtained and a waiver of consent was granted due to the retrospective nature of the review.
Results: 79 medical records were retrospectively analyzed, of whom 49 had a confirmed diagnosis of IE, according to Duke criteria. Most of the patients: 83.6% (41/49) had congenital heart defects (CHD), of which 63% (26/49) were acyanotic. IE was more frequent in patients with unrepaired CHD (36%, 15/49). 34% of patients (17/49) had a history of foreign material implantation, with patches, pacemakers and stents being the most frequent. Microbiological isolation was obtained in 76% (38/49) of the patients. The most frequently isolated germs were S. aureus (32%, 14/49) and S. coagulase negative (32%, 14/49). The most frequent anatomic localization was the tricuspid valve in 32% (14/49) of the cases, followed by the aortic valve with 30% (13/49). Mechanical complications were more frequent in patients with CHD ($p = 0.008$), while there were no significant difference in heart failure development ($p = 0.38$) or embolism ($p = 0.11$) between patients with and without CHD. 24% (12/49) of the patients required surgical management of the IE. The majority

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(57%) of the patients (28/49) had resolution of IE without sequelae, 20% (10/49) had any type of sequela and mortality was 18% (9/49).
Conclusions: This study contributes to a better knowledge of the clinical and epidemiologic characteristics of pediatric patients with IE in an important cardiovascular reference center in our country.

P2234 - EARLY POST OPERATIVE OUTCOME OF BIDIRECTIONAL GLENN SHUNT IN ADULTS

Amr Farrag[1], Elia Mohie[1], Mohamed Abdelrazik[1], Omar Alaaeldin[1], Omar Masoud[1], Ahmad Eldowaik[1], Islam Elwan[1], Hatem Hosny[2], Carin Van Doorn[3], Soha Romeih[4]
Aswan Heart Centre, Aitu, Aswan-Egypt[1]; Aswan Heart Centre, Cardiac Surgery, Aswan-Egypt[2]; Leeds Teaching Hospitals, Cardiac Surgery, London-United Kingdom[3]; Aswan Heart Centre, Cardiac Imaging Department, Aswan-Egypt[4]

Background: Nowadays, patients with univentriclar circulation and low pressure, low pulmonary blood flow are usually treated with a Bidirectional Glenn shunt (BDG). Operation is often in childhood and part of a staged palliation to the Fontan circulation. In developing countries many children remain untreated. However, a BDG may still play an important role in relieving symptoms in selected patients at adult age.
Methods and Patients: Retrospective study of all patients older than 16 years who underwent aBDG as palliative procedure for univentriclar circulation since 2009 in our center. There were 8 patients (4 male) with a median age of 21 years (17 to 28 years). Preoperative percutaneous oxygen saturation was 71% (65 to 78%) and hemoglobin 21 gm/dl (16.5 to 23.9 gm/dl). Mean pulmonary artery pressure was lower than 18 mmHg in all patients with normal size pulmonary arteries. Ventricular morphology was left ventricle in 4 patients, 3 patients had right ventricle morphology and one case with congenitally corrected transposition of great arteries with pulmonary obstruction.Two patients had a previous palliative arterial shunt and 2 patients had a pulmonary artery band. The remainder had native pulmonary stenosis.
Results: There were no operative deaths. Post-operative oxygen saturation on discharge was 83% (75-90%). Six patients were successfully extubated within 24 hours and the other 2 patients required mechanical ventilation for 48 hours. Two patients were re-intubated for another 24 hours due to type II respiratory failure and impaired ventricular systolic function, respectively. Inotropic support was needed in 5 patients for 48 hours. Two patients had a temporary supraventricular arrhythmia. There were no neurological complications or need for renal dialysis. Median hospital stay was 7 days (5-12 days).
Conclusion: BDG is a effective and safe palliative procedure in selected hypercyanotic adults with univentricular circulation.

P2284 - INFECTIVE ENDOCARDITIS IN CHILDREN EXPERIENCE OF A MOROCCAN CENTER

Nadia El Idrissi Slitine[1], Mariam Makkaoui Alaoui[1], Abdellatif Daoudi[1], Ouidad Louachama[1], Fatiha Bennaoui[1], Noureddine Rada[2], Fadel Maoulainine[1]
Nicu, Mother and Child Hospital, Med Vi University Hospital, Marrakesh Medical School, Cadi Ayyad University, Pediatrics, Marrakesh-Morocco[1]; Pediatrics, Mother and Child Hospital, Med Vi University Hospital, Marrakesh Medical School, Cadi Ayyad University, Pediatrics, Marrakesh-Morocco[2]

Introduction: The impact of endocarditis in childhood accompanies many cardio-vascular disorders. Infective endocarditis (IE) is the most frequently occurring form of endocardium inflammation.
Objective: To study the epidemiological features of infective endocarditis.
Materials and Methods: In this retrospective study, we studied the clinical data, of all children with IE who had been admitted to the infection pediatrics department at the university hospital Mohamed VI Marrakech, from January 2011 to October 2016. The inclusion criteria were made based according to the modified Duke criteria.
Results: IE was found in 11 of 7627 hospitalized children, which represents a prevalence of 0.13%. The mean age was 5.1 years (Extremes [1 month; 15 years]), with a higher incidence in male (7 boys and 3 girls) and in children with cardiopathy (70%). In this study, based on the modified DUKE criteria: 7 cases were definite IE, and 3 cases were possible. Bi-antibiotherapy was the rule, of which 7 patients were treated with third-generation Cephalosporins-aminoglycosides, 2 patients with tri antibiotic therapy by adding amoxicillin and one case by rifampicin-teicoplanin. Evolution was favorable in 80% of cases and 20% had complications mainly neurological and thrombo-embolic, one of them died from pulmonary embolim.
Conclusion: Infective endocarditis occurs mostly in children with cardiac abnormalities. It is potentially lethal despite the progress made in the diagnosis, in the treatment with new effective antibiotic and surgery. IE remains a problem in our context in the absence of diagnosis of congenital heart disease, and lack of hygiene in certain urban area of the city.

P2290 - N TERMINAL PROHORMONE BRAIN NATRIURETIC PEPTIDE IN THE EVALUATION OF RESPONSE TO LEVOSIMENDAN IN PEDIATRIC PATIENTS. PRELIMINARY RESULTS

Patricio Guido Alvarez[1], Ricardo Rodriguez[1], Sandra Sepulveda[2], Juliana Medina[2], Guillermo Moreno[1], Maria Althabe[1]
Hospital Juan P. Garrahan, Pcicu - U35, Buenos Aires-Argentina[1]; Hospital Juan P. Garrahan, Pediatric Cardiology, Buenos Aires-Argentina[2]

Introduction: Besides common laboratory tests and echocardiographic assesment, an increasing number of biomarkers are proposed to evaluate treatment response and follow up in patients with cardiac failure.
Objective: To describe the usefulness of NT proBNP in the evaluation of response to Levosimendan (LEVO) in children with heart failure.
Design: Non interventional, observational and prospective study.
Setting: PCICU, Hospital "J.P.Garrahan", Buenos Aires, Argentina.
Patients and Methods: all patients with Levosimendan were included. Demographic data, cardiac diagnosis, surgical procedure, Rachs-1 score, mechanical ventilation, LOS and mortality were recorded, along with hemodynamic, and biochemical parameters. Every patient had a Pre LEVO echocardiographic evaluation performed by a senior cardiologist, NT-proBNP, lactic acid, urea and creatinine levels. All measurements were repeated after 24 hs, day 3 and 5 after LEVO. Statistical analysis: Hemodynamic, and biochemical parameters are analyzed before and after LEVO. Continuous variables are reported as median and interquartile range (IQR), categorical variables as absolute values or percentages. Wilcoxon Test was used to identify differences with $p < 0.05$ considered significant. (Stata 10.0).
Results: 13 patients were enrolled, the median age was 5 months (IQR 25-75: 2-15); median weight 4.95 kg (IQR 25-75: 2.8-7.5). 89% had complex procedures, RACHS greater than 3 most of them biventricular repair (83%). Median pre LEVO NT-proBNP

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

was 7415 pg/ml (IQR 25-75: 4185-14001) and postLEVO at day 5 of 5896 pg/ml (IQR 25-75: 3851-7658) mz < (P 0.033). In 9 patients NT-proBNP showed more than 40% reduction between preLEVO and day 5 levels. Non statistical differences in echocardiographic measurements of ventricular function were found. Mortality rate is 7,69% (1 patient).
Conclusions; Preliminary data show a statistically significant decrease in NT-ProBNP values following Levo administration, with no echocardiographic differences in ventricular function.

P2306 - NEUROSURGICAL INTERVENTIONS IN CHILDREN WITH VENTRICULAR ASSIST DEVICES

Abhishek Narayanan[1], Maura O[1], Ann Karimova[1], Troy Dominguez[1], Martin Tisdall[2], Aparna Hoskote[1], Cho Ng[1]
Great Ormond Street Hospital for Children, Paediatric Cardiac Intensive Care, London-United Kingdom[1]; Great Ormond Street Hospital for Children, Paediatric Neurosurgery, London-United Kingdom[2]

Background: There is limited published literature on the neurosurgical management of children who develop intracranial haemorrhage (ICH) while on Ventricular Assist Devices (VADs).
Objective: Describe patient demographics, management and outcome in children who required neurosurgical intervention on VADs.
Methods: Single centre retrospective observational cohort study of children (<16 years) on VADs. Outcomes assessed were survival at 30 days and 6 months.
Results: Out of 102 patients supported on VAD from November 2004 - September 2016, 5 developed ICH and required neurosurgical intervention in six instances (1 child had recurrent ICH). Three had haemorrhagic stroke [2 on Berlin heart Excor device (BH) and one on Heartware] and 3 subdural hematoma (2 on BH and 1 on Levitronix). ICH occurred between 17-103 support days on VAD. Infection concerns noted in 4 children (80%): fever, C - reactive protein (30-144 mg/L) with neutropenia in 2. Though no organisms were isolated, all were treated with empirical broad-spectrum antibiotics. One with recurrent ICH had inflammatory response - high CRP and fibrinogen with thrombus in VAD circuit. Wide fluctuations in activated partial thromboplastin time noted within 24 hours prior to ICH; anti-Xa levels remained in range. Neurosurgical interventions varied,with no immediate complications: burr hole, craniotomy and evacuation of ICH or external ventricular drain. Anticoagulation was withheld initially and unfractionated heparin restarted at low dose from day 4-8 post events. Four (80%) (including one with recurrent ICH) survived: 3 had heart transplant and 1 VAD explantation (myocardial-recovery). Neurologic outcome: residual hemiparesis in 3 children (one developed critical illness polyneuro-myopathy on nerve-conduction studies) and spastic-dystonic movement disorder in one child. All have subjective improvement in neurology during follow up.
Conclusion: Despite monitored anticoagulation, the bleeding risk in VAD patients increases with any underlying inflammation. We can safely perform neurosurgery on VAD patients with good short and medium term results.

P2343 - SPONTANEOUS CHYLOPERITONEUM AS A PREOPERATIVE COMPLICATION OF CONGENITAL HEART DISEASE

Fabiola Muller De Oliveira, Ecryd Abdala Elias, Fabiana Nossa, Rafaella Gato Calmon, Grace Van Leeuwen Bichara
Sabará Hospital Infantil, Pediatric Cardiology, São Paulo-Brazil

Background/Hypothesis: Chyloperitoneum is a rare clinical condition, characterized by an accumulation of lymph fluid in the peritoneal cavity. There are a few reports of spontaneous chyloperitoneum secondary to congenital cardiopathies in the literature. We report a case of a spontaneous chylous ascites in a patient in the preoperative period.
Methods: case report and review of the scientific literature from published articles on the subject.
Results: Forty-days old Down Syndrome patient with Complete Atrioventricular Septal Defect (cAVSD), was hospitalized for decompensated heart failure. She presented with abdominal distension, and the ultrasound showed free liquid in the cavity. For anuria and edema, she got a Tenckhoff catheter for the peritoneal dialysis. Drainage of milky fluid was observed. Triglycerides of the peritoneal fluid was 133 mg/dL, characterizing spontaneous chyloperitoneum. Started fasting and total parenteral nutrition, and after 48 hours started minimal enteral nutrition with Monogen. Peritoneal liquid triglyceride control was 20 mg/dL. She underwent complete repair of the cAVSD, presenting bilateral chylothorax in the seventh postoperative day, and underwent vancomycin-based chemical pleurodesis on two occasions, with resolution of the condition. In addition, patient evolved with enterococcus sepsis and presumed fungal infection. During the investigation, secondary immunodeficiency was observed, attributed to the losses of immunoglobulins and lymphocytes due to the large volume of chylous liquid controlled with weekly infusion of Human Immunoglobulin.
Conclusions: Spontaneous chyloperitoneum associated with congenital heart defects or its clinical complications is still poorly described in the literature. We have a case where the spontaneous chyloperitoneum and the bilateral chylothorax were abundan,t leading to significant loss of immunoglobulins, leaving the patient susceptible to serious infections. Promptly treated with the specific therapies available, patient is now in good condition, in outpatient follow-up.

P2353 - CIRCULATING MICRO RNA208A AS A NOVEL EARLY BIOMARKER FOR THE POST OPERATIVE COURSE FOLLOWING CONGENITAL HEART SURGERY

Tal Tirosh Wagner[1], Keren Zloto[2], Yoav Bolkier[1], Yishay Salem[1], Sharon Borik[1], Amir Vardi[3], David Mishali[4], ⋆Yael Nevo-Caspi[2], ⋆Gideon Paret[2]
The Safra Children, Pediatric Cardiology, Ramat Gan-Israel[1]; The Safra Children, Dept. of Pediatric Intensive Care, Ramat Gan-Israel[2]; The Safra Children, Dept. of Pediatric Cardiac Intensive Care, Ramat Gan-Israel[3]; The Safra Children, Dept. of Pediatic Cardiac Surgery, Ramat Gan-Israel[4]

Background/Hypothesis: Clinical and biochemical markers used currently following pediatric cardiac surgery are poor predictors of the perioperative course. MicroRNAs (miRNAs), a class of short non-coding RNA molecules, have been shown to be promising biomarkers for several clinical conditions due to their tissue-specific expression pattern, rapid-release kinetics and stability in plasma. We hypothesized that cardiac-specific miRNA-208a, shown to be elevated in adults with acute myocardial infarction, can serve as an early, sensitive and specific circulating non-invasive biomarker for the post-operative clinical course in pediatric patients undergoing cardiac surgery.
Materials and Methods: RNA was extracted from serum samples obtained from 79 patients who underwent cardiac surgery pre-operatively and at 6, 12 and 24 h post-op. MiRNA-208a was quantified by quantitative PCR (QPCR). Correlations between the patient's course (surgical and clinical) and miRNA levels were tested.
Results: The amount of miRNA-208a rises sharply at 6 h after the operation (107-fold), remains high at 12 h (77-fold) and then

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

declines. The amounts at 6 h and 12 h correlate significantly with the length of cardio-pulmonary bypass and aortic cross-clamp and with laboratory parameters as Troponin and Lactate. The increase in the amount of miRNA-208a at 12 h in patients with post-operative complications was 346-fold compared to 48-fold in patients without complications ($p < 0.05$). The amount of miRNA-208a at 12 h correlated with the length of hospitalization.
Conclusions: miRNA-208a is a suitable biomarker for predicting the post-operative course and complications in children following repair of congenital heart disease.

P2422 - SUCCESSFUL VENO ARTERIAL EXTRACORPOREAL MEMBRANE OXYGENATION IN CHILDREN WITH REFRACTORY SEPTIC SHOCK USING PERIPHERAL CANNULATION

Grace Van Leeuwen Bichara[1], Larissa Gondim[2], Beatriz Furlanetto[3], Ecryd Abdala Elias[1], Elssi Espinosa[1], Fabiana Nossa[1], Rafaella Gato Calmon[1], Gustavo Favaro[1], Maria Carolina Modolo[2], Nelson Horigoshi[2]
Sabará Hospital Infantil, Pediatric Cardiology, São Paulo-Brazil[1]; Sabará Hospital Infantil, Pediatric Critical Care, São Paulo-Brazil[2]; Sabará Hospital Infantil, Pediatric Cardiac Surgery, São Paulo-Brazil[3]

Background/Hypothesis: Children with refractory septic shock have high mortality. Extracorporeal membrane oxygenation (ECMO) is a possible treatment to these population. We aim to show positive outcome, achieving high flow rates, with VA ECMO using peripheral cannulation.
Materials and Methods: We have reviewed the hospital records for patients who needed ECMO between Aug/2015 and Dec/2016; patient demographic, diagnosis and outcomes were recorded.
Results: Four children with refractory septic shock were treated with VA ECMO during the study period. The mean age was 49,7 (13–104) months. The mean PIM II score was 28% (17%-37,7%), the mean vasoactive-inotrope score (VIS) was 235,8 (107,5-420). Before cannulation, the patients had pH 7,10 (6,99-7,22), lactate level 75,5 (18-122) mg/dl and PaO2/FiO2 ratio 117 (56-180). Micro-biological evidence of infection was present in 75%, streptococcus pyogenes was the most common agent. The mean time until cannulation after intubation was 15,7 h (10–20 hours). 3 children (75%) suffered cardiac arrest before cannulation requiring cardiopulmonary resuscitation (CPR). One of them was a cannulated during CPR (24 minutes). In these patients, ECMO was veno-arterial (v-a) with cephalad cannula. The maximum flow rate needed was between 100 and 150 ml/kg/min, achieved with no difficult with the peripheral cannulation. ECMO-related complications were unilateral vocal cord paralysis (50%), significant isquemic stroke (25%) and internal jugular vein stenosis (50%) and thrombosis (25%); All patients were place on Continuous Renal Replacement Therapy for fluid removal (50% continuous hemofiltration and 50% PRISMAFLEX). One patient also needed peritoneal dialysis. All patients were successfully off ECMO after 120 (62-184) hours (5 days). Three patients were successfully discharged from the hospital and one patient is still recovering, extubated.
Conclusion: ECMO using peripheral cannulation can be safely and effectively performed to rescue and support children with refractory septic shock.

P2427 - LRP1 AN ENDOCYTIC VESICLE TRAFFICKING PROTEIN ASSOCIATED WITH CONGENITAL HEART DISEASES AN UNEXPLORED PATHWAY

Jacob Mccleary[1], Jiuann-huey, Ivy Lin[2], Anupma Jha[1], Cecilia W Lo[1]
University of Pittsburgh, Developmental Biology, Pittsburgh-United States[1]; University of Pittsburgh/children, Critical Care, Pittsburgh-United States[2]

Objectives: Congenital heart disease (CHD) remains the leading cause of neonatal deaths and affects 1% of live births per year in the United States. Strong evidence exists indicating a genetic role in CHD yet the specific mechanics and developmental processes are not fully understood. From a large-scale screen, we uncovered ten endocytic trafficking genes, including LRP1 (low density lipoprotein related receptor protein), that are associated with CHD. LRP1 regulates trafficking of internalized endocytic vesicles to different endosomal compartments, some destined for fusion with lysosomes and degradation, while others are recycled to the surface.
Methods and Results: Whole Exome sequencing from mutant line 1554 (MGI 96828) identified a missense (C4232R) mutation in the epidermal growth factor repeat domain of LRP1. Homozygote mutants exhibit an array of septation and outflow tract defects such as simple membranous ventricular septal defects (VSD), endocardial cushion defect/ atrioventricular septal defect, various types of double outlet of right ventricle (DORV) with normal great arteries or D-malposition of great arteries (Taussig-Bing anomaly). MEF (mouse embryonic fibroblast) derived from LRP1 $^{m/m}$ mutants demonstrate decreased expression of the protein at the cell surface and retention of the LRP1 mutant protein in the endocytic trafficking system. LRP1 is expressed in multiple cell lineages required for cardiac development. We use conditional gene ablation to generate several tissue-specific LRP1 mutants to identify the implication of LRP1 and its targets during endocardial and outflow tract development. LRP1-Nkx2.5-cre mice demonstrate various types of DORV (subaortic VSD, Taussig-Bing Anomaly), while LRP1-Tie2-cre (endothelium and endocardial cushion tissue deletions) demonstrate perimembraous VSD with 25% of mutants demonstrating AVSD. Second heart field specific LRP1 knockout mutants using Mef2C-AHF demonstrate simple VSD.
Conclusion: We provide evidence that endocytic trafficking plays an important role in CHD pathogenesis

P2436 - THE USE OF FAT FREE SEPARATED BREAST MILK AND PARTIAL (LIPID ONLY) PARENTERAL NUTRITION FOR POST OPERATIVE CHYLOTHORAX IN A RESOURCE LIMITED SETTING CASE REPORT TECHNIQUES AND LESSONS LEARNED

Frank Molloy[1], Vedran Stojanovic[2], Vesna Trpkovska[2], Vladimir Chadikovski[2], Pavel Shauchehka[1], Marcelo Cardarelli[3]
Novick Cardiac Alliance, Cicu, Memphis, TN-United States[1]; University Clinic For Pediatric Surgery, Pediatric Surgery, Skopje-Macedonia[2]; Novick Cardiac Alliance, Cardiothoracic Surgery, Memphis-United States[3]

Background: An 8 month 5 kg infant, Trisomy 21 post ASD/VSD/PDA closure developed 30mls yellow-opaque chest drainage following the first postoperative milk feed on postop day 0 (POD.0). ECHO revealed mild-moderate tricuspid regurgitation, mild pulmonary hypertension and dilated right ventricle. No formal analysis of drainage was undertaken. Whole milk feeding was stopped, drainage rapidly cleared and a combination feeding plan started. No medium chain triglyceride milk, oils, nor fat-free milk, were available.
Materials and Methods: Breast milk was collected and left standing, refrigerated and undisturbed for 24 hours, achieving natural and

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

visible fat separation. Fat-free milk was aspirated from the base of the container, taking care not to aspirate the upper fat layer, approximately 4% by volume. Constant delivery was by syringe pump with vertical orientation so any residual fat accumulated at the syringe plunger was delivered. Juices and oral fruit purees were given to supplement breastmilk shortage Fat was delivered by Intravenous Lipid (LIPOFUNDIN MCT/LCT:10% BRAUN), peripherally commencing D1 at 0.5 g/kg/day, increasing to 3/g/kg/day D7. Fat soluble vitamin drops ADEK were added orally. Milrinone continued to POD.4, Oxygen POD.5. Sildenafil, Furosemide, Spironalactone throughout. Albumin 20% 1 g/kg/dose given per analysis.

Results: Maximal nutrition (POD.8) was calculated at 80-90 kcal/kg/day (50-60 kcal/kg/day enteral, 30 kcal/kg/day IV). Chest tubes, central venous line were removed POD.2, POD.3. Ultrasound revealed small bilateral pleural effusions on POD.3, undetectable by POD.5. A gradual re-introduction of full-fat breastmilk commenced on POD.10, was fully established on POD.12. No effusion was seen by ultrasound or x-ray following the reintroduction of enteral fat. Discharge home was achieved on POD14.

Conclusions: Human breast milk, with its nutritional and immunological advantages, can be safely utilised in postoperative chylothorax with no special equipment. Total parenteral nutrition (TPN) mandates central venous access with inherent infection risks. Peripheral venous delivery of lipid solutions is sustainable for many weeks and can be incorporated into any chylothorax strategy.

P2438 - EXTRACORPOREAL LIFE SUPPORT IN A PEDIATRIC INTENSIVE CARE UNIT IN BRAZIL

Grace Van Leeuwen Bichara[1], *Larissa Gondim*[2], *Ecryd Abdala Elias*[1], *Beatriz Furlanetto*[3], *Eduardo Miranda Teixeira*[3], *Fabiana Nossa*[1], *Rafaella Gato Calmon*[1], *Fabiola Muller De Oliveira*[1], *Regina Cesar*[2], *Nelson Horigoshi*[2]

Sabará Hospital Infantil, Pediatric Cardiology, São Paulo-Brazil[1]; *Sabará Hospital Infantil, Pediatric Critical Care, Sao Paulo-Brazil*[2]; *Sabará Hospital Infantil, Pediatric Cardiac Surgery, Sao Paulo-Brazil*[3]

Background/Hypothesis: Pediatric patients with acute respiratory and/or circulatory failure may benefit from Extracorporeal Life Support (ECLS). The aim of the study is to describe the experience of a new ECLS program developed at the PICU of a private tertiary children's hospital in Brazil.

Materials and Methods: Retrospective study including all patients who had undergone non-postcardiotomy ECMO between July 2015 and December 2016; patient demographic, diagnosis and outcomes were recorded.

Results: Eight children were treated with ECLS. The mean age and weight was 33 months (5 months to 8 years) and 13,5 Kg (4,6-20 kg). Four children (50%) suffered cardiac arrest before cannulation requiring cardiopulmonary resuscitation (CPR). One of

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

them was cannulated after 24 minutes of CPR (E-CPR). The underlying conditions were acute respiratory distress syndrome (n = 3), refractory septic shock (n = 4) and respiratory and circulatory failure after left pneumectomy (n = 1). Two children had newly diagnosed Acute Lymphoblastic Leukemia (ALL). All but one had peripheral cannulation with veno-arterial with cephalad cannula support. The other one had dual site venous-venous ECMO. ECMO-related complications were unilateral vocal cord paralysis (25%), significate isquemic stroke (12,5%) and internal jugular vein stenosis (50%) and thrombosis (25%); All patients were place on Continuous Renal Replacement Therapy for fluid removal (75% continuous hemofiltration and 25% PRISMAFLEX). One patient also needed peritoneal dialysis. Seven patients were successfully off ECLS after a mean of 216 (range 62 -621) hours (9 days). One patient died. Two patients are still recovering in the hospital, extubated. The other patients had hospital discharge.
Conclusions: In our center, the ECLS program has reached this far an 87,5% decannulation rate in non-postcardiotomy patients. A very committed multidisciplinary team and focus on continuous training may be the key feature to our successful program.

P2458 - CONGENITAL ABSENCE OF THE PERICARDIUM ASSOCIATED WITH ATRIAL SEPTAL DEFECT AND A DELETION OF CHROMOSOME 6Q13 IN YOUNG CHILD

Hyoung Doo Lee, Geena Kim, Hoon Ko
Pusan National University Children's Hospital, Department of Pediatrics, Yangsan-Korea, South

Congenital absence of the pericardium is an uncommon finding with variable presentations from asymptomatic to paroxysmal stabbing chest pain. Asymptomatic patients with congenital absence of the pericardium are typically discovered at an autopsy or during cardiac surgery. A 26-month-old female presented with severe dyspnea. Her past medical history and family history were unremarkable. A chest X-ray revealed levoposition of the heart into the left chest cavity, and severe pneumonia. An echocardiography demonstrated large sized secundum atrial septal defect with severe pulmonary hypertension. In cardiac tomography, we suspected a left lower pulmonary vein stenosis that comes from a compression of the aorta. We planned to perform a closure of atrial septal defect and a posterior aortopexy. Against our expectations, we discovered incidentally complete absence of the pericardium and no pulmonary vein stenosis during cardiac surgery, so we performed an anterior aortopexy, a fixation of pleura, and a closure of atrial septal defect. After surgery, she was improved from severe pulmonary hypertension and right ventricular hypertrophy. And we performed an array-CGH examination because of facial dysmorphism and developmental delay, and confirmed a gain of 2q21.1, and a deletion of 6q13, 6q14, 1q16.1. We experienced a case of congenital absence of the pericardium associated with atrial septal defect and a deletion of chromosome 6q13 in young child.

P2467 - RELATIONSHIP BETWEEN TROPONIN I VALUES AND POSTOPERATIVE OUTCOMES IN CONGENITAL HEART DISEASE CORRECTION REQUIRING EXTRACORPOREAL CIRCULATION

Otto Mauricio Gonzalez Pardo[1], Gabriel Cassalett[2], Emilia Prieto[3]
Clínica Shaio, Pediatric Critical Care Unit, Bogota-Colombia[1]; Clinica Shaio, Pediatric Critical Care Unit, Bogota-Colombia[2]; Clínica Shaio, Epidemiology, Bogotá-Colombia[3]

Background and hypothesis: Troponin I levels are increased in the postoperative period due to myocardial damage. We proposed that the degree of elevation correlates with the incidence of renal failure and mortality.
Materials and Methods: Retrospective and prospective cohort study between November 2014 and December 2016, and included all children under 15 years of age who undergo to correction of congenital heart disease under cardiopulmonary bypass.
Results: A total of 144 patients were collected, with a median age of 3 years (9 days - 14 years), 63% with shunt heart disease, 8% with obstructive lesions and 29% with complex heart disease, the median time of perfusion was 87 Minutes (18-340 minutes) and aortic clamp of 39 minutes (0-116 minutes). The incidence of postoperative renal failure, we found a significant difference between those who did (percentile 50 of troponin I of 12.85 mcg/Lt (p25 of 5.77 mcg/Lt and p75 of 26 mcg/Lt)) in compared to the group without postoperative renal failure (troponin I 50th percentile of 3.97 mcg/Lt (p25 of 3 mcg/Lt and p75 of 9.33 mcg/Lt)). The mortality of our work was 12%, also finding a significant difference between patients who died (troponin I 50th percentile of 19.2 mcg/Lt (p25 of 10.3 mcg/Lt and p75 of 50 mcg/Lt)) and those that survive (troponin I 50th percentile of 5.5 mcg/Lt (p25 of 3.2 mcg/Lt and p75 of 15.5 mcg / Lt))
Conclusions: The levels of troponin I taken in the postoperative period of the correction of congenital heart diseases under extracorporeal circulation are statistically correlated with the incidence of renal failure and mortality.

P2491 - RISK FACTORS ASSOCIATED WITH MORBIDITY AND MORTALITY IN PATIENTS WITH HYPOPLASTIC LEFT HEART SYNDROME (HLHS) BROUGHT TO NORWOOD PROCEDURE AT A FOURTH LEVEL INSTITUTION IN COLOMBIA

Claudia Ximena Flores-Rodriguez[1], María Constanza Basto-Duarte[2], Anderson Bermon[3], Oscar Guillermo Arévalo-leal[4], Sara E Mendoza[2]
Fundación Cardiovascular De Colombia, Cardiology, Bucaramanga-Colombia[1]; Fundación Cardiovascular De Colombia, Surgery, Bucaramanga-Colombia[2]; Fundación Cardiovascular De Colombia - Phd Student Ces, Reserach, Bucaramanga-Colombia[3]; Fundación Hospital De La Misericordia, Cardiology, Bogotá-Colombia[4]

Introduction: Norwood procedure is the surgical option for patients with hypoplastic left heart syndrome (HLHS). In developing countries, the diagnosis of HLHS is usually late, access to specialized centers is limited, experience in the surgical approach is scarce and published reports are occasional with high mortality. The objective of this study was to analyze the preoperative, postoperative and surgical risk factors associated with morbidity-mortality and determine the survival in a 4th-level institution in a developing country.
Materials and Methods: Retrospective study. We reviewed the charts of patients with HLHS taken to Norwood procedure between January 2009 and December 2015. We analyzed preoperative, intraoperative and postoperative variables. Early mortality was measured (30-day and in-hospital); morbidity was determined by the use of ECMO, length of time on mechanical ventilation, inotropes, cardiac ICU, total days of hospitalization, neurological outcome and renal failure.
Results: Between January 2009 and December 2015, 55 patients diagnosed with HLHS had a Norwood procedure. 31 had modified Blalock-Taussig (MBT) shunt and 24 had right ventricle to pulmonary artery (RVPA) shunt. Mortality at 30 days was 23% and in hospital was 36%. Weight <3000gr (p 0.03) and mechanical ventilation (p 0.022) were the preoperative risk factors associated with death at 30 days. ECMO was a intraoperative and post-operative element related to both mortality (p 0.001).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Non-restrictive atrial septal defect (p 0.011) combined circulatory arrest with periods of antegrade cerebral perfusion (p 0.024) and longer Cardiopulmonary bypass CPB (p <0.01) were risk factors for ECMO. Patients on ECMO had a higher incidence of renal failure (p 0.031). Arrest times and combined cerebral perfusion were associated with increased brain injury (p 0.04).
Conclusion: In our institution, risk factors associated with mortality are comparable with the literature. But contrary, the use RV-PA shunt was not a protective factor in the postoperative period.

P2510 - STUDY ON THE WARNING OF CENTRAL VENOUS OXYGEN SATURATION FOR CHILDREN WITH CONGENITAL HEART DISEASE

Lijuan Fu, Zhouying Zhuang
Shanghai Children Mendical Center, Heart Center, Shanghai-China

Object To study the application value of ScvO2 in the post-operative care of children with congenital heart disease.
Methods: A retrospective analysis includes 201 cases as the research object from CICU of a tertiary children's Hospital in Shanghai, who after congenital heart disease surgery and accepted the dying notice. ScvO2 values detected when the child transfer into CICU and then every 12 hours until the child out of CICU or death. Analyze the difference between the ScvO2 values of the death group and the survival group, and the change of ScvO2 value.
Results: The maximum value of ScvO2, the lowest value, the mean interval is less than or equal to 50%, the mortality rate of children was 50% or above ($P < 0.01$). The maximum value of ScvO2 and the mean value is not less than 70.1%, the mortality rate was lower than 3.1% ($P < 0.01$). The minimum value of ScvO2 is more than or equal to 70.1% and the mortality rate is 0. After the first 12 hours of testing ,there was a rising trend and after 24 hours there was a significant downward trend until death. Survival group can be showed an upward or downward trend, in 24 hours it showed a rising trend and then tends to be stable.
Conclusion: ScvO2 monitoring is valuable for the care and treatment of the critically ill children with congenital heart disease.

P2514 - ALVEOLAR CAPILLARY DYSPLASIA WITH LEFT HEART OBSTRUCTION A CASE REPORT

Veronika C. Stark[1], E. Philipp Schneider[1], Daniel Biermann[2], Rainer Kozlik-Feldmann[1], Urda Gottschalk[1]
University Heart Center, Pediatric Cardiology, Hamburg-Germany[1]; University Heart Center, Pediatric Cardiac Surgery, Hamburg-Germany[2]

Case: We report a neonate delivered after 41 weeks of uncomplicated gestation, healthy family history, normal weight, APGAR, adaptation and early discharge after four hours. Eight hours later the newborn presented with severe hypoxemia (oxygen-saturation 55%) and dyspnea suffering from metabolic and respiratory acidosis (lactate 12 mmol/l). X-Ray appeared with enhanced vascular markings similar to respiratory distress syndrome. Echocardiography showed atrial septal defect type 1, aortic coarctation with hypoplastic arch, open ductus arteriosus with right to left shunt and consecutive volume depleted left ventricle. Despite immediate shock treatment by ventilation, inotropes, diuretics, and prostaglandin E1 low cardiac output syndrome and pulmonary hypertension persisted. Therefore implantation of extracorporeal membrane oxygenation (venoarterial ECMO) was necessary. Persistent pulmonary hypertension (PPHN) was addressed with nitrogen oxide, high frequency oscillation and surfactant admission. Nevertheless, neither lung function nore adequate systemic circulation could be established without ECMO. Having excluded other left heart obstruction causing pathologies and reasons for PPHN we performed open lung biopsy on ECMO. Histology revealed immature lobulae, thickened alveloar septae, medial hypertrophy of small pulmonary arteries and muscularization of distal arterioles - typical for alveolar capillary dysplasia (ACD). ECMO was explanted, therapy was switched to comfort care and the patient passed away on their parents arms at the age of ten days.
Conclusions: ACD is a rare and lethal lung disease associated with congenital heart defects and should be considered in obstructive left heart lesions and PPHN. As soon as other causes for left heart obstruction (intra-atrial membrane, pulmonary venous stenosis, APVC etc.) and PPHN (meconium aspiration, infection, congenital diaphragma hernia, pulmonary hypoplasia etc.) are excluded, lung biopsy is the option to define pathologies like ACD. FOX gene cluster examination can complete the diagnosis. Facing the fatal prognosis early, ante mortem diagnosis is essential to avoid futile interventions for patients, families and care providers.

P2553 - NEONATAL NON COMPACTED MYOCARDIOPATHY. PREDICTORS OF POOR OUTCOME

Sheila Tubio[1], Javier Rodríguez[2], Juan Manuel Carretero[1], Carles Bautista[1], Julio Moreno[2], Carin Cristina Walter[1], Fredy Hermogenes Prada[1], Joan Sánchez[1]
Sant Joan De Déu Children, Pediatric Cardiology, Barcelona-Spain[1]; Sant Joan De Déu Children, Neonatal Intensive Care, Barcelona-Spain[2]

Background: Non-compacted myocardiopathy (NCM) is a heterogenous myocardidal disorder characterized by abnormal trabeculations in the left ventricle. It is an increasingly recognized cause of cardiomyopathy in children and carries significant morbidity and mortality. Although much has been published in the last years, little is known about NCM in the neonatal period. The objective of this study is to characterize the involvement of newborns affected with NCM in two neonatal intensive care units (NICU) and to identify risk factors associated with increased mortality.
Materials and Methods: This is a retrospective study including all neonates diagnosed with NCM between 2006 and 2016 in the NICU. Diagnosis was based on echocardiographic findings. Data about prenatal history, gestational age and weight at birth, gender, age at diagnosis, left or biventricular involvement and associated malformations, medical and surgical treatments and evolution were collected.
Results: We identified fifteen patients diagnosed with NCM. Age at diagnosis was 7.2 ± 6 days. Twelve (80%) had isolated left ventricular involvement. Fourteen patients (93,3%) had other associated heart malformations; six had ventricular septum defects and six right side abnormalities. During admission, two patients presented arrhythmic events. During the follow-up period seven patients (46,6%) died. Patients who died had more biventricular involvement and more non-cardiac malformations (3/3[100%] vs 4/12[33%] $p = 0.02$). The main cause of death was ventricular dysfunction (85,7%). In the five cases in which the family authorized the autopsy the diagnosis was confirmed and two of them presented biventricular involvement not evidenced by echocardiography.
Conclusions: Neonatal NCM is associated with a poor prognosis. The higher mortality observed in our series (46,6%) is related not only to the high association with congenital heart disease, but also to a greater presence of early and severe left ventricular dysfunction. Poor ventricular function and biventricular involvement is a predictor of poor outcome.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

P2559 - ACUTE KIDNEY INJURY AFTER CONGENITAL HEART SURGERY FREQUENCY RISK FACTORS AND OUTCOME IN A DEVELOPING COUNTRY USING KDIGO DEFINITION

Fatima Ali, Qalab Abbas, Babar Hassan
Aga Khan University, Pediatrics and Child Health, Karachi-Pakistan

Objectives: To determine the frequency, risk factors and outcome of acute kidney injury using KDIGO definition.
Methods and Materials: AKI was defined and staged as per KDIGO criteria using serum creatinine. Using this definition 150 patients who had AKI were matched to 75 patients who didn't had AKI from a total of 1680 consecutive patients between January 2007 to December 2016, making overall incidence of AKI to be 8.9% in our series. Appropriate statistical tests were applied to determine the association of different variables with development of AKI and P value of <0.05 was taken as significant.
Results: Both the groups were similar in age (mean age 4.5 years and 6 years), gender (64% male in cases and 60% males in controls) and pre op creatinine (0.35 mg/dl in cases and 0.46 in controls), RACHS scoring and anatomy. Increased cardiopulmonary bypass time and aortic cross clamp time, postoperative hypotension, postoperative inotropic support, need for blood transfusion, use of nephrotoxic drugs, low cardiac output syndrome, development of postoperative sepsis were significantly associated with development of AKI on univariate and multivariate analysis. 40 patients had stage I AKI, 60 had stage II and 50 had stage III AKI. 10 patients required peritoneal dialysis, mean length of stay was 5 days in cases and 3 days in controls, 21 patients in cases and 1 patients in controls expired during the study period. Data collection and analysis is still in progress.
Conclusions: AKI is a very common problem in postoperative congenital heart surgery patients associated with higher mortality and morbidity.

P2604 - VENO ARTERIAL EXTRACORPOREAL MEMBRANE OXYGENATION FOR ACUTE VIRAL MYOCARDITIS WITH CARDIORESPIRATORY ARREST IS IT TOO LATE TO START

Sudeep Verma[1], Nanda Kishore[2], Nagarajan Ramadoss[1], Goutami Vejendla[1], Anil Dharmapuram[1], Atul Jivan Bonde[2], Girish Tayshete[2], Sandya P[2], Im Rao[1]
Kims Hospital, Department of Pediatric Cardiac Sciences, Hyderabad-India[1]; Kims Hospital, Department of Pediatrics, Secunderabad-India[2]

Background: Severe ventricular dysfunction is one of the dreadful complication of viral myocarditis. We are sharing our experience of three cases presented to tertiary cardiac care unit with cardiorespiratory failure and arrest, subsequently needed ECMO support.
Methods, Case Details and Results: Between October 2015 to October 2016, three patients presented with viral myocarditis, severe LV dysfunction, bradycardia and hypotension on arrival to emergency room. Veno-arterial ECMO (femoral vein and artery in 2, internal jugular vein and carotid artery in one) was initiated in all while continuing or immediately after Cardio pulmonary resuscitation (CPR). Median weight and age were 22 kg (range 9.7-64 Kg) and 8 years (range 11/2-13 Years) respectively. Median duration of CPR was 90 minutes (range 60 - 100 minutes). Median Duration of ECMO was 6 days. Viral profile were send for all patients but only one showed positive virology for Echovirus and Coxsackie virus. Two patients requires CRRT while on ECMO due to acute renal failure. Two out of three patients having good LV mass index to begin with were successfully weaned off ECMO with good cardiac recovery. 8 year old girl for which virology was positive got discharged without any neurological deficit. On follow up she showed good ventricular ejection fraction and symptom free status but developed loss of right leg distal pulses without sign of limb ischemia. 11/2 years old weaned off successfully from ECMO but died after 3 days due to DIC and septic shock while for 13 year old ECMO support was withdrawn in view of cerebral uncal herniation.
Conclusion: ECMO can be initiated even during or immediately after CPR with reasonable outcome. Effective CPR and prevention of multiorgan dysfunction are key for successful outcome. Therefore ECMO should be considered before onset of end organ damage.

P2663 - CRITICAL CONGENITAL HEART DISEASE SINGLE INSTITUTIONAL EXPERIENCE AND OUTCOMES IN A LOW MEDIUM INCOME COUNTRY

Gcina Dumani, Paul Adams, Hopewell Ntsinjana, Antoinette Cilliers
Chris Hani Baragwanath Academic Hospital, Paediatric Cardiology, Johannesburg-South Africa

Background: Critical congenital heart disease is associated with high morbidity and mortality. The factors associated with increased neonatal morbidity and mortality include prematurity ≤35 weeks, low birth weight, hypoplastic left heart syndrome and complex cardiac anatomy. major extracardiac and genetic malformations, neonatal sepsis and meconium aspiration.Early diagnosis and intervention can be achieved with prenatal diagnosis and pulse oximetry screening.
Methods: A retrospective review of cases admitted in the Neonatal Intensive Care Unit (NICU) and High Care between 2005 and 2015 and presenting to the Division of Paediatric Cardiology at the Chris Hani Baragwanath Academic Hospital.There are limited prenatal screening services, no onsite cardiothoracic surgical and pulse oximetry screening services.Data related to demographics, prenatal and postnatal diagnosis,clinical presentation,treatment, surgery,mortality and follow up was collected.
Results: The diagnosis of critical congenital heart disease was made in one hundred and twenty patients (males, 62.7%). Median age at diagnosis = 2 days (1-78 days, IQR = 1-5). Mean age at presentation = 2.1 ± 2.8 days (1-18 days). Twenty three cases (19,2%) were preterm ≤35 weeks of gestation.Fifty two cases(43%) had low birth weight, mean birth weight = 1.91 ± 0.39 kg (0.97-2.49 kg). Prenatal diagnosis was made in nine patients (7.5%). Most common presentation was respiratory distress, cyanosis and shock with metabolic acidosis. Majority required invasive positive pressure ventilation (IPPV) and sixty nine patients (57.5%) received PGE2 infusion. Common cardiac lesions were hypoplastic left heart syndrome, transposition of the great vessels and pulmonary atresia with or without ventricular septal defect. Extracardiac and genetic malformations were diagnosed in sixteen patients (13.3%). Catheter interventions were done in eighteen patients (15%). Surgery either palliative or corrective was achieved in twenty two patients (18.3%). Forty five patients (37.5%) were deemed inoperable. Overall preoperative mortality was 71,7%. Preoperative mortality without the patients deemed inoperable was 34.2%.
Conclusions: Mortality is high in patients with critical congenital heart disease especially in those presenting during the neonatal period.Inadequate prenatal screening, prematurity, low birth weight,extracardiac anomalies, lack of pulse oximetry screening program and resources may have contributed to the mortality.

P2697 - ADVERSE EVENTS REPORTING A PROGRAM TO IMPROVE QUALITY AND SAFETY IN A PEDIATRIC CARDIAC INTENSIVE CARE UNIT IN ARGENTINA

Barbara Cordisco[1], Estela Dominguez[1], Carolina Arrascada[1], Raquel Quiroz[1], Cristina Herrera[1], Maria Altahbe[1], Maria Balestrini[2], Ricardo Magliola[2]
Garrahan Hospital, Pcicu, Capital Federal-Argentina[1]; Garahan Hospital, Pcicu, Capital Federal-Argentina[2]

Objective: To describe the implementation of an adverse event reporting program in a pediatric cardiac intensive care unit (PCICU).
Setting: PCICU. Garrahan Hospital, Buenos Aires, Argentina. Material and Methods: a multidisciplinary group was established to develop the program. A special form to collect selected events was designed. Events were grouped as safety (S), medication (ME), mechanical ventilation (MV), vascular lines (VL), procedures (P), nutritional support (NS), surgical (Q) and in-hospital transfer (T). All staff were trained about the program goals and how to complete the forms. A mailbox was placed in a visible place inside the unit. Any team member can report events, is voluntary and anonymous. Monthly reports are analyzed and preventive measures and/or process changes are proposed.
Preliminary Results: There were 178 events reported between December 2015 and December 2016. The most frequently reported were30% vascular lines, 24% medication,16% Safety and 8% mechanical ventilation. More than 85% were reported by nurses. 33% in the morning shift and 30% during the night one. Increasing bed side strategies and communication improvement were proposed as a result of this analysis.
Conclusions: Nurses participation in the program was very high. Adverse events reporting is a new tool which provides valuable information to provide safer and higher quality carein our PCICU.

P2715 - HEALTH PROFESSIONALS INTENSIVE CARE UNITS AND DEATH WHAT IS THE RESULT OF THIS EQUATION

Rachel Vilela De Abreu Haickel Nina[1], Erika Bárbara Abreu Fonseca Thomaz[2], João Batista Santos Garcia[3], Maria Emilia De Miranda Álvares[4], Zeni Carvalho Lamy[2]
Phisyician, Cardiovascular Unit at The University Hospital of The Federal University of Maranhao, Sao Luis-Brazil[1]; Professor, Public Health of Federal University of Maranhão, Sao Luis-Brazil[2]; Professor, Medicine I Offederal University of Maranhão, Sao Luis-Brazil[3]; Student, Psichology at at The University Hospital of The Federal University of Maranhao, Sao Luis-Brazil[4]

Background: Death is constantly present in the daily processes of intensive care units (ICUs), and it has different implications for health professionals.
Objective: To analyze factors associated with the meaning of death in the ICU and the attitudes of health professionals who are faced with death.
Design: This cross-sectional study considered 5 different outcomes: "meaning of death"; "meaning of death of terminally ill patients"; "attitude towards giving news of death"; "resuscitation of a patient without possibility of treatment"; and "discussion about do-not-resuscitate orders". The explanatory variables were demographic, socio-cultural and vocational training characteristics.
Setting/Subjects: Doctors and nurses in the ICUs (general, cardiac, pediatric and neonatal) of a university hospital in northeastern Brazil.
Measurements: Associations were estimated using a multiple regression analysis ($\alpha = 5\%$).
Results: A total of 52 doctors and 45 nurses were included. The following were associated with the meaning of death for ICU professionals: personal experience with death, professional category, type of ICU and length of service ($P < 0.05$). The attitudes of these professionals when facing death were associated with the following: importance attached to religion, professional category, length of training, discussion of the topic in the professional life, the patient's age in the first professional experience with death and the number of units in which they had worked ($P < 0.05$).
Conclusions: The death of ICU patients is associated with pain, guilt and failure for many doctors and nurses, and their attitudes reveal a strong therapeutic obstinacy. Perceptions and attitudes towards death are affected by socio-cultural aspects, previous experience and professional training. Curricular changes and

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

changes to the work process of these professionals are suggested, including the incorporation of protocols for palliative care and the communication of bad news.

P2787 - GASTROSTOMY IN INFANTS AFTER CARDIAC SURGEY INCEDINCE AND ASSICIATED RISK FACTORS

Mohammed Absi[1], Susheel Kumar[2], David Zurakowski[3], Lindsey Bird[4], Rana Khazanda[1]
University of Tennessee, Pediatric Cardiology, Memphis-United States[1]; University of Tennessee, Cardiothoracic Surgery, Memphis-United States[2]; Boston Children, Department of Anesthesiology, Perioperative and Pain Medicine Research, Boston-United States[3]; University of Tennessee, Pediatrics, Memphis-United States[4]

Background/Hypothesis: Feeding difficulty following congenital heart surgery in the neonatal period is a known complication. The aim of this study is to identify the risk factors most associated with gastrostomy placement.
Materials and Methods: We conducted a retrospective chart review of patients 0-3 months of age with congenital heart surgery and gastrostomy placement with and without fundoplication from our institutional Pediatric Research Database from July 2010 - July 2015. 37 patients were identified and 29 included in the study. A control group of 123 patients was identified and used for analysis. Preoperative, intraoperative, and postoperative factors of interest were collected. Univariate regression and multivariable logistic regression analysis of these factors was performed to identify those associated with gastrostomy placement in our cohort.
Results: In the full cohort of 152 patients, 37 patients underwent gastrostomy placement (24%) after surgery for congenital heart diseases. 8 patients were excluded for different reasons, 29 were included. The main two factors were found to be associated with need for Gastrostomy placement are vocal cord dysfunction (VCD) (odds ratio 7.0; 95% confidence interval, 1.8-27.2; $P = 0.004$) and need for surgical revision (odds ratio 7.9; 95% confidence interval, 2.5-25.4; $P = < 0.001$). Other risk factors like small body weight, high RACHS score, presence of genetic anomaly, and the need for prolonged Total parental nutrition or promotility agents were statistically significant using univariate analysis but not using multivariable regression analysis.
Conclusions: In infants undergoing congenital heart surgery in the first three months of life, patients with VCD or need for surgical revision are at a higher risk for gastrostomy placement. These results indicate a need for the early evaluation and reduction of injury leading to VCD and surgical revision.

P2816 - MULTIPLE LUNG ABSCESS SECONDARY TO SEPTIC EMBOLISM DUE TO INFECTIVE ENDOCARDITIS. PEDIATRIC CASE REPORT

Mario Guerra[1], Patricia Aroca[1], María Lidia Valenzuela[1], Margarita Aldunate[2], Acuña Mirta[3]
Hospital Roberto Del Río, Upc Cardiovascular, Santiago-Chile[1]; Hospital Roberto Del Río, Servicio De Cirugía, Santiago-Chile[2]; Hospital Roberto Del Río, Unidad De Infectología, Santiago-Chile[3]

Background: Septic pulmonary embolism is a serious and unusual condition where the focus is primarily the right infective endocarditis (IE) and less frequent from thrombophlebitis or osteomyelitis. The most cases reports of pulmonary embolism secondary to IE affect intravenous drug users or immunocompromised adults patients.
Method: Case of an inpatient at Cardiac Critical Care Unit at Children's Hospital Roberto del Rio in Santiago de Chile in October 2016 is reported.
Results: We described a 2 years old female, with history of small ventricular septal defect (VSD), consulted for 15 days of fever, illness appearance, change in cardiac murmur, with elevated C protein reactive, leukocytosis and thrombocytopenia. Color Doppler echocardiography demonstrated a small perimembranous VSD and a vegetation in septal tricuspid leaflet. Treatment with ceftriaxone and amikacin was initiated. Blood cultures for Streptococcus viridans were positive. Due to no response to antibiotherapy and onset of cough, at fifth day of treatment heart surgery was performed, vegetation was removed and VSD closure, without complications. The patient evolved with persistent fever, right interstitial infiltrate at chest radiograph (CR). Computed tomography angiography (CT angio) of chest images showed signs of pulmonary embolism with multiple areas of pulmonary infarction perfused by right pulmonary artery, thereby at ninth day of treatment, subcutaneous enoxaparin was started. Due to clinical condition and CR evolves with air-fluid levels, the antibiotherapy was changed to vancomycin with meropenem. New CT angio confirms a large air-fluid collection that compromises the right lower lobe. Percutaneous drainage was performed and collection cultures were positive to Pseudomonas aeruginosa carbapenem resistant and sensitive to ceftazidime and amikacin for which treatment was changed, achieving patient recovery.
Conclusions: In pediatrics patient the septic pulmonary embolism represent an exceptional situation. We report this case to mention the importance of basic clinical parameters and the relevance of early diagnostic recognition.

P2821 - NON WHITE RACE IS A RISK FACTOR FOR MORTALITY IN PEDIATRIC CARDIOMYOPATHY AND MYOCARDITIS PATIENTS

Jillian Olsen[1], Lie Tjoeng[2], Titus Chan[3]
Seattle Children, General Pediatrics, Seattle-United States[1]; Seattle Children, Critical Care, Seattle-United States[2]; Seattle Children, Cardiac Critical Care, Seattle-United States[3]

Background: Previous studies identify non-white race as a risk factor for mortality in patients undergoing extracorporeal membrane oxygenation (ECMO) or cardiac surgery. We investigated the association between race/ethnicity and outcomes in pediatric patients with cardiomyopathy and myocarditis using a national database.
Methods: All pediatric patients with a diagnosis of myocarditis or cardiomyopathy and without congenital heart disease in the Healthcare Cost and Utilization Project Kids' Inpatient Database from 2003 to 2012 were included. Logistic regression models were created to explore race and mortality, adjusting for year, sex, age group, diagnosis, insurance, hospital type, and organ dysfunction.
Results: A total of 34,617 patients with cardiomyopathy (71%), myocarditis (25%), or both (4%) were included. The identified racial/ethnic groups were white (39%), black (20%), Hispanic (15%), and "other" including Asian/Pacific Islander, and Native American (8%). Black race (Odds Ratio (OR): 1.28, 95% Confidence Interval (CI): 1.04-1.58) and Hispanic ethnicity (OR: 1.30, 95% CI: 1.05-1.62) were independent risk factors for mortality after adjusting for the above covariates. Black race was also a risk factor for cardiac arrest (OR: 1.25, 95% CI: 1.03-1.51) and ECMO usage (OR: 1.55, 95% CI: 1.07-2.25). After adjustment for mechanical circulatory support (ECMO and ventricular assist devices) and heart transplantation, black race was no longer associated with mortality. However, Hispanic ethnicity remained associated with poor outcome (OR: 1.31, 95% CI: 1.04-1.64).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Black race and Hispanic ethnicity are risk factors for mortality in pediatric patients with cardiomyopathy or myocarditis. In black patients, this may be due to disparities in supportive therapies.

P2822 - CAN NEWBORN WITH CONGENITAL COMPLEX HEART DISEASE BE BORN BY NORMAL DELIVERY

Juan Pablo Miranda, Carolina Garay, Romana Figueroa, Maria Jesus Garcia
Barros Luco Hospital, Neonatology, Santiago-Chile

Introduction: Prenatal diagnosis of complex congenital heart disease is frequently diagnosed and usually perinatal team propose a planned cesarean section. However, the benefit of this behavior is not yet clear.
Objectives: To determine if infants with prenatal diagnosis of complex congenital heart disease had better Apgar test than those without diagnosis or those born with normal delivery.
Patients and Methods: Retrospective study between January, 2014 and August, 2016, review of records of newborns with diagnosis of postnatal congenital heart disease. Complex congenital heart disease was defined as those that requiring some type of surgical intervention during the first year of life.
Results: Twenty-nine patients with complex congenital heart disease from a total of 11,275 live births (2.57 × 1000 NV, 16 per spontaneous delivery (56%) and 13 cesarean (44%) were born, 20% were emergency cesarean sections. Median APGAR of the complete group at 1 minute and at 5 minutes was 8 and 9, respectively. For the spontaneous delivery group, it was 8.5 and 9. For the cesarean group it was 8 and 9. The most frequent causes of cesarean section were: previous double cesarean section (50%), maternal cause (20%) and dystocia (15%). The prenatal diagnosis of congenital heart disease reached 52% and the most frequently diagnosed cases were left ventricular hypoplasia (n: 6) and atrioventricular septal defects(n: 6). Only 50% of these patients had prenatal diagnosis and half of them were born by normal delivery.
Conclusions: Diagnose of complex congenital heart disease does not imply a programmed or cesarean delivery, but it would be reserved for situations in which the maternal condition warrants it.

P2827 - IMPACT OF LEVOSIMENDAN IN HEART FAILURE PEDIATRIC PATIENTS

Catarina Perez-brandão, Conceição Trigo, Fátima F. Pinto
Santa Marta Hospital, Pediatric Cardiology, Lisboa-Portugal

Background: Levosimendan is an inodilator agent used in the treatment of low cardiac output heart failure in pediatric patients. We present a single center's experience regarding the use of levosimendan in children, evaluating its role in cases of ventricular dysfunction and low cardiac output syndrome.
Material and Methods: Patients were selected for levosimendan administration if low cardiac output heart failure was present either because of dilated cardiomyopathy or ventricular dysfunction after cardiac surgery. Retrospective analysis of data of all children treated with levosimendan from 2004 to 2016. Each patient received at least one 0.05-0.2 μg/Kg/min infusion of levosimendan, without a loading dose. Biomarkers and echocardiographic data before and after treatment were compared.
Results: Twenty-nine patients were included. The median of age was 2 years (2 months-19 years) and 65.5% of patients were female. More than 50% of all patients had dilated cardiomyopathy. Thirty-one percent had ventricular dysfunction after cardiac surgery. Levosimendan improved lactate levels (11.4 to 7.4 mmol/L, $p = 0.008$, $d = 0.85$), glomerular filtration rate (97 to 148 mL/min/1.73 m2, $p < 0.001$, $d = 1.22$), B type natriuretic peptide concentration (2655 to 498 pg/mL, $p = 0.001$, $d = 1.36$) and left ventricular fractional shortening (16.9 to 22.7%, $p < 0.001$, $d = 1.53$). After treatment, there was a trend towards left ventricular (LV) dimension reduction although it did not reach statistical significant difference (LV z-score 4.7 to 4, $p = 0.102$). There were no complications during the treatment.
Conclusions: Our results showed cardiac and renal function improvement with a better hemodynamic and metabolic profile. Although there is still little evidence about the use of levosimendan in children, these findings are consistent with other reported studies.

P2854 - MILRINONE AND ARRHYTHMIA FOLLOWING PEDIATRIC HEART SURGERY IS THERE AN ASSOCIATION

João Rato[1], Ana Sousa[1], Duarte Martins[1], Miguel Abecasis[2], José Neves[2], Rui Anjos[1], Graça Nogueira[1]
Hospital Santa Cruz - Centro Hospitalar Lisboa Ocidental, Pediatric Cardiology, Lisbon-Portugal[1]; Hospital Santa Cruz - Centro Hospitalar Lisboa Ocidental, Cardiothoracic Surgery, Lisbon-Portugal[2]

Background: Milrinone is an inotrope and vasodilator used after pediatric heart surgery. Arrhythmia is considered to be one of its most frequent side effects, but with scarse evidence in pediatric age. In our study, we evaluated the incidence of arrhythmia and its potential association to milrinone following pediatric heart surgery.
Materials and Methods: We performed a retrospective study in a Pediatric Cardiac Intensive Care Unit. Patients with ≤1 year of age submitted to heart surgery with extracorporeal circulation during the last 4 years were randomly selected. The data was analyzed by SPSS, using the Chi-square or Fisher's exact test for categorical variables and the T-test for ordinal variables.
Results: Our sample consisted of 104 patients, median of age 4 months. Diagnosis included: transposition of the great arteries (29), ventricular septal defect (25), tetralogy of Fallot (18), complete atrioventricular septal defect (14), others (25). Arrhythmia was documented in 36.5% of the patients (38): junctional tachycardia (19), atrioventricular block (5), ventricular extrasystole (5), others (9). The following factors were significantly associated with arrhythmia: coronary manipulation ($p = 0.019$), RACHS1 ≥ 4 ($p = 0.017$), use of milrinone ($p = 0.003$) or epinephrine ($p = 0.008$), and with lower significance, with the occurrence of low cardiac output syndrome ($p = 0.041$) or acute kidney injury ($p = 0.028$). Patients with arrhythmia were significantly younger (3.1 vs 5.4 months, $p = 0.004$) and presented higher lactate levels (5.4 vs 3.0 mmol/L, $p = 0.011$).
Conclusion: In our study we found a statistical association between the occurrence of arrhythmia and the use of milrinone after pediatric heart surgery. This may result from a pure side effect of milrinone or a cluster of factors that configure situations of higher arrhythmia risk.

P2900 - IDIOPATHIC ARTERIAL CALCIFICATION IN NEONATE WITH HYDROPS FETALIS – DIAGNOSIS AND THERAPEUTIC MANAGEMENT

Andressa Mussi Soares[1], Paulo Jose F. Soares[2], Bernardo M. Soares[3], Fabio R. Bortolini[4], Grazielle S. F. Grillo[5], Patricia L. Mota[5], Renata B. Pacifico[5], Luiz Fernando Lunz[5], Vitor C. Guerra[6], Luiz Daniel F. Torres[7]
Hospital Evangelico, Cardiologist Pediatric, Cachoeiro De Itapemirim-Brazil[1]; Hospital Evangelico, Interventional Cardiologist, Cachoeiro De Itapemirim-Brazil[2]; Escola De Medicina Souza Marques, Medicine, Rio De Janeiro-Brazil[3]; Hospital Evangelico, Radiologist, Cachoeiro De Itapemirim-Brazil[4]; Hospital Evangelico, Neonatologist, Cachoeiro De Itapemirim-Brazil[5]; Sick Children, Cardiologist Pediatric,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Toronto-Canada[6]; Hospital Evangelico, Cardiologist Surgery, Cachoeiro De Itapemirim-Brazil[7]

Introduction: Idiopathic arterial calcification (IAC) is a rare and generally fatal autosomal recessive disorder of unknown etiology. IAC is characterized by extensive and diffuse calcification and stenosis of the medium and great arteries due to deposition of calcium in the internal elastic lamella, which culminates in heart failure and recalcitrant arterial hypertension.
Case Report: Woman at 35 weeks of gestational age was referred to the tertiary hospital with diagnosis of hydrops fetalis and myocarditis. Newborn with 3,840 g, male, resuscitation was performed. He presented anasarca, distended abdomen, hepatosplenomegaly, hypophonetic heart sounds, cardiomegaly, arterial hypotension and anemia. Echocardiography revealed significant pericardial effusion, left ventricular dysfunction, and hyperechogenic arterial walls. IAC was hypothesized and later confirmed by angiotomography, which demonstrated diffuse arterial involvement (aorta; iliac, renal, femoral arteries, pulmonary artery). The newborn was submitted to pericardiocentesis, which improved the hemodynamic parameters. Treatment with sodium pamidronate was initiated on the fourth day after birth and lasted three days. The newborn improved progressively and was extubated at 10 days of age.The newborn needed amlodipine due systemic arterial hypertension. Sodium pamidronate was administered every two months for 12 months and every six months for further 12 months, until he was aged 24 months. The patient is currently 29 months old and stable. He has satisfactorily gained height and weight and new medication cycles are being planned. The latest echocardiogram has shown improved function of the left ventricle. According to the most recent angiotomography scan, arterial calcification has decreased significantly.
Comments: Although IAC is a rare condition with highly morbimortality, it should always be investigated in fetuses or newborns with arterial parietal hyperechogenicity and hydrops. In this case report, early echocardiographic findings combined with specific support therapy (sodium pamidronate) seem to have been crucial factors in the patient's initial progress. Serial follow up should be accomplished.

P2928 - VENOUS TO ARTERIAL CARBON DIOXIDE DIFFERENCE A MARKER OF LOW CARDIAC OUTPUT IN CHILDREN AFTER CARDIOVASCULAR SURGERY

Mercedes Montonati[1], *Jessica Claus*[2], *Guillermo Moreno*[1], *Cecilia Quaglia*[2], *Maria Balestrini*[2], *Ricardo Magliola*[1]
Garrahan Hospital, PCICU, Capital Federal-Argentina[1]; *Clinic Y Maternity Suizo Argentina, PCICU, Capital Federal-Argentina*[2]

Objective: The purpose of this study was to correlate central venous to arterial carbon dioxide difference (PCO2 gap) with mortality as the primary end point and low cardiac output syndrome (LCOS) and their relationship to other markers of impaired tissue perfusion in patients after cardiac surgery with bypass (CPB), and the positive predictive value.
Design: prospective, observational clinical study. Setting: PCICU. Material and Methods: All patients less than 6 months of age that were admitted to the PCICU after CPB. Measaurements of

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

arterial and venous CO2 were performed in every patient at 6, 16 and 24 hrs. Values of PCO2 were calculated by subtracting venous CO2 from arterial CO2. For the purpose of the study, CO2 gap >6 and ScvO2 < 70% represented hypoperfusion. Other parameters of global blood flow were assessed, venous mixed saturation (VMS), lactate (AL), NIRS, urine output and vasoactive inotropic score (VIS). We defined LCOS with a VIS >15. Data was expressed as mean and SD or percentage. Chi square test for categorical variables and spearman analysis to measure the degree of correlation between the variables.
Results: 30 infants were enrolled from 8/2016 to 1/2017. 40% were neonates, 60% male. The median weight was 3,1 kg (r2,7-8,8), more 50% were RACHS >3 and 40% had VIS > 15. In relation to the PCO2 gap, 60% of the patients with PCO2 gap >6 had ScvO2 >70%. We also finded that at 12 hrs. postoperative (PO) we had a PCO2 gap >6 with a lactate value >20 in all our patients.
Conclusion: All patients had LCOS. The widening of the CO2 gap poorly correlates with ScvO2.The first 12 hrs. postoperative we have better correlation between CO2 gap and LA.

P2932 - USE OF VD VT (DEATH VOLUME TIDAL VOLUME) AND CO2 EXHALED VOLUMETRIC AS REGARDS CLINICAL PARAMETERS LIKE PREDICTORS OF EXTUBATION IN POSTOPERATIVE PATIENTS OF CARDIAC CONGENITAL DISEASE

Jessica Claus[1], Cecilia Quaglia[2], Leonardo Perez[1], Alicia Saenz[1], Lucrecia Braco[1], Viviana Miranda[1], Gabriel Arias Miño[1], Maria Balestrini[1]
Clinic and Maternity Suizo Argentina, Pcicu, Capital Federal-Argentina[1]; Clinic Y Maternitand Suizo Argentina, Pcicu, Capital Federal-Argentina[2]

Objective: Analyze the value of Vd/Vt and CO2 exhaled volumetric like predictor of the success in the extubation in the PCICU.
Material and Method: Study of cohort, prospective, longitudinal and observational in patients <1 year from 1/2016 to 1/2017 with bypass (CPB) in assistance of mechanic ventilation (VM), which extubation criteria. We valued age, weigh, cardiac congenital disease with categorization of RACH1, vasoactive of inotrópics score (VIS), parameters VM: paFio2 (Pafi), Index of oxygenation (OI). Lactic acid (LA), CO2 volumentrics and interrelation with PaCO2, and Vd/Vt measured at 0,6,12 and 24 hrs. And a Vd/Vt relation <0,4 might relate successfully in the extubation and a relation >0,65 to defeat.
Results: 30 patients, with CPB, with medium 3,5 month and weight of 3,8 Kg, RACHS 1: 1 2% ; 2 43%, 3 48% and 4 7% VM: PaFi median 435, OI: median 2, VIS was 40% < 15, LA at the moment of the extubacion <20, The measurement of CO2 volumetric pre-extubacion 32,5 in interrelation with a Vd/Vt <0,5 when they arrived, the first day <0,5 and at the moment of extubation <0,5. Of 30 patients 5 went to nasal cannula with good tolerance without request of non invasive positive pressure (NIPP) and 25 went to cannula but they needed of NIPP a few minutes after the extubation. The analyzed patients presented at the moment of being extubated a Vd/Vt <0,6, nevertheless considering the characteristics of this group of patients the majority needed the use of NIPP. However patients did not need reintubation to VM.
Conclusion: The value of Vd/Vt contributes an important fact at the moment of the extubation, therefore we can deduce that it is a good factor predictive for successful extubation; although we cannot predict if the patient is going

P2937 - DIFFERENCE OF RESUSCITATION OUTCOME BY THE CAUSE OF SUDDEN CARDIAC ARREST OF SCHOOL STUDENTS

Mamoru Ayusawa, Masataka Kato, Akiko Komori, Yuriko Abe, Takahiro Nakamura, Hiroshi Kamiyama, Shori Takahashi
Nihon University, Pediatrics and Child Health, Tokyo-Japan

Background: Basic Life Support and Automated External Defibrillator have been contributing to decrease sudden cardiac death in school since their introductions. It is necessary to evaluate the latest results of resuscitation according to the cause of cardiac arrest.
Methods: We analyzed all reports including ECG, death or health certificates, and autopsy reports of all decease and recovered cases registered to the mutual aid system for schools between 2008 and 2013.
Results: There were 121 deceased cases and 207 resuscitated cases during these 6 years. Incidence (/100,000studente·year) of decease and recovery were 0.12 and 0.20, respectively. Estimated cause of SCA was unknown in 28% and 43% ($p < 0.01$) of decease and recovered cases, respectively. VF ($p = 0.58$), LQT ($p = 0.07$), commotio cordis ($p = 0.15$), cardiomyopathy ($p = 0.14$), coronary anomaly ($p = 0.8$), and congenital heart disease ($p = 0.054$) did not differ significantly between decease and recovery cases. The proportions of myocarditis (5% and 1%; $p < 0.05$) and aortic dissection (6% and 0; $p < 0.01$) in decease were significantly more than recovered cases.
Conclusions: Although incidence of SCA including both decease and recovery is still around a total of 0.3, approximately two thirds of them have been resuscitated successfully in school from 2008 to 2013. Favorable outcomes in arrhythmic diseases are achieved, however, difficulty of resuscitation in structural disease are enhanced for rescue of SCA in school students.

P2938 - DOES ACTIVATED PARTIAL THROMBOPLASTIN TIME OR HEPARIN LEVEL CORRELATE BEST WITH BLEEDING FOLLOWING SURGERY FOR CONGENITAL HEART DISEASE

Lynn Sleeper[1], Olubunmi Oladunjoye[2], Asha Nair[1], John Kheir[1], Christina Vanderpluym[1], Sitaram Emani[2]
Boston Children's Hospital/Harvard Medical School, Cardiology, Boston-United States[1]; Boston Children's Hospital, Cardiac Surgery, Boston-United States[2]

Background/Hypothesis: Following congenital heart surgery (CHS), patients are at risk for both bleeding and thrombosis. Assays used to monitor anticoagulation with unfractionated heparin (UFH) include the heparin level (anti-Xa) and activated partial thromboplastin time (aPTT). However, disagreement exists regarding which is optimal to guide UFH titration following CHS.
Materials and Methods: We prospectively collected dosing of UFH; aPTT; anti-Xa level; and the presence of major and clinically relevant bleeding in consecutive patients undergoing cardiac surgery and receiving postoperative therapeutic UFH at our institution between August 2015 and July 2016. Major bleeding was defined as that causing emergent surgical intervention or transfusion, intracranial bleeding, or death. Clinically relevant bleeding was defined as that requiring transfusion, imaging or additional testing. All bleeding events were adjudicated. Daily maximum aPTT and anti-Xa values were analyzed using generalized additive logistic regression and logistic piecewise regression with generalized estimating equations for significance testing and estimation of odds ratios.
Results: The analyses of aPTT and anti-Xa were based on 1488 days from 178 patients and 1105 days from 124 patients,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

respectively. Median age at CHS was 2.8 (IQR,0.3-11.4) months and 50% of procedures were RACHS ≥ 4. aPTT and anti-Xa are modestly correlated (R = 0.57). The odds of bleeding are doubled when aPTT exceeds 150 (odds ratio[OR] = 1.71 per 10-sec increase, 95% CI 1.21-2.42; p = 0.003, Figure); however, there is no association as long as aPTT is below 150 (OR = 0.92, 95% CI 0.77-1.10; p = 0.35). Anti-Xa level does not predict bleeding (OR = 1.11 per 0.1 IU/mL increase, 95% CI 0.89-1.29; p = 0.34). *Conclusions:* Following CHS, aPTT exceeding 150 seconds while on UFH is associated with an increased risk of bleeding. Anti-Xa level does not predict bleeding.

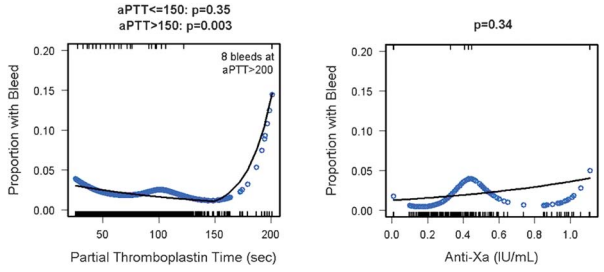

Figure.
Estimated Probability of Bleed when treated post-operatively with therapeutic heparin. Blue curves based on nonparametric model (GAM). Black lines based on parametric logistic regression.

P2946 - CLINICAL PHYSIOLOGIC RESPONSE TO SURGERY AND TO EXTUBATION IN PATIENTS UNDERGOING BIDIRECTIONAL GLENN PALLIATION

Asma Razavi [1], Dean E. Mckenzie[2], Ronald Bronicki[3]
Loma Linda University Children Pediatric Critical Care Medicine Loma Linda-United States[1]; Texas Children Cardiothoracic Surgery Houston-United States[2]; Texas Children Pediatric Critical Care Medicine Houston-United States[3]

Background: Single ventricle anatomy exists in a suboptimal physiological state. The superior cavopulmonary connection results in improved physiology by improving pulmonary blood flow, ventricular volume unloading and improved oxygen saturation (SaO2), and extubation further augmenting pulmonary blood flow. We investigated physiologic changes after the bidirectional glenn (BDG) surgery, as well as the effects of extubation after the BDG.
Methods: We retrospectively reviewed data for patients undergoing BDG over 4 years. Pre and post op ECHOs were reviewed for physiologic response to surgery. Variables averaging 6-12 hours peri-extubation were collected to demonstrate the clinical manifestations of the physiologic response to extubation.
Results: 140 out of 150 patients were intubated post-BDG surgery. Comparing pre-operative to post BDG: greater than mild atrioventricular valve regurgitation (AVVR) decreased from 25.7% to 7.9%, and 13.6% had greater than mild systolic dysfunction with improvement in 2.1%. Comparing pre and post-extubation states, the SaO2 and mean arterial pressure increased (82% to 83%, p = 0.045); (66 to 71 mmHg, p = 0.000) respectively, with an average increase in PaCO2 by 10 mmHg after extubation, and no significant clinical change in PaO2. Post-operative UOP increased, with a decrease in mean pulmonary artery pressure and creatinine post extubation. In 10 patients with an average pre-extubation SaO2 ≤75%, an increase in SaO2 (73% to 76%, p = 0.047), MAP (69 to 74 mmHg, p = 0.011), and post-operative Cr was demonstrated post-extubation.
Conclusion: This large descriptive of patients undergoing the BDG palliation demonstrates clinical trends in certain physiologic variables, with surgery resulting in improvement of AVVR. Extubation improved SaO2, MAP, mean pulmonary artery pressure and demonstrated an average increase in PaCO2 during the post extubation period. We describe these clinical trends in hopes of aiding clinicians gain a better understanding of the physiologic changes after the BDG surgery and clinical response to extubation in this patient population.

P2962 - INFECTIONS IN PEDIATRIC SINGLE VENTRICLE PATIENTS ASSOCIATED WITH INCREASED MORBIDITY AND MORTALITY

Erin Kritz [1], Claire Bocchini[2], Yunfei Wang[3], Paul Checchia[1], Elena Ocampo[4]
Baylor College of Medicine, Pediatric Critical Care Medicine, Houston-United States[1]; Baylor College of Medicine, Pediatric Infectious Disease, Houston-United States[2]; Texas Childrens Hospital, Pediatric Cardiology, Houston-United States[3]; Baylor College of Medicine, Pediatric Cardiology, Houston-United States[4]

Children with single ventricle (SV) physiology represent a vulnerable population with multiple hospitalizations and surgeries. Data is limited on the infectious morbidity and mortality in these patients. Our hypothesis is that SV infants will incur a variety of bacterial and viral infections in the first year of life, which will be associated with worse clinical outcomes. We performed a retrospective chart review of infants with SV physiology born 12/2009 to 4/2015. Of 122 infants, 65% had HLHS; 54% were male; 122 (100%) underwent stage one palliation and 96 (79%) underwent stage two palliation. All cause mortality at one year was 21%. Seventy-six (62%) patients had at least one infection during the first year of life. Thirty patients (25%) had a viral infection, identifying rhinovirus/enterovirus (12), RSV (8), parainfluenza (5), adenovirus (3). The majority (91%) of patients were symptomatic, most often with cough or respiratory compromise. Most viral infections were community-acquired (75%). Infants with viral infections were more likely to have readmission (p = 0.04) and have a heart transplant by one year (p = 0.04). Sixty-two patients (51%) had 149 positive bacterial cultures, identifying 170 organisms from the respiratory tract (64), blood (57), urine (25), other (24). Most common organisms were Enterobacter (29), CoNS (29), Pseudomonas (26), and E. coli (18). The majority (80%) of bacterial infections were nosocomial and symptomatic (88%). Most common symptoms were fever and respiratory compromise. Infants with bacterial infections had longer initial hospital and iCU LOS (both p < 0.01). Infants with bacterial infection prior to Glenn were more likely to have received ECMO (p < 0.01) and to die by one year (p = 0.04). Bacteremia was independently associated with death (p = 0.03). Eight of 26 infants who died had a positive culture in the 48 hours preceding death. Children with single ventricle physiology have frequent infections, which are associated with increased morbidity.

P2966 - A RETROSPECTIVE STUDY OF POST OPERATIVE INTENSIVE CARE MANAGEMENT OF VENTRICULAR SEPTAL DEFECT WITH SEVERE PULMONARTY ARTERIAL HYPERTENSION IN A DEVELOPING COUNTRY

Dr Gopi Nallaiyan
Devadoss Multispeciality Hospital, Paediatric Cardiac Surgery, Madurai-India

Hypothesis: A Retrospective study of Post operative Intensive care management of VSD with severe PAH by a single surgeon form June 2013 TO December 2016 and its results.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Material and Methods: All cases of surgical closure of VSD with severe PAH was evalvauated restrospectively from June 2013 to December 2016 by a single surgeon. There was 113 cases of Surgical closure of VSD with severe PAH of various age form 4 months to 12 years. All cases were managed with milrinone loading dose during cross clamp release and post operative infusion for 48 hours and then Tab Enalapril 0.2 mg/kg/day and Tab Sildenafil 0.1- 0.2 mg/kg/day in divided doses for 3 months.All patients ventilated with PCO2 of <35mm Hg for 24 – 48 hours with continuous sedation.
Results: 2 mortality out of 113 cases due to PAH crisis and Post operative PA pressures were less than ½ of the systemic in 87 out of 111 cases.
Conclusion: Milrinone is a very good Pulmonary vasodilator for VSD with severe PAH cases in developing nations where there is non availability of Nitric oxide. This is one of the effective way of post operative management in developing countries with financial contriants.

P2970 - PICU OUTCOME OF FULMINANT DILATED CARDIOMYOPATHY AND MYOCARDITIS IN A DEVELOPING COUNTRY

Beyra Rossouw [1], Andrew Argent[2], Brenda Morrow[2], John Lawrenson[2]
Red Cross War Memorial Children's Hospital, Division of Critical Care and Children's Heart Disease, Cape Town-South Africa[1]; Red Cross War Memorial Children's Hospita, Division of Critical Care And Children's Heart Disease, Cape Town-South Africa[2]

Background: Internationally mechanical cardiac support and transplantation have improved long term outcome of children with cardiomyopathy and myocarditis. These treatment modalities are not readily available in the developing world.
Method: A retrospective 7-year single center review of children admitted with fulminant dilated cardiomyopathy (DCMO) or myocarditis to PICU between January 2010 to January 2017 in a setting without available mechanical cardiac support or transplantation.
Results: 112 children with a median age of 27.8 months were included. All presented in Ross stage 4 cardiac failure (77% in cardiogenic shock). Admission median lactate was 6.5 mmol/l. Admission left ventricular ejection fraction was <30% in 79% of patients and 12 developed intra-cardiac clots. Etiology was presumed viral myocarditis in 87% and idiopathic DCMO in 13%. Adenovirus PCR was positive in 28, Parvovirus in 19 with multiple positive viral studies in 32. The median number of PICU admissions per patient was 1.5 (range 1-5) and length of ICU stay was 14.9 days (1-69). 55% required ventilation for median of 8.1 days. 100% required inotropic support for a median of 8.2 days. 82% received Milrinone, 78% Dobutamine and 33% Adrenaline infusions. The median maximum inotrope score was 21.9. Complications during PICU stay included acute kidney injury in 68% of which two patients needed dialysis, liver derangement in 43%, neurological events in 25% and 34% suffered a cardiac arrest episode. 33% had arrhythmias of which 27% needed electrical cardioversion and 57% drug treatment. 63 (66%) children survived to PICU discharge. The overall hospital survival was 47%. Of the PICU survivors the median number of ward readmissions was 3.7 (range 1-19). Total median length of ward stay was 23.2 days (1-138).
Conclusions: In our setting without transplantation availability, DCMO and myocarditis is associated with significant duration of hospital stay, morbidity and mortality.

P2973 - PAEDIATRIC CARDIAC CRITICAL CARE ADMISSION PROFILES AND OUTCOME IN THE DEVELOPING COUNTRY

Beyra Rossouw [1], Andrew Argent[2], Brenda Morrow[2], John Lawrenson[2]
Red Cross War Memorial Children's Hospital, Division of Critical Care and Children's Heart Disease, Cape Town-South Africa[1] Red Cross War Memorial Children's Hospita, Division of Critical Care and Children's Heart Disease, Cape Town-South Africa[2]

Background: In South Africa Paediatric Cardiac Critical Care (PCCC)no uniform PCCC health care model exist. This is the first study to describe a one-year single center South African PCCC patient population.
Methods: A prospective review between January 2015 to December 2015 of all consecutive patients with a cardiac diagnosis admitted to a combined medical and surgical PICU.
Results: 472 PCCC admissions included of which 274 followed elective cardiac surgery, 37 post elective general surgery and 161 emergency admissions. Indications for emergency admission included: shock (28%), respiratory support (22%), cyanosis (18%), decompensated cardiac failure (18%), post cardiac arrest (8%) and life threatening arrhythmias (3%). Comparing elective to emergency admissions the median age was 24 vs 5 months ($p < 0.0001$), length of PICU stay 3 vs 6 days ($p < 0.0001$), length of ventilation 1 vs 2 days ($p = 0.13$), length of inotropes 1 vs 2 days ($p = 0.08$) and median maximum inotrope score 1 vs 9 ($p = 0.46$). A cardiac diagnosis was made for the first time on PICU in 57 patients. 85 emergency theatre procedures were undertaken from PICU. 81 Patients needed PICU readmissions,19 needed redo cardiac surgery. In both groups 4.1% suffered a cardiac arrest during PICU stay ($p < 0.0001$). PICU complications in the elective versus the emergency admission group included failed extubation in 5.7% vs 13% ($p = 0.006$), chest infection on admission in 20.6% vs 45% ($p < 0.0001$), blood stream infection in 3.8% vs 17.4% ($p < 0.0001$), AKI in 17.4% vs 32.9% ($p = 0.001$), liver impairment in 3.5% vs 19.3% ($p < 0.0001$), neurological sequelae in 1.9% vs 14.9% ($p < 0.0001$), PICU readmission in 10.3% vs 30.4% ($p < 0.0001$), PICU mortality 1.6% vs 12.4% ($p < 0.0001$) and standardized mortality 0.25 vs 0.8.
Conclusions: During 2015 34.9% of all PICU admissions were PCCC. Emergency PCCC have a higher morbidity and mortality. This data will be used as benchmarking and towards establishing an outcome based PCCC database.

P3036 - PREVALENCE OF CONGENITAL HEART DISEASE AMONG NEONATES IN A TUNISIAN NEONATAL UNIT OF A TERTIARY CARE HOSPITAL

Jihen Mathlouthi[1], Nabiha Mahdhaoui[1], Houda Ajmi [2], Hedia Ayech[1], Manel Bellaleh[1], Sonia Nouri[1], Hassen Seboui[1]
Farhat Hached Teaching Hospital, Neonatology, Susah-Tunisia[1]; Sahloul Teaching Hospital, Pediatric, Susah-Tunisia[2]

Background: Congenital heart diseases (CHD) have an incidence of 6 to 8 for 1000 live births. Early diagnosis is essential in order to improve prognosis.
Objective: To study the epidemiological and clinical features of CHD in our maternity.
Methods: Retrospective study including CHD diagnosed prenatally or postnatally among the neonates admitted in our department during eight years.
Results: 181 neonates with CHD wère enrolled, 149 of them being inborn among a total of 78,165 live births during the same period (overall incidence of 1.91‰). CHD was diagnosed during first 3 days after birth in 54.7% and before the end of first week in

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

64.1% of cases. Diagnosis was suspected prenatally in only 16 patients (8.8%). 159 patients were symptomatic at birth. Symptoms were mainly: presence of an isolated murmur in 39% of cases, cyanosis associated with a murmur in 23.3% of cases, isolated cyanosis in 17.6% of cases and respiratory distress signs in 9.4% of cases. Cardiac ultrasound allowed diagnosis in 179 patients. Non-cyanotic heart diseases with left-right shunt were the most frequent (45.3%) dominated by the interventricular communication (22.65%) and the interatrial communication (11.6%), followed by atrio-ventricular canal (11.05%). Cyanotic heart anomalies due to right to left shunt were present in 28.7% of cases. Tetralogy of Fallot and transposition of the great arteries were the most frequent (8.83% and 7.73% respectively). Obstructive heart diseases observed in 19.9% of the cohort, were dominated by coarctation of the aorta (6.07% CC) and right heart obstructions were dominated by pulmonary stenosis (4.97%). Complex heart malformations represented 6.1% of CHD and were dominated by the single ventricle (4.97%). CHD was isolated in 128 cases. Chromosomal anomalies were found.

P3037 - NEONATES WITH AORTIC COARCTATION AND CARDIOGENIC SHOCK PRESENTATION MANAGEMENT AND OUTCOMES

Jihen Mathlouthi[1], Nabiha Mahdhaoui [1], Houda Ajmi[2], Manel Bellalah[1], Sonia Nouri[1], Hassen Seboui[1]
Farhat Hached Teaching Hospital, Neonatology, Susah-Tunisia[1] Sahloul Teaching Hospital, Neonatology, Susah-Tunisia[2]

Background: Aortic coarctation represents the fifth congenital heart disease in term of frequency. Neonatal forms are generally severe and could be revealed by cardiac failure which is an emergent situation. The aim of this study is to review clinical features, management and short and mid-term outcomes of infants presenting with cardiac failure secondary to aortic coarctation.
Methods: Descriptive study conducted in neonatology department of Farhat Hached universitary hospital (Sousse-Tunisia) during a period of 12 years. Were enrolled all neonates presenting with cardiac failure secondary to aortic coarctation.
Results: Twenty seven neonates were diagnosed with aortic coarctation. Eight of them (29.6%) presented with cardiac failure at the moment of diagnosis. Antenatal diagnosis wasn't performed in any pregnancy. Average age on admission was 10 days, ranging from 7 to 15 days. Continuous perfusion of E1 Prostagnlandines, sodium and fluid restriction associated with vasoactive agents were prescribed to all neonates. Outcome after medical management was good in 5 neonates who underwent surgery after stabilization. Mortality rate was of 50%. Recoarctation was observed in 20% of survivors.
Conclusion: Cardiac failure complicating aortic coarctation is a life threatening situation needing emergent medical and surgical management in order to minimize morbidity and mortality rates. Aortic coarctation screening before decompensation is the best alternative.

INTERVENTIONALCARDIOLOGY

P1022 - REVERSE SZABO TECHNIQUE FOR STENTING A SINGLE MAJOR AORTOPULMONARY COLLATERAL VESSEL IN PULMONARY ATRESIA WITH VENTRICULAR SEPTAL DEFECT

Igor Polivenok [1], John Breinholt[2], Sri Rao[3], Olga Buchneva[4]
Zaitcev Institute of General and Urgent Surgery, Department of Interventional Cardiology, Kharkiv-Ukraine[1]; University of Texas Health Science Center At Houston, Division of Pediatric Cardiology, Houston-United States[2]; The William Novick Global Cardiac Alliance, Interventional Cardiology Development Coordinator, Memphis-United States[3]; Zaitcev Institute of General And Urgent Surgery, Department of Cardiac Surgery, Kharkiv-Ukraine[4]

Management of pulmonary atresia with ventricular septal defect (PA-VSD) in the neonatal period presents numerous challenges. Endovascular stenting of the ductus arteriosus or of a collateral vessel in ductal-dependent pulmonary circulation as an alternative to the Blalock-Taussig (BT) shunt has become increasingly popular in the last decades. The utilization of the original modification of reverse Szabo (anchor-wire) technique for single collateral vessel stenting in a case of PA-VSD is described.

P1025 - ARTERIAL DUCT STENT IMPLANTATION AMONG DUCT DEPENDENT CONGENITAL HEART DISEASES

Justine Iris Yap , Dexter Eugene Cheng, Andrea Orel Valle
University of the Philippines - Philippine General Hospital, Pediatric Cardiology, San Fernando-Philippines

The objective of the study was designed to determine the outcome of arterial duct stenting in patients with ductal-dependent cyanotic heart disease.
Methods: Between January 2010 and March 2014, 60 cases with duct-dependent pulmonary circulation underwent cardiac catheterization with the intent to do ductal stenting after full assessment by echocardiogram and angiogram. Fifty two cases were included in the study, 22 cases of pulmonary atresia with intact ventricular septum, 12 tricuspid atresia with pulmonary atresia, 9 tetralogy of fallot with pulmonary atresia, 6 double outlet right ventricle with pulmonary atresia, 2 cases of single ventricle physiology with pulmonary atresia and 1 case of tetralogy of fallot with severe infundibulovalvar pulmonary stenosis. All procedures were retrograde through the femoral artery, except four through carotid artery approach.
Results: Twenty five cases were not intubated during the procedure. Twenty six cases underwent balloon atrial septostomy. The mean fluoroscopy time and stay in the hospital from procedure were 15.6 ±11.6 min and 2.7 ±3.3 days. The mean saturation before and after intervention were 62.8%, 85% respectively. Complications pre and post procedure were seen in 21 patients, none of which were via carotid approach. Procedure-related deaths were observed in 7 patients. The causes of death were ductal spasm (n = 6), stent thrombosis (n = 1) and jailed left pulmonary artery (n = 1). One patient expired due to respiratory failure (n = 1), another died a month after discharge due to unrelated cause (n = 1). All 41 cases had stent patency during 4-6 months of follow up. Five among these cases successfully underwent Glenn operation.
Conclusions: Arterial ductal stent implantation is a practicable, effective, safer and less invasive than surgical palliation. Patients with ductal stenting have growth of the pulmonary artery which provides additional time for surgical repair. The carotid artery access is a practical approach among vertical type arterial duct.

P1046 - PERCUTANEOUS BALLOON VALVULOPLASTY FOR SEVERE PULMONARY VALVE STENOSIS IN INFANTS: A 10 YEAR INSTITUTIONAL EXPERIENCE AND LONGTERM OUTCOMES

Fang Liu
Children's Hospital of Fudan University, Heart Center, Shanghai-China

Objective: We retrospectively reviewed and analyzed the immediate and long-term outcome and safety of percutaneous

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

balloon pulmonary valvuloplasty (PBPV)in neonates and infants with severe or critical valvular pulmonary stenosis.
Methods: One hundred and nine patients aged 2d ~ 3y with critical or severe pulmonary valve stenosis admitted to our hospital from January 2005 to December 2014 underwent balloon valvuloplasty. Right ventricular systolic pressure in all patients was equal to or greater than systemic pressure.
Results: The pulmonary valvuloplasty was successfully performed in 105 of the 109 patients, and the dilatation success rate was 96.3%. Immediately after dilatation, the systemic pressure gradient (PG) from right ventricle to pulmonary artery decreased from 50 ~ 132 mmHg to 4 ~ 96 mmHg. No significant complications in all patients during or post dilation except cardiac tamponade in one. During a 12 months to 9.6 years follow-up (mean 5.01years), data showed that pressure gradient crossing pulmonary valve measured by echocardiography further decreased or remained stable in 103 cases, except one neonate and three infants, whose PG increased and needed a second dilatation (Re-dilatation rate was 3.73%).Mild pulmonary regurgitation was seen in most of patients post-dilatation, except moderate in six and severe in one. All patients were doing well with asymptomatic.
Conclusions: PBPV is safe and effective in attaining both immediate and long term reduction of pulmonary valvular gradients and is currently the preferred therapeutic modality for valvular PS even in small baby patients with severe or critical stenosis.

P1047 - STENTING OF CONGENITAL PULMONARY VEIN STENOSIS A NOVEL HYBRID APPROACH

María-Teresa González-López[1], Ana-María Pita-Fernández[1], Ramón Pérez-Caballero-Martínez[1], Alejandro Rodríguez-Ogando[2], José-Luis Zunzunegui-Martínez[2], Juan-Miguel Gil-Jaurena [1]
Gregorio Marañón Hospital, Pediatric Cardiac Surgery, Madrid-Spain[1]; Gregorio Marañón Hospital, Pediatric Cardiology, Madrid-Spain[2]

Background: Congenital pulmonary vein stenosis is a rare, frustrating and difficult to manage condition with a high mortality rate. New surgical and interventional procedures for treatment suggest an improving prognosis. However, the outcome of patients affected remains unclear and requires often repeated procedures. Our purpose is to present a novel hybrid approach for management of selective pulmonary vein stenosis as alternative to standard percutaneous or surgical repair.
Case: A 6-month-old patient with persistent ductus arteriosus and hypoplastic left pulmonary veins was referred. A failed percutaneous closure of ductus was attempted and surgical closure was then carried out. One month later, he underwent cardiac catheterization for assessment of pulmonary vascular resistances. Two failed attempts for left upper pulmonary vein (LUPV) stenting were performed (left atrium and aortic root perforation resolved with surgical repair). Three days later, he was re-catheterized. A critical diameter (1 mm) of LUPV and left pulmonary wedge pressure of 21 mm Hg were noted. We managed this lesion using a hybrid technique to perforate, dilate and stent the obstructed vessel: the surgical exposure of the Sondergaard's groove was done, and a direct insertion of a bioresorbable stent (3 × 8 mm) using this access controlled by angiography was carried out. The LUPV was then successfully recanalizated. Sternal closure was performed uneventfully.
Results: No significative postoperative complications were detected and he was discharged at home on 11st day. At 18-month follow-up, he is progressing well and echocardiography has shown continuous flow into the stented LUPV and good biventricular function.
Conclusions: This novel hybrid approach should be considered in infants when percutaneous access to the pulmonary veins is challenging or unfeasible. A close partnership of cardiac surgeons with interventional cardiologists is mandatory and it may be the only option for dealing with these lesions in this scenario.

P1050 - IMPLANTATION OF BIOABSORBABLE SCAFFOLDS IN A BABY WITH REPEATED STENOSES OF ALL PULMONARY VEINS

Peter Zartner , Benjamin Bierbach[2], Boulos Asfour[2], Martin Schneider[1]
German Paediatric Heart Centre, Cardiology, Sankt Augustin-Germany[1]; German Paediatric Heart Centre, Cardiac Surgery, Sankt Augustin-Germany[2]

History: At the age of 3 months a male patient developed severe stenosis of all pulmonary veins. In the cathlab all stenosis were dilated using Paclitaxel covered balloons (IN.PACT Falcon, Invatec, Germany) and conventional balloons (Sapphire, Orbus Neich, Hong Kong). Patient was dismissed home. After three months restenoses occurred. Surgical correction with the sutureless operation was performed and assisted by intraoperative balloon dilation with Paclitaxel covered balloons (Elutax, Aachen resonance, Germany). Again the patient was dismissed home. Three months later he reappeared with hypersystemic right ventricular pressures. Under compassionate care regulations and after having obtained informed consent by the parents, decision was made to implant bioabsorbable Novolimus covered scaffolds (DeSolve, Elixir, USA). Angiography and/or other diagnostic tests: stenosed and stented left lower pulmonary vein.
Procedure: A hybrid approach was chosen to reduce procedure time and radiation. All but the right upper pulmonary veins were found severely obstructed and were consequently stented with 4 ⋆ 18 mm and 3.5 ⋆ 14 mm DeSolve scaffolds under x-ray guidance. After proper placement the delivery material was completely removed and the chest closed. The patient could be extubated after 24 hours and was sent home twelve days later. Medication was diuretics, aspirine and clopidogrel.
Conclusion: Bioabsorbable scaffolds with cytostatic drugs may help to overcome the otherwise often fatal prognosis of intrinsic pulmonary vein stenosis. It rapidly improves the acute life-threatening situation and possibly reduces the chance of restenosis by its continuous cytostatic delivery to the tissue.
Comments: This is a single case with only short term follow-up, so more data and longer follow-up will be needed to allow a conclusion on the possible efficiency of scaffolds in congenital heart diseases. The use of bioresorbable material is still of great interest is all young patients with further growth of their vessels to expect.

P1062 - LONG TERM RESULTS OF BALLON VALVULOPLASTY OF AORTIC STENOSIS

Oleg Reich, Petr Tax, Ondřej Materna, Jan Kovránek, Jiří Gilík, Viktor Tomek
University Hospital Motol, Children, Prague-Czech Republic

Background: In years 1987 to 2010, the balloon valvuloplasty was the only method of treatment of congenital aortic stenosis deemed for biventricular circulation in our centre. Long-term results are provided for comparison with emerging surgical methods such as a leaflet shaving and plasty.
Material: Total of 421 consecutive patients were treated at the age of 0 – 23 years (median 109 days, IQR 4 days – 8 years), 141 newborns (33.5%), 105 infants (25.0%), and 175 patients older than 1 year (41.5%). Median follow-up was 10 years (IQR 4 – 16 years).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Method: Percutaneous valvuloplasty with median balloon-to-annulus ratio of 0.96 (IQR 0.91–1.00). Single-institution regular follow-up. Restenosis defined as Doppler gradient over 70/40 mmHg and severe regurgitation as equal or bigger than the grade 3 of 4. In operated patients, the last values before surgery are used as the latest follow-up.
Results: Before valvuloplasty, after it, and at latest follow-up, the median(IQR) peak Doppler gradient was 85(68-98), 43(35-55), 49.5(35-66) mmHg and the aortic regurgitation ECHO garde was 0(0-0.5), 1(0-2), 2(1-3) (all $P < 0.001$). 57 patients (13.5%) died. 133 patients (31.6%) required surgery. Actuarial probabilities (% ± SEE) at 20 years after the valvuloplasty were as follows: restenosis-freedom 47 ± 4.5, severe-regurgitation-freedom 50 ± 4.6, survival 77 ± 3.8, surgery-free-survival 39 ± 4.4. All the probabilities were significantly lower in newborns than in the other two groups. For the risk factors see Table 1.
Conclusion: Balloon valvuloplasty is a good palliation. Restenosis and severe regurgitation incidences increase over the follow-up period. Risk factors are: small body size, small aortic annulus, LV dysfunction and fibroelastosis, mitral stenosis, and less than 3 aortic cusps.

Table. Cox Proportional Hazard Ratios.

	Restenosis HR	5% CI	95% CI	Severe regurgitation HR	5% CI	95% CI	Death HR	5% CI	95% CI
Fibroelastosis Grade	2.28	1.45	3.56	NS			3.44	1.98	5.96
Mitral Stenosis	2.94	1.65	5.21	NS			3.06	1.61	5.83
Body Surface Area	0.49	0.34	0.71	0.75	0.57	0.98	0.55	0.37	0.82

CI - confident interval, HR - hazard ratio, LV - left ventricle.

P1068 - PATTERN OF CONGENITAL HEART DISEASES AND TREATMENT OPTIONS IN A BANGLADESHI CENTER ANALYSIS OF 6914 CASES FROM NONINVASIVE CARDIAC LABORATORY

Nurun Nahar Fatema Begum
Combined Military Hospital Dhaka, Paediatric Cardiology, Dhaka-Bangladesh

Objective: To see the pattern of congenital heart diseases and available treatment facility in a cardiac center.
Background: Echocardiography is the most sensitive tool to diagnose congenital heart diseases efficiently. It can be repeated as many times as required to see the progress, outcome of treatment and complications. Echocardiography laboratory can give a scenario of pattern of congenital heart diseases existing in Bangladesh as well as natural history of the cases and treatment options offered.
Methods: It is a retrospective review of database of echocardiography patient from pediatric noninvasive laboratory of a cardiac hospital in 2012.
Result: Out of 6914 cases 55.73% were male and 44.27% female. Neonates include 8.48%, 36.62% were infant, 34.02% were under 5 years, 17.97% were children and adolescents and 2.96% were adults. Normal Echocardiography finding was found in 17.28% cases of total echocardiography .Ventricular septal defect (VSD) was found in 18.60% cases, Atrial septal defects (ASD) in 15.41% cases, patent ductus arteriosus (PDA) in 8.59% cases, atrioventricular septal defect (AVSD) in 1.97% cases, tetralogy of Fallot (ToF) in 4.79% cases, transposition of great arteries (TGA) in 2.26% cases and Patent Foramen in 265(3.83%) cases. Down syndrome was the commonest chromosomal abnormalities seen in 2.4% cases. Total 599 (8.66%) cases had various types of percutaneous interventions of which PDA device closure was commonest (296 cases). Total 545 (7.88%) cases had various types of surgery of which VSD closure was commonest (107 cases).Four hundred and seventy cases(6.80%) were lost from follow up.
Conclusion: This study proves that VSD is the commonest congenital heart lesions in Bangladeshi children followed by ASD. Frequency of surgery and intervention was almost equal.Some special features of disease pattern were observed in study cases. Some of the cases had spontaneous cure.

P1082 - MID TERM RESULTS OF PERCUTANEOUS VSD CLOSURE WITH ADO II IN PEDIATRIC POPULATION

Ozge Pamukcu, Nazmi Narin, Ali Baykan, Suleyman Sunkak, Onur Tasci, Kazim Uzum
Erciyes University, Pediatric Cardiology, Kayseri-Turkey

Background: Nowadays percutaneous VSD closure is accepted as an alternative surgery but still no ideal device was determined for pediatric population.
Objective: The aim of this study was to share mid term results of Percutaneous VSD closure with ADO II in pediatric population
Methods: VSD closures of 49 patients with ADO-II device were performed in Erciyes University Medical Faculty Children Hospital, Pediatric Cardiology Department.
Results: Mean age of patients: 86.8 ± 52.6months. The youngest patient was 4months old and the oldest patient was 18years old. 19of patients were female, 30were male. Weight of the patients was between 24.3 ± 16 kg (minimum was 5 kg,maximum was76kg). Mean diameter of VSD was 3.7 ± 1,4mm. Mean fluoroscopy and total procedure time were 37 ± 19.3, 74.1 ± 27 minutes respectively. VSD types were muscular in 6patients, rest of the defects were all perimembranous type. No major complications like death, vascular complications, device embolizations was seen. Only complete AV block was seen in one patient month after the procedure and pacemaker was implanted.
Conclusion: Up to our knowledge our study includes the largest series of pediatric patient series that percutaneous VSD closure was done with ADO II. When the complications are taken into consideration in 42 months' follow-up period ADO II device is a good choice in selected cases for VSD closure even in the infants less than 1 year of age.

P1085 - PERCUTANEOUS VSD CLOSURE OF A BABY WEIGHED 3KG

Nazmi Narin, Ozge Pamukcu, Ali Baykan, Suleyman Sunkak, Onur Tasci, Kazim Uzum
Erciyes University, Pediatric Cardiology, Kayseri-Turkey

Objectives: Main aim of our study to share our experience in percutaneous closure of VSD of 3 kg weighed safely with low complication rates.
Background: Surgery is the definitive treatment for ventricular septal defects (VSD) however for muscular defects because of their

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

location and coarse trabeculations it is very hard to find and approach these defects.
Case Report: Two months old baby with 3000gr bodyweight was referred to us for tachypnea, tachycardia and growth failure. Pansystolic murmur 2-3/6 in degree was found by physical examination. Apical 4 mm large VSD was detected in the echocardiography, left side of heart was enlarged. 20 mmHg gradient was detected between two ventricles. Her symptoms continued despite anti-congestive treatment. Treatment options were discussed with family. Since VSD is apical located; surgery was found hard and risky. Percutaneous closure was done from arterial route with 5 × 4 ADO II AS (St. Jude Medical, Plymouth, MN) device. We did not face any complications like atrioventricular block during or after the procedure. No vascular complication was seen up till now. In control transthoracic echocardiography no aortic or tricuspid insufficiency was detected. She was discharged on the next day after the procedure.
Conclusion: Up to our knowledge our case is the smallest infant that percutaneous VSD closure was performed successfully in the literature. In this report we emphasized that percutaneous VSD closure is safe even in small infants if appropriate device with appropriate size was used with good technique in experienced hands.

P1124 - CARDIAC CATHETERIZATION IN THE EARLY POST OPERATIVE PERIOD AFTER CONGENITAL CARDIAC SURGERY

Taner Kasar[1], Ibrahim Cansaran Tanidir[1], Erkut Ozturk[1], Hasan Candas Kafali[1], Murat Sahin[1], Akin Topkarci[2], Sertac Haydin[3], Alper Guzeltas[1]

Background: Our aim is to evaluate data of patients who underwent cardiac catheterization in the early post-operative period after congenital cardiac surgery (CHS).
Patients and Methods: We retrospectively evaluated the data of the patients who underwent cardiac catheterization within 30 days after CHS.
Results: 2584 patients were operated in our clinic due to CHD between 2011-2016. Cardiac catheterization was performed to 50 (%1,93) of these patients in early postoperative period. 29 of the patients were males, 21 were females. Median age was 8 years (2 months- 12,5 years) and median body weight was 6 kg (3-35 kg). 56% of the patients had biventricular (n = 28), 44% had single ventricular physiology. Median RACHS-1 score was 3 (1-6). Cardiac catheterization was performed under ECMO support in 16 of the patients. Twenty four (48%) of the patients had only diagnostic catheterization while 26 out of 50 (52%) had invasive procedures. Fifteen patients (30%) were re-operated due to anatomic problems demonstrated during catheterization. Minor complications developed in 7 (14%) patients.
Conclusion: After CHS, during early postoperative period, interventional and/or diagnostic cardiac catheterization can be performed safely to identify and treat problems.

P1125 - ARRHYTHMIAS IN PEDIATRIC CARDIAC CATHETERIZATION LABORATORY

Ibrahim Cansaran Tanidir , Taner Kasar, Hasan Candas Kafali, Gulhan Tunca Sahin, Selman Gokalp, Yakup Ergul, Alper Guzeltas
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Introduction: Arrhythmia is a well-known complication of cardiac catheterization in children. Most of them are transient, classified as minor, and don't require treatment. We evaluated arrhythmias emerging during cardiac catheterization in our center.
Patients and Methods: Cardiac catheterization data were collected prospectively under Filemaker® program. Among 2324 patients who underwent cardiac catheterization between January 2012 and November 2016, 143 (6.1%) had arrhythmias during the procedure. Data of these patients were retrospectively reviewed. Arrhythmias during transcatheter ASD/VSD closure, and ST-segment changes were excluded.
Results: In 143 patient, 155 arrhythmia events occurred. Complete AV block (n = 56, 36%) and SVT (n = 36, 23%) were the most common arrhythmias seen. 72(46%) resolved spontaneously in less than 1 minute and 19(12%) resolved just with catheter manipulation. Whereas 35(23%) arrhythmia events needed medical treatment (atropine, adrenalin for AV block and adenosine for SVT) or electrical cardioversion, 26(17%) needed cardiopulmonary resuscitation, one patient with complete AV block needed transient pacemaker, and two others underwent permanent pacemaker implantation one week after catheterization. None of the patients died in the cath-lab and none of them needed extracorporeal life support due to rhythm problems. Diagnostic cardiac catheterization 96/143 (67%) was the most common procedure. Common interventional procedures were pulmonary valve dilation (n = 14), PDA stenting (n = 10). The common cardiac abnormalities were tetralogy of Fallot (n = 27), heterotaxy syndrome (n = 14), double inlet ventricle (n = 14), ccTGA (n = 10). Forty (28%) patients had underwent prior cardiac surgery (palliation or complete repair).
Conclusions: Most of the arrhythmias during cardiac catheterization may resolve spontaneously. But some of them need either catheter manipulation or medication and electrical cardioversion/defibrillation. Life threatening arrhythmias are not as rare as we might think. Pediatric cardiologist should be ready for every kind of arrhythmias during intervention. Judicious catheter manipulation and interfere rapidly to these arrhythmias are crucial to prevent morbidity and mortality.

P1144 - TRANSCATHETER CLOSURE OF PATENT DUCTUS ARTERIOSUS 25 YEARS OF CLINICAL EXPERIENCE IN ISTANBUL MEDICAL FACULTY PEDIATRIC CARDIOLOGY DEPARTMENT

Serra Karaca, Kemal Nisli, Rukiye Eker, Aygun Dindar, Umrah Aydogan
Istanbul Faculty of Medicine, Pediatric Cardiology, Istanbul-Turkey

Transcatheter closure of patent ductus arteriosus (PDA) has been suggested to be the standard treatment of PDA.To evaluate the effectiveness of transcatheter closure of PDA this was a retrospective study on patients who underwent transcatheter closure of PDA during the period of 1991–2015. Hospital registry was reviewed and data about patients' characteristics, PDA severity, procedure, and outcomes were retrieved. There were 500 patients, of whom 151 were males, who underwent transcatheter closure of PDA during the study period. Median age was 3.4 years (1 months–18 years), and median body weight was 12 (1.8–65) kg. The diameter of PDA ranged from 1.5 to 10 mm with a median of 2.7 mm. Device could be deployed in all patients, in which most were the coil (52.4%) and Amplatzer ductal occluder (37.8%) and the remainders were umbrella (8.4%), Nit Occlud PDA-R device (1.4%). Complete closure was achieved in most patients (90.3%), minimal residual shunt occured in 8.7% of patients, whereas device migration occurred in (3%) of patients. Coil migration ocurred in 12 patients, 8 patient had bigger than 3 mm PDA and the other 4 patients had smaller than 3 mm PDA. 10 of these migrated coils were retrieved in the same procedure with snare. 2 small coils were not retrieved. All of these patients PDA's were closed in the same procedure with second coil or device. Two patients were not suitable for transcatheter closure and surgery was the choice after the procedure. After closure of PDA with coil, 4 patients had mechanical hemolysis due to residual shunt. All of these patients underwent a second procedure for closure of residual shunt.For closing the residual shunt 1-4 more coils were used. Most patients were discharged from the hospital at 1 day after the procedure.

P1151 - IMPACT OF PULMONARY VALVE REGURGITATION TO EVALUATION OF SEVERITY OF PULMONARY VALVE STENOSIS IN PATIETNTS WITH TETRALOGY OF FALLOT AFTER REPAIR

Shinichiro Sakaki[1], Tomoaki Murakami[1], Mamoru Yamamoto[2], Masahiro Shiraishi[1], Yukie Ito[1], Ryo Mafune[1], Kouji Higashi[1], Hiromichi Nakajima[1], Hiroyuki Aotsuka[1]
Chiba Children, Cardiology, Chiba-Japan[1]; Chiba Children, Medical Engineering, Chiba-Japan[2]

Backgrounds: Pulmonary valve stenosis (vPS) and regurgitation (PR) are major postoperative complications in patients with Tetralogy of Fallot. We usually evaluate the degree of vPS by a peak to peak pressure difference between right ventricle and pulmonary artery. However, it is overestimated when PR exists. The purpose of this study is to elucidate the impact of PR to evaluation of severity of vPS.
Materials and Methods: We enrolled 13 patients with vPS without significant PR and 8 vPS patients with PR. First, we examined a relationship between the peak to peak pressure difference and a valve orifice area in patients without PR from their cardiac catheterization data. Secondly, an estimated peak to peak pressure difference, which means the peak to peak pressure difference assuming no PR, was calculated in patients with PR from their valve orifice area using the relationship between the peak to peak pressure difference and the valve orifice area in patients without PR. Moreover, an excess of pressure difference, which means the difference between the measured and estimated pressure difference, was calculated. Lastly, the relationship between the excess of pressure difference and the regurgitant fraction in patients with PR was analyzed.
Results: There was a strong relationship between the valve orifice area and the peak to peak pressure difference in patients without PR ($R^2 = 0.84325$, $P < 0.01$). The excess of pressure difference had a significant correlation with the regurgitant fraction in

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

patients with PR ($R^2 = 0.78067$, $p < 0.01$). From this relationship, the PR over 25% of regurgitant fraction could augment the peak to peak pressure difference depending on the regurgitant volume. *Conclusion:* Severity of vPS could be overestimated in post-operative patients of tetralogy of Fallot with PR when it is evaluated by peak to peak pressure gradient, especially if their regurgitation fraction were over 25%.

P1160 - BRAZILIAN SINGLE CENTER EXPERIENCE IN PERCUTANEOUS CLOSURE OF PATENT DUCTUS ARTERIOSUS

Luciana S. Nina De Azevedo, Jamille Campos, Raianne Cord, Fernanda Canut, Diego C. M.l. D, Marcio Miranda Brito, Joao Saba, Celia Maria Camelo Silva
Federal University of Sao Paulo, Cardiology, Sao Paulo-Brazil

Background: The percutaneous transcatheter occlusion of the patent ductus arteriosus (PDA) had shown great improvement and became a safe method in the last few years. The aim of this study was to describe the experience of a Brazilian Center with percutaneous closure of PDA.
Methods: It was a retrospective single-center study conducted between 2010 to 2016.
Results: From August 2010 to November 2016, a total of 88 patients underwent percutaneous occlusion of the PDA. Sixty patients were female (68%). The mean age was 4.5 years (5 months to 44 years). Based on the Krichenko classification, 59 patients had type A (78.4%), 11 type C (12.6%), 3 type D (3.4%) and 5 type E (5, 7%). In patients with pulmonary hypertension (PH), type C was the most frequent. The most used device was AVP II (52.2%), followed by Coil Flipper (34%), ADO II (5.7%), AVP IV (2.4%). Six patients (6.8%) had associated mild congenital heart disease without hemodynamic repercussion. Immediate complete occlusion was seen in 85 (96,5%) patients. The serial echocardiograms on the follow –up confirmed the initial results. Complications were seen in 5 (5.8%) patients, all in whom were used Coil Flipper, the only device avaliable for PCA closure in our Service until 2005. The embolization of device to left pulmonary artery was the most common complication. Residual shunt after 1 year of the initial closure was seen in 2 patients (2%), in whom were first used a Coil Flipper. In these patients a second closure was perfomed using AVP II, without residual shunt.
Conclusion: In our center, percutaneous treatment of ductus arteriosus was effective and with low risk for the patients. The residual shunt was observed only with Coil Flipper.

P1163 - INTERMEDIATE TERM FOLLOW UP ON THE RESULTS OF TRANSCATHETER CLOSURE OF VSD USING AMPLATZER® DEVICE AND NIT OCCLUD® LEˆ COIL

Kritvikrom Durongpisitkul[1], Paweena Chungsomprasong[1], Pornthip Panjasamarnwong[2], Suphalak Darunaitorn[3], Prakul Chanthong[1], Chodchanok Vijarnsorn[1], Jarupim Soongswang[1]
Faculty of Medicine Siriraj Hospital, Mahidol University, Division of Pediatric Cardiology, Department of Pediatrics, Bangkok-Thailand[1]; Faculty of Medicine Siriraj Hospital, Mahidol University, Siriraj Piyamaharajkarun Hospital, Bangkok-Thailand[2]; Faculty of Medicine Siriraj Hospital, Mahidol University, Division of Pediatric Nursing, Department of Nursing Siriraj Hospital, Bangkok-Thailand[3]

Introduction: Transcatheter ventricular septal defect (VSD) is alternative treatment of VSD closure especially in perimembranous type (Pm VSD) and doubly committed subarterial (DCSA) VSD.
Material and Methods: The aim of this retrospective study is to review intermediate term (up to 5-years) results of transcather closure of VSD using Amplatzer® device (device) or Nit Occlud® Leˆ VSD Coil (coil).
Results: 240 out of 247 patients (97.1%) underwent transcatheter closure successfully (187-device and 53-coil). The median age and weight were 12 years (1-67) and 40.3 kg (10-97), respectively. The median VSD size in device group was larger than coil group. [7 mm (3-18) VS 5 mm (2.5-9.3), $p < 0.001$]. Complete closure was comparable among both groups. Twenty-six patients (49.1%) in coil group were DCSA VSD while only 42.2% in device group. Sixty-nine (26%) of all patients had DCSA VSD (43-device and 26-coil). Although pre-closure aortic regurgitation (AR) was comparable on both groups (22.9% VS 32%, $p = 0.448$). AR were significant higher in coil group ($p < 0.001$) than in device group. Comparing VSD type, AR post procedure was higher in DCSA VSD than Pm VSD ($p = 0.001$). At the end of 5-year FU, 98.6% of DCSA VSD had less than mild AR.
Conclusions: We found comparable closure rate by using either device or coil for transcatheter closure of VSD in both Pm VSD and DCSA. The progression of AR was higher in DCSA VSD patients but majority of them had less than mild AR at end of 5-year follow up.

P1169 - BALLOON ANGIOPLASTY FOR COARCTATION OF AORTA IN INFANTS

Suresh Kumar Raghavannair , Eapen Thomas, Salim Al Maskari, Abdullah Al Farqani, Philip P.k. Wilson, Boris Dimitrov
National Heart Centre, Paediatric Cardiology, Muscat-Oman

Background: Few studies have compared the outcomes of balloon dilatation for post-surgical and native coarctation in infancy .This study evaluated procedural outcome,reintervention and late clinical outcomes of balloon angioplasty in infants with post-surgical recoarctation and native coarctation .
Materials and Methods: Retrospective case sheet analysis of 35 consecutive infants (Group A: post surgical re-coarctation; Group B: Infants above 3 months with native coarctation), who underwent a total of 45 procedures of Balloon angioplasty during 2011-2015. Results are shown in Table 1(Figures with ± denote mean ± standard deviation.
There were no major complications. One baby(group B) did not respond and underwent surgery. 7/36 babies had femoral artery occlusion requiring heparin infusion. Clinical/echo follow up was available for 34 patients, additional imaging in 21 patients.

Table.

	Group A (n = 25)	Group B (n = 10)	p value
Age at surgery, days	11.5 ± 9.19	-	-
Time to balloon, months	5.50 ± 0.71	-	-
Age at first cath, months	5.92 ±2.55	5.90 ± 2.69	0.98
Weight at first cath, kg	6.04 ± 2.18	5.94 ± 1.63	0.90
Arch hypoplasia, number	10/25	1/10	-
Balloon/aorta ratio	0.99 ±0.18	0.91 ± 0.19	0.24
% increase in diameter	63.24 ± 35.46	61.18 ± 39.51	0.88
% drop in gradient	54.00 ± 20.75	49.10 ± 32.17	0.60
Recath, number	12/25	4/10	0.72
Follow up , months	34.00 ± 33.94	24.00 ± 25.46	-
BP > 95th percentile	7/24	1/10	0.39
Upper-lower limb BP gradient > 15 mmHg	4/24	2/10	1.00

Figures with ± denote mean ± standard deviation

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Localized aneurysm was noted in one. Intervention for recurrent CoA (n = 10)showed increase in diameter of 61.33 ± 35.68% and drop in gradient t of 57.22 ± 23.38%. Nine babies underwent planned surgery/intervention for associated lesions. 27/35(77%) children were free of hypertension and/or significant BP gradients between upper and lower limbs .
Conclusion: Infants with post-surgical recoarctation and selected cases of native coarctation respond to balloon angioplasty with good procedural outcomes and similar freedom from hypertension in childhood.

P1170 - ATRIAL SEPTAL DEFECT DEVICE CLOSURE IN CHILDREN WEIGHING LESS THAN TEN KILOGRAMS

Eapen Thomas, Suresh Kumar Raghavannair, Abdullah Al Farqani, Salim Al Maskari, Philip P.k. Wilson, Boris Dimitrov
National Heart Center, Pediatric Cardiology, Muscat-Oman

Background: Trans catheter device closure is the standard of care in children with ostium secundum ASD.The procedure is generally deferred till the child is about 15 kg. Selected children do need to undergo ASD device closure at an younger age. This study evaluated the safety and efficacy of the procedure in these children and the impact of the procedure on their growth.
Material and Method: Retrospective case sheet analysis of 14 consecutive children weighing <10 kg who underwent device closure of secundum ASD during the period January 2011 through December 2015,for heart failure, failure to thrive or recurrent respiratory infections.
Results: Results are shown in Table 1.
There were no major complications. One patient had transient complete heart block while another had mild SVC obstruction (Doppler mean gradient = 3 mmHg). At a mean follow-up of 22.45 months (±18.18) the weight for height Z-score of the group improved marginally from -2.96(±1.98) to -2.53(±1.51). The proportion of children having a Z-score more than -2 dropped from 11/14 (78.5%) to 6/11(54.5%). Failure to gain weight was associated with major co-morbid conditions including chromosomal anomalies (n = 4) and multi-organ anomalies (n = 1).
Conclusion: When indicated ASD device closure can be performed safely in children weighing less than 10Kg with excellent long term outcome. Weight gain following the procedure is adversely affected by associated chromosomal syndromes or multi-organ anomalies.

Table.

PARAMETER	MEAN(± SD)
Age (months)	20.92 (±13.73)
Weight (kg)	7.83 (±1.61)
Wt./Height Z-score	-2.96 (±1.98)
Fluoroscopy time (mts)	9.66 (±6.56)
Radiation (mGy)	40.50 (±32.72)
Device size (mm)	13.14 (±3)
ASD size (mm)	11.98 (±2.83)
ASD size/Weight ratio	1.59 (±0.53)

P1202 - TRANSCATHETER INTERVENTION FOR COR TRIATRIATUM IN 41 YEAR OLD MALE

Madhu Gangadhara, Nicholas Hayes
University Hospitals Southampton NHS Trust, Paediatric Cardiology, Southampton-United Kingdom

Forty one year old gentleman was referred to cardiology when he started to experience symptoms of breathlessness and effort intolerance. Transthoracic echocardiogram revealed clear membrane in left atrium with high velocity flow suggestive of obstructive Cortriatriatum. Estimated pulmonary arterial pressures were systemic. Cardiac MRI confirmed Cortriatriatum with small perforation and ascending vein communicating between left superior pulmonary vein and left innominate vein resulting in left to right shunt quantified at 3:1. Cardiac multidisciplinary meeting decided primary surgical repair would carry an increased risk because of longstanding pulmonary hypertension and balloon dilation of the Cortriatriatum membrane as initial palliative procedure to try and reduce his pulmonary pressures would be an appropriate step. In Catheter Lab, pulmonary artery pressures were near systemic (77 systolic compared with femoral arterial systolic 85 mm Hg). The Cortriatriatum membrane was ballooned with 25 × 45mm Crystal balloon, inflated to 4 atmospheres pressure on three occasions. Each balloon inflation abolished the waist but this returned on deflation. Transoesophageal echo showed the Cor orifice was enlarged by approximately 50%, however it was unclear if this was adequate as pulmonary artery pressures remained high due to persistent significant left to right shunt through the ascending vein. We therefore abandoned the procedure and the patient went for surgery. Intraoperatively, the Cor membrane was found to be torn, this was resected and ascending vein ligated. Recent follow-up after surgical repair, patient is well with no symptoms and marked improvement in his estimated right heart pressures seen on transthoracic echocardiogram.
Conclusion: The transcatheter intervention was partially successful, however the result of balloon dilation was difficult to quantify as pulmonary artery pressures remained high due to significant left to right shunt through ascending vein. We believe balloon dilation could be considered as a palliative or corrective option when primary surgical repair is high risk.

P1213 - PULMONARY VASCULATURE REMODELING IN A HYPOPLASTIC LEFT HEART PATIENT

Tiago A. Meniconi [1], Renato S. Assad[2], Petrônio G. Thomaz[2], Maria Fernanda S. Jardim[3], Mauricio Saito[4], Gustavo A. G. Favaro[5], Ana Cristina Aliman[6], Carlos A. Pedra[7], Jorge Y. Afiune[8], Teresa M. L. O. Uras Belém[9], Vera D. Aiello[1]
Incor, Pathology, São Paulo-Brazil[1]; Hospital Samaritano, Cardiovascular Surgery, São Paulo-Brazil[2]; Hospital Samaritano, Pediatric Cardiology, São Paulo-Brazil[3]; Hospital Samaritano, Fetal Medicine, São Paulo-Brazil[4]; Hospital Samaritano, Fetal Cardiology, São Paulo-Brazil[5]; Hospital Samaritano, Anesthesiology, São Paulo-Brazil[6]; Hospital Samaritano, Catheterization Lab., São Paulo-Brazil[7]; Instituto De Cardiologia De Brasília, Pediatric Cardiology, Brasília-Brazil[8]; Hospital Samaritano, Chief Of Neonatal Intensive Care Unit, São Paulo-Brazil[9]

Background: Patients with hypoplastic left heart syndrome (HLHS) and restrictive atrial septal defect (ASD) may benefit from fetal septostomy.
Objective: We assessed the extent of pulmonary vascular lesions in a newborn diagnosed with HLHS and restrictive ASD, from birth to the 26th day of life.
Methods: Patient was submitted to intrauterine balloon septostomy at the 28th gestational week. At birth, obstruction to left atrial egress was observed on echocardiogram. Immediate hybrid procedure was carried out, with stents implanted in the atrial septum and the patent ductus arteriosus. A lung biopsy was harvested on day 1 of life. The patient evolved with progressive signs of

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

pulmonary congestion due to persistent restriction of the ASD. On the 19th day of life, atrial stent ballooning did not relieve pulmonary venous congestion. Atrial septal resection under cardiopulmonary bypass support was performed on the 26th day of life. A new lung biopsy was collected. Patient did not survive the operation.
Results: After conventional histological processing, the lung biopsies were evaluated by qualitative analysis and morphometry, with calculation of the percentage of arterial medial thickness. The first biopsy (Day 1) showed diffuse and moderate hypertrophy of the arterial medial layer (Rabinovitch grade B), lymphatic dilation and venous wall thickening. The percentage of arterial medial thickness varied from 0.71 to 1.66 times the normal reference for age (mean Z value = + 0.65). Histologic changes of the second biopsy (Day 26) were more severe. Congestive pulmonary findings persisted. Severe occlusive intimal lesions were noticed in both pre and intra-acinar arteries. The medial thickness was increased up to 3.55 times the normal reference value (mean Z value = + 1.74).
Conclusion: Pulmonary vascular lesions progressed rapidly after birth due to unsuccessful repeated attempts of ASD enlargement. Probably, early relief of the obstruction would be more efficient to improve survival of these patients.

P1233 - CHARACTERISTICS AND OUTCOMES OF CHILDREN WITH TAKAYASU'S ARTERITIS AT A SOUTHERN AFRICAN TERTIARY CARE CENTER

Antoinette Cilliers, Paul Adams, Gcina Dumani, Hopewell Ntsinjana
C.H. Baragwanath Academic Hospital, University of the Witwatersrand, Paediatric Cardiology, Johannesburg,-South Africa

Introduction: Takayasu's Arteritis (TA) is a rare granulomatous, fibrosing arteritis of the aorta and its branches resulting in stenosis, occlusion, dilatation or aneurysm formation. Hypertension (HT) and reduced or absent pulses are common manifestations. A dilated cardiomyopathy (DCMO) is often contributed to HT, mitral and or aortic valve disease but myocardial involvement itself may be the cause. The aetiology is unknown, but tuberculosis (TB) and autoimmune aetiologies have been suggested. Management includes anti-inflammatory and chemotherapeutic agents, and revascularization.
Objective: To assess the characteristics and outcomes of patients with TA at a large Southern African Tertiary care centre.
Methodology: Retrospective analysis of all children diagnosed with TA over a 20 year period.
Results: A total of 55 children were documented with an average age of 9.7 years (SD, 3.4), F:M ratio 3:1, involvement of the abdominal aorta 34/55 (62%), renal artery stenosis 35/55 (64%), positive TB skin test recorded in 40/55 (73%) and a DCMO in 37/55 (67%) with an average shortening fraction (SF) of 20% (SD, 11%). The majority manifested with HT 39/55 (71%), heart failure in 24/55 (44%), and seizures in 15/55 (27%). All patients were treated with steroids, chemotherapeutic agents (cyclophosphamide and methotrexate), and TB treatment. Twenty three patients underwent 30 percutaneous revascularization procedures to treat uncontrolled HT: 8 stents (aorta 5, renal arteries 3), 22 balloon angioplasties (aorta 6, renal arteries 15, branch pulmonary artery 1). The systolic blood pressure decreased from 153 ± 23 to 133 ± 24 mmHg ($p = 0.005$). All patients required continued antihypertensive treatment after intervention. The SF improved in both the intervention and non-intervention groups.
Conclusion: TA at our institution is commonly associated with HT, heart failure and seizures. Percutaneous intervention, although not curative, achieves better control of HT. Reduced left ventricular function improved in all patients receiving medical and/or percutaneous interventional therapy.

P1237 - 3D ROTATIONAL ANGIOGRAPHY WITH 3D ROADMAP GUIDANCE IN CHD INTERVENTIONS

Seong-Ho Kim, Sang Yun Lee, So Ick Jang, Su Jin Park, Hye Won Kwon, Hyo Bin Lim, Eun Yeong Choi, Ji Seok Bang
Sejong General Hospital, Pediatrics, Bucheon-Si-Korea, South

Background: Nowadays, interventional cardiac catheterization has become an important component of the management for congenital heart diseases. Important advances in imaging modalities such as 3D rotational angiography (RA) with 3D roadmap guidance (RG) allows for both advanced diagnostic and interventional cardiac catheterization procedures. Recently, in our institute 3D RA with 3D RG was available first in Asia. This new technology is tremendously helpful in cardiac interventional procedures, that is, easier procedure, reducing angiography, radiation exposure and contrast amount. We would like to share our initial experiences with the audience.
Method: Between November 2013 and January 2016, 3D RA with 3D RG was used in 27 CHD interventions.
Results: 3D RA with 3D RG was used for pulmonary arterial interventions in 23 patients: congenital multiple peripheral pulmonary stenosis (13), postoperative pulmonary stenosis (8), and Fontan (2), stent for coarctation of aorta in 2 patients, and embolization of pulmonary arteriovenous fistula in 2 patients. Mean age was 13 ± 5 years, and mean body weight was 41 ± 20 kg. The number of target vessel was 2.3 ± 1.7. Mean contrast amount for 3D RA was 1.2 ± 0.5 ml/kg. Fluoroscopic time and procedure time were 32 ± 17 and 128 ± 35 min., respectively.
Conclusions: 3D RA with 3D RG is a promising modality for CHD diagnosis and treatment. 3D roadmap overlaid onto live fluoroscopy is tremendously beneficial for some CHD interventional procedures. It reduces contrast dose and procedural time.

P1256 - DRUG COATED BALLOON ANGIOPLASTY FOR PULMONARY VEIN STENOSIS IN PATIENTS WITH RECURRENT PULMONARY VEIN STENOSIS AFTER SURGERY INITIAL EXPERIENCE WITH A NEW TREATMENT TECHNIQUE

Toshikatsu Tanaka, Michio Matsuoka, Yuki Taniguchi, Sachiko Kido
Kobe Children's Hospital, Cardiology, Kobe-Japan

Background: Pulmonary vein stenosis (PVS) is a serious complication following TAPVR repair. The main therapies for PVS include surgical repair, balloon angioplasty (BAP) and stenting, but these treatments are complicated by a high rate of restenosis. We describe the use of a paclitaxel drug-coated balloon(DCB) for the treatment of recurrent PVS.
Materials and Methods: We used 4mm DCB (SeQuent Please, B. Braun, Hessen, Germany) to treat PVS for 3 patients with recurrent PVS after TAPVR repair, surgical PVS release, and conventional BAP. For 2 patients, we used conventional 5mm high-pressure PTA balloon in advance, then introduced DCB, and for 1 patient, used DCB from the beginning. We performed follow-up angiography 2 months later in 2 patients, 6 months later in 1 patient.
Results: Follow-up angiography showed effectiveness of DCB for the reduction of restenosis compared to the conventional BAP underwent previously for the same lesions in all 3 patients. All patients showed no complication and no adverse effect in 6 months follow-up period.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: Combination therapy using high-pressure PTA balloon and DCB for recurrent PVS after TAPVR repair is feasible and safe. This novel strategy may postpone the timing to perform next intervention and provide good long-term results for patients suffering from a serious and life-threatening complication after surgery.

P1296 - IS BALLOON AORTIC VALVOTOMY STILL THE PREFERRED INTERVENTION IN NEONATES AND INFANTS WITH CONGENITAL AORTIC STENOSIS SINGLE CENTER EXPERIENCE AND LITERATURE REVIEW

Supratim Sen, Santosh Wadile, Snehal Kulkarni, Suresh Rao
Kokilaben Hospital, Children's Heart Centre, Mumbai-India

Neonates and infants with congenital aortic stenosis are hemodynamically fragile. While most institutions, prefer balloon aortic valvotomy (BAV) for treatment, few centers have demonstrated excellent outcomes with surgical valvuloplasty (SAV). We studied our immediate and mid-term results for BAV in these patients.
Methods: Retrospective records review of neonates and infants who underwent BAV at our center from 2010 to 2015: baseline characteristics, procedural details and follow-up variables analyzed.
Results: 26 infants (6 females, 15 neonates) studied. Median age 1 month [2 days - 10 months]. Mean weight 3.92+ /- 1.36 kg. 58% patients had significant LV dysfunction (34.6% severe) at presentation. Mean aortic annulus during BAV 7.1 mm + /- 1.2. Mean balloon width to aortic annulus ratio 1.04 + /- 0.25. Mean AS gradient 60.9 + /- 14.9 mm Hg. Mean post valvotomy gradient 19.2 + /- 13.6mm Hg. Mean reduction in AS gradient 43.8 + /- 15.9 mm Hg.
Immediate post valvotomy, 5 (19%) moderate AR, 10 (38%) mild AR, 11 trivial/no AR; 3 (11.5%) had mild dysfunction, 2 (7.7%) severe dysfunction. Median hospital stay 2 days [1-22 days]. Median follow-up duration 54 months [6–76 months]. 6 patients (23%) required repeat BAV; median interval of 6 months [0.8-24 months]. Predictors of reintervention: insufficient decrease in gradient and post-valvotomy gradient > 30 mm Hg.
No immediate mortality. 1 child expired during reintervention (3.8%). None of our patients required surgical reintervention till date. Mortality and reintervention was significantly lower than reported in literature. Repeat balloon valvotomy required in only 23%.
Conclusion: Balloon aortic valvotomy can achieve good immediate and mid-term results in neonates and infants with very low procedural and early mortality and morbidity. Present results support BAV as the preferred intervention in these patients.

P1398 - EARLY AND LATE PRESENTATION OF CORONARY ARTERY FISTULA AN EXPECTED NATURAL PROGRESSION

Nicholas B Zaban[1], Huda Elshershari[2], W. Aaron Kay[1], Mark H Hoyer[1]
Indiana University School of Medicine, Pediatrics, Indianapolis-United States[1]; Indiana University School of Medicine, Deaconess Riley Children's Specialty Center, Evansville-United States[2]

Background: Coronary artery fistulas (CAF) are rare. They arise proximally or distally and most often drain to the right heart. They do not usually cause symptoms or complications in childhood, especially when small. However, symptoms and complications occur frequently in adults and include congestive heart failure, myocardial steal, thrombosis, myocardial infarction, stroke, arrhythmias, and sudden death.
Hypothesis: CAF if untreated in childhood, undergo a natural progression from the chronic shunts that create more complications in adults.
Materials and Methods: Two patients are compared with the same CAF. A 10 yo girl was diagnosed as a newborn, was asymptomatic for many years, and recently developed exertional chest pain. Echocardiogram showed a dilated left main coronary artery (LMCA) and large proximal CAF draining to the RA. Also, a 43 yo lady presented with a yearlong history of recurrent extremity numbness, palpitations, and dyspnea on exertion. Echocardiogram showed an enlarged LMCA with a large, tortuous CAF. Coronary CT angiography (CTA) confirmed a large proximal CAF draining to the RA.
Results: In both instances, the CAF arose from a large LMCA proximal to the bifurcation of anterior descending and posterior circumflex branches, turning sharply posteriorly and rightward to course tortuously behind the aorta and enter the right atrium superiorly. The CAF in the adult was significantly larger, as expected. CTA provided important anatomic detail to help plan a treatment strategy. Transcatheter device closure was successful in both, but challenges occurred due to tighter catheter turns in the child and due to the very generous CAF diameter in the adult, who had a complicated post-procedure course.
Conclusions: CAF closure is indicated when symptoms exist. Delay in treatment until symptom onset can create complications and a more challenging substrate for successful intervention. Closure should be considered at younger ages to minimize later complications.

P1400 - USE AND SAFETY OF CARDIAC CATHETERIZATION PERFORMED IN POST NEONATAL HEART SURGERY WITH POOR HEMODYNAMICS EVOLUTION. STUDY IN A CENTER OF MEDIUM COMPLEXITY

Alberto Robredo
Children and Mother Hospital, Cardiology, Salta-Argentina

Background: When a persistent and severe hemodynamic decompensation occurs in the immediate postoperative of infants with systemic pulmonary shunt surgeries, patent ductus arteriosus and coarctation of the aorta, it raises the use of diagnostic methods that exceed the clinical analysis and echocardiogram. In these cases, the cardiac catheterization study is the standard for diagnosis and occasionally, also therapeutic.
Material and Method: We analyzed the 498 cardiac catheterizations performed in the last five years. Twenty-four procedures were in severe and persistent hemodynamic compromise after neonatal postoperative in this group of patients.
Results: In the systemic pulmonary shunt surgeries were found: A) Severe stenosis of the subclavian artery: five cases and we dilated the subclavian artery in 2 cases with balloon alone and in 2 with stents. B) Stenosis of the pulmonary arteries: 3 cases. C) Shunt thrombosis/Thrombolitic therapy: 2 cases. D) Large aorto-pulmonary collateral: 1 case. E) One shunt anastomosis from the subclavian to an unobtrusive total anomalous pulmonary venous collector. F) Giant pseudoaneurysm: 1 case. In coarctation of the aorta: A) Severe stenosis in surgical repair: 4 cases. Dilation the recoartation in 3 cases and dilation of ductus in 1. B) Hypoplasia of the aortic arch: 2 cases. In closing patent ductus arteriosus: A) Pulmonary sequestration: 1 case with posterior embolization B) Hepatic arteriovenous malformation 1 case C) Thrombosis in superior vena cava with posterior percutaneous transluminal angioplasty: 1 case. In two patients the anatomy of the surgery was the correct one. No patient died during the diagnostic or the therapeutic procedures.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: Diagnostic and therapeutic cardiac catheterizations are useful and safe in this group of patients.

P1402 - OUTCOMES OF RADIOFREQUENCY PERFORATION FOR PULMONARY ATRESIA AND INTACT SEPTUM VENTRICULAR SEPTUM AND CRITICAL PULMONARY VALVE STENOSIS WITH CORONARY FISTULAS. A SINGLE CENTER 20 YEARS EXPERIENCE

Maria Vall Camell, Javier Rodríguez-Fanjul[1], Carles Bautista Rodríguez[2], Julio Moreno Hernando[1], Ana Morillo[1], Fredy Prada[2], Martin Iriondo Sanz[1], Joan Sanchez-De-toledo[2]
Bcnatal. Hospital Sant Joan De Déu-hospital Clinic. University of Barcelona, Neonatology Department, Barcelona-Spain[1]; Hospital Sant Joan De Déu-hospital Clinic. University of Barcelona, Pediatric Cardiology Department., Barcelona-Spain[2]

Background and Aims: Newborns with Pulmonary Atresia with intact ventricular septum (PAIVS) and Critical Pulmonary Stenosis (CPS) are cyanotic at birth and require prostaglandins (PGE) for maintenance of pulmonary blood flow. These patients' spectrum is wide, ranging from those with relatively good-sized RV chambers to those with significant RV hypoplasia or RV-dependent coronary circulation. The presence of coronary fistulas has been classically a contradindication for opening the pulmonary valve.
The main objective of this study is to review our 20-year experience in managing PAIVS and CPS, to analyze early and long-term results and the main decision features toward a biventricular or a univentricular pathway with the strategy of opening the valve although the presence of coronary fistulas.
Methods: This is a descriptive retrospective study where we identified all patients diagnosed with PAIVS or CPS admitted to the neonatal intensive care unit (NICU) between January 1996 and October 2016. For each patient, available medical records, echocardiograms, angiograms, and operative reports were reviewed. Morphologic RV features, coronay fistulas, surgical management, percutaneous intervention and long-term outcome data were collected and analysed.
Results: 52 patients were admitted. Major features between both groups can be seen in Table 1. A total of 9 (17.3%) patients died during the follow-up period. 8 APSI and 1 CPS. None of the patients with coronary fistulas died. The 43 survivors were followed up for 107.81 months (±53.56). New York Heart Association functional classification at the most recent examination was for the overall group 1.2, being 1.2 for the ones with BV, 2 for the UV and 1.3 for the 1.5 V. Regarding the CHD SPS survivors had a functional class of 1.1 and the PAIVS a 1.6.
Conclusions: Strategy of aggressive and precocious early opening of the pulmonary valve has a good global survivence correlated with

Table 1. Patients' clinical characteristics data.

Variable	CPA (n = 23)	PAIVS (n = 29)	p value
Female sex	12 (52.2%)	15 (51.7%)	0.624
GA weeks ± SD	37.7 ± 3.8	38.7 ± 2.0	0.794
Prematures (<37 GA weeks)	4 (17.4%)	4 (14.2%)	0.316
BW (Kg) ± SD	2.85 ± 0.80	3.11 ± 0.59	0.337
SGA	3 (13.0%)	5 (18.5%)	0.885
Prenatal Diagnosis	15 (65.2%)	24 (86.2%)	0.042
Extracardiac malformations	1 (4.3%)	6 (20.6%)	**0.037**
RV partite status			
Tripartite	19 (82.6%)	22 (78.6%)	0.623
Bipartite	4 (17.4%)	5 (17.2%)	0.756
Unipartite	0	2 (7.1%)	**0.021**
TV Z score	-1.73 ± 0.62	-2.17 ± 0.85	0.08
RVOT Z score	-2.65 ± 1.18	-3.64 ± 1.63	0.17
Coronary fistulas	2 (9.1)	6 (21.4)	0.23

CPS: Critical Pulmonary Stenosis. PAIVS: Pulmonary atresia with intact ventricular septum. GA: gestational age. SD: Standard Deviation. BW: Birth weight. Kg: kilograms. SGA: small for gestational age (BW < p10). TV: tricuspid valve. RVOT: right ventricular outflow tract. Significant values are in bold numbers.

P1409 - PROCEDURAL OUTCOME AND SHORT TERM FOLLOW UP OF PATIENTS UNDERGOING ENDOVASCULAR STENTING FOR COARCTATION OF AORTA A SINGLE CENTRE EXPERIENCE

Sreeja Pavithran, Lakshmi Sadasivan, Kothandam Sivakumar
The Madras Medical Mission, Department of Pediatric Cardiology, Chennai,-India

Background: Endovascular stenting is the preferred option in managing coarctation of aorta (COA) in older children and adults. Covered stents are used in selected or high risk catergory of patients.
Materials and Methods: Patients with severe coarctation of aorta who underwent endovascular stenting during the period May 2013 to November 2016 were retrospectively analysed. CT aortogram was used for preprocedural imaging.Procedural outcome complications and short term follow up were noted.
Results: 26 patients (eight females) aged 1-54 years (median 29), weighing 7.8 -86.4 (median 55.1) kg, underwent stenting of COA. All except one had postsubclavian coarctation. 70% of patients had hypertension and were on treatment. Mean gradient at catheterisation was 69.2 ± 29.4 mm hg and mean gradient postprocedure was 3.5 ± 4 mmhg. A total of 27 stents were deployed, Covered CP (17), Cook Formula (1), Advanta V12 Atrium (2), Intrastent Mega (3), Palmaz (2), Andrastent. (1), Bare CP (1). Covered stents were used in 59.1%. The mean stent length and balloon diameter were 34.73 ± 11.56 mm and 16.3 ± 2.42 mm respectively. Pre dilatation was done in two patients including one with near interruption. Post dilatation was needed in 35% of patients. Procedural complications included dissection in one patient needing a second covered stent and right femoral artery occlusion in another. Retroperitoneal hemorrhage in one resulted in mortality. Follow-up ranged from 1 month to 3.5 years. 36.4% required continuation of antihypertensive therapy even after stenting. One patient with presubclavian coarctation required redilatation 6 months after stenting.
Conclusions: Stent implanation is a safe and effective alternative to surgical repair in COA. It provides immediate and near complete relief of obstruction which is sustained on short term follow up. Long term follow up is required to look for restenosis, aneurysm formation and persistent systemic hypertension.

P1410 - STENTING OF RIGHT VENTRICULAR OUTFLOW TRACT CONDUITS AND PULMONARY ARTERIES – PROCEDURAL OUTCOME AND MEDIUM TERM FOLLOW UP

Sreeja Pavithran[1], Ramyashri Chandrasekaran[1], Ejaz Ahamed Sheriff[2], Kothandam Sivakumar[1]
The Madras Medical Mission, Department of Pediatric Cardiology, Chennai, -India[1]; The Madras Medical Mission, Department of Cardiac Surgery, Chennai, -India[2]

Background: Stent angioplasty is an accepted treatment for narrowed pulmonary arteries(PA). It also postpones surgical conduit replacements and offers landing zones for percutaneous pulmonary valves.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: Retrospective analysis of patients who underwent PA and RVOT stenting over a period ranging from June 2008 to June 2016. Patients were divided into Group A with elevated right ventricular(RV) pressures due to narrowed conduits, main PA or bilateral branch PA and Group B with unilateral PA stenosis. Their etiology, outcome complications and short term follow up were analyzed.
Results: Among 80 patients(39 males) between 0.25-37 years (mean 10), weighing 4.5-82(mean 27) kg divided into 46 in Group A and 34 in Group B, 73 patients had prior surgery 3 days to 17 years earlier.Conduit stenting in 20 patients were successful in all, uniformly postponed their replacements and offered landing zones for percutaneous valves in six. One among the four MPA stenting did not give adequate result and required surgery. Bilateral PA stenting procedure was successful in all 22 patients, often needed simultaneous deployment. On a five-year follow-up, five needed reinterventions. Unilateral PA stenting was successful in 32 out of 34 patients, one died of vessel rupture and other needed surgery for embolization. Stent migration in two and fractures in two needed additional stent placements. There were eight complications (10%)in total; young age and fresh suture lines were risk factors.
Conclusions: Stenting postponed surgical replacement in stenosed conduits and served as landing zones for percutaneous pulmonary valves. Bilateral PA stenting was uniformly effective in reducing RV pressures, and often needed simultaneous deployment. As reinterventions might be needed with somatic growth, the stents should be post-dilatable. In discrete LPA origin stenosis, short stents and stents with poor radial strength should be avoided to prevent stent migration and fractures.

P1416 - COMPARISON OF CARDIAC INDEX MEASUREMENTS BY CATHETRIZATION AND PHASE CONTRAST MRI IN CHILDREN WITH PULMONARY HYPERTENSION

Michal Schäfer, Uyen Truong, Lorna Browne, Gareth Morgan, Michael Ross, Kendall Hunter, Dunbar Ivy, Neil Wilson
Children's Hospital Colorado, Cardiology, Aurora-United States

Background: Hemodynamic evaluation via catheterization is essential for diagnostic and therapeutic investigation of children with pulmonary hypertension (PH). Measurement of pulmonary flow is required to calculate pulmonary vascular resistance index (PVRi), an important component of investigation and a predictor of outcome. Calculation of cardiac (CI) index using the Fick principle in most catheter laboratories relies on an estimate of oxygen consumption which may limit its reliability. In this study, we compared CI assessed by the Fick principle and thermodilution (TD) with gold-standard flow waveform evaluation technique – phase-contrast MRI (PC-MRI).
Materials and Methods: Twenty-four patients with pre-diagnosed idiopathic PH (n = 19) or PH associated with congenital heart disease (n = 5) (age: 14.2 ± 4.6 (range: [4, 20]), M:F = 10:14) underwent same-day right-heart catheterization and PC-MRI for hemodynamic evaluation. CI computed from the catheterization (Fick and TD) were compared with PC-MRI (indexed integrated flow waveform multiplied by heart rate) using linear regression models (beta ± standard error) and Bland-Altman analysis.
Results: CI measured by the Fick principle and PC-MRI failed to show significant correlation (0.06 ± 0.24, p = 0.8030). Furthermore, no significant correlation existed between TD and PC-MRI (0.78 ± 0.44, p = 0.1080). Respective Bland-Altman analysis revealed a bias in CI of -2.8 and -2.4 L/min/m2 between Fick vs. PC-MRI and TD vs. PC-MRI, respectively. The limits of agreement for the Fick method vs. PC-MRI were -2.6 to 2.4 L/min/m2 and -2.1 to 2.1 L/min/m2 for TD vs. PC-MRI.
Conclusions: CI calculations differ significantly between catheterization and PC-MRI. Stronger agreement existed between TD vs. PC-MRI than between Fick vs. PC-MRI. The Fick calculation and thermodilution techniques have well recognized limitations and errors; however PC-MRI assessments are not without their limitations. Future studies are required to evaluate the relative prognostic value of PVRi and CI calculated using different modalities.

P1428 - INITIAL EXPERIENCE OF TRANSCATHETER CLOSURE OF SUBARTERIAL VENTRICULAR SEPTAL DEFECT WITH THE AMPLATZER DUCT OCCLUDER

Tsung-Cheng Shyu, Ming-Chih Lin, Yeak-Wun Quek, Sheng-Je Lin, Hean-Pat Saw, Sheng-ling Jan, Yun-Ching Fu
Taichung Veterans General Hospital, Pediatrics, Taichung-Taiwan

Background: Traditional treatment of subarterial ventricular septal defect is open heart surgery. This study aimed to evaluate the feasibility, safety and outcome of transcatheter closure with the Amplatzer duct occluder.
Methods: Between March 2012 and June 2015, a total of 16 patients with subarterial ventricular septal defect who underwent transcatheter closure with the Amplatzer duct occluder were enrolled retrospectively. There were 8 males and 8 females. The age ranged from 3.0 to 65.6 years with the median of 35.6 years. The body weight ranged from 14 to 92 kg with the median of 60 kg. All patients had a prolapse of right coronary cusp without subaortic rim. Mild aortic regurgitation was noted in 11 (69%) patients.
Results: Left ventriculogram showed ventricular septal defect size ranged from 1.3 to 9.3 mm with the median of 3.5 mm. Device was successfully implanted in 88% (14/16) patients. One patient had mild skin allergy to contrast medium. No other complication was noted. Complete closure rate was 64%, 86%, 86% and 86% at 1-day, 1-month, 6-month and 12-month follow-up respectively. Two patients developed new or worsening aortic regurgitation during follow-up.
Conclusions: Transcatheter closure of subarterial ventricular septal defect with Amplatzer duct occluder is technically feasible and safe in patients older than 7 years old. However, development or worsening of aortic regurgitation needs long-term follow-up.

P1449 - PERCUTANEOUS VSD CLOSURE UNDER 1 YEAR OF AGE

Nazmi Narin, Ozge Pamukcu, Ali Baykan, Suleyman Sunkak, Onur Tasci, Kazim Uzum
Erciyes University, Pediatric Cardiology, Kayseri-Turkey

Background: Untreated large Ventricular septal Defects (VSD) are important reason of congestive heart failure in early infancy. This population usually fails togrow and surgical closure is challenging because of congestion in their lungs prone to respiratory infection, their bad nutritional status.
Objective: The aim of this study was toshare our experience in VSD closure of children under 1 yearof age percutenously.
Methods: We have performed VSD closure of 7patients under 1year of age between the dates September2012-May2016 in Erciyes University Pediatric Cardiology Department.
Results: Age of patients ranged between 4months-12months. Weight of the patients during the procedure was between 5.3-9 kg. Mean VSD diameter was 3.19 ± 0.47mm. One of defects was muscular, rest of them were perimembranous. All defects were

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

closed with Amplatzer Ductal occluderII (ADO-II). Mean fluoroscopy duration and total radiation dosage were 78.5 ± 94.6 min, 2069 ± 1395 cGy/min respectively. We didnot face with any major complication except in one patient: complete AV block was seen one month after the procedure. Pacemaker was implanted. No aortic regurgitation was seen in patients after device implantation.
Conclusion: The procedure of VSD closure, whether it is surgical or percutaneous, is very risky. The risks were higher when the children were smaller than 1 year of age and low body weight. Percutaneous VSD closure may be an alternative to surgery in early infancy that carry the similar risks but less invasive.

P1465 - TRANSCATHETER EMBOLIZATION OF COLLATERAL VESSELS USING N BUTYL 2 CYANOACRYLATE IN FUNCTIONAL SINGLE VENTRICLE PATIENTS

Kentaro Aso, Yousuke Osada, Kenzo Sakurai, Masanori Mizuno, Yoshimitsu Tsuzuki, Kenjiro Goto
St. Marianna University School of Medicine, Pediatrics, Kawasaki-Japan

Background: Transcatheter coil embolization of collateral vessel such as aortopulmonary shunt (APS) and vena cava to pulmonary vein fistula is established procedure. However, it comes technically difficult when those vessels have a complex form. Also sometimes it requires many coils. As a result catheter intervention tend to be a time and money consuming procedure. N-butyl-2-cyanoacrylate (NBCA) is a monomeric acrylic glue that polymerizes rapidly when brought into contact with ionic media such as blood, and produces permanent occlusion. Utility of NBCA as an embolization material has already confirmed especially in nerouvascular area however, there are few published data that noted about its utility in congenital heart disease.
Aim: To evaluate an utility of NBCA as an embolization material for collateral vessels in functional single ventricle patients.
Case 1: Three year-old boy with Double outlet RV, MS and multiple VSD underwent TCPC at 29 months of age. We performed cardiac catheterization just before TCPC. Numerous APSs were detected by right IMA angiography. We embolized APSs with Target Coil. 360 Ultra 4mm × 6 cm was detained at distal side of right IMA. After coil detainment, we inserted microcatheter and infused 50% NBCA quickly. We confirmed complete right IMA occlusion. Case 2: Two-year-old girl with polysplenia, double outlet RV and multiple VSD. We underwent TCPS at 14 months of age. We performed cardiac catheterization just before TCPC operation. We confirmed SVC to pulmonary vein fistula. Eleven Coils were detained at distal of SVC-PV fistula. Then we inserted microcatheter to proximal side of fistula and inject NBCA quickly and fistula was completely collapsed. Arterial O2 saturation raise up from 82 to 86%
Conclusions: We achieved complete embolization of collateral vessels with coils and emulsion of NBCA in functional single ventricle patients. Embolization with NBCA may be attractive, especially for complex and small caliber vessels.

P1466 - SHORT TO MID TERM RESULTS OF TRANSCATHETER CLOSURE OF PERIMEMBRANOUS OR OUTLET TYPE VENTRICULAR SEPTAL DEFECTS USING AMPLATZER DUCT OCCLUDERS

Jou-Kou Wang[1], Ming-Tai Lin[2], Chu-An Chen[2], Hsin-Chia Chen[2], Sheun-Nan Chiu[2], Jun-Wei Lu[2], Mei-Hwan Wu[2]
National Taiwan University Hospital, Pediatrics, Taipei-Taiwan[1]; National Taiwan University Hospita, Pediatrics, Taipei-Taiwan[2]

Objectives: We investigated the safety and efficacy of Amplatzer duct occluder (ADO) in transcatether closure of perimembranous or outlet type ventricular septal defect (VSD).
Methods: During a 4.2-year period, transcatheter closure of perimembranous or outlet type VSD using ADOs was attempted in 154 patients. Patients with a body weight <12 Kg, VSD diameter >10mm, pulmonary hypertension or moderate degree of aortic valve prolapse were excluded. Transesophageal echocardiography was used to monitor the procedure. ADOI or II were used to close perimembranous VSD, & ADOII was used to close outlet type VSDs. The size of ADO selected was 1-3 mm larger than narrowest jet width measured on the angiograms. Clinical evaluation, ECG & echocardiography follow-up were performed at 1, 3, & 6-month & annually after the procedure.
Results: Failure occurred in 7 patients including 1 complicated with ADOII migration. Of the 147 patients with successful deployment of ADOs, their age ranged from 3.3 to 65 years (20 ± 15 years). The mean Qp/Qs ratio was 1.4 ± 0.3. Of them, 125 had perimembranous type VSD & 22 had outlet type VSD. The mean defect diameter was 4.3 ±1.4 mm. ADOI was used in 74 (mean device size 6.5 ± 1.5 mm) & ADOII in 73 patients (5.7 ± 0.6 mm). No major complications occurred except 2 cases with embolization. One failure case was managed with emergent surgery. Percutaneous retrieval of an ADOI & implantation of a larger ADOI were performed in the other patient. All were available for 1 & 3-months follow-up. There were 9 patients with small residual shunt & 1 with mild-to-moderate residual shunt after a mean follow-up period of 35 ± 17 months. No one developed heart block or more than mild new-onset aortic or tricuspid regurgitation.
Conclusion: Transcatheter closure of perimembranous or outlet type VSD using ADOs is safe and effective.

P1482 - EFFICIENCY OF TRANSCATHETER PATENT FORAMEN OVALE CLOSURE WITH HYPERION PFO OCCLUDER

Mateusz Knop[1], Bialkowski Jacek[1], Szkutnik Malgorzata[1], Fiszer Roland[1], Karwot Blandyna[1], Smerdzinski Sebastian[1], Wawrzynczyk Maciej[2]
Silesian Center for Heart Diseases, Congenital Heart Diseases and Pediatric Cardiology Dept in Zabrze, Zabrze-Poland[1]; Medical University of Silesia, Neurology Dept in Zabrze, Zabrze-Poland[2]

Introduction: Patent Foramen Ovale (PFO) may result in paradoxical embolism event (EE). Transcatheter closure of PFO remains still interesting treatment alternative in selected patients. Experience with application of Hyperion PFO Occluders (similar to Amplatzer PFO Occluders) in such circumstancies was not evaluated yet.
Aim: To analyse clinical data and mid-term outcomes of patients (pts) with PFO after cryptogenic EE who underwent transcatheter PFO closure with Hyperion Occluder.
Methods: Among 67 patients (pts) with cryptogenic EE in whom in years 2014-2016 PFO was closed percutaneously with Hyperion PFO Occluder in our institution. There were 36 woman with mean age 41 (21-62) and 31 man with mean age 41 (19-68) years. The indications for the procedure were established by neurologist: Transient Ischemic Attack (TIA) in 15 pts, ischemic stroke in 49 pts, migraine with aura in 3 pts. Transcranial Doppler (TCD) was performed in all pts (with MES > III degree in all pts). Follow up was performed 3, 6 12 months after the procedure and thereafter yearly. Control TCD was performed after 6 months after procedure.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: The procedure was successfully completed in all patients and no procedure-related complications were observed during hospitalization. Following devices were used (accordingly to the anatomy of PFO) – PFO Hyperion Occluder 18 mm (6 pts), 24 mm (49 pts), 30 mm (8 pts) and 34 mm (4 pts). Fluoroscopy time was 2,4 (0,9-22) min. During follow-up no neurological events were observed in any pt. TCD results were available in 54 pts (4 were lost from follow-up)-48 pts had complete PFO closure and 6 pts residual shunt. In 1 pt paroxysmal atrial fibrilation was observed.
Conclusion: Transcatheter PFO closure with Hyperion device is safe and effective procedure, however long-term follow-up and randomized study with other devices are necessary. ⋆Device produced as SHMSA by Lepu Company (Beijging, China)

P1484 - OFF LABEL PERCUTANEOUS PULMONARY VALVE IMPLANTATION IN SMALL CONDUITS

Alain Fraisse[1], Jose Diogo Martins[2], Hayssam Baho[3], Saule Kadirova[4], Fadi Bitar[5], Abdelfatah Abu Haweleh[6], Anselm Uebing[7], Olivier Ghez[8], Philippe Acar[9], Sebastien Hascoet[9]
Royal Brompton Hospital, Paediatric Cardiology, London-United Kingdom[1]; Hospital De Santa Marta, Paediatric Cardiology, Lisboa-Portugal[2]; King Faycal Specialist Hospital, Paediatric Cardiology, Jeddah-Saudi Arabia[3]; National Research Cardiac Surgery Center, Paediatric Cardiology, Astana-Kazakhstan[4]; American University of Beirut Medical Center, Paediatric Cardiology, Beirut-Lebanon[5]; Queen Alia Heart Institute, Paediatric Cardiology, Amman-Jordan[6]; Royal Brompton Hospital, Adult Congenital Cardiology, London-United Kingdom[7]; Royal Brompton Hospital, Paediatric Cardiac Surgery, London-United Kingdom[8]; Chu Toulouse, Paediatric Cardiology, Toulouse-France[9]

Background: Guidelines allow percutaneous pulmonary valve implantation (PPVI) in conduits above 16 mm diameter. Balloon dilatation of a conduit to a diameter greater than 110% of the original implant size is also not recommended. We analyzed patients undergoing PPVI in such conditions.
Materials and Methods: Nine patients (May 2008-July 2016) from 8 institutions underwent PPVI in conduits < 16 mm diameter. Five patients with 16-18 mm conduit diameter underwent PPVI after over-expansion of the conduit >110%. Mean age and weight of the 14 patients was 12.1(7.7 to 16) years and 44.9(19 to 83) Kgs.
Results: Median conduit diameter at PPVI was 12(10 to 17) mm. Median systolic right ventricular pressure was 70(40 to 94)mmHg. Procedure was successful in all cases. A confined conduit rupture occurred in 7 patients (50%) and was treated with covered stent in 6. One patient experienced dislocation of 2 pulmonary artery stents that were parked distally. The post-implantation median systolic right ventricular pressure was 36(28 to 51) mmHg. A fistula between right-ventricle outflow and aorta was found in one patient, secondary to undiagnosed conduit rupture. This was closed surgically. After a median follow-up of 27.4(2.5 to 93.8) months, all the patients are asymptomatic with no significant RVOT stenosis.
Conclusions: PPVI is feasible in small conduits but rate of ruptures is high. However such ruptures remain contained in the majority of cases because of surrounding fibrosis. It is then possible to implant the largest available pulmonary valve in small conduits. Surgical back-up should be available in case of uncontrolled conduit rupture.

P1488 - ATRIAL SEPTAL STENT IMPLANTATION FOR THE MANAGEMENT OF CONGENITAL HEART DISEASE IN INFANTS

Adolfo Sobrino Baladron[1], Alejandro Rodríguez Ogando[1], Fernando Ballesteros Saturnino[1], Reyes Álvarez García-rovés[1], Ramón Pérez-caballero Martínez[2], Constancio Medrano López[1], Jose Luis Zunzunegui[1]
H.G.U. Gregorio Marañon, Paediatric Cardiology, Madrid-Spain[1]; H. G.U. Gregorio Marañon, Congenital Cardiac Surgery, Madrid-Spain[2]

Introduction: The creation of an unrestrictive atrial septal defect could be crucial for the management of complex congenital heart defects in different situations, such to relieve atrial hypertension, to maintain cardiac output, or to achieve adequate atrial mixing to improve systemic oxygen saturation. The aim of this study is to report an institutional experience performing percutaneous atrial septal stenting to relief atrial restrictions in various scenarios.
Objective: We retrospectively reviewed all pediatric cardiac catheterization procedures that included transcatheter atrial septal stent implantation (or an attempt), that were performed between 2005 and 2015.
Results: Thirty-seven patients underwent 40 transcatheter interventions. Thirty-nine implantations attempts (97,5%) were successful. The median weight was 4 kg [2-80 kg] and median age 3,5 months [0-193 months]. About 40% of patients had an intact atrial septum (IAS), and radiofrequency perforation of the interatrial septum was used before septal stent implantation. Left or right venous femoral access, were used in all patients. Indications were categorized in: to relief left atrial hypertension (45%) in the setting of hypoplastic left heart syndrome (N = 14) or left heart obstructive defects (N = 4); to maintain cardiac output in the setting of severe pulmonary hypertension or right ventricle dysfunction (35%); and to unload left cavities in the context of severe left ventricular dysfunction and ECMO assistance (20%). Major adverse events were seen in 12% of procedures: 3 stent migration, and 2 cardiac tamponade (one periprocedural death). About 20% of patients required stent overdilation. All stented atrial septum remained widely patent until elective surgical stent explant (54%), or until last follow-up (median follow-up time 32 months).
Conclusion: A restrictive atrial septal defect or IAS, could be a challenging problem in different situations, for the management of cardiac diseases in infants. Atrial septal stent implantation could be a feasible and effective technique in selected situations.

P1490 - FIRST 100 NEW COBALT CHROMIUM STENTS IMPLANTED IN LARGE VESSELS AND OTHER POSITIONS

Roland Fiszer, Jacek Bialkowski, Malgorzata Szkutnik
Medical University of Silesia, Congenital Heart Diseases and Pediatric Cardiology Department, Zabrze-Poland

Background: Stent implantation is well established method of treatment in patients with large vessels narrowing. We present our experience with application of first 100 new cobalt – chromium AS XL/XXL stents implanted in several positions.
Materials and Methods: There were 98 patients treated with 100 stents - 57 (aged 8-65 years) with native aortic coarctation (CoAo) or recoarctation, 17 (aged 6-64 years)with left or right or left PS closely to the bifurcation (native or postsurgical). In 21 pts (aged 11-40 years) the procedure was presenting before Melody valve implantation (in calcified pulmonary homograft or native right ventricle outflow tract- RVOT). In 3 patients stents were implanted in some other places to dilate stenosis of: superior vena cava (in 7,5 years old child), Fontan tunnel (in 17 years old boy), and atrial septal defect (interatrial septum in complex heart defect in 19 years old boy). Mean follow-up was 3,4 (0,2-5,4) years.
Results: All procedures were finished successfully in all but two patients without any complications with significant clinical improvement. Two migration of stents occurred – one in RVOT and another in left pulmonary artery (without clinical consequences). In all cases successful dilation of stenosed place with

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

significant gradient reduction occurred. In 2 cases of native CoA (23 and 34 years old man) in early follow-up (6 and 8 months after the procedure) in angio CT small aneurysm formations was observed. Both patients were treated successfully with covered stents. In follow-up in one patient (presented for valve implantation) stent fracture was found and no other complications were observed.
Conclusions: Implantation of new cobalt-chromium AS XL and XXL is a good therapeutical option for the treatment of stenosed great vessels.

P1556 - PATIENTS AGE IMPACT ON THE RESULTS OF THE TRANSCATHETER ATRIAL SEPTAL DEFECT CLOSURE

Anna Kaneva-nencheva[1], Elisaveta Levunlieva[1], Lubomir Dimitrov[1], Kiparisija Nenova[1], Ivan Velkovski[1], Rumen Marinov[1], Stojan Lazarov[2], Dobri Dobrev[1]
National Heart Hospital, Pediatric Cardiology, Sofia-Bulgaria[1]; National Heart Hospital, Congenital Heart Surgery, Sofia-Bulgaria[2]

Transcatheter closure with self-expandable double disc devices (DDD) became a method of choice in the treatment of secundum atrial septal defects (ASD). The complications remain the main concern of the procedure despite the gained experience. The aim of the study is to assess the relationship between the patients age and event-free procedure.
Patients and Methods: We retrospectively reviewed the data base of 169 consecutive patients, 112 children, mean age 9,8 (3,2) years (group 1) and 57 adults, mean age 39 (14,6) years (group 2), with attempted DDD, Amplatzer type, performed in a tertiary heart center.
Results: Event-free course was observed in 148 pts. (88%). There were 6 major complications (1 death due to unrecognized retroperitoneal bleeding; 3 early and 1 late embolizations with surgical removal and 1 acute pulmonary edema in patient on chroniodyalisis). Fifteen minor complications were observed (3 explantations before release due to unstable DDD position; 3 transcatheterly removed embolizations; 1 gastrointestinal bleeding; 1 small pericardial effusion; 7 postprocedural dysrhythmias - atrial fibrillation/flutter). Table. Comparison of the type and rate of complications in both groups
Conclusions: ASD device closure is an effective and relatively safe procedure at any age. Patients age has no impact on the major complications and embolizations. They are related mainly to the preprocedural assessment of the ASD size and morphology. Patients age influences dysrhythmias that need precise pre- and postprocedural estimation and treatment.

Table.

	Group 1(N = 112)	Group 2(N = 57)	p
Closure rate (%)	97	92	ns
Total complications (%)	4,6	28,6	0,000
Major complications (%)	1,9	7,1	ns
Total embolizations (%)	2,8	7,1	ns
Dysrrhythmias (%)	0,9	10,7	0,007
TTE size (mm)	14,3 ± 3,1	18,6 ± 4,4	0,000
TEE size (mm)	14,8 ± 3,3	20 ± 5	0,000
Qp/Qs	1,9 ± 0,5	2,2 ± 1	ns
Device size (mm)	16,5 ± 4	23,3 ± 5,7	0,000
Difference DDD-TTE (mm)	2,1 ± 2,4	4,7 ± 4,2	0,000
Septal aneurism (%)	35,2	41,1	ns

P1559 - RIGHT VENTRICLE DEPENDENT CORONARY CIRCULATION IN A NEWBORN CRITICAL PULMONARY VALVE STENOSIS

Lourdes Gomes, César Esteves, Ranulfo Matos, Ralph Coutinho, Luciana Nina, Diego Macedo, João Saba, Antônio Carlos Carvalho, Célia Silva
UNIFESP, Cardiology, São Paulo,-Brazil

Introduction: Coronary-cavitary connections often associated with pulmonary atresia with intact interventricular septum, may occur in neonates with critical pulmonary stenosis (PS), which adds a worse prognostic.
Objectives: To describe a rare case of critical PS with coronary circulation dependent on the right ventricle (RV) .
Case report: –baby girl, born at term, BW = 3350 g. Maternal history of gestational diabetes and systemic arterial hypertension. A systolic murmur was heard at the first day, being well in hospital time she was discharged home on the third day of life. On her ninth day, she presented to a pediatric cardiologist with tachycardia and weight loss. In her investigation: Chest x-ray showed mild cardiomegaly, slight oligaemic pulmonary fields ; ECG - sinus rhythm, QRS + 60° and incomplete RBBB. Echocardiographic findings: critical PS, PFO with bidirectional shunt, moderate tricuspid regurgitation, a hypertrophied good-sized right ventricle (RV). Estimated RV pressure was 118 mmHg, and a 2mm patent ductus arteriosus. She was admitted to the hospital and started on prostaglandin. At 28 days of life, she was referred to our center for pulmonary balloon valvuloplasty (PVB). Hemodynamics findings: RV-PA gradient of 45 mmHg and RV/AO ratio of 1.39. After RV angiography, PVB with a Power-flex balloon 10 × 2, was performed, followed its deflation, the patient went to complete atrioventricular block, cardiogenic shock and death despite exhaustive CPR manoeuvers. Going back to review her angiographies the left coronary artery were seen arising directly from the right ventricular outflow tract.
Conclusion: decompression of the RV was probably the cause of death. Aortography should be performed prior to PVB in suspected cases

P1569 - LONG TERM RESULTS OF ULTRAHIGH PRESSURE BALLOON ANGIOPLASTY FOR PERIFERAL PULMONARY ARTERY STENOSIS. COMPARISON ANALYSIS WITH STENT PLACEMENT

Mizuhiko Ishigaki[1], Sung-Hae Kim[2], Tanomo Ono[2], Keisuke Sato[2], Jun Yoshimoto[2], Norie Mitsushita[2], Masaki Nii[2], Kisaburo Sakamoto[2], Yasuhiko Tanaka[2]
Shizuoka Children's Hospital, Cardiology, Shizuoka-Japan[1]; Children's Hospital, Cardiology, Shizuoka-Japan[2]

Background and Objectives: Balloon angioplasty for postoperative pulmonary artery stenosis is an important therapeutic option to maintain and facilitate the pulmonary circulation. During the past decade, manykinds of non-compliant balloons which provide excellent trackablity have been widely used. Especially, efficacy of ultra-high-pressure balloons (UHPB) such as CONQUEST@ has been also reported, but their long term benefits are not known. To analyze the long term efficacy of UHPBs against postoperative branch pulmonary artery stenosis compared to stent implantation.
Methods: Retrospective analysis of follow-up catheterization data over three years after angioplasty by UHPBs or stents against the lesions with biventricular corrective surgery. Five cases, 11 branches of UHPB group and 8 cases, 9 branches of stent groups are included.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: Mean follow up period was 4.7 years in UHPB group, and 6.8 years in stent group. Mean gain of minimal lumen diameter (MLD) at post-/pre- angioplasty was 122 (100-300) % in UHPB group and 189 (131-560) % in stent group. Whereas the changes in MLDs between the follow up period (MLD at the latest follow up/just after initial intervention) was 162 (129-231) % in UHPB group and 102 (63-143) % in the stent group, which displays significant advantage in vascular growth in UHPB group ($P < 0.01$). Balloon redilation procedure was performed 0.8 times in UHPB group and 3.0 times in stent group.
Discussion and Conclusions: Stent implantation revealed efficacy in acute vascular dilation and its maintenance. Furthermore, UHPB provided long-term benefits in vascular growth.

P1570 - TWO CASES OF COMPLICATION OF CORONARY FISTULA AFTER AMPLATZER SEPTAL OCCLUDER

Yusuke Koteda, Kenji Suda, Shintarou Kishimoto, Yoshiyuki Kagiyama, Hironori Kuwahara, Hasuto Maeda
Kurume University, Pediatrics, Kurume-Japan

Background: Transcatheter occlusion of atrial septal defect (TC-ASD) has been first treatment option of this disease, but various complications such as migration and embolization, erosion have been reported.
Purpose: We report another rare complication of TC-ASD, development of multiple coronary artery fistulae found in two adult patients. Numerous fistulous coronary arteries run toward inter-atrial septum and surround device.
Cases: Patient 1: 43-year-old female underwent successful closure of ASD; 26 mm in diameter, using 30mm Amplatzer septal occluder. She did not have coronary artery disease or coronary fistula. When she underwent transesophageal echocardiography (TEE) one year after TC-ASD as our protocol, turbulent flows were demonstrated around the device. Cardiac catheterization revealed numerous coronary fistulae running from both left and right coronary arteries toward the device giving Qp/Qs ratio of 1 to 1.42. Patient 2: 72-year-old female underwent successful closure of ASD; 24.2 mm in diameter, using 26mm Amplatzer septal occluder. Because she was complicated by pulmonary hypertension, she underwent cardiac catheterization periodically that did not showed coronary abnormality up to 16months after TC-ASD. After 4 years and 8 months, we found numerous coronary fistulae running from both left and right coronary arteries towards the device.
Conclusions: We report development of coronary fistulae as rare complication after TC-ASD. Cardiologists must be aware of this complication and needs careful follow up of these patients. Obviously, further study is required to determine frequency and clinical implication of this complication.

P1585 - AORTOARTERITS MYRIAD MANIFESTATIONS CHALLENGING DECISIONS SHORT AND MEDIUM TERM OUTCOMES

Usha Mk[1], Jayaranaganath M[1], Anand Subramanian[1], Bharath Ap[1], Manjunath Cn[2]
Sri Jayadeva Institute of Cardiovascular Sciences, Pediatric Cardiology, Bangalore-India[1]; Sri Jayadeva Institute of Cardiovascular Sciences, Adult Cardiology, Bangalore-India[2]

Introduction: Aortoarteritis is a chronic inflammatory disorder of aorta and branches. The etiology is unknown, disease progression with stenosis/aneurysm formation is difficult to monitor and treatment is not standardised.
Methods: Retrospective and prospective. From January 2011 to January 2017 all children with takayasu arteritis at a tertiary care pediatric cardiology centre.
Results: Total of 33 children with takayasu arteritis were seen. Median age was 12 years (range 3 yr-18yr). M: F was 1:3. Hypertension 32(96%) and cardiac failure 27(81%) were the common presentations. Elevated ESR (>20) was seen in 38% (10/26). Renal artery stenosis with shrunken kidney was present in 11 (33%) children at presentation including a 3 year old(R -4, L -6, b/l- 1). 21 (64%)children (R-2, L-7, b/l 11,) had renal involvement and 21(64%) had aortic involvement. Aortic arch branches were occluded in 12(36%). Biventricular dysfunction was seen in 4 patients suggestive of myocarditis. Thirteen children underwent aortic interventions (balloon 6, stenting 7). Thirteen children underwent renal intervention (Balloon 6, Stent 7). There was normalisation of blood pressure and resolution of failure after intervention. Methotrexate and steroid were used for immunosuppression. Aspirin was given to all stented children. Seven children had evidence of tuberculosis. Three children are lost to

Table.

follow up. Follow up ranged from 3 to 48 months. Six (20%) children required re intervention. Four (13%) children died, three in acute phase and one after 6 months.
Conclusion: Hypertension and heart failure are most common manifestation. End organ damage can be present at initial presentation. Monitoring disease activity is difficult. Intervention with ballooning + stenting is lifesaving. There is a strong association with tuberculosis. Steroids and methotrexate are not effective in preventing recurrence. Studies with newer anti-inflammatory drugs are necessary.

P1586 - 3D PRINTING TECHNIQUES FOR INTERVENTIONAL PLANNING

Mari Nieves Velasco Forte[1], Nick Byrne[2], Tarique Hussain[3], Kuberan Pushparajah[4], Eric Rosenthal[4], Shakeel Qureshi[4], Reza Razavi[1], Israel Valverde[1]
King, Division of Imaging Sciences & Biomedical Engineering, London-United Kingdom[1]; Guy, Medical Physics, London-United Kingdom[2]; UT Southwestern Medical Center, Dept. of Pediatrics, Dallas-United States[3]; Evelina London Children, Paediatric Cardiology, London-United Kingdom[4]

Background: The spatial relationships of anatomical structures in patients with complex congenital heart disease can represent a challenge for interventional planning. Cardiac magnetic resonance and multi-detector computed tomography provide information that can be reproduced in a 3D printed model to assess the feasibility of interventional treatment.
Methods: Interventional planning was reproduced using a patient-specific 3D-printed heart in cases in whom cardiac catheterisation was controvertible. Segmentation was performed from previous imaging acquired dataset (CMR/MDCT) with Mimics software. Models were fabricated by polyjet technology or fused deposition modelling. Cardiac catheterisation was performed in the model before proceeding in the patient.
Results: Seventeen patients were referred for cardiac 3D-printing (88% adults). Five patients had partial anomalous pulmonary venous drainage(PAPVD); three transposition of the great arteries(TGA); five coronary artery fistulas, one aortic aneurysm post aortic valve replacement; one tetralogy of Fallot (TOF) and one had multiple ventricular septal defects (VSD). 65% patients underwent cardiac catheterisation, one coronary fistula and one TGA (13%) were considered unsuitable after reviewing the model and 35% are awaiting further management. LPA stenosis motivated printing for 2/3 of TGA patients and the TOF case, stent length and size were selected based on the models. The remaining TGA had a previous Senning operation, developing a baffle leak that was considered unsuitable for stent closure given its proximity to the mitral valve. Three coronary fistulas were successfully closed. Occlusion of the aortic aneurysm was achieved using an AVP II device and a large VSD was closed with an amplatzer device in the case with multiple VSDs. All patients who underwent catheterisation had a successful result.
Conclusions: 3D models provide the opportunity to select materials and plan access routes before cardiac catheterisation. This is beneficial where spatial complexity obstructs expert led treatment, providing the interventional cardiologist with confidence to address conditions that might otherwise be resolved with cardiac surgery.

P1590 - ECHOCARDIOGRAPHIC FEATURES OF SECUNDUM ATRIAL SEPTAL DEFECTS ASSESSED AS UNSUITABLE FOR TRANSCATHETER DEVICE CLOSURE. A PEDIATRIC SINGLE CENTER EXPERIENCE

Murat Muhtar Yilmazer[1], Timur Meşe[1], Rahmi Özdemir[2], Mustafa Karaçelik[3], Ömer Faruk Gülaşti[3], Osman Nejat Sariosmanoğlu[3]
Izmir Dr.Behçet Uz Children!s Hospital, Pediatric Cardiology, Izmir-Turkey[1]; Dumupinar University Evliya Çelebi Training and Research Hospital, Pediatric Cardiology, Kütahya-Turkey[2]; Izmir Dr.Behçet Uz Children!s Hospital, Pediatric Cardiovascular Surgery, Izmir-Turkey[3]

Objectives: To review our experience about morphological characteristics of secundum atrial septal defects (ASDs) for which percutaneous closure was thought inappropriate.
Methods: The study included 46 consecutive patients (mean age 7.67 ± 3.9 years; range: 2-1 years) assessed as unsuitable for transcatheter device closure of an secundum ASD, either directly referred to surgery or after assessment in the catheter laboratory between 2012 and 2016. Patients data, echocardiographic findings and procedural informations were retrospectively reviewed from the medical records.
Results: One hundred and fifty-one children underwent closure of an secundum ASD in our institution between 2012 and 2016 either surgically (n:46, 30%) or percutaneously (n:105, 70%). Among the patients with surgically closed, 33 children was referred directly to the surgery, 7 were thought unsuitable for device closure during the catheterization and 6 were referred after failed transcatheter attempts. Patients were referred to the surgeon for the following reasons: defects with deficient rim(s) (n:23), insufficent total septum(8), defect sized too large(n:6), multiple defects (n:4), aneurysmal IAS (2), a defect close to the superior vena cava (n:2), device entrapment within a Chiari network (1).
Conclusion: Transcatheter closure of isolated secundum ASD provides, excellent results with a lower complication rate with a shorter hospitalization period. However some of ASDs are not suitable for a percutaneous closure. In accordance with the current litaratures rim deficiencies are the most common reason of deferral of device closure was found in our study. However the requirements of large implants, defiencies of total septum, presence of multiple defects and some of other causes continue to constitute an impediment in front of the percutaneous closure.

P1619 - THE ASSESSMENT OF THE EFFECTIVENESS OF BALLOON ANGIOPLASTY OF NATIVE AORTIC COARCTATION IN NEWBORNS AND INFANTS YOUNGER THAN FIVE MONTHS OWN EXPERIENCE

Jacek Kusa[1], Pawel Czesniewicz[2], Agnieszka Skierska[3], Leslaw Szydlowski[3], Malgorzata Ras[2], Elzbieta Skiba[2], Elzbieta Wojcik[2]
Medical University of Sielsia/Regional Specialized Hospital, Pediatric Cardiology Department, Wroclaw/Katowice-Poland[1]; Regional Specialized Hospital, Pediatric Cardiology Department, Wroclaw-Poland[2]; Medical University of Sielsia, Pediatric Cardiology Department, Katowice-Poland[3]

Introduction: Balloon angioplasty of aortic coarctation in children is an established method of treatment but is not recommended in patients under six months of age due to significant risk of rapid recoarctation. The aim of study is to evaluate the effectiveness of this method in newborns and youngest infants.
Material/Methods: Between 01.03.2011 and 01.12.2016 balloon angioplasties of aortic coarctation were performed in 21 patients aged between 6 and 149 days (mean-80 ± 56). Only patients with naïve form of coarctation were qualified for percutaneous procedure. There were 7 newborns (33.3%). Eight patients had a bicuspid aortic valve. Seven patients (33.3%) had critical form of coarctation (heart failure), five (24%)- patent ductus arteriosus (2 of them with Prostin).
Results: After procedure the stenosis diameter increased from 1.9 (0,4-2,8) to 4.1mm (1,9-6,2)mm. The maximum echocardiographic gradient decreased from 70.6 (48-120)mmHg to 28,2 (15-38)mmHg, average from 37 (21-62)mmHg to 11,4 (6-17)mmHg, and hemodynamic gradient from 35.7 (6-69) to 9.3 mmHg (1-30)mm Hg. There were complications associated with procedure- limb ischemia in two cases (9,5%), In one- the normal blood flow returned after heparin administration. In the second patient, despite heparin and actylise the pulse did not returned, but the efficient collateral circulation developed. During FU- 39 ± 22 (6-69) months 6 patients required some intervention. Three patients (14,3%) required surgical plasty (1 month after angioplasty) because of the ineffectiveness of percutaneous intervention, in another 3 patients the treatment was effective, but during FU stenosis returned and after 18 (6-36) months the successful repeated balloon angioplasty was performed. In the remaining patients the good effect of treatment is still present.
Conclusions: Percutaneous angioplasty of aortic coarctation in the youngest age groups may be an effective treatment, alternative for cardiac surgery. The incidence of recoarctation during medium-term FU does not differ significantly from cardiac surgery and can be successfully treated by repeated percutaneous angioplasty.

P1621 - ASYMPTOMATIC EARLY NON INFECTIOUS THROMBOSIS OF THE MELODY® VALVE

Fadli Demir, Nazan Ozbarlas, Sevcan Erdem, Celal Varan
Çukurova University, Pediatric Cardiology, Adana-Turkey

Bioprosthetic valve thrombosis is an uncommon complication. Acute dysfunction of a bioprosthetic valve may lead to hemodynamic compromise and evaluation with initiation of appropriate therapy is required. We report a patient with prior uncomplicated percutaneous pulmonary valve replacement (The Melody®, Medtronic, Inc. Minneapolis, MN) who later developed early asymptomatic severe pulmonary valve stenosis without evidence of infection. A 17-year- old male with congenital ventricular septal defect and pulmonary atresia underwent uncomplicated transcatheter pulmonary valve replacement with a 22-mm Melody® valve. At 4 months post-implant echocardiography revealed 80 mmHg gradient at the Melody® valve. Stent integrity was normal. Two blood cultures were obtained independently and were negative. Thrombophilia risk factors was normal. His D-dimer was found elevated at 1.1 mg/L (≤ 0.55 mg/L). After recombinant tissue plasminogen activator (rt-PA) infusion gradient decreased. Repeat echocardiogram demonstrated normal appearance of the Melody® valve leaflets and gradient of 28 mmHg. Acute changes in Melody® valve function should prompt a thorough investigation for and treatment of thrombosis.

P1668 - SAFETY AND EFFICACY OF TRANS CATHETER CLOSURE OF SMALL RESTRICTIVE PERIMEMBRANOUS VSDS WITH MIDTERM FOLLOW UP IS IT REALLY SMALL

Hemanta Nayak[1], Nurul Islam[1], Satyajit Bose[1], Srirup Chatterjee[1], Joydeep Mookerjee[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Introduction: Transcatheter closure of small to medium perimembranous VSD is gaining its importance with less traumatic technique. In a developing country like India we found many reasons to close such VSDs like: 1) Recurrent respiratory tract infections (RTI) and poor weight gain, 2) Denial of pediatrician to treat simple URTI, 3) Financial burden to treat the morbidities, 3) psychological trauma to the family and patient inspite of counseling, 4) Social issues like denial of job and marriage.
Materials and Methods: A prospective study was designed September 2014 – October 2016. A total of 254 cases of VSD device closures were done using ADO II devices. Age ranged from 0.5 to 18 years (median 5 years), weight ranged from 5.0 to 55 kg (median 14 kg), height ranged from 59 to 169 cm (median 105 cm), Median fluoroscopic time was 6.25 minutes (1.27 to 58.16 minutes) and the median VSD diameter was 4mm (3 to 6 mm).
Results: The complete VSD closure rate was 93%, 95% and 97% at 6 months, 1 year and 2 years follow-up respectively. At 6 months follow up most children demonstrated appropriate weight gain reaching weights >10th centile, decreased incidence of RTI. Immediate complications were one device embolization to the pulmonary artery, another patient had severe aortic regurgitation (AR), both devices were retrieved successfully and the patients were sent for surgery. One patient required PPI for complete AV dissociation, which later on reverted to sinus rhythm. 15 children developed new onset trivial AR which remained same at 2 years follow up.
Conclusion: Our study clearly demonstrated beneficial effects of transcatheter closure of small VSDs especially with the newer ADO II device in terms of improved left ventricular dimensions, better weight gain and freedom from recurrent respiratory tract infections in small children with negligible midterm complications.

P1676 - AN UNUSUAL CAUSE OF CHEST PAIN AFTER PERCUTANEOUS CLOSURE OF ATRIAL SEPTAL DEFECT IATROGENIC PNEUMOMEDIASTINUM

Timur Meşe[1], Murat Muhtar Yilmazer[1], Aysun Hacer Saritaş, Rahmi Özdemir[3]
Izmir Dr.behçet Uz Children, Pediatric Cardiology, Izmir-Turkey[1]; Izmir Dr.Behçet Uz Children, Pediatrics, Izmir-Turkey[2]; Dumlupinar University Evliya Çelebi Training and Research Hospital, Pediatric Cardiology, Kütahya-Turkey[3]

Introduction: We present an unusual complication associated with ASD closure procedure .
Case: A seven years old boy with 11 mm secundum ASD was electively scheduled for percutaneous ASD device closure. His preprocedural examinations were normal. In our instution anestiesiology clinic prefers to use deep sedation of a pediatric patient with ketamine during the procedure. In this case anetesiologist switched to genereal anestesia with intubation because of an ineffective sedation. Standart percutaneous ASD device closure procedure was completed without any problem or complication with the guidance of transesophageal echocardiography (TEE). After completion of procedure some blood in the saliva was seen on the TEE probe. Examination of oral cavity and throat revealed a 3-4 mm mucosal laseration in the retrofarengeal area without any persisting bleeding. Post procedural period under monitorization was uneventful up to 4 hours. When child became fully concious he had complained a chest pain. Vital signs and standart 12-lead-ECG was normal. An urgent echocardiographic examination was unsuccessful because of an insufficient visualization of the cardiac structures in many echocardiographic windows. His chest x -ray revealed a lienear air lucency on the border of left ventricle suggested the diagnosis of pneumomediastinum strongly, which was confirmed with lateral chest x ray. This "air curtain" between our probe and heart prevented to get an optimal echocardiographic images. Patient followed up for 3 days there was no sign or clue of any mediastinitis, cardiac or respiratory distress. After three days of follow up pneumomediastinum disappeared spontaneously and echocardiographic images were fully obtained.
Conclusions: Pharyngeal abrasions and hemorrhage are the most common complications associated with TEE insertion. Esophageal perforation, a rare but life-threatening event can cause hemorrhage, subcutaneous emphysema and pneumomediastinum.

Figure.

P1688 - MID TERM FOLLOW UP RESULTS OF THE SOLYSAFE SEPTAL OCCLUDER FOR PERCUTANEOUS CLOSURE OF SECUNDUM ATRIAL SEPTAL DEFECTS

Izmir Dr.Behçet Uz Children, Pediatric Cardiology, Izmir-Turkey[1]; Near East University, Pediatric Cardiology, Nicosia-Cyprus[2]; Tepecik Training and Research Hospital, Pediatric Cardiology, Izmir-Turkey[3]; Dumlupinar University, Evliya Çelebi Training and Research Hospital, Pediatric Cardiology, Izmir-Turkey[4]

Objective: Septal occluder (SSO) (Swissimplant AG,Solothurn, Switzerland) which was withdrawn from the market, due to wire fractures since 2010. Limited data exists on the Solysafe device and outcomes related to this ASD device closure in children. We report mid-term results of the patients whose defects closed percutaneously with SSO.
Methods: A total of 25 patients– with mean age of 8.44 ± 3.6 years with secundum atrial septal defect (ASD) underwent attempted transcatheter closure between July 2008 and June 2010. The device was implanted successfully in 22 of 25 patients. Mean follow up period was 6.10 ± 0.53 years.
Results: Mean stretched diameter of the ASD determined by balloon sizing was 13.6 ± 4.43 mm. Nine 15-mm devices, eight 20-mm devices, six 25-mm devices and two 35 mm devices were used. A twenty mm, and 2 of 35 mm devices were intended to be used in 3 patients whose attempts were unsuccessful. There were 2 major complications (8%). First, an embolization into the pulmonary artery in a 17-year-old girl. Another case was a 11 year-old girl who had implantation of 15 mm SSO device into the 8 mm defect was developed right hemiparesis after the procedure. During the 6 years of follow-up we did not observe wire fractures, pericardial effusion, endocarditis, hemolysis, ECG changes, valvular problems or suspicious echocardiographic findings. We observed device embolization and hemiparesis as major complication related to the procedure
Conclusions: We did not observe any significant complication in the mid term follow-up period excluding major complications during periprocedural period. Probably the main reason not to observe wire fracture might be related the selection of appropriate

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

patient with smaller defect size. Although the device was fully covered by endothelial tissue, long term monitoring must be requried for wire fractures and related complications.

Objective: to demonstrate that the endovascular treatment is an alternative for VSD closure.
Material and Methods: Observational analysis. From May 2010 to March 2016. 47 patients (p) were treated. Median age: 7 yo (0.33 to 15a). Median weight: 26 kg (4.3 to 83 kg); 5 p <10 kg. Sex: 28 f 19 m. Complications: Major: severe. Minor: mild. Devices: PFM® coils, Amplatzer devices, CERA® (Lifetech) and MEMOPART® (Lepu Medical Technologie).
Results: Successful: 43 procedures (84.3%). Frustrated: 4 procedures: 2 AV Block. 1 embolization (musc Cera). 1 p: acute collapse of the right ventricular. Types: 20 perimemb VSDs (46.5%), 11 high musc (25.5%), 6 midventricular (13.9%), 3 apical (6.9%) and 3 postsurgical (6.9%). Complications: Major: 3p (6.9%): 1 tricuspid stenosis and 1 hemolysis (PFM); 1 p <10 kg post-procedural severe AR (ADO II) followed by death. Minor: 3 arrhythmias: required steroids (2: Lifetech, 1: ADO II); 1 p: the device embolized and repositioned (Lifetech); 2 p: transient hematuria (PFM); 1 coil fracture (PFM); 2 p: moderate tricuspid insufficiency (PFM); 1 patient: mild to moderate aortic insufficiency (PFM). The most important complications were during our firsts cases experience. Devices: Le VSD coil: 3 hemolysis: 2 self-limited, 1 severe. 1p tricuspid stenosis that required surgery. 1 fracture a week after procedure. Cera 12 p: 2 embolizations within the first cases, 1 residual shunt treated at 2 years (residual shunt vs other VSD). Memopart: 8 p. We had no complications or residual shunt. Amplatzer: 7 p: 3p ADO II. 4 p muscle VSD. There was no AV block at follow-up.
Conclusions: 1) The endovascular VSD closure is a feasible procedure. 2) The existence of different types of devices allows closing different types and sizes of VSDs. 3) There were not AV block along the follow up. 4) The learning curve was inexorable.

P1699 - FONTAN CIRCULATION CATHETER INTERVENTIONS AND MORTALITY

María Victoria Lafuente[1], *Claudia Natalia Villalba*[1], *Mariela Mouratian*[1], *Analia Martin*[1], *Fernando Diez Mori*[1], *Jorge Barretta*[2], *José Alonso*[3], *José Luis Pibernus*[3], *Francisco Comas*[3], *Pablo Garcia Delucis*[2], *Alberto Sciegata*[3], *Horacio Capelli*[1]
Children's Hospital,Juan P Garrahan, Cardiology Department, Buenos Aires-Argentina[1]; *Children's Hospital,juan P Garrahan, Cardiovascular Surgery Department, Buenos Aires-Argentina*[2]; *Children's Hospital, Juan P Garrahan, Cardiac Catheter Laboratory, Buenos Aires-Argentina*[3]

Introduction: Patients with Fontan circulation demand a careful follow -up. Cardiac interventional catheterizations are an essential tool in the management of these patients .(pts)
Objective: The aim of this study was to describe the clinical indications of percutaneous interventions and related mortality in Fontan's pts.
Methods: Between 1989-2016, 431pts underwent a modified Fontan procedure with a median follow-up of 5,6 years (IQR--75 = 2,25-11,1 years). In 113pts, 159 catheter interventions were undertaken. According to the median interval between surgery and the first interventional catheterization two groups were identified: Group I: early: 0.05 years(IQR 0.04-0.1), 27pts. Group II: late 2.07 years(IQR 1.2-4.1), 86 patients.
Results: The most frequent clinical indication in group I was a Fontan circulation dysfunction (p 0.0000) and an increased cyanosis in group II (p0.0000). Hemoptysis was the main event in those patients requiring subsequent procedures (p0.0001) The percutaneous treatment included: group I: balloon fenestration dilation 8p(29,6%), balloon dilation of pulmonary branches 9p (33,3%) stent deployment in 7p(25,9%), and thrombolysis 3p (11.1%). group II: fenestrations closure 42p(48,8%) and coiling aortopulmonary collaterals 37p(44,2%). There were 13 deaths (11.5%): group I : 9pts(32,1%) group II : 4pts. (4,7%), (p 0.0002). By univariate analysis mortality was associated to Fontan circulation dysfunction (p0.0000), early postoperative period (p0.0000), balloon fenestration dilation (p0.003)and increased cyanosis (p0.04). Multivariare analysis mortality was related to Fontan circulation dysfunction OR 11,69 (1.73-79.09) p 0,01
Conclusions: Fontan circulation dysfunction was the main clinical reason for interventional catheterizations in the early postoperative period as it was cyanosis in the late follow-up. Hemoptysis was the most frequent cause for cardiac recatheterizations. A broad spectrum of percutaneous procedures was performed. Mortality was mainly related to unstable hemodynamic status but not to the interventional procedure in itself. Interventional percutaneous procedures are mandatory

P1705 - CARDIAC MECHANICS IN CHILDREN POST PERCUTANEOUS TRANSCATHETER CLOSURE OF PERIMEMBRANOUS VENTRICULAR SEPTAL DEFECT RIGHT AND LEFT VENTRICULAR PERFORMANCE ASSESSED BY ECHOCARDIOGRAPHY

Lijian Xie, Xunwei Jiang, Tingting Xiao, Min Huang
Shanghai Children's Hospital, Shanghai Jiaotong University, Cardiology Department, Shanghai-China

Background: Percutaneous transcatheter closure of perimembranous ventricular septal defect (pmVSD) with occluder has been

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

most widely used in China. However, whether impaired ventricular performance occurs in pediatric patients post transcatheter closure of pmVSD, is not known. Two-dimensional speckle-tracking echocardiography (2D-STE) is increasingly used to evaluate ventricular performance in children. In this study, we aimed to analyze left ventricle (LV), right ventricle (RV) performance post percutaneous transcatheter closure of pmVSD.
Methods: 40 pediatric patients post percutaneous pmVSD closure and 40 healthy children were recruited. All subjects were studied with conventional and tissue Doppler echocardiography. Strain and strain rate of LV and RV were assessed by 2D-STE.
Results: 40 pmVSD patients (6.0 ± 1.2 years) and 40 healthy controls (5.8 ± 1.1 years) were studied. Mean diameter of pmVSD was 3.82 ± 0.59 mm, mean diameter of pmVSD occluder was 6.3 ± 1.0 mm, and mean time after percutaneous pmVSD closure was 3.22 ± 0.78 years. No significant differences were observed in LV eject fraction, RV Tei index and transatrioventricular velocity between pmVSD closure and control. More tricuspid regurgitation was observed in pmVSD closure subjects by measuring the ratio of tricuspid regurgitation jet area and right atrial area (TRJA/RAA) ($p = 0.009$). Interventricular septal tissue Doppler image showed less early diastolic ($p = 0.01$), more late diastolic ($p = 0.04$) velocity and less e/a ratio ($p = 0.005$) in pmVSD closure subjects. No significant difference in global longitudinal and circumferential strain and strain rate between pmVSD closure and control. For RV deformation, pmVSD closure subjects tended to be lower global longitudinal strain($p = 0.06$). For pmVSD closure cohort, the diameter of pmVSD occluder correlated negatively with LV longitudinal strain rate ($r = -0.324$, $p = 0.044$) and circumferential strain ($r = -0.354$, $p = 0.027$). Furthermore, TRJA/RAA correlated positively with diameter of pmVSD ($r = 0.727$, $p < 0.001$) and occluder ($r = 0.777$, $p < 0.001$).
Conclusion: 2D-STE appears that percutaneous closure of pmVSD is safe and effective in selected pediatric patients.

P1716 - EARLY POST OPERATIVE INTERVENTIONAL CATHETERIZATION OF CONGENITAL HEART DEFECTS SHORT TERM RESULTS

Juan Gallego, De La Osa Carlos, Mendoza Sara, Santiago Justo, Blanco Leonardo
FCV, Hemodinamics, Bucaramanga-Colombia

Introduction: Interventional cardiac catheterization is an alternative to surgery in the management of residual postoperative defects. There are very few studies published in the literature that evaluate its efficacy, safety and describe its complications.
Materials and Methods: We performed a retrospective study over a period of 5 years in patients under 18 years of age, who underwent catheterization in the first 30 days after the congenital heart surgery. Data on demographic, clinical, diagnostic, surgical, hemodynamic, required support, complications and 30-day survival were collected to determine the types of procedures, outcomes, and complications.
Results: 42 catheterizations were performed in 34 patients, most of them male (70.6%), with a median age of 183 days and weight of 6 Kgrs. The main surgical procedures were the truncal corrections followed by Norwood surgeries. A median of 6 days elapsed between surgery and catheterization, with hypoxemia, dependence on ventilatory assistance and suspicion of obstructions in the operated areas being the main indications of catheterization. 62% were interventional catheters, with angioplasty being the most frequent, with balloon (54%) and stent (27%). The most affected sites were the pulmonary arteries (57%), followed by the aortic arch (11%) and the cavus pulmonary junction (9%). Complications were recorded in 7% (5 patients): Arrhythmias in 3 patients, need for ECMO in 1 case and 1 with cardiac arrest. There were no deaths related to the procedure, the survival at 30 days was 84%. The need for inotropes and mechanical ventilation was reduced in more than 50% of the cases.
Conclusions: Early diagnostic and therapeutic post-surgical catheterization can be performed with low mortality and morbidity and with adequate efficacy.

P1720 - LONG TERM PROGNOSIS OF TRIPLE BALLOON ALLOPLASTIC IN PATIENTS WITH PULMONARY VALVE STENOSIS

Hidemi Takata, Takashi Higaki, Masaaki Ohta, Tomozo Moritani, Masashi Takahashi, Ryo Tashiro, Toshihisa Miyata, Eiichi Ishii
Ehime University, Pediatrics, Toon-Japan

Percutaneous pulmonary valved stents implantation for patients with right ventricle outflow tract stenosis is now considered feasible and safe, however, there are some limitations. Triple balloon valvuloplasy for these patients has been reported its efficacy and safety, however, the long-term prognosis of patients is still unknown, especially whether pulmonary valve regurgitation is getting worse or not. Here, we analyzed the long-term prognosis of patients receiving triple balloon valvuloplasty. Five patients (median age 31years, 4 females, 1 male, tetralogy of Fallot after surgical repair 2, ventricular septal defect after surgical repair 1, native pulmonary valve stenosis 2) underwent the procedure safely and successfully. The median diameter of pulmonary valve annulus was 23.0 mm, and balloon diameters ranged from 12 to 15 mm. The median peak right ventricular-to-pulmonary artery systolic pressure gradient was 40.0 mmHg before intervention and was reduced to 10 mmHg after that. No major complication was occurred. The median follow-up period was 73.5 months. There were no patients who got worse in pulmonary valve regurgitation after the procedure. Four patients were no need for additional operation during observation period. One patient who had residual shunt after intracardiac repair of ventricular septal defect was needed surgical repair because the left-to-right shunt was increased. Triple balloon valvuloplasty is effective and safety procedure, and can be useful as a palliative therapy because of small risk of the deterioration in pulmonary valve regurgitation.

P1732 - BALLOON PULMONARY VALVULOPLASTY SINGLE CENTER EXPERIENCE AND LONG TERM OUTCOME

Raianne Cord[1], Luciana S. Nina De Azevedo[1], Jamille Campos[1], Fernanda Rego[1], Diego Macedo[2], Marcio Miranda Brito[1], Joao Chaker Saba[1], Celia Maria Camelo Silva[3]
Federal University of Sao Paulo, Cardiology, Sao Paulo-Brazil[1]; Federal University, Cardiology, Sao Paulo-Brazil[2]; Federal University of, Cardiology, Sao Paulo-Brazil[3]

Background: Balloon pulmonary valvuloplasty (BPV) is the treatment of choice for pulmonary valve stenosis. Besides its effectiveness, the long-term outcome have to be better understand.
Objective: To describe a single-center experience and long-term outcome with BPV.
Methods: A retrospective study between 2001 and 2016. The catheterization laboratory records from all patients who underwent BPV were reviewed and compared with the recent echocardiography findings.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: From November/2001 to November/ 2016, eighty-five patients (Pts) underwent BPV. Thirty-four patients were males (40%), the median age was 4 years (2 days ~ 61 years). Forty-eight (56%) patients were younger than 1 year and within this group, twenty-two (46%) were newborns. The mean peak systolic pressure gradient across the pulmonary valve in the whole group decreased from 65.4 to 16.8 mmHg (136 mmHg ~ 35 mmHg) and from 56 to 12.0 mmHg in the group of patients <1 yr. BVP was successful in 90% of the cases with a global mortality of 1.9%. Mild complications occurred in 9 patients (11%), all of them were in the group <1 yr: arrhythmia (4), infundibular spasm (3), cardiac tamponade (1), dissection of IVC (1). Thirty –three patients (65%) with >5 year follow-up had an echocardiogram performed, twenty-five (75%) of them presented pulmonary regurgitation (PR). Twelve (36%) with moderate/important PR, thirteen (40%) with trivial and eight (24%) without PR. The balloon/annulus ratio >1.4 was seen in 75% in of Pt with moderate/important PR, 23% with trivial and 30% without PR.
Conclusion: BPV is a safe and effective procedure for pulmonary valve stenosis. The balloon/annulus ratio >1.4 seemed to be a prediction of PR in this study. Further studies with MRI may be useful for better assessment of the right ventricular function on the follow-up of these patients.

P1747 - TRUE RISK FACTORS FOR LOSS OF ARTERIAL PEDAL PULSE FOLLOWING CARDIAC CATHETERIZATIONS IN INFANTS

Thomas Yohannan, B. Rush Waller, Travis Kauffmann, Kaitlin Balduf, Hannah Lloyd, Shyam Sathanandam
University of Tennessee, Lebonheur Children, Pediatrics, Memphis-United States

Background: The objective of this study was to compare the prevalence of acute loss of pedal pulse (LOP) in infants (≤1 year) who had ultrasound guided femoral arterial access (UGFAA) during cardiac catheterizations between three time periods: Period-1 (Jan2003–Dec2011), Period-2 (Jan2012–Dec2014) and Period-3 (Jan2015–Dec 2016). A prospective study was previously conducted during Period-2. The diameter of the accessed femoral artery (FA) <3mm was found to be the only independent predictor for LOP. Since then, we attempted to avoid FA cannulation if the vessel size was <3mm and use smaller catheters if FA access was necessary during Period-3.
Methods: A retrospective study was performed including 808 cardiac catheterizations in infants, 516 in Period-1, 166 in Period-2 and 124 in Period-3. LOP was defined as a loss of palpable pedal pulse at the end of the procedure. The FA size was measured prior to USGFAA and a ratio of the outer diameter of the arterial sheath to the luminal diameter of the cannulated artery (OD/AD ratio) was calculated during Periods-2&3.
Results: There was a significant decrease in the FA access rates during Period-3 (64.5% vs. 93.8% during Period-1 and 90.4% during Period-2; $P < 0.001$). This coincided with a decrease in the prevalence of LOP during Period-3 to 3.5% compared to 13.4% during Period-1 and 15.7% during Period-2 ($P < 0.001$). By multivariate analysis, smaller FA size and a larger OD/AD ratio were the only significant independent predictors for LOP (OR:6.48, 95% CI: 2.31–11.42, $P < 0.001$ and OR:4.16, 95% CI: 1.79–8.65, $P < 0.01$, respectively).
Conclusions: Limiting access of FA <3mm during cardiac catheterizations was associated with a significant decrease in the prevalence of LOP in infants. This study validates the findings of our previous study that smaller FA size and a larger OD/AD ratio are the only significant predictors for LOP in infants.

P1749 - CHANGE IN LIMB TISSUE PERFUSION DURING CARDIAC CATHETERIZATION UTILIZING THE FEMORAL ARTERY IN CHILDREN

Kaitlin Balduf, B. Rush Waller, Kim Allen, Hannah Lloyd, Tom Fagan, Shyam Sathanandam
University of Tennessee/lebonheur Children's Hospital, Pediatrics, Memphis-United States

Background: Arterial access during cardiac catheterization in children can effect distal limb tissue perfusion (Fdl); the risk factors for which are unknown. The objectives of this study were to measure changes in Fdl and identify risk factors for decreased Fdl in children during cardiac catheterization.
Methods: This is a prospective, single center, pilot study of distal limb perfusion during pediatric cardiac catheterizations from August-November 2016. Laser Doppler flowmetry was used to continuously measure Fdl using real-time, tissue RBC Fluxes. The percentage difference in the pre-to-immediate post-procedure Fdl (ΔP-Fdl) and the pre-to-lowest Fdl during the procedure (ΔL-Fdl) were calculated. A 6-hour post-procedure Fdl (6h-Fdl) was also measured. The ratio of the outer diameter of the arterial sheath (OD) to the luminal diameter of the cannulated artery (AD) OD/AD ratio was calculated. Risk factors for the greatest change in Fdl during a procedure (highest ΔL-Fdl) were determined.
Results: 50 children (median age = 15 months, median weight = 10 kg) were included in the study. The ΔP-Fdl ranged between 0% and 85% (median 22.4%), and the ΔL-Fdl ranged between 17.5% and 96.8% (median 36.2%). An OD/AD > 50% was the only significant predictor for greatest change in Fdl during a procedure (OR:4.6, 95% CI: 2.7–11.4, $P < 0.001$). The luminal diameter of the cannulated artery, procedure length and pre-post procedure change in AD were not found to be significant predictors. Pulse loss was not encountered in any patient. The 6h-Fdl was 0-21% (median = 7%) lower than the pre-procedure Fdl ($P = 0.34$).
Conclusions: This pilot study is the first to determine real-time changes in distal limb tissue perfusion in children during cardiac catheterization using arterial access; the clinical implications of which are still unknown. The knowledge that an OD/AD ratio >50% could significantly affect Fdl may be useful for practitioners in preventing any long term sequelae from these procedures.

P1752 - TRANSCATHETER IMPLANTATION OF SAPIEN XT VALVE WITHOUT PRE STENTING IN RIGHT VENTRICULAR OUTFLOW TRACT HOMOGRAFT FOR SEVERE PULMONARY REGURGITATION FOLLOWING TETRALOGY OF FALLOT REPAIR

Lakshmi Gokanapudy[1], Marc Cohen[2], Rajiv Verma[3]
Childrens Hospital of New Jersey, Pediatrics, Newark-United States[1]; Newark Beth Israel Medical Center, Cardiology, Newark-United States[2]; Childrens Hospital of New Jersey, Pediatric Cardiology, Newark-United States[3]

Background: Surgical reconstruction of right ventricle outflow tract (RVOT) is often performed in patients undergoing repair of tetralogy of Fallot (TOF). Pulmonary homograft valve deterioration is expected over time. Previously, correction of pulmonary insufficiency or stenosis required repeat cardiac surgery. Percutaneous pulmonary valve implantation (PPVI) has emerged as a viable alternative in patients with RVOT dysfunction. The Sapien XT system has recently been approved for PPVI with conduit prestenting necessary.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Case report: A 24 year old female with TOF and absent pulmonary valve syndrome underwent complete surgical repair in 1998; Dacron patch closure of the VSD, 21 mm pulmonary homograft reconstruction of the RVOT. She had chronic, hemodynamically significant, pulmonary regurgitation with RV volume overload and required right pulmonary artery (RPA) stent angioplasty in 2013. Her clinical status worsened with increasing fatigue, disproportionate increase in RV size, and development of arrhythmia; but she declined surgery. Her minimum conduit diameter is 20.3 mm, annulus 23.3 mm and aneurysmal RVOT proximal to homograft is 34.8 mm. Balloon stretch diameter of the homograft potential landing zone is 22 × 23 mm. However, anatomy was unsuitable for pre-stenting due to 9-12 mm distance to the mouth of the RPA stent, thus precluding use of a Melody valve. Instead, she had transcatheter Sapien XT 26 mm valve implantation, delivered via an 18 Fr delivery system, without pre-stenting to avoid compromising flow into the RPA. The Sapien valve remained in stable position with no valvular or paravalvular leaks identified and trivial obstructive gradient.
Discussion: The Sapien XT transcatheter valve serves as an excellent adjunct to therapy in congenital pulmonary valvular disease and high success rates have been demonstrated. We report a case of Sapien XT PPVI implantation without pre-stenting with successful outcome as demonstrated by resolution in pulmonary regurgitation and no compromise to flow into the RPA.

P1778 - IN VIVO AND IN VITRO TESTING FOR HAND MADE TRILEAFLETS PERICARDIAL PATCH VALVED CONDUITS IN PULMONARY VALVE RECONSTRUCTION

Jieh-Neng Wang[1], Chung-Dann Kan[2], Jui-Te Wu[3], Zhi-Jia Zheng[3], Min-Ling Hsieh[1], Jing-Ming Wu[1]
National Cheng Kung University Hospital, Department of Pediatrics, Tainan-Taiwan[1]; National Cheng Kung University Hospital, Department of Surgery, Tainan-Taiwan[2]; National Chiayi University, Veterinary Teaching Hospital, Chiayi-Taiwan[3]

Background: The hand-made trileaflets pericardial patch valved-conduits might be used as the pulmonary valve replacement substitute materials. The aim of this study was to investigate the valve function of the hand-made trileaflets pericardial patch valved-conduits by mock system (in vitro) and their short-term conditions in piglet animal model (in vivo) to justify the applicability of clinical purpose.
Methods: The competency of the hand-made trileaflets pericardial patch valved-conduits were tested on the pulmonary circulation mock system. The valved-conduit assembled into a delivery system to deploy into the pig animal destroyed pulmonary valve model via femoral vein under general anesthesia. In vivo functional and morphology analysis were tested during a 4-week period.
Results: On mock circultatory system, the hand-made trileaflets pericardial patch valved-conduit, although not as perfect as the silicon trileaflets valve, can effectively rise the mean pulmonary pressure from 10.2 to 14.4 mmHg with compared to the defected silicon valve one. The regurgitation fraction (RF) value of hand-made trileaflets pericardial patch valved-conduit group is 15.9-18.1% significantly improved compare with the defected valve group (RF = 73.5-85.7%). The in-vivo pulmonary condition experiments showed their good valve position conditions and the valve and leaflets characteristics and function. The histological analysis of the valved-conduits adjacent pulmonary area also revealed no significant signs of inflammation reaction.
Conclusion: The hand-made trileaflets pericardial patch valved-conduits for pulmonary valve reconstruction on both mock and animal experiments showed with acceptable performance and outcome. It might implicate that this hand-made trileaflets pericardial patch valved-conduits can be used in further clinical purpose. However, the long-term animal results still need time to justify.

P1798 - IS ADO II IDEAL FOR CLOSING CONGENITAL GERBODE DEFECTS

Balekundri Vijayalakshmi
PMSSY, Super Specialty Hospital, Bengaluru Medical College and Research Institutel, Pediatric Cardiology, Bengaluru-India

Background: Congenital left ventricle to right atrial communications (Gerbode defects) are extremely rare (0.08%) type of ventricular septal defects. They were traditionally closed by surgery in the past. There are few case reports and small series of acquired and congenital Gerbode defects, closed with various types of devices. We report a series of only congenital Gerbode Defects closed by Amplatzer duct occluder II (ADO II). Aim of our study is to assess the feasibility, efficacy, and complications of transcatheter closure of congenital Gerbode defects with ADO II.
Material and Methods: 13 consecutive cases of Gerbode defects, age ranging from 10 months to 16 years (mean 6.7 years), weight ranging -6.5 kg to 34 kg (mean 19.3 kg), were diagnosed on transthoracic echocardiography and left ventricular angiogram done in AP, RAO view with 10 0 cranial angulation, were closed with ADOII by retrograde approach The fluoroscopic time was 6.2 +1.4 min.
Results: Transcatheter closure of Gerbode defects,(both type A and B) with ADO II was successful in all 13 cases (100%). Only one patient had transient complete heart block, made a complete recovery with temporary pacing for 48 hours and steroids for five days. No aortic or tricuspid regurgitation or residual shunt occurred.
Discussion: Soft low profile, easily trackable ADO II appears to be ideal for closure of Gerbode defects, as the central cylinder fits in the defect and the soft retention discs on either side, without polyester material, do not impinge on either aortic, mitral, or tricuspid valve.
Conclusions: Transcatheter closure of congenital Gerbode defects with ADO II is safe, effective, and an attractive alternative to surgical closure. ADO II appears to be tailor made for Gerbode defects, as the success rate is 100%

P1799 - TRANSCATHETER INTERVENTIONS IN APICAL NON COMPACTION TO REDUCE THE PUMP FAILURE

Balekundri Vijayalakshmi
PMSSY, Super Specialty Hospital, Bengaluru Medical College and Research Centre, Pediatric Cardiology, Bengaluru-India

Background: Apical non-compaction (ANC) of both ventricles and septum is not reported much in literature. For the first time, we report interventions for associated lesions in ANC.
Aim: To know feasibility of transcatheter interventions for associated lesions in ANC to reduce the pump failure.
Material and Results: Out of 100 consecutive patients of ANC 36 cases underwent various transcatheter interventions, formed the material. Age ranged 3days to 17 years (mean 8 years). Device closure was done for 2 PDA, 16 VSDs, 1 ASD, one each of ALVT, ARVT, ARAT, 5 ABV, 2 PBV, 1 aortoplasty, 2 PTMC, I for

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

CTD, 3 pericardiocentesis. 5 patients underwent two procedures in the same sitting eg ABV and PBV, ABV and PTMC, ABV and VSD device closure, ASD and VSD device closure and PDA and VSD device closure. 3 cases of VSD were post- operative residual shunts and one was closed with multiple devices. One 8 months infant had apical VSD closed with ADO II. 2 year old child underwent hybrid surgery for closure of VSD with 14 mm device. Mid muscular VSD was closed with ADO II in mirror image dextrocardia.
Discussion: Interventions in ANC are challenging in presence of LV/RV dysfunction with or without thrombosis. Positioning device in apical VSD in ANC cases is very challenging as the device gets caught in trabeculae in RV and if more tug is given the device slips through spongy myocardium. The results of interventions are very gratifying as pump failure due to pressure or volume overload caused by associated lesions improves significantly.
Conclusion: Transcatheter interventions though challenging are feasible safe effective and are lifesaving. Transcatheter interventions certainly reduce the morbidity and mortality in ANC patients who are at high risk for surgery or redo surgery.

P1822 - PERCUTANEOUS CLOSURE OF PDA IN BABIES BELOW 7KG WHAT WE HAVE LEARNED IN THE LAST YEARS

Renata Mattos, Raizza Fernandes Da Costa, Luciana Almenara, Gabriela Mesquita, Alexandre Abla, Fabio Bergman, Paulo Soares, Victor Hugo Oliveira, Luiz Carlos Simões, Marcio Mizrahy
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Background: Percutaneous closure of patent ductus arteriosus (PDA) is well established. However, most of low weight infants are still sent to surgery. Our aim is to show our experience with percutaneous treatment of children below 7 kg in the last 5 years.
Material and Methods: We reviewed all medical records of patients who underwent percutaneous occlusion of PDA from January 2011 to August 2016. We analyzed characteristics of the patient (sex, age, weight and clinical status), the ductus (Krichenko classification and size at the pulmonary end) and the procedure (type and size of the device, hospitalization time, complications).
Results: Of 252 patients referred for PDA occlusion, 15 (5,9%) had less than 7 kg. Eight were female and 7 male. Ages ranged from 2 months to 1 year of age and weights from 5 to 7 kg. Twelve patients (80%) had signs and symptoms of congestive heart failure (CHF). Three patients had Down syndrome and 4 had other cardiac malformations. Extracardiac malformations were found in 2 patients. Most PDAs were Krichenko type A, although 2 were type C. The pulmonary end of the PDA ranged from 2 to 6mm (median 4mm). We were able to implant devices in 14 patients. Of these, 6 received AMPLATZER devices of various types, 7 CERA devices and 1 NIT OCCLUD PDA-R device (as displayed in the graph). Only one patient had residual shunt after 6 months of follow-up. There was no obstruction of the descending aorta or of the pulmonary branches, no vascular complications and no death related to the procedure.
Conclusion: Infants weighing less than 7 kg with PDA often have CHF and other comorbities, therefore closure is urgent and a less invasive treatment is more suitable. We concluded that the procedure is safe, especially if we can choose the most appropriate device for each case.

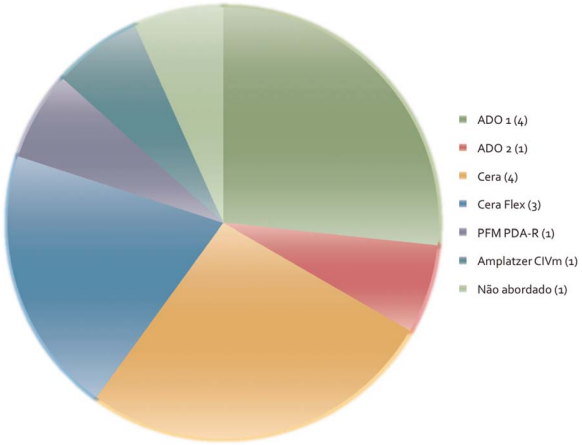

Figure.

P1829 - ATRIAL SEPTAL DEFECT (ASD) IN SMALL CHILDREN DO WE NEED TO WAIT TO CLOSE THEM

Renata Mattos, Luciana Almenara, Alexandre Abla, Gabriela Mesquita, Raizza Fernandes Da Costa, Maritza Anzanello, Gabriel Camargo, Victor Hugo Oliveira, Andrea Viviani, Lina Miura
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Background: ASDs often cause right ventricular overload, which progressively gets worse and eventually progresses to pulmonary hypertension. As soon as a cardiac malformation is diagnosed, the family is anxious for it to be resolved. Therefore, we believe that ASDs should be closed as soon as possible. Our aim was to demonstrate that small patients (below 18 kg), percutaneous occlusion of ASD is feasible.
Material and Methods: We reviewed clinical records of all ASDs closed percutaneously from January 2011 to August 2016. We analyzed sex, weight, age, clinical and echocardiographic features, size and type of device and complications related to the procedure.
Results: In this 5-year period, we closed percutaneously 158 ASDs. Of these, 23 (14,4%) were in patients with less than 18 kg; 15 female and 8 male. Age ranged from 3 to 7 years and weight from 13 to 18 kg. All of them were referred to treatment because of right ventricular overload. There were 3 cases of aneurysmal septum with multiple defects; 2 of our residual shunts were in this group. The devices we used were AMPLATZER ASD (4), OCCLUTECH FIGULLA (12), NIT OCCLUD ASD-R (5) and CARDIA ATRIASEPT (2). We performed balloon measurement in all cases; stretched diameter ranged from 10 to 24mm. The size of the device chose varied from 4% to 36% bigger than the measured diameter. We had no vascular complication and no death. We were aided by transesophageal echo (TEE) in all cases, and there was no complication related to the probe. Until the present date, there was no erosion and no arrythmia in this group.
Conclusion: Moderate and large ASDs with right ventricular overload can be approached early, with excelent results and no complications in short and medium term follow-up.

P1842 - DUCTAL STENTING AS AN ALTERNATIVE TO THE BLALOCK TAUSSIG SURGERY

Renata Mattos, Salem Fraga, Marilia Domingues, Clayne Valadao, Danielle Soares, Grazielli Gigiane, Victor Hugo Oliveira, Carla Verona, Paulo Renato Travancas, Adriana Innocenzi

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Background: The Blalock-Taussig (BT) shunt is a life-saving surgery, but it still presents significant morbidity and mortality. In this scenario, stenting the ductus arteriosus (DA) appears as a less invasive alternative. Our goal is to describe the results of stent implant in place of BT as a palliation in children with cyanotic malformations.
Material and Methods: A review of the charts of all intended stent implantation from 2008 to 2016 was carried out. We analyzed the following characteristics: sex, age, weight, diagnosis, anatomical features of the ductus, causes for failure and complications.
Results: Twenty-nine cases of attempted stent implantation were surveyed, with a success rate of 82,8% (5 failures). Seventeen patients were male and 12 female. Ages ranged from 5 days to 16 months and weights from 2.4 kg to 10.4 kg. The echocardiographic diagnosis were: pulmonary atresia and ventricular septal defect (13 patients), pulmonary atresia with intact ventricular septum (9), severe pulmonary stenosis (3), tricuspid atresia (1), double outlet right ventricle with pulmonary stenosis (1), pulmonary atresia with single ventricle and right isomerism (1) and tetralogy of Fallot (1). As to the characteristic of the ductus, 6 were horizontal and straight, 2 horizontal ant tortuous, 10 vertical and straight and 11 vertical and tortuous. There were 2 cases of pericardial effusion, one of them in the success and the other in the failure group. Of the cases with successfully implanted stents, there were 3 deaths, one due to cardiogenic shock and two due to sepsis. Among the 5 cases of failed implantation, there was 1 death in the same day of the procedure and the other 4 patients were referred to BT surgery. The failure cases were due to ductus tortuosity or stenosis.
Conclusion: The results show that stent implantation is a good alternative to BT surgery in cyanotic patients who present a favorable ductus morphology.

P1846 - OCCLUSION OF WINDOW LIKE DUCTUS WITH ATRIAL SEPTAL DEVICE

Renata Mattos, *Luciana Almenara, Victor Hugo Oliveira, Luiz Carlos Simoes, Monica Celente, Paulo Renato Travancas, Ana Helena Dorigo, Adriana Innocenzi, Lina Miura, Maritza Anzanello*
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Background: Percutaneous occlusion of Krichencko type B ductus arteriosus (DA), also called window-like ductus, is a challenge to the interventional cardiology. Devices designed for ductus closure are unsuitable for this morphology, with a high risk of displacement or protrusion to the aorta or the pulmonary artery. We report a case of percutaneous closure of a type B ductus successfully performed with an atrial septal defect (ASD) device.
Case Report: Our patient was a 4 month-old boy, weighing 4.8 kg with Down syndrome and a history of fatigue during breastfeeding. Physical examination showed tachypnea, tachycardia, oxygen saturation of 96%, and a loud systolic murmur. Electrocardiogram showed signs of right atrial and right ventricular enlargement. The first echocardiogram showed a small ASD, a moderate DA and a pulmonary artery pressure (PAP) estimated by the tricuspid regurgitation of 50 mmHg. He was initially treated with diuretics. Nine months later, his saturation were lower (85%) and the PAP was 80 mmHg. In this stage, he was given SILDENAFIL and referred to intervention. During the procedure, we were able to document a fall in the PAP after temporary occlusion of the DA with a balloon. We then proceeded to successfully implant the OCCLUTECH FIGULLA ASD FLEX II size 6. The patient was discharged the following day and has been asymptomatic.
Coments: Success of the percutaneous closure of the window-like DA brings the possibility of correction of this defect using a method less invasive, with less complications and lower hospitalization time.

P1850 - TRANSCATHETER TREATMENT OF COARCTATION OF AORTA AND DUALLY CONNECTED ANOMALOUS VERTICAL PULMONARY VEIN

Mehnaz Atiq[1], *Kamran Younus[1], Muneer Amanullah[2]*
Aga Khan University Hospital, Pediatrics and Child Health, Karachi-Pakistan[1]; Aga Khan University Hospital, Cardiac Surgery, Karachi-Pakistan[2]

Introduction: Partial anomalous pulmonary venous connection is failure of one or more pulmonary veins to connect with left atrium during fetal development. It is frequently associated with atrial septal defects, and rarely with other congenital cardiac abnormalities. We describe transcatheter treatment of aortic coarctation and occlusion of partial anomalous pulmonary venous connection in the same patient.
Case Report: Thirteen year old girl was diagnosed to have coarctation of aorta an anomalous left upper pulmonary vein to innominate vein. She was planned to have the coarctation treated with covered stent and the anomalous vein treated surgically at a later date. Cardiac catheterization and angiography showed juxtaductal coarctation, narrowest segment measured 3.8 mm with a pressure gradient of 40 mmHg across the coarctation. Oxygen saturations were 99% in the pulmonary veins, 93% in the innominate vein and pulmonary artery, and 82% in the proximal superior vena cava. Qp /Qs was 4.5. Left pulmonary angiogram showed normal pulmonary venous connection to left atrium with a large vertical venous channel connecting the confluence of left pulmonary veins to innominate vein. Balloon occlusion of the vertical vein did not interfere with left pulmonary venous drainage. Coarctation of aorta was treated with NuMED covered CP stent, 39mm X 8 zig mounted over a 12mm X 4 cm Z Med balloon reducing the gradient to 4 mmHg. Vertical vein measured 13 mm in diameter and was closed with 20 mm Amplatzer vascular plug II, released after confirming unobstructed pulmonary venous return.
Discussion: Historically, multiple cardiac pathologies, such as in the present case, would be treated with surgery. Improved technics have made it possible to address multiple defects by percutaneously at the same time. In our patient we stented the coarctation first and then addressed the vertical vein, which was possible due to dual pulmonary venous connection.

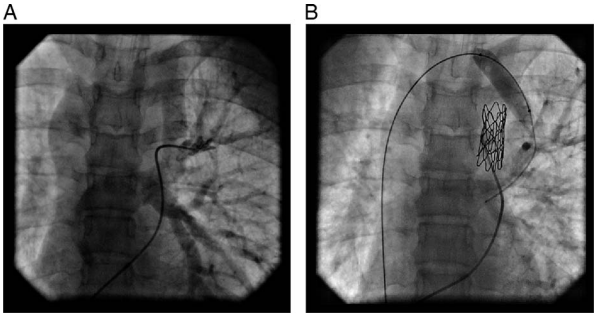

Figure 1.
Anomalous vertical vein with dual pulmonary venous connection 9A0 and balloon occlusion (B) with coarctation stent in place.

P1871 - PROLONGED CARDIAC CATHETERIZATION THE INFLUENCING FACTORS AND SEQUENTIAL TIME ANALYSIS

Kachaporn Nimdet, Preyaporn Chu-iad
Suratthani Hospital, Pediatric, Suratthani-Thailand

Background: Cardiac catheterization has developed worldwide. Apart from success rate, the procedural time is an important parameter for efficacy. Shorter duration could reduce costs and risk of complications. This study aims to identify the influencing factors and sequential times for prolonged cardiac catheterization.
Material and Methods: The retrospective study conducted from November 2009 to November 2016 at Suratthani Hospital, Thailand. Pediatric and adult patients who underwent cardiac catheterization under general anesthesia were included in the study. Demographic data, types of procedures, and the procedural time for all processes were recorded. Prolonged cardiac catheterization was defined as cases in which procedural time was greater than the mean time. Identification of the influencing factors and comparisons of the times of all processes between groups were assessed using t-test and Chi-square test. A statistically significant level was defined by p-value <0.05.
Results: Of 140 patients, 68 had prolonged cardiac catheterization (the mean time was 101.85 ± 35.54 minutes). Of the four comparative factors: age ≤ 1 year, body weight ≤ 10 kilogram, cyanotic heart diseases and interventional cardiac catheterization, age ≤ 1 year is an influencing factor on prolonged cardiac catheterization ($p = 0.008$). A sequential time analysis revealed a higher preparation time by nurses and anesthesiologists, catheterization time, and post-procedural time in the prolonged cardiac catheterization group compared with the other group. These parameters were also significantly longer in patients aged ≤ 1 year.
Conclusions: Age ≤ 1 year is an influencing factor on prolonged cardiac catheterization which was affected by multiple processes. Although low age is difficult to avoid in patients with absolute indications for cardiac catheterization, the procedure should be delayed in elective cases. Recognition of the causes of prolonged catheterization in each processes and implementation of more effective methods could reduce the procedural time and increase the efficacy of cardiac catheterization.

P1904 - TRANSCATHETER STENTING AND CLOSING A DUCTUS IN A NEWBORN WITH BILATERAL DUCTUS

Min-ling Hsieh, Jieh-neng Wang, Yung-chieh Lin, Jing-ming Wu
National Cheng Kung University Hospital, Pediatrics, Tainan-Taiwan

Background: With the advance of transcatheter technique, transcatheter closure or stenting of a ductus is now regarded a safe and feasible procedure in selected infants.
Materials and Methods: We report a newborn patient (birth body weight: 2280 g) who presented with dyspnea and cyanosis 6 hours after birth. Differential cyanosis (SpO2 of right arm: 98%; SpO2 of right leg: 83%). Chest plain film revealed cardiothoracic ratio: 56% and uneven pulmonary vascular markings between bilateral lung. Echocardiogram showed a perimembraneous ventricular septal defect, main pulmonary trunk giving rise to right pulmonary artery and large right ductus arteriosus, left ductus arteriosus which arises from aortic arch close to the origin of left brachiocephalic artery connecting to left pulmonary artery, interruption of right and left pulmonary artery, right arch, and hypoplastic aortic ach. Majority of flow from pulmonary trunk goes to descending aorta through right ductus arteriosus. Considering high risk of total repair, we performed palliation procedure for this patient.
Results: Our strategy is balloon angioplasty for hypoplastic arch if significant pressure difference is present between ascending and descending aorta, transcatheter closure of right ductus, and placement a stent in left ductus. During cardiac catheterization, there was no pressure gradient between ascending and descending aorta. Amplatzer® vascular plug 10mm in diameter was used to occlude right ductus. We put an OMEGA™ stent, 4.0mm*8.0mm, in left ductus to promote left pulmonary artery growth. This patient was discharged soon without complications.
Conclusions: With the advance of transcatheter technique, closure or maintenance of patency of ductus can be both achieved without surgery. We report our experience in both closing and stenting a ductus through cardiac catheterization in a newborn with complex congenital heart disease.

P1915 - STEPWISE APPROACH TO CONDUIT PUNCTURE FOR ELECTROPHYSIOLOGICAL PROCEDURES IN PATIENTS WITH FONTAN CIRCULATION

Jae-Sun Uhm[1], Nam Kyun Kim[2], Jung Ok Kim[2], Jae Young Choi[2], Moon-Hyoung Lee[1], Jo Won Jung[2], Hui-Nam Pak[1], Boyoung Joung[1], Tae-Hoon Kim[1], Sang-Yun Lee[3], Mi Kyoung Song[4]
Severance Cardiovascular Hospital, Yonsei University College of Medicine, Cardiology, Seoul-Korea, South[1]; Severance Cardiovascular Hospital, Yonsei University College of Medicine, Pediatric Cardiology, Seoul-Korea, South[2]; Sejong General Hospital, Bucheon, Pediatric Cardiology, Gyeonggi-Do-Korea, South[3]; Seoul National University Children's Hospital, Pediatric Cardiology, Seoul-Korea, South[4]

Background: Electrophysiological procedures are challenging in patients with Fontan conduit,the conduit should be punctured for electrophysiological procedure.
Methods: In our study, 12 patients with lateral tunnel or extracardiac conduit Fontan circulation [median age (interquartile range), 21.5 (16.0–25.3) years; 6 men] who had undergone electrophysiological procedures were enrolled. We performed stepwise approach to Fontan conduit puncture; 1st step, Brockenbrough needle; 2nd step, Brockenbrough needle + snare; 3rd step, Brockenbrough needle (XS series) ± snare; 4th step, radiofrequency transseptal needle ± snare; 5th step, wiring through the puncture; 6th step, conduit dilation with non-compliant balloon; 7th step, cutting balloon; 8th step, Inoue dilator.
Results: In 2, 1, and 2 patients with lateral tunnel made of the pericardium or right atrial wall, conduit puncture was performed by step 1, 2, and 4, respectively. In 2, 1, and 1 patient with the Goretex lateral tunnel or extracardiac conduit, conduit puncture was performed by step 6, 7, and 8, respectively. Puncture time was

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

significantly longer in patients with Goretex conduit than in patients with pericardial conduit [91.0 (59.8–130.5) and 11.5 (10.0–14.8) minutes, respectively; $p < 0.001$].
Conclusions: Stepwise approach to conduit puncture is feasible and safe in patients with lateral tunnel and extracardiac conduit Fontan circulation. Goretex conduit puncture is more difficult than pericardial conduit puncture.

P1924 - ABSENT PORTAL VEIN AND BLEEDING HAEMORRHOIDS IN A TWO YEAR OLD CHILD POSTED FOR LIVER TRANSPLANTATION

Sudeep Verma[1], Gouthami V[2], Raja Mannar[3], Sethu Babu[4], Nagarajan R[5], Sachin Daga[6]
Kims Hospital, Pediatric Cardiac Sciences, Hyderabad-India[1]; Kims Hospital, Peddiatric Cardiac Sceinces, Secunderabad-India[2]; Kims Hospital, Intervention Radiology, Secunderabad-India[3]; Kims Hospital, Department of Gastroenterology, Secunderabad-India[4]; Kims Hospital, Pediatric Cardiac Anesthesia, Secunderabad-India[5]; Kims Hospital, Departement of Surgical Gastrocenterology, Secunderabad-India[6]

Background: Haemorrhoids is rare in paediatric age. Presenting a rare case of bleeding per rectum due to haemorrhoids secondary to portal hypertension and congenital absence of portal vein (Abernathy malformation I) referred for liver transplantation. Balloon occlusion of the aberrant vessel demonstrated presence of portal radicals, followed by successful closure of the aberrant channel. Follow up showed good growth of the portal radical, otherwise reported as absent during initial assessment.
Description: 2 years old, weighing 10.5 kg presented with complaints of recurrent bleeding per rectum. Examination showed severe pallor and splenomegaly. Suspected to have portal hypertension hence CT scan and MRI was done that showed congenital absence of portal vein with abnormal drainage of portal confluence to right iliac vein (Abernathy type I - Morgan classification and Kobayashi classification type C). Haemoglobin was 7 gm% and LFT were normal. Sigmoidoscopy revealed large venous channel into rectum with multiple internal haemorrhoids. Balloon occlusion test of the draining channel using 16×40 TYSHAK BALLOON demonstrated presence of portal radicals to the liver. Portal pressure measured 19 mm Hg after test occlusion. Device closure of the aberrant channel was done using 24/26 duct Occluder from right jugular vein route. Ammonia level dropped from 95 to 20 after the procedure. Eight months follow up showed decreased rectal bleeding and stable haemoglobin level of more than 11 gm%. Follow up angiogram showed good growth of portal radical to liver with normal LFT.
Conclusion: Bleeding haemorrhoids is a rare presentation of portosystemic shunt. Diagnosis of Absent portal vein should always be consider only after balloon occlusion test. Surgical ligation or transcatheter closure of aberrant vessel is feasible option if portal pressure remained less than 25-30 mm Hg. Long term follow up is needed to assess portal venous pressure, growth of intrahepatic portal radicals.

P1925 - INFRARENAL IVC DUPLICATION AND DECOMPRESSING SPINAL VEINS AS A CAUSE FOR SEVERE IVC SPASM IN A EUVOLEMC PATIENT DURING PDA DEVICE CLOSURE

Sudeep Verma[1], *Gouthami V*[1], *Nagarajan R*[2], *Anil Dharmapuram*[1], *I.M Rao*[1]
Kims Hospital, Pediatric Cardiac Sciences, Hyderabad-India[1]; *Kims Hospital, Pediatric Cardiac Anesthetist, Secunderabad-India*[2]

Background: Spasm of the vessel is a known entity during manipulation of hardwares during catheterization. We are describing a case where severe IVC spasm happened during PDA device closure in a euvolemic patient precluding catheter to advance into RA. Evaluation revealed infrarenal duplication of IVC and filling of left paraspinal venous plexus causing decreased effective lumen of the IVC. This case highlights the importance of suspecting IVC abnormality in case of unusual spasm of the major vessels.
Description: 14 months old weighing 8.5 kg diagnosed to have PDA during vaccination. Examination revealed bounding pulses and continous murmur at left upper sternal border. Chest X ray revealed cardiomegaly and increased lung vascularity. After securing femoral venous access, PA and RA pressures were measured showing mean of 6 & 15 mm Hg respectively. After crossing PDA from venous side, 6 Fr delivery sheath was introduced but sheath was unable to negotiate suprarenal IVC due to severe venous spasm not relieved with saline push and Nitrate injections. While reattempting procedure contrast injection into femoral vein revealed duplication of infrarenal portion of IVC along with filling up of left paraspinal venous plexus causing decreased effective lumen of supra renal IVC in presence of normal RA pressure. Duplication was missed during the initial injection given high into one of the IVC lumen. After saline boluses and Nitrate injections 6/4 Duct Occluder was deployed successfully.
Conclusion: Venous spasm is more pronounced with low filling pressures. In presence of duplication of IVC with another venous egress effective lumen of IVC is reduced making it more prone for spasm even in presence of adequate filling pressure. Delineating IVC anatomy with contrast given into femoral vein becomes crucial to diagnose such spasm which was missed otherwise if injected

P1928 - TANDEM PLACEMENT OF TWO DUCT OCCLUDERS GENERATION II DEVICES IN SUPEROINFERIOR VENTRICLES WITH CRISS CROSS ATRIOVENTRICULAR FLOWS

Sudeep Verma, Gouthami V, Nagarajan R, Anil Dharmapuram, I.m Rao
Kims Hospital, Pediatric Cardiac Sciences, Hyderabad-India

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Introduction: Superior inferior ventricles with criss cross atrioventricular flows associated commonly with discordant Ventricular-arterial relationship. Here we are presenting a case of membranous septal aneurysm with multiple VSD in superoinferior ventricles and criss cross AV connection with AV - VA concordance, closed with tandem placement of two AMPLATZER DUCT OCCULDER II (ADO II) devices.

Case Details: 15 months old toddler weighing 7.2 kg presented with poor weight gain and recurrent respiratory tract infection. Referred with diagnosis of CCTGA and VSD. Examination revealed features of large left to right post tricupsid shunt with poor localisation of apex beat. Chest X-ray showed cardiomegaly, differential vascularity with right lung plethora. ECG revealed sinus rhythm, left superior QRS axis and biventricular forces. Echocardiogram revealed situs solitus, levocardia, juxtaposed right atrial appendage, superior inferior ventricles, AV-VA concordance, membranous septal aneurysm and multiple VSD's with moderate pulmonary artery hypertension. Oximetry run showed step up of 15% across right heart with QP/Qs of 2:1. PA pressure were 60% of the systemic pressure with mean of 35 mm Hg. Ventricular injections revealed superior position of RV and LV in inferior position with elongated LVOT. LPA was angulated with physiological oligemia due to streaming from MPA to RPA.Two ADO II devices (6/4 and 5/4 respectively) were deployed in tandem manner across septal aneurysm from retrograde technique with complete abolition of shunt and drop in PA pressure. In both cases VSD were crossed using 6Fr JR 3.5 guide catheter with 0.032 TERUMO ANGLED WIRE.

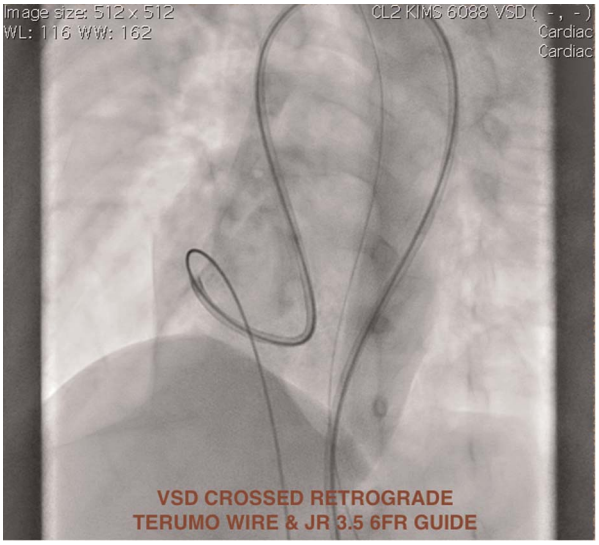

Figure 1.

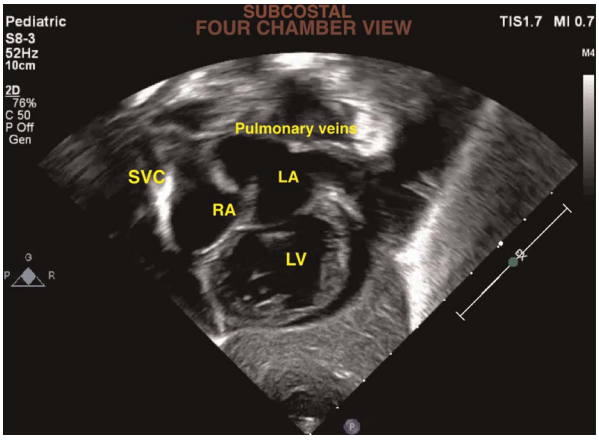

Figure 3.

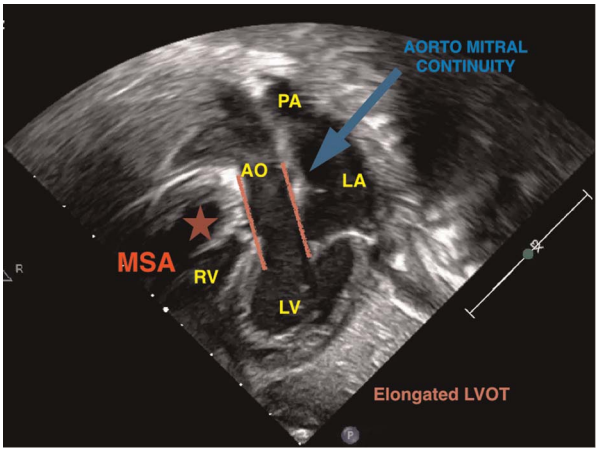

Figure 4.

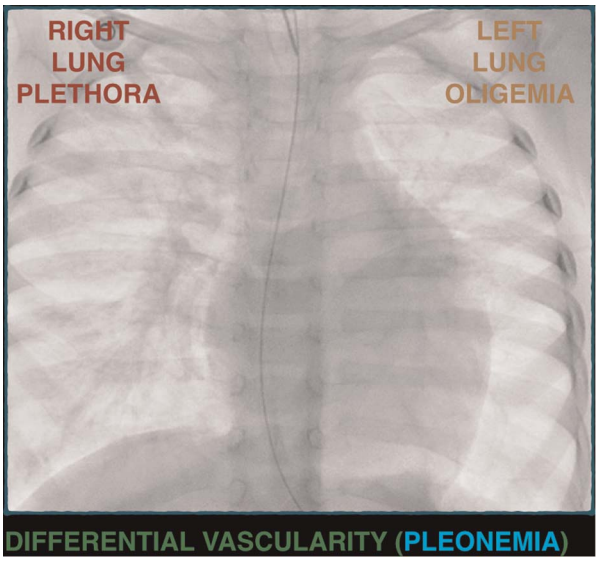

Figure 5.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

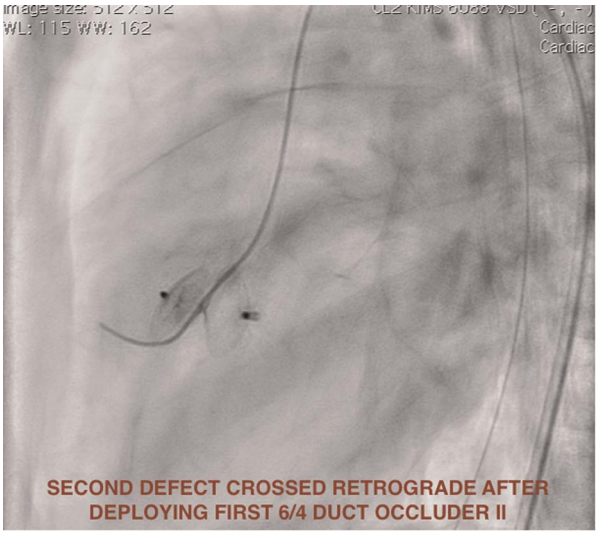

Figure 6.

Figure 7.

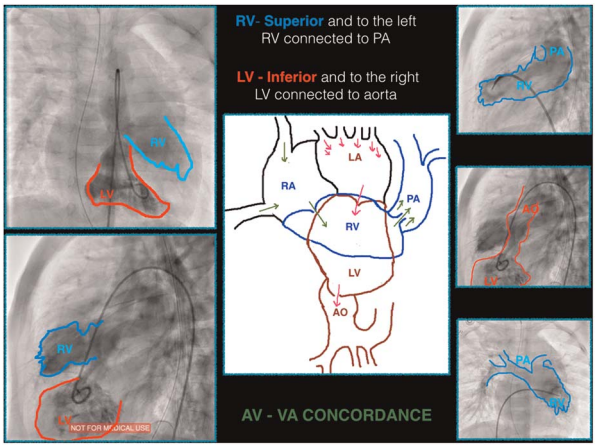

Figure 8.

Conclusion: Orientation of the IVS changes hence device closure is challenging in such cases. Delineation of the VSD by angiogram is difficult hence meticulous echocardiographic evaluation is needed. Tandem device placement with multiple ADO II is possible in such cases with membranous septal aneurysm and multiple defects.

P1958 - ASD WITH CYANOSIS EISENMENGER SYNDROME

Neeraj Awasthy[1], Dinesh Bhisht[2]
Max Hospital, Saket, Pediatric Cardiology, Delhi-India[1]; Max Hospital, Pediatric Cardiology, Delhi-India[2]

We Present A Series Of Cases Of Atrial Septal Defect Which Were Cynosed And Being Followed Up As Eisenmneger Syndrome. Case1: A 56 Year Old Female With Bronchiectasis Who Underwent Diagnostic Evlaution With Interesting Hemodynamics, Case2: 45 Year Case Of Connective Tissue Disorder, Case 3: With Lutembacher Syndrome, With Unroofed Coronary Sinus And Other Cases Have Been Enlisted. This Description Shows How A Case Of Asd With Cynosis Can Be Worked Up To Yield And Treat The Underlying Etiologies Of Pulmonary Artery Hypertension

P1960 - LV PSEUDOANEURYSM. PERCUTANEOUS CLOSURE

Neeraj Awasthy[1], Dinesh Bhisht[2]
Max Hospital, Pediatric Cardiology, Delhi-India[1]; Max Saket, Pediatric Cardiology, Delhi-India[2]

Percutaneous device closure of a left ventricular (LV) pseudoaneurysm have been rarely reported. We describe the case of a 60-year-old woman with a history closed mitral valvotomy at 18 years of age, Mitral Valve (MV) replacement at 53 year of age in Feb 2016 at 60 year of age. She presented with shortness of breath and chest pain since for 2 weeks. Echocardiography (Echo) revealed LV pseudoaneurysm with neck size of 12mm. Cardiac MRI showed a large LV pseudoaneurysm (36 × 32 mm) that was filling

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

from a small leak in the anterolateral aspect of the ventricle. Considering high-risk candidate for surgical treatment in view of three previous sternotomies, the pseudoaneurysm was closed percutaneously with use of a 16-mm AMPLATZER muscular VSD occlude sucessfully. The patient was discharged from the hospital the next day and was asymptomatic on followup.

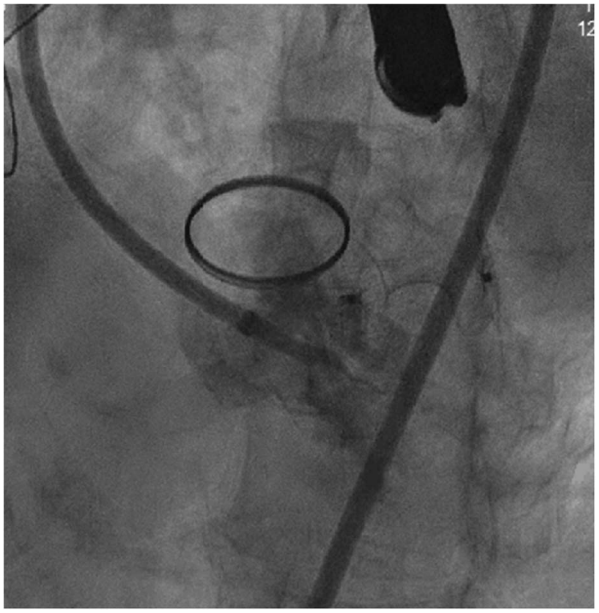

Figure 2.

P1968 - RETURNING BACK TO NATIV RIGHT VENTRICLE OUTFLOW

Irfan Levent Saltik, Sezen Ugan Atik, Ayşe Güler Eroğlu
Istanbul University Cerrahpaşa Medical Faculity, Pediatric Cardiology, Istanbul-Turkey

Here in, we present a case with both native PA and non valved conduit that have been undergone closure of conduit due to RV enlargement after finding out the adequate native pulmonary outflow.

Case: A 24-years-old female who had been operated for double outlet right ventricule was admitted to our out-patient clinic for routine echocardiographic evaluation. She had undergone the Rastelli procedure at the age of four. Native PA reconstruction had not been performed due to the coronary anomaly. Transthoracic echocardiography showed enlarged RV, severe insufficiency in the nonvalved conduit. A detailed assessment revealed the presence of the native PA. At catheterization, RV injections showed two different outflows from the RV; one the native PA and the second the conduit (Fig. 1). By total occlusion of the conduit with sizing balloon, right ventricle systolic pressure rose from 40 to 90 mmHg. After establishing the adequate pulmonary annulus and valvular pulmonary stenosis, balloon pulmonary valvuloplasty was performed with a 24-mm balloon. RV pressure monitored again when the conduit was totally occluded with balloon. RV pressure remained unchanged about 40 mmHg. RV

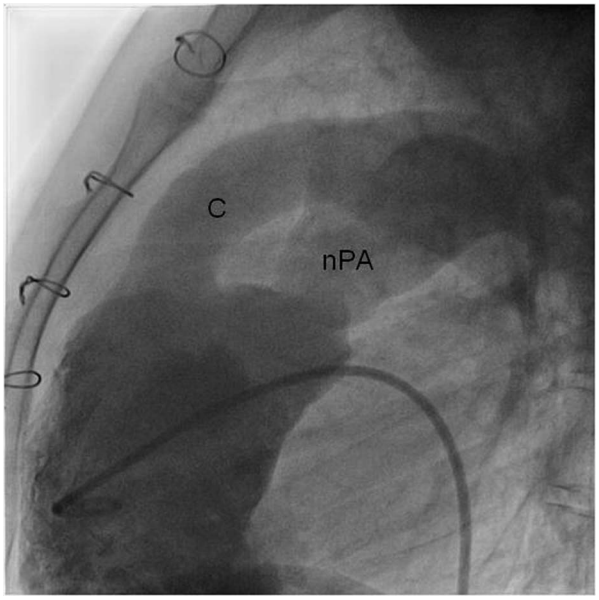

Figure 1.

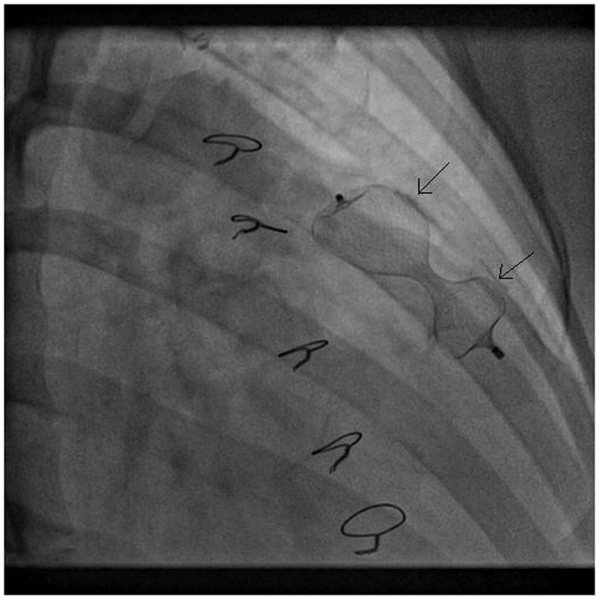

Figure 2.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

injection demonstrated the total occlusion of the conduit and RV decompression by native pulmonary artery. A 17 mm AmplatzerTM atrial septal defect occluder was deployed at the appropriate segment of the conduit (Fig 2). Post procedure echocardiography revealed mild degree of native PA stenosis and a residual forward flow in the conduit with mild degree of regurgitation. She did well without any complaints.
Conclusion: Finding out a native and adequate pulmonary outflow in a patient that undergone biventricular repair with a RV-PA conduit is an unexpected status. To our knowledge, this is the first case that right ventricle outflow redirected to native PA by transcatheter closure of the nonvalved RV-PA conduit.

P1998 - USEFULNESS AND SAFETY OF TRANSCATHETER CLOSURE OF ATRIAL SEPTAL DEFECT IN SMALL CHILDREN WEIGHTING 10KG OF LESS

Ah Young Kim, Se Yong Jung, Nam Kyun Kim, Jo Won Jung, Jae Young Choi
Severance Cardiovascular Hospital, Department of Pediatrics, Yonsei University College of Medicine, Division of Pediatric Cardiology, Congenital Heart Disease Center, Seoul-Korea, South

Background & Objectives: Transcatheter closure of atrial septal defect (ASD) has been accepted as a standard treatment. The risk-benefit relationship of transcatheter closure of ASD in the very young and small patients has not been clearly defined yet. Thus, to investigate the efficacy of safety of transcatheter closure of ASD in small children weighting less than 10 kg, we compared the data of patients with device closure and surgery.
Methods: From April 2004 to December 2015, 1149 ASD patients were treated with transcatheter closure. Among them, 124 patients weighting less than 10 kg were included as Device Group. During same periods, 350 patients were treated surgically, and among those 45 patients weighting less than 10 kg were included as Surgery group. Baseline characteristics, hemodynamic features, comorbidities, success rate and complication rate were compared between two groups.
Results: Although surgery was performed in younger, smaller children with relatively large defects, combined condition such as rim deficiency, multiple defects were not different between two groups. Except 4 cases (3.2%) of mitral encroachment in device group, all were successfully treated by either percutaneously or surgically. In both group, there was no major complication. Minor complication rates were significantly lower in device group than in surgical group (1.6% vs 8.8%, $p = 0.04$). Hospital stays were also significantly shorter in device group (4.0 ± 0.3 vs 11.1 ± 5.4, $p < 0.001$)
Conclusion: Transcatheter closure of secundum ASD with the ASO is technically feasible, safe and effective even in small children weighing less than 10 kg. We could suggest that even in very young children with ASD, no need to wait until they grow for transcatheter closure (>7.5 kg or age >1 year).

P2023 - TRANSCATHETER CLOSURE OF PATENT DUCTUS ARTERIOSUS IN VERY LOW BIRTH WEIGHT PRETERM INFANT FIRST REPORT IN THAILAND

Ratthapon Wongwandee, Boonchu Sirichongkolthong, Paweena Kaladee Thammasat, Pediatric (Cardiology), Bangkok-Thailand

Background: Transcatheter closure of Patent Ductus Arteriosus (PDA) under 2.5 kg preterm baby continues remain challenging due to difficult vascular access, variable duct diameter, temperature control and obstruction of adjacent vascular structures.
Method And Results: We report 2 preterm infants with procedural age 6, 12 days and procedural weight 2.4, 1.3 kg, respectively. Two babies had vascular access time 2, 4 minutes under ultrasound guided and procedure time 48, 58 minutes, respectively. Hemodynamic significant PDA(tubular type) were 3, 4 mm in mid diameter. Both of them used only venous access, 4 Fr JR catheter and Amplatzer Duct Occluder II additional size (ADO II AS, 04-04, 05-06) under echocardiogram and fluoroscopy. Successful device placement was achieved in 2 cases (100%). There were minor complications such as nonsignificant obstruction of left pulmonary artery and descending aorta, short period of platelet consumption in very low bithweight case (1.3 kg).
Conclusions: Transcatheter closure of PDA in very low bithweight infant remains challenging. We will develop technical skill to another choice for treatment of preterm PDA in our country.

P2056 - CARTO-ABLATION OF ATRIAL TACHYCARDIAS IN PRESCHOOL CHILDREN

Sergey Krivolapov[1], Roman Batalov[1], Liliya Svintsova[1], Olga Dzhaffarova[1], Irina Plotnikova[1], Sergey Popov[1], Igor Kovalev[2]
Cardiology Research Institute Pediatric cardiology department Tomsk-Russia[1]; Research and Clinical Institute for Pediatrics Pediatric cardiology department Moscow-Russia[2]

Importance: Prolonged X-ray radiation during RFA is a risk of remote complications especially in children of yearly age. Navigation mapping in such category of patients is perspective to reduce fluoroscopy time.
Aim: To assess the efficiency and safety of navigation mapping in RFA of atrial tachycardias in children.
Results: 30 RFA with CARTO system were performed to 23 children with atrial ectopic tachycardias during 2006 – 2016 years. The patients' age was 5,0 years (IQR: 3,58-6.0), ranging from 7 months to 7 years old. 7 patients were less than 15 kilos. The minimal age of the child who was performed CARTO was 7 months, the minimal weight – 7,4 kg.
As minimal size of the diagnostic catheter used in this system is 7 Fr (NaviStarTM), it is necessary to make a preliminary assessment of the diameter of femoral vessels by echocardiography.
Ectopic focus in most patients was in right atrium ($n = 20$). In two cases the approach to left atrium was performed by transseptal puncture, in one case – through patent foreman ovale.
The overall efficiency of CARTO ablation considering recurrences and retreatments was 91,3%. Vessel injuries and other complications, associated with a procedure, were absent. Due to CARTO ablation decrease of fluoroscopy time in 2,3 times in comparison with standard fluoroscopy mapping ($p < 0,001$) was marked.
Conclusion: RFA with navigation mapping is effective and safe in children weighing more than 7 kilos and allow reducing time of X-ray radiation to minimize complications associated with radiation exposure.

P2059 - RADIOFREQUENCY ABLATION OF TACHYARRHYTHMIAS IN CHILDREN TILL 5 YEARS OLD

Sergey Krivolapov[1], Roman Batalov[1], Sergey Popov[1], Liliya Svintsova[1], Igor Kovalev[2], Olga Dzhaffarova[1], Irina Plotnikova[1]
Cardiology Research Institute Pediatric cardiology department Tomsk-Russia[1]; Research and Clinical Institute for Pediatrics Pediatric cardiology department Moscow-Russia[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

88 patients under five years old underwent RFA. 22 of them were till one year old. Arrhythmias were WPW syndrome, atrial and ventricular tachycardias, AVNRT. Ablation was performed after failure of medication. Signs of arrhythmogenic cardiomyopathy had 68% of patients. One 5 Fr or 7Fr ablation catheter and one diagnostic catheter were for EP-study and RFA. Usually bifemoral access was used but in some cases we also used transesophageal reference catheter. In 20 patients with atrial ectopy we used non-fluoroscopic navigation system that allows minimizing radiation exposure. Access to the left side of the heart was performed through PFO, otherwise in 8 patients it was femoral artery puncture and in 3 patients it was atrial septal puncture. RFA was performed with 55 C with starting power 20 W, in case of conduction system damage risk a starting power was 5-10 W.
Results: First RFA procedure was effective in 78 patients (88,5%) but in 18 cases (23%) there was recurrence that was treated with 2nd procedure in all cases. There were still 3 cases of second recurrence in this group and third effective procedure was performed with good long term follow up. In 10 patients that was ineffective with first procedure in 6 cases there was a second procedure with good long term efficacy. The overall efficiency was 95%. Intraprocedural complications were transient AV-conduction disturbances in 4 patients. In one case with septal puncture there was asymptomatic hemopericardium. Reverse remodeling of arrhythmogenic cardiomyopathy in all patients.
Conclusions: RFA is safe and effective approach for difficult heart rhythm disorders management when medication fails. There is higher recurrence rate possibly due to minimally effective power applied. It is important to have echo and cardiac surgery back up for management of possible complications.

P2071 - A SYSTEMATIC REVIEW OF DEVICE CLOSURE OF PERIMEMBRANOUS VENTRICULAR SEPTAL DEFECT

Haripriya Santhanam[1], Linqi Yang[1], Zhaojin Chen[2], Swee Chye Quek[1]
National University Healthcare System, Paediatrics, Singapore-Singapore[1]; Yong Loo Lin School of Medicine, Investigational Medicine Unit, Singapore-Singapore[2]

Background/Hypothesis: Device closure of ventricular septal defects (VSDs) is gaining popularity, although there remain concerns about adverse events; particularly heart block in perimembranous VSDs (pmVSDs). The aim of this study is to ascertain the outcomes (efficacy and complications) of device closure of pmVSDs, through a systematic review of currently available literature.
Materials and Methods: A PubMed and Scopus search for studies in English on device closure of pmVSDs published till mid-January 2017 was performed. Exclusion criteria included small series that had been included in multicenter studies, studies with sample size <5, and patients who had acquired VSD following myocardial infarction. The random effects model was used to obtain pooled estimates of success and complications.
Results: A total of 74 publications comprising 9165 patients with pmVSDs were included in this analysis. The age of patients ranged from 30 days to 73 years. The pooled estimate of successful device implantation was 97.3% (95% CI: 96.2%-98.2%). The most common complication was residual shunt (pooled estimated 10.9%; 95% CI: 7.2%-15.2%). Other complications included valvular defects (pooled estimate 3.8%; 95% CI: 2.4%-5.5%) and arrhythmias (pooled estimate 10.6%; 95% CI: 8.2%-13.2%). Of note, complete atrioventricular block (cAVB) occured in 1.5% (pooled estimated 0.8%; 95% CI: 0.4%-1.3%).
Conclusion: Our analysis suggests that device closure of pmVSDs is safe and yields good results. The complication of cAVB, while a concern especially with perimembranous type of VSD, is low (incidence = 1.5%). This is likely to be even more so with newer devices which are less stiff, and improved profiles. One limitation of the study is that different devices were used, and the results of each type could not be analyzed individually. Further studies validating this will be useful in formulating guidelines for the device closure of pmVSDs.

P2078 - CAN NUMERICAL SIMULATIONS SUPPORT PERCUTANEOUS PULMONARY VALVE IMPLANTATION FOR THE TREATMENT OF THE RIGHT VENTRICLE OUTFLOW DYSFUNCTION

Francesca Pluchinotta[1], Alessandro Caimi[2], Francesco Sturla[2], Luca Giugno[1], Francesco Secchi[3], Alberto Redaelli[2], Mario Carminati[1]
IRCCS Policlinico San Donato, Pediatric Cardiology and Adult Congenital Heart Disease, Milano-Italy[1]; Politecnico Di Milano, Bioengineering Department, Milano-Italy[2]; IRCCS Policlinico San Donato, Radiology, Milano-Italy[3]

Background: Percutaneous pulmonary valve implantation (PPVI) is a valid alternative to open-heart surgery for the treatment of right ventricle outflow tract (RVOT) dysfunction. However, an accurate pre-procedural evaluation of PPVI candidates is mandatory to minimize procedural complications (mostly arterial rupture, coronary compression, device embolization). For this purpose, we proposed a virtual simulation of PPVI implantation to assess the feasibility of the procedure and to elucidate potential PPVI-related risks before going in-vivo.
Methods: We enrolled five patients undergoing PPVI for right ventricle-to-pulmonary artery conduit failure. Each patient-specific anatomy, including the RVOT conduit, the calcifications, the aortic root and coronary arteries, was reconstructed from CT images using a commercial software (Materialise, Leuven-Belgium). Subsequently, the patient-specific computational model was complemented by the PPVI armamentarium, including the numerical model of both the stent and balloon as commercially available. Finally, a finite element analysis (FEA) was performed to reproduce the stent deployment in the RVOT after stent positioning and progressive balloon inflation, according to the real procedural PPVI standards.

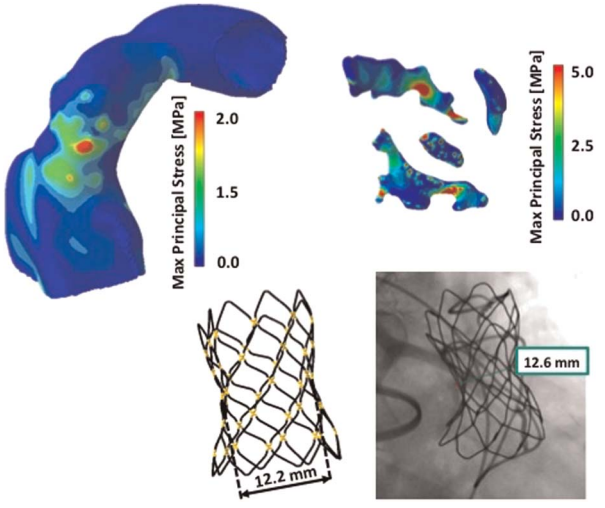

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: The numerical approach proved able to virtually assess the anatomical RVOT changes after stent implantation in the single clinical scenario. Also, it quantified the interaction between the deployed stent and the anatomical RVOT structures pointing out anchoring forces, arterial wall stress, mechanical deformation of calcium, and risk of compression of the surrounding coronaries. Numerical results well compared to clinical evidences coming from the "in vivo" PPVI procedure performed in the Catheterization Suite: in-vivo diameters of the deployed stents were closed to what simulated, distances between the deployed stent and the left coronary were comparable, stent deformations occurred in the same locations. Figure 1.
Conclusions: Numerical methods can reliably reproduce the PPVI procedure and, in complex clinical-scenario, can effectively support the pre-procedural patient selection in order to minimize procedural complications.

P2099 - TRANSCATHETER CLOSURE OF AORTOPULMONARY WINDOW A CASE SERIES

Biswajit Bandyopadhyay[1], Amitabha Chattopadhyay[2], Mahua Roy[1], Saurabhi Das[1], Rhitajyoti Sengupta[3]
Rabindranath Tagore International Institute of Cardiac Sciences, Mukundapur, Kolkata, India., Pediatric Cardiology, Kolkata-India[1]; Narayana Superspeciality Hospital, Howrah, West Bengal,india, Pediatric Cardiology, Kolkata-India[2]; Rabindranath Tagore International Institute of Cardiac Sciences, Mukundapur, Kolkata, India., Pediatric Cardiac Intensive Care, Kolkata-India[3]

Background: Aortopulmonary window (AP window) is rare and early closure is recommended to prevent rapid development of pulmonary vascular obstructive disease. Transcatheter closure has low immediate and late complications, avoiding an extensive open heart surgery. We present our series of 9 children who underwent transcatheter closure.
Materials and Methods: 9 children (5 females, 4 males) between 1 to 6 years of age, underwent transcatheter closure of AP window over a period of 5 years (July 2011-August 2016) at our hospital. 8 had native lesions, one had a post operative residual lesion. The lesions were well defined echocardiographically from all views, contemplating the size and type of devices to be used along with estimation of the pulmonary arterial pressures. Oximetry run were done for all, before proceeding for the device closures. All had reversible PAH. Amplatzer Duct Occluder - I were used in 4, Atrial Septal Occluders in 2 and Amplatzer Duct Occluder II in 2. A muscular septal occluder was used for the post operative residual lesion.
Results: Per procedural transthoracic echocardiography were done for all to confirm the position of the devices. No residual leaks, aortic valve damage or coronary involvements were noted. One child with an ASD device had post intervention hematuria, which lasted for 3 days.7 had severe pulmonary arterial hypertension, which came down immediately after the procedure. One child had residual PAH post procedure, normalizing within 6 months. None of them had any complications on five years follow up.
Conclusion: Transcatheter closure of AP window in children is an effective and safe procedure with minimal complications. It should be considered in a favorable anatomy. Various devices may be used, the choice depending on the child's age and weight along with size of the defect, location and distance from the coronaries.

P2116 - MYOCARDIAL BRIDGING OF LEFT DESCENDING CORONARY ARTERY CAUSING MYOCARDIAL ISCHEMIA IN TWO BOYS

Sanja Dorner[1], Dragan Novosel[2]
University Hospital Osijek, Department of Pediatrics, Osijek-Croatia[1]; University Hospital Osijek, Department of Cardiology, Osijek-Croatia[2]

The authors present a two patients aged 12 and 14 who were admitted in the emergency room due to an anginal chest pain accompanied by nausea. The younger boy felt chest pain while he was running fast during football match in school. The older boy felt sharp chest pain after going out on cold winter day. Upon arrival, the both patients had normal clinical status, blood pressure and pulse rate, and no subjective problems. Recorded electrocardiograms were normal, but there were elevated levels of troponin I. Additional diagnostic procedures were done - in younger patient (12) echocardiography showed a structurally normal heart, no regional dyskinesia or valvular insufficiency. A MSCT coronarography showed myocardial bridging in the middle segment of the LAD. In the second patient (14) echocardiography revealed slight regional dyskinesia in apicoseptal region of the left ventricle. Coronary angiography performed at left anterior oblique projection showed narrowing in the middle LAD during systole, which returned to normal during diastole. Myocardial bridging (MB) is intramural course of the coronary arteries and a normal anatomic variant. The most common location is the middle part of the left descending coronary artery, but there was also described the involvement of the right coronary artery and left circumflex artery. The relevance of MB to clinical symptoms has been so far controversial. Though in the majority of cases isolated MB is a benign anomaly it may cause symptoms and in some cases may be a risk factor for sudden death. The challenges we are facing are to determine if the symptoms in symptomatic patients are caused by MB and to identify patients who are at increased risk for complication - especially a sudden death.

P2123 - STENT TREATMENT OF BRANCH PULMONARY ARTERY STENOSIS IN CHILDREN WITH CONGENITAL HEART DISEASE AFTER CARDIAC SURGICAL CORRECTION

Saule Kadirova[1], Frank Ing[2], Serik Alimbaev[1], Dmitriy Gorbunov[3], Almira Baygalkanova[4], Eric Otarbaev[1], Gulmura Momanova[5]
National Research Center For Cardiac Surgery, Interventional Cardiology, Astana-Kazakhstan[1]; Children's Hospital Los Angeles, Pediatric Cardiology, Los Angeles-United States[2]; National Research Center For Cardiac Surgery, Pediatric Cardiac Surgery, Astana-Kazakhstan[3]; National Research Center For Cardiac Surgery, Pediatric Cardiology, Astana-Kazakhstan[4]; National Research Center For Cardiac Surgery, Cardiac Catheterization Laboratory, Astana-Kazakhstan[5]

Background: Residual or recurrent branch pulmonary artery stenosis is a common finding after cardiac surgery for congenital heart disease. We report our experience using stents to treat branch pulmonary artery stenosis in children with congenital heart disease following surgical correction of stenotic or hypoplastic pulmonary arteries.
Materials and Methods: 22 children (15 males, 7 females) with post operative branch pulmonary artery stenosis were treated with stents between November 2014 to December 2016. Mean weight was $15{,}7 \pm 8{,}5$ kg (2,2 kg- 35 kg); mean age was $4{,}6 \pm 3{,}1$ years (1,5 months – 11 years). All patients had stenosis and/or hypoplasia of pulmonary artery branches associated with their congenital heart diseases prior to surgery. After surgical correction, stenosis developed at various areas along the pulmonary arterial tree including the ostium, and proximal branches. The stenoses varied from discrete or long segment and were either unilateral or bilateral.
Results: Stent implantation was successful for all 22 patients. 17 patients underwent transcatheter stent implantation of pulmonary branches and 5 patients received pulmonary artery stent implantation by a hybrid approach. Palmaz Genesis XD stents were used in 14 patients, Valeo Vascular stents in 7 and Genesis stent

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

premounted on OPTA PRO in 1. After the procedure, the minimal diameter range of the pulmonary artery increased from 3,4 ± 1,6 mm to 8,8 ± 2,3 mm and the mean deviation of the right ventricular/pulmonary artery gradient decreased from 69 ± 10,4 mm Hg to 22 ± 4,3 mm.
Conclusion: Surgical correction of congenital heart disease and pulmonary artery stenosis can result in residual or recurrent stenosis requiring further treatment with stents. Our recent experience with this group of patients suggests that transcatheter and hybrid stenting of pulmonary artery branch stenosis is safe and effective.

P2135 - LEFT ATRIAL SIZE WILL INCREASE POST ASD DEVICE CLOSURE IN CHILDREN LESS THAN 3 YEARS OR LESS THAN 15 KG

Sherien Abdelsalam Mohamed Bakr, Hassan Mohamed Kamel
Magdi Yacoub Hospital, Pediatric Cardiology, Aswan-Egypt

Objectives: To evaluate how does the left atrial size change post atrial septal defect (ASD) occlusion in children ≤15 kg or less than 3 years old.
Background: small left atrial size is frequently encountered problem in patients with ASD specially in those who are ≤15 kg or less than 3 years old. We used the Amplatzer device in the ASD closure. The size of the left atrium in these patient had been followed up for 2 years post procedure.
Methods: Retrospective review of ASD procedures performed in children ≤15 kg or less than 3 years old.
Results: Between October 2009 and January 2017, 468 children underwent ASD Device closure. Amplatzer Device placement was successful in 440 of 468 patients. The number of patient who were less than 3 years old or less than 15 kg was 32. The weight of the patients ranged(11.6 ± 2.3 kg; P < 0.01) with Age of (2.5 ± 0.5 years P < 0.01). The left atrium transverse size was (1.9 ± 0.5 cm P < 0.01) which increased to (2.4 ± 0.3 cm P < 0.01) and longitudinal diameter of the left atrium was (2.5 ± 0.4 cm P < 0.001) which increased to (4.1 ± 0.6 cm P < 0.001). Major complications in all of the ASD device closure (n = 468) include 10 device embolization which retrieved percutenously apart from 2 retrieved by surgery, tamponad 1 patient required pericardiocentisis, complete heart block in 2 patients which improved after 2 weeks, supraventricular tachycardia in 3 patient one of them has CCTGA another 2 patients with AVNRT who required ablation post ASD closure.
Conclusions: The ASD device in children ≤15 kg or less than 3 years old is safe procedure. The LA size will increase with the follow-up although the left disc of the device seemed occupying most of it during the procedure.

P2146 - DEVICE INDUCED COARCTATION POST PDA CLOSURE

Sherien Abdelsalam Mohamed Bakr[1], Hassan Mohamed Kamel[2]
Magdi Yacoub Hospital, Pediatric Cardiology, Aswan-Egypt[1]; Magdi Yacoub Hospiatl, Pediatric Cardiology, Aswan-Egypt[2]

Background: Patent ductus arteriosus (PDA) device transcatheter closure is a safe and effective procedure. Device induced coarctation is a well known complications which has been shown to be an avoidable complication.
Objectives: To evaluate that transcatheter closure with this device using different types of devices will show different incidence of device induced coarctation (DIC) .
Patients and Methods: Between January 2010 to January 2017, 489 patients (342 females and 147 males) with PDA underwent cardiac catheterization device closure using Amplatzer duct occluder (n = 293, 60%), PFM(PDA-R)occluder in (n = 161,33%) and coils (n = 35, 7%).
Results: The patient's age ranged from 3 months to 45 years (median 6 months). Successful PDA closure was achieved in 479 patients (97.9%) with 98% complete closure rate within 24 hours after the procedure. 10 patients (2.1%) had unsuccessful attempts, embolization of the device occurred in 5 of the patients (1.6%), encroachment of the aorta with angiography shown in 13% of the patient with no significant gradient (less than 30 mmHg) across the arch with invasive measurements before the release of the device. 10 patients out of the 489 had gradient of 30 mmHg at time of release of the device. Follow-up of the patients showed 5 patients developed significant obstruction of the arch post PDA device closure on which included 4 patients with Amplatzer device and 1 patient (all of which had been removed surgically)with one patient PDA-R, the obstruction was discovered on the follow-up between 6 month to 2 years. One of the patients who had surgical removal of the device developed recoarctation on the 6 month follow-up.
Conclusions: Duct device closure is safe and effective but carries mild risk of encroachment on the aortic arch which is minimally higher rate with Amplatzer Device compared to the PDA-R device.

P2174 - IMPLANTATION OF THE TRANSCATHETER HEART VALVE FOR PULMONARY POSITION IN NATIVE LARGE RIGHT VENTRICULAR OUTFLOW TRACT WITH SEVERE PULMONARY REGURGITATION

Alper Guzeltas, Ibrahim Cansaran Tanidir, Murat Sahin, Taner Kasar, Selman Gökalp, Hasan Candaş Kafali
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey

Background: We aimed to review the outcomes for the EDWARDS SAPIEN-XT® valve (Edwards Lifesciences, Irvine, California) for percutaneous pulmonary valve implantation (PPVI) in patients with native right ventricular outflow tract(RVOT).
Materials and Methods: Retrospective analysis was performed for all patients who have undergone PPVI using the EDWARDS SAPIEN-XT® valve with native RVOT.
Results: Five-teen patients (57% female, mean age 23 ± 10 years (range 12 to 46 years) were identified. Primary underlying diagnosis was tetralogy of Fallot (n = 13), Double outlet right ventricle (n = 1) and pulmonary stenosis (n = 1). Procedures were successful in all of the cases. In 3 cases (20%) pre-stenting was performed during the same procedure, and 6 or 10 weeks earlier in the rest of the cases. Among earlier stented patients, two cases had a second stent before PPVI because of stent fracture during the same procedure. Valve sizes were 26 mm (n = 2) and 29 mm (n = 13). Complications: one patient had moderate tricuspid regurgitation due to the procedure. There were no deaths during a median follow-up of 8.2 months (range 1 to 24 months). Valve function was preserved in all of the patients during follow-up.
Conclusions: The Edwards EDWARDS SAPIEN-XT® valve may be an alternative for patients with native large RVOT.

P2197 - CARDIAC CATHETERIZATION AND ANGIOGRAPHY IN THE NEWBORN PERIOD IN A SINGLE PEDIATRIC CARDIAC SURGERY CENTER

Alper Guzeltas[1], Gulhan Tunca Sahin[1], Ibrahim Cansaran Tanidir[1], Hasan Candas Kafali[1], Taner Kasar[1], Erkut Ozturk[1], Selman Gokalp[1], Akin Topkarci[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Anesthesia, Istanbul-Turkey[2]

Background: Nowadays, increasing number of diagnostic and interventional cardiac catheterization procedures can be performed during childhood even in the newborn period. Catheterization indications are usually different during newborn period because newborn patients are more prone to severe complications. We aimed to evaluate cardiac catheterization and angiography results and indications during newborn period.
Materials and Methods: Cardiac catheterization data were collected prospectively under Filemaker® program. Data of the newborn patients were retrospectively reviewed. Between January 2012 and November 2016, 2422 patients underwent cardiac catheterization, among them; 218 (9%) were newborn patients.
Results: One-hundred-twenty-five patients (57%) were male. The median age at cardiac catheterization was 7 days (1-30 days) and the median weight was 3 kg (1.8-4.2 kg). Diagnostic procedures were performed in 30 (14%) and interventional procedures were performed in 86% (n = 188) patients. Among interventional procedures stenting ductus arteriosus (n = 92), balloon pulmonary valvuloplasty (n = 35), balloon aortic valvuloplasty (n = 22), and balloon atrial septostomy/septoplasty were the most common procedures. Diagnostic cardiac catheterization revealed new or different anatomic information then echocardiography and cardiac CT in 6 patient. Median procedure time was 30 minutes (range 10-180 minutes), mean fluoroscopy time was 14.6 minutes (range 0-50 minutes). Mild to moderate complications (rhythm problems, femoral arterial spasm, respiratory/air way problems and bleeding) were observed in 40 patients (18%). Severe complications (cardiac tamponade in 3, and dead in 3) occurred in 6 patients (2.7%). Four patients underwent urgent surgical procedure.
Conclusions: Interventional procedures are more common during newborn period as an alternative for surgery or ameliorate the patient's condition before surgery. Surgery team should be aware of the patients undergoing interventional cardiac catheterization procedures in case of urgent surgical assistance requirement.

P2199 - THE HEMODYNAMIC EVALUATION OF SINGLE VENTRICLE PATIENTS WITH PULMONARY BANDING BEFORE BIDIRECTIONAL CAVOPULMONARY ANASTOMOSIS SINGLE CENTER EXPERIENCE

Hasan Candas Kafali, *Ibrahim Cansaran Tanidir, Erkut Ozturk, Gulhan Tunca Sahin, Alper Guzeltas*
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey

Background: Our aim is to determine the risk factors for bidirectional cavopulmonary anastomosis (BCPA) in single ventricle patients with pulmonary banding.
Patients and Methods: 173 single ventricle patients who underwent diagnostic cardiac catheterization before BCPA were found at the hospital database search between January 2009 and December 2016. Out of 173 patients 34 patients who had pulmonary banding previously were found. The patient group was divided into 2 subgroups in accordance with their BCPA suitability at diagnostic cardiac catheterization. The data was analyzed to identify the risk factors of patients who were found unsuitable for BCPA.
Results: Twenty-five patients had banding of the main pulmonary artery (%74, MPAB), and 9 patients had bilateral pulmonary artery banding (%26, BPAB). All BPAB patients had concomittant aortic arch surgery, and 5 patients in total from both groups had atrial septectomy. There were no correlation between BCPA suitability and age at banding, age at diagnostic catheterization, ratio of pulmonary artery to aortic pressure (PAB/AOP) during banding, type of congenital heart defect, concomittant surgeries, type of banding (MPAB vs. BPAB). According to the method used to adjust band tightness (Trussler's formula vs. Adjustment just according to the pulmonary artery pressure and systemic O2 saturation), although not statistically significant the second method values was smaller in unsuitable patients. A positive correlation, between the age at catheterization and the PAP/AOP ratio for adjustment during banding was found.
Conclusion: Although older age at banding was reported as a risk factor in previous studies, no significant risk factors determined for BCPA suitability in the present study.

P2206 - TRANSCATHETER CLOSURE OF CORONARY FISTULAS EVENT FREE SURVIVAL AND SIZE OF THE FEEDING CORONARY ARTERY

Wolfgang Radtke[1], *Varsha Bandisode[2], Takeshi Tsuda[1]*
Nemours Cardiac Center, Cardiology, Wilmington, DE-United States[1]; Musc, Cardiology, Charleston, SC-United States[2]

Background: During followup after transcatheter closure of coronary fistulas, ischemic events appear to occur more frequently after fistula closure at older age. It has been inferred that earlier closure may ameliorate the risk of such late complications. Supporting evidence for an underlying mechanism is lacking.
Methods: We performed a retrospective review of our experience with transcatheter closure of coronary fistulas during infancy and childhood with emphasis on event-free survival and size change of the feeding coronary artery. Fourteen patients underwent transcatheter closure of coronary fistulas at age 10 days to 18 years (weight 3.6-64.8 kg). The fistula originated from the right coronary in 5, from the left in 7, and from both in 2. There were no major procedural complications. Followup ranged from 1 month to 18 years.
Results: There were no ischemic events during followup. Recanalization of the fistula occurred in 1 patient and was successfully occluded in a second procedure. At the time of the procedure, the feeding coronary artery measured 3.2-9.0 mm in diameter by angiography and 3.6-8.3 mm by echocardiography. At latest followup, the echocardiographic diameter of the former feeding coronary measured 3.3-8.2 mm, suggesting only minimal regression in the size of the feeding vessel. The patient with recanalization had an increase in the size of the feeding coronary from 7.0 to 8.5 mm over 3 years. Our findings suggest that there is little regression in the size of the feeding coronary during followup but closure of the coronary fistula appears to prevent a size increase.
Conclusion: The benefit of coronary fistula closure at early age may be prevention of further coronary dilatation and allowing young patients to grow into the size of their feeding coronary vessel thus decreasing the risk of thrombotic events.

P2261 - AN AUDIT OF BALLOON AORTIC VALVOTOMY IN NEONATES WITH SEVERE AORTIC STENOSIS

Mani Ram Krishna Singaravelu, *Jonathan Merivs, Philip Roberts, Gary Sholler*
Children, Paediatric Cardiology, Westmead-Australia

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: There is no consensus among the international pediatric cardiac community about the optimal management of neonatal aortic stenosis. The choice of per-cutaneous versus surgical valvuloplasty remains one of an institutional preference. We reviewed the instituitional experience with neonatal balloon aortic valvuloplasty over a period of 6 years.
Methods: This was a retrospective case record analysis of all neonates who underwent a balloon aortic valvuloplasty at The Children's Hospital at Westmead from January 2011-November 2016.
Results: During the study period, 26 neonates underwent balloon aortic valvuloplasty. The median age at intervention was 4 days and the mean weight was 3.2 kg. 3 babies had moderate ventricular dysfunction and 6 had severe ventricular dysfunction. The valve morphology was bicuspid in 13 and unicuspid in 11. The median valve annulus was 6 mm (4.4-7.5 mm). The mean peak-to-peak gradient on cardiac catheterization was 52.5 mm Hg. Post procedure there was no or trivial aortic regurgitation in 10 patients, mild in 10 patients and moderate to severe in 6 patients. A higher balloon diameter to annulus ratio was associated with severe regurgitation ($P < 0.05$). There were 3 procedural complications. 1 neonate had an external iliac dissection and pulse loss that was managed conservatively and 2 suffered a peri-procedure cardiac arrest requiring resuscitation and extra-corporeal support. There were 16 re-interventions (11 in the same admission) with a median time to re-intervention of 21 days. There were 3 deaths in the group all of which were primarily attributed to the cardiac condition. There were no significant predictors for death and re-intervention in the group.
Conclusion: Balloon aortic valvotomy is a reasonable first line management for neonates with aortic stenosis. A high balloon diameter to annulus ratio is associated with an increased risk of significant aortic regurgitation.

P2262 - TRANSCATHETER CLOSURE IN PATIENTS WITH LARGE PATENT DUCTUS ARTERIOSUS AND MODERATE TO SEVERE PULMONARY HYPERTENSION A FOUR YEAR EXPERIENCE FROM NATIONAL REFERRAL CENTER IN INDONESIA

Radityo Prakoso[1], Rony Mario Candrasatria[2], Poppy Soerwianti Roebiono[2], Indriwanto Sakidjan Atmosudigdo[2], Anna Ulfah Rahajoe[2], Oktavia Lilyasari[2], Yovie Kurniawati[2], Ganesja Moelia Harimurti[2]
Faculty of Medicine Universitas Indonesia/National Cardiovascular Center Harapan Kita, Cardiology and Vascular Medicine, Jakarta Barat-Indonesia[1]; Faculty of Medicine Universitas Indonesia/National Cardiovascular Center Harapan Kita, Department Cardiology and Vascular Medicine, Jakarta Barat-Indonesia[2]

Background: Trans-catheter closure has become a preferred procedure as compared to surgical ligation for the patent ductus arteriosus (PDA). However in large PDA with moderate to severe pulmonary hypertension, the studies are limited. This study aims to evaluate the efficacy and complications of this procedure.
Methods: Retrospective study has been conducted from January 2013 until December 2016 in National Cardiovascular Center Harapan Kita, Jakarta-Indonesia. Thirty three patients underwent trans-catheter closure. The inclusion criteria were PDA with diameter ≥8mm with recorded moderate to severe pulmonary hypertension mean pulmonary arterial pressure (mPAP) ≥ 40 mmHg by right heart catheterization). The results after procedure were observed clinically and by echocardiography.
Results: Median age was 19 years old (3-47 years old). Mean duct size was 9.8 (8.0-20)mm and with average mPAP was 58.7 ± 8.1 mmHg. There was no cardiac death. During the procedure, there was one case of—— device dislodge which underwent surgical ligation afterwards. Initial residual PDA before discharge was 60.6% which all comprises of minimum centrally residual. Upon follow up from one week to four months, no residual PDA was detected. A patient developed AV fistula after the procedure and underwent uneventful surgical ligation afterwards. The median length of stay in hospital was 3 (2-9) days.
Conclusions: Trans-catheter closure in large PDA with moderate to severe pulmonary hypertension was effective with minimum complication.

P2265 - SHORT TERM RESULTS OF PERCUTANEOUS BALLOON PULMONARY VALVULOPLASTY IN PULMONARY VALVE STENOSIS SINGLE CENTER EXPERIENCE

Rony Candrasatria[1], Radityo Prakoso[1], Poppy Roebiono[1], Anna Rahajoe[1], Indriwanto Sakidjan[1], Oktavia Lilyasari[1], Yovie Kurniawati[1], Ganesja Harimurti[2]
University of Indonesia-National Cardiovascular Center Harapan Kita, Cardiology, Jakarta-Indonesia[1]; University of Indonesia, Cardiology, Jakarta-Indonesia[2]

Background: Percutaneous balloon pulmonary valvuloplasty (BPV) is the preferred interventional procedure for pulmonary valve (PS). The aim of this study was to evaluate the short-term efficacy of this procedure, from infant to adult, in our center.
Methods: This study included 62 patients with PS underwent BPV between January 2013 and December 2015 in National Cardiovascular Center Harapan Kita, Jakarta, Indonesia. Short-term efficacy such as residual trans-valvular gradient, pulmonary regurgitation, and complications were evaluated.
Results: Median age was 5 years old (range 1 month-40 years old). Median trans-pulmonary gradient before BPV, measured during the procedure, was 71 (range: 28-128) mmHg and 28.5 (range: 8-91) mmHg immediately after ($p < 0.001$). There was no cardiac death. Four patients developed acute limb ischemia, one patient developed total AV block and one patient developed acute pulmonary edema. Mild pulmonary regurgitation was observed in 33.9% and moderate pulmonary regurgitation occurred in 6.5% during one week follow after the procedure
Conclusions: Percutaneous balloon pulmonary valvuloplasty is an effective procedure in the treatment of pulmonary valve stenosis with good short-term results in our center.
Keywords: Pulmonary stenosis, balloon pulmonary valvuloplasty, short-term results

P2271 - BALLOON ATRIAL SEPTOSTOMY GUIDED BY ECHOCARDIOGRAPHY AT NATIONAL CARDIOVASCULAR CENTER HARAPAN KITA JAKARTA INDONESIA

Wendy Saragih, Radityo Prakoso, Rony Candrasatria, Poppy Roebiono, Indriwanto Sakidjan, Yovie Kurniawati, Oktavia Lilyasari, Anna Rahajoe, Ganesja Harimurti
Universitas Indonesia, Cardiology and Vascular Medicine, Jakarta-Indonesia

Background: Traditionally, balloon atrial septostomy (BAS) was carried out in catheterization laboratories assisted by fluoroscopy. During the 80 s, people found the advantages of echocardiography guiding during this procedure and performed at neonatal intensive care unit.
Methods: Subjects were all patients who underwent BAS at National Cardiovascular Center Harapan Kita Hospital during 2013 until 2015. The procedure was carried out either in the catheterization laboratory assited by fluoroscopy or in the intensive care unit guided by echocardiography.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: There were 40 patients underwent BAS, but 7 patients were excluded due to lack of data. The median age during the procedure was 38 (range 1 to 433) days old. Twenty (60%) patients were diagnosed with transposition of the great arteries with intact ventricular septum. The remainder of patients was tricuspid atresia, pulmonary atresia with intact ventricular septum, and hypoplastic left heart syndrome. There were 8 patients (group A) who underwent BAS at catheterization laboratory and 25 patients (group B) at intensive care unit. No intra-procedural mortality was documented. There was no significant difference found between the 2 groups in age and hospital length of stay (90.7 + /- 159.9 vs. 19.8 + /- 27.3, p = 0.72, and 21.8 + /- 8.8 vs. 29.8 + /- 12.2, p = 0.13, respectively). No statistically difference was also found between the 2 groups in the difference of oxygen saturation level pre and post-procedure and the difference of inter-atrial septum defect diameter pre and post-procedure (30.5 + /- 23.3 vs. 29.7 + /- 14.7, p = 0.91, 6.0 + /- 1.5 vs. 5.8 + /- 1.7, p = 0.88, respectively).
Conclusion: Balloon atrial septostomy performed in the intensive care unit guided by echocardiography gives the same effectiveness and results compared to the one performed in the catheterization laboratory guided by fluoroscopy. This is very important to minimize the cost in developing country such as Indonesia with economic issues.

P2275 - NEW PERSPECTIVES IN CARDIAC SURGERY THE VIRTUAL VENTRICLE AND THE MOLECULAR CARDIAC SURGERY

Athos Capuani
Private Institution, Cardiothoracic Surgery, Carrara-Italy

Purpose: Congenital Heart Surgery in complex malformations still carries high risk and poor outcome. Is there any new treatment on the light of the modern tools offered by the molecular biology?
Methods: We anatomically assessed the hypothesis that the cardiac ventriculo-arterial malformations in any morphological settings are sequential stages of the same embryogenetic and teratological process at ventricular level: the malrotation of the Trabecula Septomarginalis (TSM Leonardo's cord, Virtual Ventricle). We reviewed the current tools offered by the Molecular Biology with the enrichment strategies to amplify the targeted DNA and the potential of CRISPR/Cas9 technique in Congenital Heart malformations.
Results: 1- The TSM on the normal V shape or variants follows the development of the right ventricle what we refere as Virtual Ventricle. Te sequential TSM malrotation is an anatomical teratological continuum (Swalbe 1906) what we propose as Human Model for investigating the developing heart. 2- Each cardiac phenotype has a specific molecular expression and the CRISPR/Cas9 represent a very promising technique for interfering with the ongoing cardiogenesis.
Conclusions: The TSM malrotation model and the new techniques of molecular biology open to the possibility of not invasive early diagnosis in CHD and consequent molecular treatments during pregnancy what we refer as Molecular Cardiac Surgery.

P2277 - TRANSCATHETER CLOSURE OF VERY LARGE PATENT DUCTUS AARTERIOSUS (>1.0 CM) IN CHILDREN

Khin Maung Oo[1], Do Nguyen Tin[2], Woraken Promphan[3], Nakanishi Toshio[4], Hideshi Tomita[5]
Yankin Children Hospital, Pediatric Cardiology Department, Yangon-Burma[1]; Children Hospital 1, Pediatric Cardiology Department, Ho Chi Minh-Vietnam[2]; Queen Sirikit 's Children Hospital, Pediatric Cardiology Department, Bangkok-Thailand[3]; Tokyo Women's Hospital, Pediatric Cardiology Department, Tokyo-Japan[4]; Yokohama University Hospital, Pediatric Cardiology Department, Ypkohama-Japan[5]

Background: Transcatheter treatment of very large PDA especially associated with pulmonary hypertension is challenging. Large PDA can associate with severe pulmonary hypertension and occlusion may result in hypertensive crisis, device embolization, aortic and left pulmonary artery obstruction and residual shunts.
Material and Methods: From August 2015 to July 2016, total 123 children with PDA were underwent transcatheter closure in Cardiac Medical Ward, Yankin Children Hospital, Yangon, Myanmar. Among these, seven patients, aged 7–13 years, with very large PDA and systemic or near systemic pulmonary arterial pressure were included.
Results: Successful device delivery and complete closure occurred in all patients (100% occlusion rate). Pulmonary arterial pressures were decreased significantly after closure. Follow-up evaluations

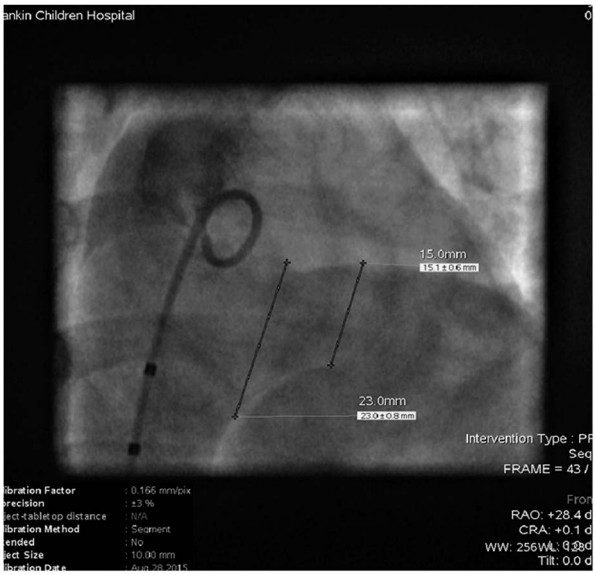

Figure 1.

Figure 2.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

were made at 24 hours and 1, 6 months after closure. There were no complications.
Conclusions: Transcatheter Closure method is effective and successful in very large PDA associated with high pulmonary arterial pressure. Careful selection of device size and type is essential to avoid complications.

P2282 - Y STENTING IN COMPLEX PULMONARY ARTERY BIFURCATION STENOSIS

Maartje Conijn, Gregor Krings, Mirella Molenschot, Hans Breur
Wilhelmina Kinderziekenhuis (WKZ), Pediatric Cardiology, Utrecht-The Netherlands

Background: In complex pulmonary artery bifurcation stenosis (PBS) the distal pulmonary artery (PA) as well as the right and left PA ostia are involved. Literature on the effectiveness of different interventional strategies for PBS treatment is limited. We report on 11 children who were treated for complex PBS using the Y-stenting technique. Procedure data and long-term outcomes were analyzed.
Methods and Results: A stent is placed traversing the MPA to one PA branch. The telescope- and anchor technique are used to obtain access to the contralateral PA. By balloon dilatation the stent struts are opened after which a second stent is advanced through the stent struts into the contralateral PA. The second stent is placed with a 3-4 mm overlap with the MPA stent (clinched) or in the PA ostium (non-clinched). 11 Y-stenting procedures were performed, 9 in the main pulmonary bifurcation and 2 in the PA periphery. Control angiography showed unrestricted blood flow after all procedures. No major or minor adverse events were seen after stent implantation. 6 children needed re-intervention due to restenosis during median follow-up of 39 months. 4 of them received non-clinched bifurcation stents during the initial procedure.
Conclusion: Y-stenting was a safe and effective treatment in 11 children with complex PBS. It creates an artificial bifurcation close to the natural anatomy. Stenting sequence, the right materials and the telescope- and anchor technique are essential for a successful procedure. Due to high rates of restenosis in non-clinched stents, bifurcating stents should always be clinched.

P2303 - OUTCOME OF EMERGENCY INTERVENTIONS IN SICK NEONATES

Ramakrishnan Sivasubramanian, Saurabh Gupta, Birdivender Singh, Rajnish Juneja, Shyam Kothari, Anita Saxena
AIIMS, Cardiology, New Delhi-India

Introduction: The outcome of emergency interventions in sick neonates is not well established.
Methods: We retrospectively reviewed the records of sick neonates undergoing emergency cardiac intervention at our institute over a 7 year period. Neonates needing resuscitation, inotropes, prostaglandin or ventilatory support prior to the procedure were included. Neonates needing a procedure during non-working time of catheterization laboratory were also included.
Results: We identified 161 neonates who satisfied the inclusion and exclusion criteria for our study. Majority of neonates underwent an emergency balloon atrial septostomy (62.1%) with transposition of great arteries as the underlying lesion. Mean age of neonates in our study was around 10 days with mean change in saturation of 24% with BAS. 28 neonates needed an emergency aortic valve balloon dilatation, 11 needed a pulmonary valve balloon dilatation and 5 needed emergency coarctation of aorta dilatation. In all neonates AVBD or PVBD resulted in significant improvement in ventricular function. There were seven deaths out of 161 interventions done (3 in BAS, one each in AVBD, PV perforation, coarctation dilation, and PDA stenting). One of these neonates had B/L renal vein thrombosis with acute kidney injury and anuria. The local complication rate was also less than 5%.
Conclusion: Even emergency neonatal interventions are effective and rewarding in sicker neonates. However, they are associated with significant challenges. Hence, fetal diagnosis or early neonatal diagnosis and early referral should be emphasized.

P2308 - ATRIAL FLOW REGULATOR FOR LEFT HEART FAILURE A PILOT STUDY

Ramya Shri Chandrasekaran, Sudipta Bhattacharjya, Rajesh Kumar Ramasamy, Sreeja Pavithran, Sivakumar Kothandam
Madras Medical Mission, Pediatric Cardiology, Chennai-India

Background: Left ventricular diastolic dysfunction is commonly characterized by elevated left atrial pressure. Our limited study suggested that the reduction of LAP by creating a left-to-right interatrial shunt using a Atrial flow regulator resulted in significant reduction of LA pressure. This device helps in improving exercise tolerance and protecting from episodes of acute pulmonary edema.
Materials and Methods: our study includes 3 patients. One was a 67 yrs old male hypertensive post CABG with diastolic heart failure in class III NYHA,with episodes of Acute pulmonary edema. Second patient was a 13 yrs old girl with Restrictive cardiomyopathy in class III NYHA. Third patient was 35 yrs old DORV VSD, severe PAH, congenital MS with both precapillary and postcapillary hypertension in class III NYHA.
Results: First patient had a basal LA mean of 21, RA mean 8, he underwent interatrial device with AFR 8/5 mm device his post LA mean was 7. Second patient with restrictive cardiomyopathy had a LA pressure of 20 and reduced to 11 after 6/5 mm AFR device. Third patient had a RA mean of 13 mmhg and Basal LA mean was 17 mmhg, post AFR with a 10/5 mm device his RA and LA mean was 13mmhg Post procedure all the 3 patients had significant improvement of their symptoms. 2 patients are in class I NYHA, the 3 patient with severe PAH is in class II NYHA.
Conclusion: AFR regulates the rising LA pressures, thus improving exercise tolerance and protecting from episodes of acute

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

pulmonary edema. This might lead to a reduction of hospitalizations, increase of quality of life and potentially diminish mortality in patients with diastolic heart failure. But further studies are needed to establish its effectiveness in long term follow up.

P2316 - COMBINED SEMILUNAR VALVE STENOSIS IN NEWBORN

Isabel Barranco Fernández, Ana Caro Barri, Marta Flores Fernández, Alberto Mendoza Soto, Rebeca Sánchez Salmador, Belén Toral Vázquez, Estíbaliz Valdeolmillos Padrino, Marta Yagüe Martín
Hospital Universitario 12 De Octubre, Instituto Pediátrico Del Corazón, Madrid-Spain

Background: Combined pulmonary and aortic valve stenosis is an extremely rare congenital heart anomaly. Neonates with this combination often present a life-threatening situation and require urgent treatment. The management approach for this cardiopathy is not well defined though percutaneous valvuloplasty seems to be the better option.
Case Report: We present the case of a newborn prenatally diagnosed with moderate pulmonary valve stenosis with intact ventricular septum. Postnatal echocardiographic assessment confirmed the presence of pulmonary valve stenosis and revealed the existence of associated aortic valve stenosis. Infusions of prostaglandin E1 and respiratory support with noninvasive mechanical ventilation were started immediately after birth. Patient remained stable and maintained a normal cardiac output. The intervention showed a severe combined semilunar valve stenosis and, accordingly, bilateral balloon valvuloplasty was performed. The procedure was successful. Pulmonary valvuloplasty was first performed, significantly reducing RV-PA gradient (from 77 to 25 mmHg) and slightly increasing LV-AO gradient (48 to 61 mmHg). Subsequent aortic valvuloplasty reduced LV-AO gradient to 27 mmHg. Patient was maintained in observation care status for 4 days and remained hemodynamically stable. Mild combined valve stenosis persisted as residual lesion.
Conclusion: Isolated pulmonary valve stenosis and isolated aortic valve stenosis are relatively common congenital heart diseases. However, combination of right and left ventricular outflow tracts obstruction is a very infrequent condition which warrants an early intervention. Very few cases are reported and there is not a universal agreement in the available literature on the approach to managing these patients. Nonetheless, the interventional transcutaneous approach is probably the best treatment option. Sequencing is controversial but it is probably better to start with the most affected valve (in our case the pulmonary one) considering that an increase of the transvalvular aortic gradient is very likely after the dilatation. It would be desirable to develop guidelines for sequential interventional therapy for this lesion.

P2319 - TRANSCATHETER CLOSURE OF MULTIPLE ATRIAL SEPTAL DEFECTS OUR EXPERIENCE

Ramya Shri Chandrasekaran, Bijesh Viswambaran, Sreeja Pavithran, Vimala Jesudian, Sivakumar Kothandam
Madras Medical Mission, Pediatric Cardiology, Chennai-India

Background: Transcatheter closure of multiple secundum ASD is technically challenging. We present our experience with double ASD device closures.
Materials and Methods: From May 2014- June 2016, 16 patients underwent transcatheter closure of multiple ASD defects in our Centre. Double device was considered only if the distance between two defects were more than 6 mm. Patients age ranged from 11 to 57 yrs with a mean of 37. The weight ranged between 30 kgs to 80 kgs with a mean of 58 kgs. The smallest ASD measured in TEE was 5mm and largest was 32 mm. Usually the two devices were positioned as a sandwich if both are larger devices but sometimes if both the devices are smaller the devices were interlaced .
Results: Totally 32 devices were deployed in 16 patients. The mean diameters of the larger and smaller defects were 30 and 9 mm. Balloon sizing was used in 10 patients. In 6 patients device was chosen only based on our TEE. The mean larger and smaller device diameters were 32 and 11 mm,.The largest device in a single patient was 32 mm and 20 mm, and smallest being 12 mm and 14mm.The mean Pre procedural PA pressure was 25mmhg and post mean PA pressure was 19 mmhg. Out of 14 patients 4 were snare assisted. Post procedure 12 patients had complete closure and 4 had residual shunts. At 1 month followup 2 patients had residual shunts, and at 6 months follow up none of them had residual shunts. All the patients were followed up on dual antiplatlets for 1 year.
Conclusion: Transcatheter closure of multiple ASD defects is a safe and reproducible technique. However appropriate patient selection and preprocedure TEE imaging play a vital role for better clinical outcome

P2329 - TRANSCATHETER VENTRICULAR SEPTAL DEFECT CLOSURE WITH PLATINUM COATED NITINOL DEVICE

Pornthep Lertsapcharoen[1], Suphot Srimahachota[2], Vidhavas La-Orkhun[1], Kanyalak Vithessonthi[1], Apichai Khongphatthanayothin[1]
Chulalongkorn University, Pediatrics, Bangkok-Thailand[1]; Chulalongkorn University, Medicine, Bangkok-Thailand[2]

Background: Transcatheter closure of perimembranous ventricular septal defect (pmVSD) remains a challenging issue due to the potential risk of heart block. The heart block mechanism is possible from too much stenting or radial force from the central waist of the device. A platinum-coated nitinol VSD device (Cocoon VSD device by Vascular Innovations Co Ltd, Thailand) was designed with the concept of soft central waist to minimize the risk of heart block.
Materials and Methods: During September 2011 to August 2016, 30 cases of pmVSD underwent transcatheter closure with Cocoon VSD device. The patients' ages ranged from 2 to 36 years, median of 7.5 years; and weights ranged from 10 to 86 kg, median of 30.2 kg. All patients had evidence of left ventricular volume overload and the Qp:Qs ranged from 1.3 to 2.8 with the mean of 1.8 + /-0.4.
Results: There were 28 successful device implantation cases with 2 failure cases. The 2 failure cases had surgical closure. Of the 28 successful cases, 4 cases developed hemolysis. Two hemolysis cases had device removal and VSD closure by surgery. Hemolysis resolved spontaneously in one case and after implantation of an additional ductal occluder in the other case. The complete closure rate was 57.7, 80.8 and 100% at 1 day, 3 month and 1 year, respectively. Within the mean follow-up period of 32.7 + /-11.8 months, there was no heart block in any cases. The hemolysis cases looked like to have too small size for the pmVSD diameter. The recommended size of the device should be at least 2 mm larger than that of left-ventricular-end pmVSD diameter.
Conclusions: Transcatheter pmVSD closure with platinum-coated nitinol device is safe and has a good closure result. With the property of soft central waist, it should minimize the risk of heart block.

P2338 - HYBRID LARGE STENT IMPLANTATION FOR AORTIC RECOARCTATION IN AN INFANT

Grace Van Leeuwen Bichara[1], Salvador Cristóvão[1], Luciana Fonseca Da Silva[2], José Pedro Da Silva[2]
Beneficência Portuguesa De Sp, Interventional Pediatric Cardiology, São Paulo-Brazil[1]; Beneficência Portuguesa De Sp, Pediatric Cardiac Surgery, São Paulo-Brazil[2]

Background/Hypotesis: Stent implantation is widely used to treat aortic coarctation. However, in small patients this procedure is limited by small size of peripheral arteries and growth concerns.
Materials and Methods: Report a novel hybrid procedure for implantation of large balloon expandable stent in an infant performed via right axillary thoracotomy
Results: A 9 kg 6-month-old infant with aortic coarctation underwent surgical repair at the age of 15-days and 45-days but remained with 60 mmHg transaortic gradient. He had had balloon aortoplasty but remained with transaortic pressure gradient (decresead from 60 to 35 mmHg). It was planned to use a stent that could be dilatable to adult size, by multiple dilatations during life. The novel hybrid procedure was performed in the cardiac catheterization laboratory under general anesthesia. The ascending aorta was achieved through a right axillary minithoracotomy, with a 3 cm horizontal skin incision between the anterior and posterior axillary lines, with a spare muscle technique, entering the chest in the third intercostal space. The patient received 100UI/Kg of heparin. A double suture purse string was done using a 5.0 polypropylene and a 7 F sheath was located into the ascending aorta under direct vision. Stent implantation was performed using a PALMAZ GENESIS 1910 stent mounted on 7 × 20mm POWERFLEX balloon. The stenosis waist disappeared at 6 atm and the pressure-gradient dropped from 60 to 0 mmHg. Good immediate angiographic, clinical, and hemodynamic results were obtained. There were no procedural complications. The patient was doing well at the 6-month follow-up. The transaortic pressure gradient remained low (15 mmHg by echo). Reintervention has not been required so far.
Conclusion: Large stent implantation through the ascending aorta via right axillary minithoracotomy, in a hybrid approach, to treat aortic recoarctation, was effective, enabling application of a large sheath and the implant of a re-expandable stent.

P2345 - CATHCHAT AT RED CROSS CHILDREN'S HOSPITAL (RCWMCH) A NOVEL LIVE ONLINE TEACHING AND LEARNING PLATFORM FOR INTERVENTIONAL PAEDIATRIC CARDIAC CATHETERISATION

Rik De Decker[1], Jerome Corns[2], Andre Gouws[3], John Lawrenson[4]
University of Cape Town and Red Cross Children's Hospital, Paediatric Cardiology, Cape Town-South Africa[1]; University of Cape Town, It, Faculty of Health Sciences, Cape Town-South Africa[2]; Private Company, Kathea Communication Solutions, Cape Town-South Africa[3]; University of Stellenbosch and Tygerberg Children's Hospital, Paediatric Cardiology, Cape Town-South Africa[4]

Background: In Africa, paediatric cardiologists receive training in general cardiac catheterisation, but interventional skills can usually only be gained by undergoing fellowship training at overseas centres, or attending costly international interventional congresses. Consequently, there is a shortage of fully trained interventional paediatric cardiologists in Africa and only limited opportunities for such training exist. The incidence of paediatric heart disease is equal to, or may exceed that of developed countries and the majority of affected children will receive no treatment. There is a shortage of cardiac catheterisation laboratories in Africa, and an even greater, dire shortage of facilities for paediatric congenital heart surgery. Interventional cardiac catheterisation, however, holds promise to begin to address the epidemiological need, since surgical or intensive care facilities are usually not required for the interventional management of common, "simpler" congenital heart defects, e.g. ASDs, PDAs, and pulmonary stenosis.
Methods: At the RCWMCH, we have developed CATHCHAT, a system whereby interventional cardiac catheterisation procedures can be streamed live via the Internet. Local and international audiences log in to witness the procedures in real time and are able to interact directly with the operators in the cath lab. The online audience is able to follow the procedure in high-definition, step-by-step detail.
Results: CATHCHAT has been growing steadily over the past 3 years, and has broadcast more than 60 live cases to date. All paediatric cardiac centres in South Africa, as well as centres in Africa, Australia, India and Europe have viewed CATHCHAT, often simultaneously. The power of CATHCHAT is that renowned interventional experts can be invited to log in and advise the operators live while the procedure is performed. The logged-in audience may then witness the procedure, and learn from this interaction.
Conclusion: CATCHAT will stimulate the growth of paediatric interventional cardiac catheterisation capacity in Africa.

P2346 - COMPLETE HEART BLOCK FOLLOWING TRANSCATHETER CLOSURE OF PERIMEMBRANOUS VSD USING AMPLATZER DUCT OCCLUDER II

Sanjiban Ghosh, Anuradha Sridhar, Muthukumaran Sivaprakasam
Apollo Children's Hospital, Pediatric Cardiology, Chennai-India

Trasnscatheter closure by device is now a well-established method of closure for perimembranous ventricular septal defect (PmVSD).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

One of the most serious complications of VSD device closure is complete atrioventricular block which has been reported in 3-18% is various studies following VSD device closure. Amplatzar Duct Occluder II (ADO-II) device is now commonly being used for closure of small to moderate sized PmVSD. Complete heart block has not been reported with ADO-II device. We are reporting 2 cases of complete heart block following transcatheter closure of PmVSD using ADO-II device where sinus rhythm was established following early surgical removal of the device. Case1: PmVSD device closure was done with 6/4 ADO-II device for a 8-year-old girl who developed CHB within 24 hours of procedure. She was started on intravenous steroid without any effect. Subsequently she was sent for surgical removal of VSD device and surgical closure of VSD after 48 hours of steroid therapy. She regined sinus rhythm after surgical removal of the device. Case 2: PmVSD device closure was done with a 6/4 ADO-II device for a 9-year-old boy who also developed CHB within 24 hours of VSD device closure. He was also started on intravenous steroid initially without any effect and subsequently sinus rhythm was regained after surgical removal of VSD device.
So CHB, though rare, can be seen after transcatheter closure of PmVSD using ADO-II device. This may be due to mechanical rubbing of the perinodal tissue by the discs of the device. It usually manifests early, within 24 hours of procedure. Late onset CAVB is very rare and has not been seen in our experience. Oral or intravenous steroids are having doubtful role in reversal of CAVB after VSD device closure. Early surgical removal of device prevents permanent damage of AV node and can restore sinus rhythm.

P2356 - PDA CLOSURE WITH CERAFLEX OCCLUDER IS THERE ANY ADDITIONAL BENEFIT

Ahmet Celebi, Ilker Kemal Yucel, Orhan Bulut, Sevket Balli, Emine Hekim Yilmaz, Mehemt Kucuk
Dr. Siyami Ersek Hospital for Cardiology and Cardiovascular Surgery, Pediatric Cardiology, Istanbul-Turkey

Introduction: Although transcatheter closure of PDA is an established standard method, most frightening complication is protrusion of the aortic disc to the descending aorta (DAO) which may cause iatrogenic COA, especially in small children with small aorta. Ceraflex duct occluder (CDO) is a new device with similar properties with Amplatzer duct occluder (ADO). Device comes preassembled with the delivery cable by a loop connection through the holes and ready to load via the loader on the delivery cable. The loop made of surgical thread that provides the device to become flexible in 3600 directions.
Method: 21 patients underwent transcatheter closure with CDO.
Results: The median age was 1.2 years (6 months to 28 years) and weight was 9.6 kg (5.4-82). 11 patients were <1year and 11 had pulmonary hypertension. All had continuous murmur and all were type A. Narrowest PDA diameter was 4.1 ± 1.7 mm (2.2-8.2 mm). Intervention was successful in all. Final angiogram showed complete closure in 17/21 of them. Echocardiography achieved complete occlusion in all on the next day. There was no procedural complication.None of them showed evidence of stenosis at left pulmonary artery and DAO.
Discussion and Conclusion: Our results showed us CDO is a safe and efficacious in closure moderate to large PDA's whose duct morphology fit to the ADO. Its uniquely designed delivery system has an advantage in view of no applying tension to the device which provides the device in stable position and not changing the device position during and immediate after the releasing. It may give us an opportunity to be sure that the device not protrudes to the aorta after releasing, especially in infants those have small DAO.

P2361 - CORONARY BALLOON ASSISTED RETRIEVAL OF EMBOLISED VENTRICULAR SEPTAL OCCLUDER DEVICE

Vijay Bohra, Saurabh Kumar Gupta, S Ramakrishnan, Anita Saxena, Rajnish Juneja
All India Institute of Medical Sciences, Cardiology, New Delhi-India

History: An eight year old boy underwent cardiac surgery with intraventricular tunnel repair of the VSD and valve sparing Konno procedure for DORV with LVOT obstruction. Follow up echocardiogram showed multiple jets of residual VSD with largest measuring 5 mm with evidence of severe PAH. In view of sizeable VSD and significant PAH it was decided to close the largest of the residual VSD's. Device occlusion was preferred over surgical closure given the extensive patch and the PAH.
Imaging: After multiple attempts index residual VSD was crossed and 8 mm AGA muscular VSD device was deployed under fluoroscopic and TEE guidance. After confirming satisfactory position of the device on TEE, it was released. Unfortunately, approximately 15 minutes later the device embolized to RPA. Surgical retrieval was not immediately available and percutaneous retrieval was attempted. Despite multiple attempts with various catheters and usual hardware it was not possible to retrieve the device or even manipulate it into a favorable position. Thereafter, hard end of BHW coronary wire was introduced through the NITINOL mesh of the device and a 4 × 10 mm coronary balloon was placed over the wire. The coronary balloon was then inflated within the device and whole assembly was pulled across the pulmonary and the tricuspid valve up to the lower end of IVC. The device was then retrieved using bioptome through the 14 Fr sheath in right femoral vein.
Learning Point: Timely improvisation resulted in successful retrieval of embolized device in a child with difficult RVOT.

P2369 - TRANSCATHETER INTERVENTIONS AFTER GLENN ANASTOMOSIS AND FONTAN OPERATION IN PATIENTS WITH UNIVENTRICULAR HEART

Ahmet Celebi, Ilker Kemal Yucel, Orhan Bulut, Sevket Balli, Taliha Öner, Emine Hekim Yilmaz
Dr. Siyami Ersek Hospital for Cardiology and Cardiovascular Surgery, Pediatric Cardiology, Istanbul-Turkey

Introduction: We aimed to present transcatheter treatment of patients with a single ventricle physiology, experiencing low cardiac output (LCOS) or severe systemic desaturation (SSD).
Method: We retrospectively evaluated 33 patients between 2007 and 2016.
Results: The mean age was 7.6 years (6 months-21 years) and weight was 25.2 kg (6-54). The procedures were performed after a Kawashima, Glenn and Fontan surgery in 3, 12 and 18, respectively. SSD was encountered in 17. Closure of a Fontan fenestration was performed in 9. We occluded decompressing vein in 5 and pulmonary arteriovenous fistula in one. Closure of residual right SVC-atrium connection was performed in one and stent implantation to reroute the hepatic blood flow to the right lung in one, after Kawashima operation. The oxygen saturation of 79.3 8.1% increased to 92.25.6. LCOS and /or increased PA pressure was detected in the remaining 16. One was on an ECMO support. Amongst these 16, antegrade pulmonary flow (APF) was occluded using a number of devices in 7, APF was closed with the use of a covered stent, resolving associated left PA stenosis at the same time in two. Among 5 patients suffering from branch PA stenosis, 4 received stent implantation while the remaining was treated via cutting balloon angioplasty. Two separate stents were needed to treat branch PA and extracardiac conduit stenosis in one. In the patient on ECMO, fenestration was dilated with a balloon to ensure cardiac output. Fenestration was created in one. In patients with LCOS, the PA pressure decreased from mean 20.6 mmHg (15-27) to 14.9 mmHg (11-18). There was no procedural mortality. Circulatory failure regressed in all except one.
Conclusion: In the presence of LCOS or SSD, urgent catheterization should be considered. Significant PA stenosis should be treated even if there exists no pressure gradient throughout the circulation.

P2372 - ARTERIAL SEPTAL DEFECTS REPAIR IN CHILDREN BORN PREMTERM – LONG TIME FOLLOW UP

Gustaf Tanghöj[1], Estelle Naumburg[1], Petru Liuba[2]
Department of Clinical Science, Umeå University, Umeå, Sweden, Pediatrics, Östersund-Sweden[1]; Pediatric Heart Center, Skåne University Hospital Lund and Lund University, Lund, Department of Cardiology, Lund-Sweden[2]

Background and Hypothesis: One of the most common heart defects is atrial septal defect (ASD). The aim of this retrospective study was to asses long time follow up adverse events in preterm and term born children treated with ASD closure. We hypothesis increased adverse events among preterm children compared to term children due to the complex morbidity and cardiac remodelling in these children.
Material and Method: This is a retrospective cohort study including all children born in Sweden under the age of 18 years treated with percutaneous or surgical repair of ASD secundum between 2000 and 2014 at the Skåne University Hospital in Lund, Sweden. Demographic and adverse event data were retrieved from medical records and the Swedish National Birth Registry. Post-procedural complications occurring within short-term follow-up: ≤ 90 days and long-term follow-up: ≤365days was recorded and classified into minor and major events. Statistical analyses and Kaplan-Meier curve comparing differences and adverse events between preterm and term children were preformed.
Results: In total 344 children were included in the study; 269 term born children and 75 preterm born children. Preterm children were younger and lighter compared to term children at time of ASD closure. There was no difference according to method of ASD closure (device or surgical), the occurrence or the probability of occurrence of an adverse event between preterm and term children (Table 1). Further, there was no difference in

‡‡Within 365 days
Major: death, cardiac or respiratory arrest, stroke, device erosion, device embolization, permanent limb injury, emergent surgical, persitant arrhythmias, severe pericardial/pleural effusion, valvular insufficiency, vein obstruction, severe bleeding, pulmonary hypertension crisis, discharge >24 hours.
Minor: deployment malfunction, infection, minor bleeding, access site hematoma, prolonged limb paraesthesia, transient hypoxia during procedure, pericardial/pleural effusion, transient arrhythmia.

time to first event between preterm children and term children (Image1-4).
Conclusion: There is no difference in post-procedural adverse events between preterm and term born children, although the preterm born children were younger and less heavy at the time of ASD repair.

P2373 - TRANSCATHETER CLOSURE OF TUBULAR (TYPE C) PDA'S IN PATIENTS WITH PULMONARY HYPERTENSION

Ahmet Celebi, Ilker Kemal Yucel, Orhan Bulut, Sevket Balli, Taliha Oner, Gokmen Akgun
Dr. Siyami Ersek Hospital for Cardiology and Cardiovascular Surgery, Pediatric Cardiology, Istanbul-Turkey

Introduction: In this report, we will present our experience in transcatheter closure of Type C PDA's.
Method: Between 2005-2016, 898 patients underwent transcatheter PDA closure in our clinic. 41 of them had Type C PDA with pulmonary hypertension.
Results: The median age was 8 months (range 1 month to 6.5 years). The age groups were as follows: <1 year, 29/40 patients (73%); 1–2 years, 9/40 (22%) and >2 years 2/40 (5%). Median weight was 5.9 kg (range 3–15) with 53% of patients weighing less than 6 kg. The median measurements for minimal ductal diameter, length, and aortic ampulla were, 4.7 mm (3–11.7), 11 mm (4.3–24), and 7.7 mm (4–14), respectively. Pulmonary hypertension was found in all. PDA was closed with Duct occluder I (DOI) in 31, vascular plug (VP) 2 in five, VP I in two, VP4 in one, DO II in one and DO II AS in one. Procedure was successful in 37/40 (93%). Two patients sent to surgery after embolization of VP I and DOI. Significant aortic obstruction occurred before releasing the DOI device in another. Device displaced to descending aorta after 24 hours and repositioned with a bioptome in one. Occlusion rate was 100% after six month follow up. DOI slightly protrude to aortic lumen without significant obstruction in 13/31 infants. In these peak velocity at descending aorta decreased at follow up.
Conclusion: Although technically challenging, transcatheter closure of large Type C PDA especially in infants with various devices is possible. In a relatively small aorta, a larger aortic retention skirt diameter of DOI is one clinical concern; however, the somatic growth of aorta allows unimpeded aortic flows on late follow-up. In order to prevent aortic obstruction, plugs can be used to occlude the long Type C PDA especially in infants.

P2374 - TETRASOMY 5P MOSAICISM AND MULTIPLE CONGENITAL HEART DEFECTS

Shari Slyder, Abraham Groner
University of Chicago, Pediatrics, Chicago-United States

Background: Tetrasomy 5p mosaicism is a rare genetic anomaly. There is a paucity of information on the relationship of Tetrasomy 5p mosaicism and associated congenital heart defects. We report the first case of a large atrial septal defect and other associated congenital cardiac anomalies in a patient affected with Tetrasomy 5p mosaicism.
Materials and Methods: A 2 year, 9 month old female was referred by pediatric genetics for evaluation. Her mother reported that the pregnancy was complicated by polyhydramnios and the patients past medical history was complicated by failure to thrive, hypotonia and severe scoliosis. She had not previously been referred or evaluated by a pediatric cardiologist despite an extensive medical evaluation at multiple outside institutions.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: Her initial echocardiogram was significant for a large secundum atrial septal defect (ASD), moderately enlarged right atrium, moderately dilated right ventricle, tricuspid valve dysplasia, mild-moderate tricuspid valve regurgitation, estimated right ventricular systolic pressure of 50 mmHg, mitral valve dysplasia, mild mitral valve regurgitation and a small patent ductus arteriosus (PDA). A cardiac catheterization was performed and hemodynamics showed Qp/Qs = 4:1, indicating significant left to right shunting. Device closure of the ASD and PDA were not attempted because of concern for increased mitral valve regurgitation noted on a simultaneous transesophageal echocardiogram. Therefore she underwent subsequent surgical ASD patch closure and PDA ligation. Skin biopsy performed at the time of cardiac surgery was positive for Tetrasomy 5p mosaicism. The patient was discharged without any reportable concerns and continues to be followed for her tricuspid and mitral valve disease.
Conclusion: Our patient demonstrates previously unreported presence of multiple congenital heart defects in a child with Tetrasomy 5p mosaicism. If Tetrasomy 5p mosaicism is suspected the patient should be referred to a pediatric cardiologist and an echocardiogram performed.

P2376 - DIAGNOSTIC AND INTERVENTIONAL CARDIAC CATHETERIZATION IN CHILDREN SUPPORTED BY EXTRACORPOREAL MEMBRANE OXYGENATION A TEN YEAR SINGLE INSTITUTION REVIEW

Carrie Herbert[1], Jeffrey Jacobs[2], Tom Karl[2], Gary Stapleton[1]
Johns Hopkins All Childrens Hospital, Pediatric Cardiology, St Petersburg-United States[1]; Johns Hopkins All Childrens Hospital, Cardiovascular Surgery, St Petersburg-United States[2]

Background: Cardiac catheterization plays an important role in the management of children on extracorporeal membrane oxygenation (ECMO). We report our experience with diagnostic and interventional cardiac catheterization of children on ECMO.
Methods: A retrospective review of all children who underwent cardiac catheterization on ECMO at a single institution from January 1, 2007 through December 31, 2016.
Results: 41 catheterizations were performed on 35 patients (median weight 3.45 kg; range 2.0-63) within 3.1 ± 3.2 days of ECMO cannulation. 35/41 (85.3%) were performed in patients <1 year of age (21 < 1 month). 27 were performed in patients with congenital heart disease (24 within 30 days of cardiac surgery), 6 with cardiomyopathy/myocarditis, 6 post heart transplant, and 2 with non-cardiac diagnosis. 7 catheterizations revealed data that prompted surgical intervention. 28 cases had 31 interventions performed including: Transeptal puncture(3), Atrial septostomy/septoplasty (11), ASD closure(1), endomyocardial biopsy(1), Balloon angioplasty of aortic arch(1), coronary artery(1), or branch pulmonary artery(1), and stent placement in BT shunt(7), branch pulmonary arteries(4), right ventricle to pulmonary artery conduit(1), and Fontan fenestration(1). 17/35 patients survived to hospital discharge, including 3 who had heart transplant after ECMO. One patient required mediastinal exploration for bleeding. 2 patients had new onset seizures within 24 hours of catheterization, both of whom had their catheterization within 24 hours of going on ECMO. There were no other major adverse events, no vascular access complications, and no complications related to patient transport.
Conclusion: Cardiac catheterization with complex interventions can be performed safely in children supported by ECMO including smaller and post operative patients. This approach plays an important role in the diagnosis and treatment of hemodynamic and structural abnormalities in these patients.

P2381 - SAFETY AND EFFICACY OF PERCUTANEOUS CLOSURE OF PERIMEMBRANOUS VENTRICULAR SEPTAL DEFECTS IN CHILDREN IN A LIMITED RESOURCE SETTING IN SOUTH AFRICA

Marelize Bosman[1], Ebrahim Gm Hoosen[2]
Inkosi Albert Luthuli Central Hospital, University of Kwazulu Natal, Paediatric Cardiology, Durban-South Africa[1]; Inkosi Albert Luthuli Central Hospital, Paediatric Cardiology, Durban-South Africa[2]

Background/Hypothesis: Ventricular septal defect (VSD) is the most common congenital cardiac lesion. Surgical closure is the gold standard but in an isolated perimembranous ventricular septal defect (PMVSD) percutaneous closure is an attractive alternative, particularly in a limited resource setting. Our experience suggests that percutaneous closure of a perimembranous VSD, in the appropriately selected patient, is safe and effective.
Materials and methods: We performed a retrospective chart review of all children that underwent percutaneous closure of a PMVSD at Inkosi Albert Luthuli Central Hospital from October 2010 until December 2016. Patients that had percutaneous closure of any VSD other than PMVSD, including residual VSD post-surgical closure were excluded.
Results: Fourty-two patients were included in our retrospective analysis, 27 females and 15 males with a mean age of 6 years 6 months (Range: 2 years 9 months to 15 years 9 months). Mean follow up was 2 years 3 months. A total of 30 patients (71.4%) had complete closure of their defect. Eleven (26.2%) patients had a residual but haemodynamically insignificant defect and only 1 patient (2.4%) required surgical intervention due to failed percutaneous closure. Two patients had mild aortic regurgitation post procedure. Significant complications included 1 patient with moderate tricuspid regurgitation and 2 patients with device embolisation. In one of these patients, the embolised device was retrieved and replaced with a larger device. In the second patient, surgical retrieval and closure was required. No cases of heart block were recorded.
Conclusions: In our experience percutaneous closure of a perimembranous ventricular septal defect in a child appears to be safe and effective.

P2397 - HEALING OLD BROKEN HEARTS – THE EFFECT OF AGE ON THE RECOVERY FROM PERCUTANEOUS ATRIAL SEPTAL DEFECT (ASD) CLOSURE

Duarte S Martins[1], Kohta Takei[2], Yuku Saikawa[2], Isabel Menezes[1], Rui Anjos[1], Satoshi Yasukochi[2]
Hospital Sta Cruz, Pediatric Cardiology, Lisbon-Portugal[1]; Nagano Childrens Hospital, Pediatric Cardiology, Matsumoto-Japan[2]

Background: Percutaneous ASD closure is performed to both adults and children with hemodynamically significant ASDs. Right heart reverse remodeling has been demonstrated, though no study to our knowledge has looked at the differences according to age.
Materials and Methods: Retrospective study of 12 patients submitted to percutaneous ASD closure at a single center (6 <7 years and 6 >39 years). Echocardiographic 3D and strain data was acquired at fixed time points before and up to 2years after ASD closure.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Longitudinal data analysis was performed with a linear mixed effects model.
Results: At baseline there was no statistically significant difference between age groups in terms of Qp/Qs (mean 1,92) and right ventricle end-diastolic volume (RVEDV) z score (mean +3,05). A tendency towards bigger right atria (RA, mean volume z score of 1,13 vs -0,34 p 0,04) and smaller left atria (LA, mean volume z score of -2,33 vs -1,42 p 0,04) was found in the adult population, while distensibility was not different at baseline. After repair, RV reverse remodeling was observed over time in both groups (mean RVEDV at 1 year -0,96, time term p value 0,001) without significant difference, with a tendency for steady lower RV ejection fraction in the adults (p 0,06). LA distensibility was lower through time in the adult population in both volumetric (p <0,001) and speckle tracking (p < 0,001) techniques, displaying a tendency to further diminish over time (group.time interaction p value: volumetric method 0,013; speckle tracking 0,098).
Conclusion: In our dataset both children and adult patients benefited equally from ASD closure concerning RV remodeling. However, LA distensibility showed a tendency to progressive impairment in the adult population. While further studies are needed to assert the clinical implications of these findings, this raises concerns about triggering of atrial arrhythmias.

P2402 - IMPLANTATION OF STENTS FOR POSTSURGICAL RECOARCTATION OF THE AORTA IN ADOLESCENTS AND ADULTS

Luiza Zalewska[1], Jacek Bialkowski[1], Malgorzata Szkutnik[1], Roland Fiszer[1], Szymon Pawlak[2], Beata Chodor[1]

Background: Results of stent implantation (SI) of postsurgical recoarctation of the aorta (ReCoA) are not frequently published. This study sought to retrospectively evaluate results of SI in ReCoA in older children and adults.
Material and Methods: Twenty-eight SI were performed on 26 ReCoA patients with a median age of 23 (10-65) years. Dependent upon availability, the following stents were applied - Palmaz, Cheatham Platinum (CP), Andrastents XL/XXL(AS), Covered CP (CVCP) stents and selfexpanding stents (Smart). Generally high pressure balloons were applied to dilate stents.
Results: The procedure was effective in 20/26 patients (77,7%). The mean gradient reduced from 40,5 + /- 18,7 mmHg to 13,1 + /- 12,1 mm Hg (p < 0,05) and the stenosed segment increased from 7,5 + /- 3.02 mm to 13,1 + /- 3,32 mm (p < 0,05). In 6 cases (including a patient treated with a Smart stent) transaortic gradient after SI remained >20 mm Hg (stiff postsurgical lesion). For one patient (40 year old male), an acute dissection of the aorta occurred during balloon predilatation. Immediate CVCP implantation resolved this problem. Two more CVCP were used – one to close a small aortic aneurysm which appeared 5 years after a Palmaz SI and one other to stabilize a broken CP bare metal stent. There were no deaths nor the aortic dissection during follow-up and most patients were able to reduce or suspend their medication for systemic hypertension.
Conclusions: Endovascular stenting of recoarctation of the aorta in adults and adolescents appears to be good a method of treatment in experienced hands. However, for some patients the presence of a stiff lesion can provoke suboptimal results. Considering the serious complications which may occur after SI, following surgery all patients should have regular follow up (including an imaging study). Covered stents should always be available in the cathlab as rescue device when implanting stents in CoA patients.

P2423 - PLANNING OF INTERVENTIONAL CORRECTION OF SINUS VENOSUS DEFECT WITH PARTIAL ANOMALOUS PULMONARY VENOUS DRAINAGE USING 3D PRINTING TECHNIQUES

Mari Nieves Velasco Forte[1], Nick Byrne[2], Antony Hermuzi[3], Gorka Gomez Ciriza[4], Pimpak Prachasilchai[3], Gur Mainzer[3], Kuberan Pushparajah[3], Tom Zellers[5], Michael Luna[5], Tarique Hussain[5], Israel Valverde[6], Shakeel Qureshi[3], Eric Rosenthan[3]
King, Division of Imaging Sciences And Cardiovascular Engineering, London-United Kingdom[1]; Guy, Medical Physics, London-United Kingdom[2]; Evelina Children, Paediatric Cardiology, London-United Kingdom[3]; Institute of Biomedicine, Cardiovascular Physiopathology, Seville-Spain[4]; UT Southwestern Medical Center, Paediatric Cardiology, Dallas-United States[5]; Institute of Biomedicine, Paediatric Cardiology, Seville-Spain[6]

Background: Sinus Venosus Defects (SVD) with anomalous pulmonary venous drainage (PAPVD) have traditionally been treated surgically. Cardiac magnetic resonance (CMR) is often used for confirmation of diagnosis and procedure planning. The introduction of a novel interventional approach was supported by 3D-printing techniques.
Methods: 3 patients (males, 74-128 kg, 30-66 years) diagnosed with SVD and PAPVD (right upper pulmonary vein to superior vena cava (SVC)) underwent CMR as part of our institutional protocol. A patient-specific 3D model was printed for each patient (figure1).

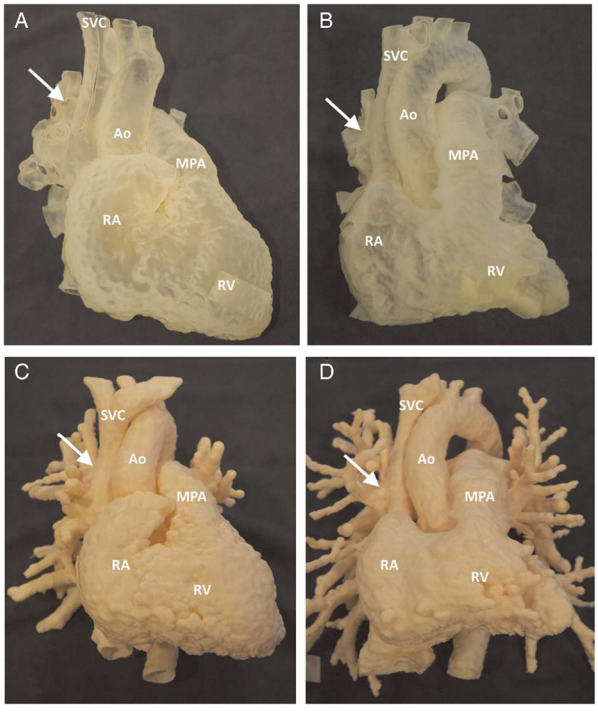

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Whole heart anatomy was segmented from 3D balance steady-state free precession images in two patients and time-resolved angiography in one, using Mimics Medical software (version 18.0). All models were printed in TangoPlus. A second polyurethane replica was printed for two patients. A stent was inserted in the SVC of the model to assess whether SVD closure and PAPVD flow redirection to left atrium (LA) could be achieved with a catheter based approach.
Results: CMR verified the diagnosis for all patients. Model based phantom stent insertion confirmed SVD closure and patency of the RUPV to the LA(figure 2). Measurements from the model and CMR were obtained for stent size. The technique was subsequently applied in the patients. A sizing balloon was used to size the SVC and occlude the defect. Simultaneously, a catheter was placed in the RUPV demonstrating patency of PAPVD, as previously shown in the model. This was also confirmed with transoesophageal echocardiography (TOE) and rotational angiography. Custom made covered Cheatham-Platinum stents were then mounted on a 28mm (2patients) and 26 × 60mm balloon. Once implanted, TOE and angiography confirmed closure of the defect with unobstructed pulmonary venous flow to the LA. There were no complications.
Conclusions: Transcatheter repair of SVD PAPVD is feasible using 3D printing techniques to select patients. This can be performed without complication avoiding cardiopulmonary bypass

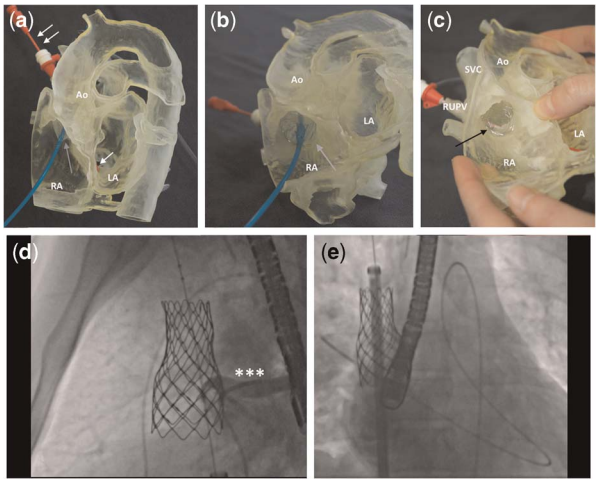

Figure 2.

P2437 - DUAL VENOUS CONNECTION OF PULMONARY VEINS WHY IS SO IMPORTANT TO DIFFERENTIATE IT FROM PARTIAL ANOMALOUS PULMONARY VENOUS RETURN (PAPVR) OUR CENTRE EXPERIENCE PHYSIOLOGICAL AND THERAPEUTICAL CONSIDERATIONS

Francisco González-Barlatay, Ana Méndez-Santos, Nagib Dahdah, Joaquim Miro
Sainte-Justine University Hospital, Pediatric Cardiology Service, Montreal-Canada

A dual venous connection of pulmonary veins with the left atrium and systemic veins has been described in the past. The prevalence has not been stablished, and at first sight seem to be a very rare condition, but this can be due to under-diagnosis. Some physiological particularities make this entity different to PAPVR. The connections with the left atrium predispose to have higher QP/QS than the expected for an isolated PAPVR, and in certain cases can also predispose to have a right to left shunt. We present our series of 5 patients which can represent the spectrum of clinical presentation, from a high QP/QS and right chambers dilatation to a right to left shunt whose initial sign was a cerebral abscess, and their therapeutic approach.
Conclusions: Dual venous connection of pulmonary veins is a particular entity that needs to be highly suspected to be diagnosed. A percutaneous approach is almost always the treatment of choice with very low morbidity and mortality.

P2442 - COR TRIATRIATUM DEXTER PERCUTANEOUS APPROACH TREATMENT IN A CHILD. FEASIBILITY OF THE TECHNIQUE AND RESULTS

Francisco González-Bartalay, Ana Méndez-santos, Marie-Josée Raboisson, Joaquim Miro
Sainte-Justine University Hospital, Pediatric Cardiology Service, Montreal-Canada

Remnants of the right sinus venosus valve can have several forms of presentation, from a fortuity echo finding to different degrees of right heart failure end cyanosis (Cor Triatriatum Dexter). The most frequent therapeutic approach of this very rare malformation is the surgical removal of the membrane. We report a new percutaneous technique performed in a toddler, which is the first case described in a pediatric patient.

P2446 - 10 YEARS SINGLE CENTER EXPERIENCE IN CARDIAC CATHETERIZATION IN HYPOPLASTIC LEFT HEART SYNDROME

Grace Van Leeuwen Bichara, Paulo Vasconcelos, Armando Mangione, Salvador Cristóvão
Beneficência Portuguesa De SP, Interventional Cardiology, São Paulo-Brazil

Background/Hypothesis: Hypoplastic left heart syndrome (HLHS) patients are more likely to have catheter interventions as the prognosis of this condition has improved over the years. Various transcatheter procedures can be performed in order to access the hemodynamic and morphological status and to ameliorate the patient condition. We reviewed our institutional experience of transcatheter cardiac catheterization in HLHS patients.

Materials and Methods: Retrospective review of all HLHS patients who underwent cardiac catheterization from 2006 to 2016 in our institution.

Results: Eighty-six patients had a total of 159 transcatheter procedures (diagnostic or therapeutic). Eighteen procedures were performed after the first stage of palliation (post-norwood) (11%), at the mean age of 0,3 ± 0,1 years, 95 were after second-stage (post-Glenn) (60%) at the mean age of 2,2 ± 1,1 years and 46 procedures were after third-stage (post-Fontan) (29%) at the mean age of 6 ± 3,1 years. Therapeutic interventions were more commonly required in patients after second-stage (66%). Forty-six patients (53%) needed 71 therapeutic interventions. Interventions performed included collaterals arteries embolization = 44%, pulmonary arteries stents = 10%, aortoplasty using balloon or stent = 9%, venovenous channels embolization = 6%, balloon PA angioplasty = 6%, pulmonary vein angioplasty using balloon or stent = 2%, stent or balloon fenestration opening = 1%, occlusion of fenestration = 1%, venous system stent placement = 4%. Most of the procedures (75%) were performed after 2010 .

Conclusion: The optimal treatment of patients with HLHS is a process in evolution. Transcatheter procedures are commonly required and contribute for the success of the palliation. Most commonly we have performed diagnostic catheterizations and interventions after the second-stage of the treatment, preparing the patient for the Fontan procedure.

P2490 - OFF LABEL USE OF AMPLATZER DUCT OCCLUDER II; TRANSCATHETER RETROGRADE CLOSURE OF PERIMEMBRANOUS VSD IN CHILDREN SINGLE CENTER EXPERIENCE

Sahar Elshedoudy[1], Eman Eldoklah[2]
Tanta University, Cardiology, Tanta-Egypt[1]; Tanat University, Cardiology, Tanat-Egypt[2]

Objectives: To assess the safety and the efficacy of transcatheter closure of perimembranous ventricular septal defects (pmVSDs) by a retrograde transarterial approach using the Amplatzer Duct Occluder II (ADO II).

Background: Transcatheter closure of ventricular septal defects by antegrade method is well established technique, but require arteriovenous loop which add considerable time to the procedure, and the high incidence of developing atrioventricular block.

Material and Methods: This is a prospective study from a single center, from June 2015 to December 2016, 10 children were enrolled for Transesophageal echography (TEE) guided transcatheter retrograde closure of pmVSDs using ADO II device

Results: Successful closure was achieved in all patients. The mean age was 3.4 ± 1.58 years. The mean weight was 14.65 ± 3.93 kg. The mean VSD diameter measured with left ventricular angiography was 4.4 ± 0.52 mm at its exit. The mean VSD diameter measured with TEE was 4.4 ± 0.52 mm. All patients had aneurysmal tissue. Aortic rim was <3 mm in two patients. The mean Qp/Qs was 2.28:1 ± 0.20. The mean pulmonary artery pressure was 25 ± 3.33 mmHg. The mean fluoroscopic time was 15.9 ± 1.19 minutes. There were no procedure related complications, the follow up evaluation include ECG, TTE one day after the procedure, one month, 3, 6, and one year. Residual shunt was present in 20% of patients which decreased significantly to 10% 3 months later

Conclusion: Percutaneous retrograde device closure of pmVSD using ADO II device is a simple, safe and time saving technique in selected cases

P2542 - A STUDY OF ANGLE FORMED BETWEEN PATENT DUCTUS ARTERIOSUS AND DESCENDING THORACIC AORTA IN BEATING HEART

Hoon Ko, Gil Ho Ban, Geena Kim, Hyoung Doo Lee
Pusan National University Yangsan Hospital, Pediatric Cardiology, Yangsan-Korea, South

Percutaneous transcatheter closure is an established method of treatment for patent ductus arteriosus (PDA). However, PDA device closure in infants or in patient with certain morphological types of PDA may be difficult due to protrusion of device into the descending aorta. However there has been few data about angles of PDA since 1951. In this study, we measured angles between PDA and descending aorta through angiography in beating heart. From Dec. 2008 to Nov. 2016, 190 patients who underwent percutaneous PDA occlusion was included in this study. Retrospectively, the angle of PDA was measured by 3 cardiologists between ampulla base of PDA and longitudinal axis of PDA through aortography. Patients were divided into 3 groups according to age (Group A: under 1 year, Group B: 1-6 years, Group C: more than 6 years). And also we stratified the patients by the PDA type according to Krichenko's classification. Of the 190 study patients, 134 patients were female. The median age was 7 years(range from 75 days to 60 years), and the average angle of PDA was $48.3 \pm 12.1°$. Compared with Mancini's results ($n = 24$; average angle of PDA $= 31.8 \pm 3.3°$), this study resulted in higher average angle of PDA($p < 0.001$). In Group A($n = 41$), average angle was $47.5 \pm 10.3°$. In Group B($n = 111$) and Group C ($n = 38$), average angle was $47.1 \pm 11.2°$ and $52.3 \pm 15.3°$ respectively. According to Krichenko's classification, 136 patients was included in type A("conical") and average angle was $48.5 \pm 11.6°$. In type C("tubular") and type E("elongated"), 21 and 32 patients were included and average angle was $49.7 \pm 18.2°$ and $46.6 \pm 9.2°$ respectively. In this study we measured the angle of PDA by using radiologic data from beating heart in bigger population. The average angle of PDA was 48.3°, which was higher than Mancini's results. We hope that our data will be useful to develop the new device for percutaneous PDA occlusion.

P2544 - ENDOVASCULAR STENT GRAFT REPAIR OF AORTIC DISSECTION TYPE B IN ADOLESCENTS

Lyubomir Dimitrov[1], Ivo Petrov[2], Kiparisia Nenova[1], Elisaveta Levunlieva[1], Anna Kaneva[1]
National Heart Hospital, Pediatric Cardiology, Sofia-Bulgaria[1]; City Clinic, Cardiology, Sofia-Bulgaria[2]

Limited reports on the subject of aortic dissection in children and adolescents indicate that from 0.67% to 3.5% of aortic dissections occur in persons ≤21 years old. Rarely occurring in the pediatric population, aortic dissection is a condition with many predisposing factors: congenital cardiovascular disorders, connective tissue disorders, fibromuscular dysplasia, systemic hypertension and trauma. Surgical and endovascular procedures might cause the occurrence of aortic dissections. From September 2014 to December 2016 two adolescent patients underwent an endovascular stent-graft procedure for acute symptomatic type B dissection. Indication for endovascular repair is a complicated course of type B dissection, including visceral and/or peripheral ischemia, uncontrollable hypertension, and therapy-resistant pain. The first patient was a 15-year-old boy who at the age of 6 months underwent a surgery – PDA transection. He was hospitalized with accute chest pain. The computed tomography scan (CT) showed dissection of the descending aorta, Stanford type B. The mesenteric artery and left renal artery were involved. In first stage the mesenteric artery and abdominal aorta were stented. 20 days later, due to renal insufficiency, we implanted stent in the left renal artery. In the third stage the thoracic aorta was stented. The second patient was a 17-year-old boy with headache and high blood pressure. The patient's past medical, familial, and drug history was unremarkable. The CT showed aortic dissection type B, without abdominal arteries involved. Due to the presence of therapy resistant hypertension the patient underwent an endovascular procedure two weeks after the hospitalization. Three stents were implanted in the descending aorta. Aortic dissection is an important differential diagnosis in adolescents with acute chest pain, which is hard to diagnose. The early recognition and rapid treatment is lifesaving. Endovascular stent-graft repair of the thoracic aorta is an alternative to surgical repair.

P2554 - OUTCOMES OF AMPLATZER VASCULAR PLUG II (AVP II) DEVICE FOR OCCLUSION OF PDA – 2 CENTRE EXPERIENCE

Atul Kalantre[1], Mehnaz Atiq[2], Ram Ramaraj[1], Nilesh Oswal[1], Gordon Gladman[1], Ian Peart[1], Ram Dhannapuneni[3], Rafael Guerrero[3], Arjamand Shauq[1]
Alder Hey Childrens Hospital, Cardiology, Liverpool-United Kingdom[1]; Aga Khan University Hospital, Cardiology, Karachi-Pakistan[2]; Alder Hey Childrens Hospital, Cardiothoracic, Liverpool-United Kingdom[3]

Background: Patent ductus arteriosus (PDA) has significant variation in morphology. Different devices have been used but not all devices are suitable for all types of PDA. Few case series have been published on using Amplatzer Vascular Plug II (AVPII) for PDA. We have used AVP II mainly in long tubular type but also other shapes of PDA. We believe our series is the largest to report.
Objective: To evaluate use of AVPII device for PDA closure and incidence of complications.
Method: A retrospective study of all the data where AVPII was used for PDA closure.
Results: TABLE 1
50 patients underwent PDA closure by using AVPII from June 2014 to January 2017 in 2 different centres in children as small as 4.4 Kg. AVPII size ranged from 6mm to 14 mm. In all except one (neck approach) femoral venous approach was used to deploy the device. In all except one case, it was possible to close the PDA. All cases had complete closure except one with small residual shunt noted on the following day. One device embolised in the first 24 hours which was retrieved. There were no procedure-related complications. There was no increased gradient across pulmonary artery or aorta.
Conclusion: AVP II is a safe and effective device for all PDA closure especially Krichenko type C and type E.

Table 1. Results.

Demographics (N = 50)	Median	Range	Ductal Morphology[1]
Age (months)	15	3–144	A = 3/50 (6%)
Weight (Kg)	8.8	4.4–30	B = 1/50 (2%)
Narrowest ductal diameter (mm)	4.5	1.5–8	C = 21/50 (42%)
Length of duct (mm)	13	6–20	D = 1/50 (2%)
Diameter of aortic ampulla (mm)	8.5	4.5–14	E = 24/50 (48%)
Procedure time (min)	61	31–137	
Fluoroscopy time (min)	7.4	1.3–25

P2562 - OCCLUSION OF MUSCULAR VENTRICULAR SEPTAL DEFECTS IN SMALL INFANTS USE OF THE AMPLATZER DUCT OCCLUDER II

Stephanie Kleppe[1], Ulrike Herberg[1], Ralf Knies[1], Christine Bernhardt[1], Ingo Heinze[2], Oliver Dewald[3], Bahman Esmailzadeh[3], Johannes Breuer[1]
University Children's Hospital, Paediatric Cardiology, Bonn-Germany[1]; University Hospital, Anaesthesiology, Bonn-Germany[2]; University Hospital, Paediatric Cardiac Surgery, Bonn-Germany[3]

Background: Complete closure of haemodynamically relevant muscular ventricular septal defects (mVSD) can still be challenging by conventional surgery. Moreover, delivery sheaths for the available mVSD-occluders are relatively large when used for interventional procedures in infants.
Materials and Methods: Six patients aged three months to five years (weight 3-12 kg, median 7.39 kg) underwent interventional closure of a muscular VSD (5 apical, 3 midmuscular) with an AMPLATZER DUCT OCCLUDER II (ADOII). Two patients with multiple mVSDs received succesful implantation of a second ADOII in a separate session. All procedures were guided by transoesophageal (TOE) or transthoracic echocardiography (TTE). Vascular access was obtained via the jugular vein and the femoral artery via a 4 F sheath. The double-mushroom shape of the ADOII with its bigger rim and easy adapting to the rims of the septum allows choosing devices with exactly the same waist as the size of the mVSD measured by TTE or TOE. Via an arteriovenous loop the sheath was forwarded from the right jugular vein to the right ventricle (RV) and via the VSD into the left ventricle (LV). Then, the ADOII was advanced through this sheath and finally deployed.
Results: Seven procedures were completed successfully without facing major complications. A 3.5 months old girl showed transient significant bradyarrhythmias while forwarding the delivery catheter leading to abruption of the intervention. The mVSD was then closed with an ADOII using a hybrid approach. On follow-up of all patients no residual shunt across the devices was observed and no dislocation of any devices occurred.
Conclusion: The ADOII can be used safely even in small infants to close mVSDs not being suitable for a conventional surgical approach.

Figure 1.

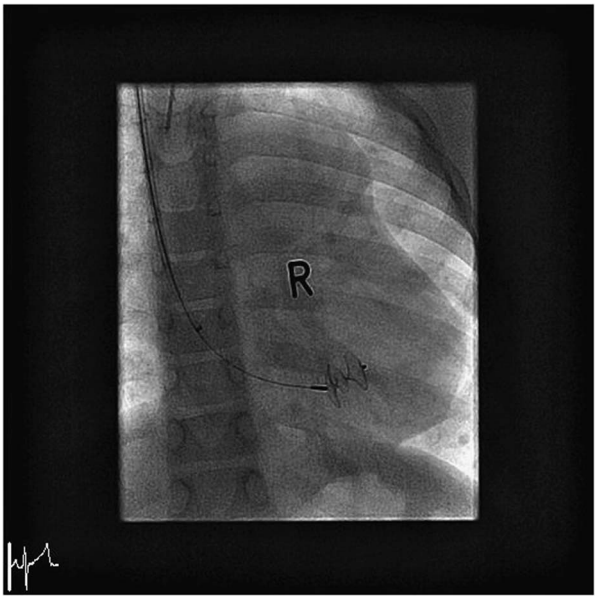

Figure 2.

P2567 - DEVICE CLOSURE OF A LEFT VENTRICULAR APICAL ANEURYSM A FIRST CASE REPORT

Mani Ram Krishna Singaravelu[1], Philip Roberts[1], David Murphy[1], Peter Grant[2]
Sydney Children's Hospital Network, Paediatric Cardiology, Westmead-Australia[1]; Sydney Children's Hospital Network, Cardiothoracic Surgery, Sydney-Australia[2]

Background: LV diverticula are outpouchings of the left ventricle with contractile myocardial tissue. They are classified into sub-diaphragmatic and supra-diaphragmatic diverticula. The sub-diaphragmatic type may be part of a Pentalogy of Cantrell. Surgical resection has remained the treatment of choice. We present a minimally invasive alternative to surgery in this condition.
Methods: This was a case report of a young infant who underwent per-cutaneous closure of a LV apical aneurysm. This is the frost reported intervention in literature.
Results: A neonate who was antenatally diagnosed to have a large VSD was evaluated postnatally at 15 days of life. Clinical examination suggested a moderately large shunt. In addition a pulsatile mass wa s seen in the epigastrium. Echocardiogram confirmed mesocardia with a large VSD. A small diverticulum was seen

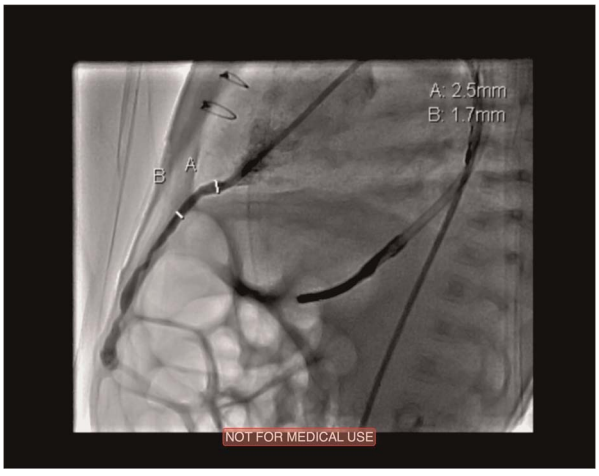

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

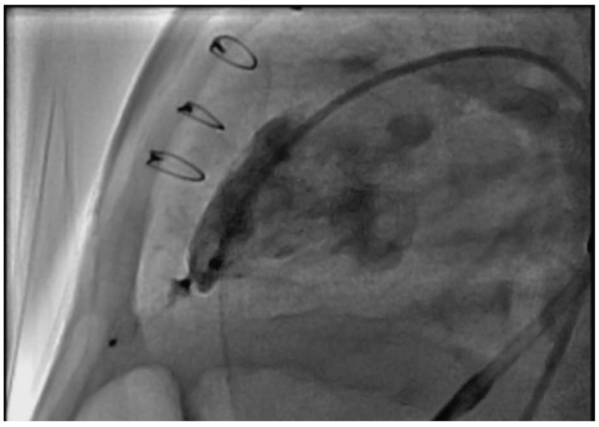

Figure 2.

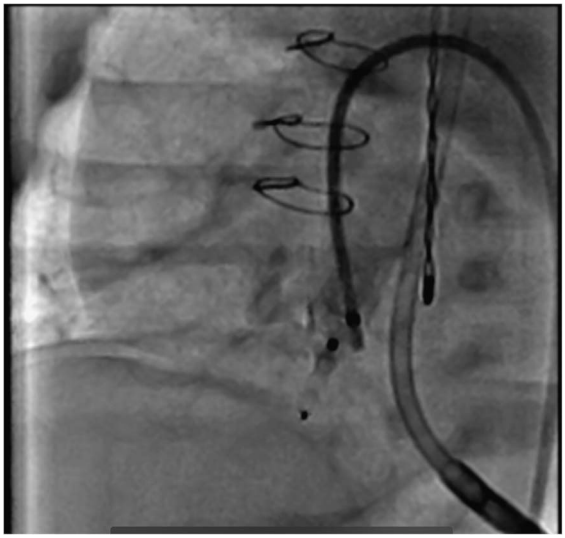

Figure 3.

Figure 4.

arising from the LV apex and tracking below the diaphragm. The bay was initially palliate with a pulmonary artery band. Subsequently, cardiac catheterization revealed a restrictive 2, mm LV diverticulum apex. This was closed with a 3mm x 6 mm ADO Ii AS device. The pulsatile mass disappeared instantaneously and there were no residual flows.
Conclusion: Per-cutaneous occlusion with a device offers a safe and non-invasive alternative to management of infants with a LV apical diverticulum

P2574 - RETROGRADE TRANSCATHETER CLOSURE OF VENTRICULAR SEPTAL DEFECT USING AMPLATZER DUCT OCCLUDER II

Suprohaita R. Talib[1], Mulyadi M. Djer[2]
Jakarta Heart Centre, Pediatric Cardiology, Jakarta-Indonesia[1]; Cipto Mangunkusumo Hospital, Child Health Department, Jakarta-Indonesia[2]

Background: One of ventricular septal defect (VSD) transcatheter closure complications is total atrioventricular block (TAVB), occurring in 3% to 20% of cases. Butera et al. reported 6 of 104 subjects (5.7%) required pacemaker implantation. TAVB may occur immediately due to squeezing effects of disks or late due to device-induced inflammation and fibrous tissue formation. Amplatzer Duct Occluder II (ADO II, St. Jude Medical, St. Paul, Minnesota, USA) with nitinol wire and lack of patches inside the occluder was used in order to eliminate the risk of TAVB.
Materials and Methods: All datas of retrograde transcatheter closure of VSD using ADO II were collected from intervention database of 2 hospitals, Cipto Mangunkusumo Hospital and Jakarta Heart Centre Indonesia. We analysed data using IBM® SPSS® Statistics version 24. We selected weight of subjects at least 6 kg and VSD diameter less than 6 mm to be eligible for this study.
Results: Between January 2015 and December 2016, 35/54 patients underwent retrograde transcatheter closure of VSD using ADO II (19 male and 16 female). Their age ranged from 1 to 22 years (median 6.2 years) and weight ranged from 7.3 to 82 kg (median 21.4 kg). Median fluoroscopic and procedure time were 34 (10 to 89) min and 125.9 (50 to 190) min. Devices used (device diameter/length in mm) were 3/6 (n = 1), 4/5 (n = 1), 4/6 (n = 11), 5/6 (n = 10), and 6/6 (n = 12). Post-procedure of TAVB complication was not found. The defect was totally closed and there was no rhythm or conduction abnormality.
Conclusions: Retrograde transcatheter closure of VSD using ADO II can be performed safely and successfully. ADO II with gentle construction can be used in order to eliminate the risk of TAVB. Monitoring of rhythm still remain mandatory during long term follow-up.

P2575 - EFFICACY OF AMPLATZER DUCT OCCLUDER II IN NON DUCTAL POSITION

Balekundri Vijayalakshmi
PMSSY, Super Speciality Hospital, Bengaluru Medical College and Research Institute, Cardiology, Bengaluru-India

Background: Amplatzer Duct Occluder II (ADO II) is actually designed for closing long ducts in infants. There are few reports of "off-label" use of ADO II in non-ductal positions.
Aim: To evaluate the feasibility and efficacy of ADO II in non ductal position by transcatheter method.
Material and Results: 102 cases of VSDs and 4 cases, one each of aorto right ventricular, aorto right atrial tunnel, infantile hepatic endothelioma, common iliac artery aneurysms and 2 coronary

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

cameral fistulae were closed with ADO II of various sizes, formed the material for this prospective study. Age ranged from 28 days to 23 years (mean 9.1 years). 74 perimembraneous VSDs, 14 muscular VSDs,13 Gerbode defects, one midmuscular VSD with dextrocardia, were closed from retrograde approach by wire only technique. The shortest fluoroscopic time was 4.2 min, mean was 8.4 ± 4.1 min. Seven cases developed transient complete heart block and four cases had junctional rhythm, which resolved with oral steroids. Only one of them needed temporary pacing for 48 hours.
Discussion: ADO II has a very low profile, as there is no polyester material in it and can be easily delivered through a 4-5 F guiding catheter, needs very short fluoroscopic time as artero-venous (AV) loop is not needed in this retrograde approach. Cost is 1/3 the cost of regular ventricular septal occluder. However, it is not useful in VSDs measuring more than 6 mm and in those with insufficient aortic rim. Trackability of ADO II is excellent in rare, tortuous tunnels and fistulae.
Conclusions: ADO II is an excellent device in some non ductal positions like VSD, Gerbode defects, CAVF, ARVT. The procedure time and the cost is significantly lesser than regular devices. The success rate is very high and complication rate is very low.

P2582 - ASD DEVICE CLOSURE IS TRANSOESOPHAGEAL ECHOCARDIOGRAPHY MANDATORY

Karthik Surya Ramanujam, Premsekar Rajasekaran
Kauvery Hospital, Paediatric Cardiology, Chennai-India

Background: Transcatheter closure of Atrial Septal Defects (ASD) is generally considered to be best undertaken with trans esophageal echocardiography(TEE) to guide optimal placement of the device. However, in our experience, Transthoracic echocardiography (TTE) combined with specific fluoroscopic views provide sufficiently adequate imaging for undertaking safe ASD device closure procedures in children and thin individuals.
Materials and Methods: We report our experience of performing 185 device closures of ASD between April 2014 and January 2017 without TEE guidance. Age ranged from 2 years to 60 years and weight from 10 kg to 58 kg. TTE imaging was performed using subcostal sagittal & coronal views, four chamber & parasternal short axis views to determine the defect morphology, thickness or lack of it along defect margins and aneurysms of the septum. An allowance of 2-4mm more in device size was given for floppy or aneurysmal defect margins. Under deep conscious sedation or local anaesthesia, the device is deployed from the left or right upper pulmonary vein in Postero-Anterior (PA) view. Balloon sizing was undertaken in 12 patients when the chosen size of the device was found grossly inadequate. The seperation between the two discs astride the aortic torus in this view is used as a good guide to the suitability of device size. Device stability and all around disc seperation is assessed in LAO view with a gentle pull and push manoeuver. After TTE confirmation of device position, the release is effected in PA view.
Results: Immediate device embolisation occurred in 4 patients necessitating surgical retrieval and subsequent patch closure. There were no morbidities or mortality.
Conclusion: Apart from obese patients, it is feasible to safely undertake ASD device closure without TEE guidance. The avoidance of endotracheal intubation, general anesthesia and oesophageal echocardiography probe placement with its attendant risk is avoided.

P2589 - SIMULTANEOUS TRANSCATHETER TREATMENT OF COARCTATION OF AORTA COMBINED WITH PATENT DUCTUS ARTERIOSUS BY USING A COVERED STENT

Ahmet Celebi, Ilker Kemal Yucel, Emine Hekim Yilmaz, Orhan Bulut, Taliha Oner, Sevket Balli
Dr. Siyami Ersek Hospital for Cardiology and Cardiovascular Surgery, Pediatric Cardiology, Istanbul-Turkey

Background: Beyond infancy coexistence of coarctation of aorta (COA) and patent ductus arteriosus (PDA) occasionally occur. Age of the patient, anatomy of the coarctation, size and type of the ductus arteriosus all have importance while considering the treatment options for the patients with coexistent CoA and PDA. We will present our experience in transcatheter treatment of CAO combined with PDA.
Method: With the diagnosis of coarctation 198 patients underwent stent implantation between 2007-2016 in our institute. 12 of them had associated PDA. Hemodynamic assessment and pulmonary vascular reactivity testing for pulmonary hypertension performed in patients with severe pulmonary hypertension. Covered CP stents (CCP) were used in all.
Results: Median age was 15 (6.5-35 year). PDA type were type E in six, type C in four, Type A in one and type B in one. The median PDA diameter was 3.9 mm (2-9.9). The median peak to peak gradient was 43 (10-71) mmHg across the coarctated segment which was reduced to 0 (0-8) mmHg. The diameter of coarctated segment of aorta increased from a median 8.4 (2.6-10.8) mm to16 (9-24) mm after CCP implantation. Among four patients with severe pulmonary hypertension before the procedure, only in one of them it persisted (this patient had also large VSD). Fourteen covered stents used for 12 patients. After deployment of covered stent, four of them had residual PDA flow. Proximal part of the stents was flared with larger diameter semi compliant balloons. After flaring, there was no residual shunt across the PDA. CT angiography performed to all at the first year of intervention. None had recoarctation and no reintervention required during the median 20 months of follow-up.
Conclusion: By using a covered stent, COA combined with PDA can be treated safely and effectively in a single stage in older children, adolescents and adults.

P2596 - INITIAL EXPERIENCE WITH STENT IMPLANTATION IN THE RIGHT VENTRICLE OUTFLOW TRACT IN PATIENTS WITH TETRALOGY OF FALLOT

Paulo Valderrama[1], Francisco Garay[1], Yeny Briones[2], Daniel Sprinmuller[1], Daniel Aguirre[3], Rodrigo Gonzalez[4], Pedro Becker[4], Guillermo Zamora[5], Luis Sánchez[5], Gabriel Castillo[6], Gilberto Palominos[6], Luis Cardenas[2]
Pontifical Catholic University of Chile, Cardiology and Respiratory Disease, Santiago-Chile[1]; Dr. Luis Calvo Mackenna Children´s Hospital, Pediatric Cardiology, Santiago-Chile[2]; Dr. Roberto Del Rio Children´s Hospital, Pediatric Cardiology, Santiago-Chile[3]; Pontifical Catholic University Of Chile, Cardiovascular Diseases, Santiago-Chile[4]; Dr. Luis Calvo Mackenna Children´s Hospital, Cardiovascular Diseases, Santiago-Chile[5]; Dr. Roberto Del Rio Children´s Hospital, Cardiovascular Diseases, Santiago-Chile[6]

Introduction: Tetralogy of Fallot (TOF) treatment is difficult in low birth weight newborns particularly when significantly ill or with unfavorable anatomy. Stent implantation in the right ventricle outflow tract (RVOT) is an option for them. We report our initial experience with RVOT stenting in patients with TOF.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Methods: Retrospective and descriptive study conducted in 3 pediatric cardiovascular centers in Chile between 2012-15, including all TOF patients in whom a stent was implanted in the RVOT as first procedure. Clinical records, echocardiographic, interventional and surgical reports were reviewed for demographics and information of RVOT and pulmonary arteries (PA).
Results: RVOT stents were implanted in 12 newborns with TOF (9 female). Median age was 16 days (1–70). Mean gestational age was 34 weeks (28–40). Mean weight was 2.178 g (1.400–3.414). In 58% birth weight was below 2.500 grs. Oxygen saturation increased from 74,3% ± 7,3 (55–88) to 88,5% ± 4,0 (80–98%), ($p < 0,01$) after the procedure. No complications or mortality were related to interventions. Follow up was mean of 11 months (7–36). In 50% an additional procedure was needed. Mean PA diameters were at baseline and at the moment of surgery: right 2,3 ± 0,3 mm/5,3 ± 0,6 mm ($p < 0,05$) and left 2,2 ± 0,4 mm/ 4,0 ± 1,1 mm ($p < 0,05$). The surgical repair was performed median of 4 months (2-7) in 11 patients. No surgical mortality. The median postop stay was 7 days (6-32).
Conclusions: RVOT stenting is a safe and useful option for small patients with TOF and surgical risk factors or unfavorably anatomy. It increases the pulmonary blood flow, improving oxygen saturation and pulmonary arteries growth as bridge for surgical repair.

P2601 - SAFETY AND EFFICACY OF DUCTAL STENTING – SINGLE CENTRE EXPERIENCE

Giridhar Gopal Dhandayuthapani[1], Sudipta Bhattacharjya[2], Sivakumar Kothandam[3], Sreeja Pavitran[3]
Madras Medical Mission Hospital, Paediatric Cardiac Intensive Care, Chennai-India[1]; Madras Medical Mission Hospita, Paediatric Cardiology, Chennai-India[2]; Madras Medical Mission Hospital, Paediatric Cardiology, Chennai-India[3]

Background: Ductal stenting (DS) is a less morbid alternative to surgical shunts in patients with duct-dependency.
Objective: To analyse patient profile, outcomes and complications of ductal stenting.
Methods: DS procedures in the past three years (2013–2016) in infants below 4 months were analyzed for procedural outcomes and follow up till their definitive procedure.
Results: Among 33 patients weighing 3.29 ± 1.26 kg (2.2-5.3 kg), 14 had PA in univentricular heart, 5 had TOF with PA, 1 had TOF, 2 had critical PS, 5 had PA and IVS and 1 was with large rhabdomyoma causing severe RV inflow obstruction required DS for pulmonary blood flows. 3 patients had retraining of regressed ventricle in transposition and 1 had revascularization of isolated left PA. 2 patients with non-confluent PAs needed bilateral DS. 1 patient with HLHS underwent DS as a part of Hybrid procedure. Procedural time was 91.51 ± 49.4 minutes (30-240 minutes) with saturations improving from 67 ± 11% to 88 ± 5%. Sirolimus/ Everolimus eluting stents were used in 14 patients. 5 patients needed additional stent to cover the entire ductal length. Procedural complications included arrhythmia in three, distal stent migration in three, 2 of which were stabilized with additional stent, low cardiac output state in six and retroperitoneal bleed in one. The mean ICU stay was 84.1 ± 141.8 hours(6 hours to 28 days). 3 patients had instent restenosis between 3 to 6 months. Ingrowth was not seen in drug eluting stents. Mortality occurred in 5 patients. Improvement of PA sizes were found in all. 6 patients had biventricular repair, while univentricular palliation was carried out in 5 patients. The mean duration of follow up for patients awaiting surgery was 444.53 ± 237.29 days, but still not hypoxic to warrant their next palliation.
Conclusion: DS is feasible, effective, safe procedure, which can act as a bridge to more definitive surgical intervention in the future.

P2614 - IMMEDIATE AND MID TERM RESULTS OF BALLOON AORTIC VALVULOPLASTY (BAV) FOR SEVERE CRITICAL AORTIC VALVE STENOSIS IN NEWBORNS. A SINGLE CENTER EXPERIENCE

Marek Raczka, Piotr Werynski, Jacek Kuzma, Zbigniew Kordon, Andrzej Rudzinski
Jagiellonian University, Pediatric Cardiology, Cracow-Poland

Assessment of immediate/mid-term BAV outcome in neonates with severe/critical AVS.
Material: 28 neonates with severe/critical AVS were referred to BAV. The group consisted nine premature infants (GA 34.7 ± 1.3 weeks, body mass 2.54 ± 0,4 kg). BAV was performed at the age: x = 12.8 ± 9 days, body mass: 3.14 ± 0.6 kg. Follow-up time was x-5.19 ± 2.9 years.
Methods: We analyzed LVEF (depending on values: ≤40% and >40%), initial and post-BAV transvalvular pressure-gradient (TVPG) and significant (≥3o) AV-regurgitation (AVR) incidence, re-BAV and/or surgical operation necessity. In follow-up, NYHA class of the patients, residual TVPG, LVEF and significant AVR incidence were analyzed.
Results: In 14 pts, LVEF was ≤40% (x = 28.3%) (GrI), while in the remaining 14 (GrII) - x = 63.3%. Post-BAV TVPG in GrI and GrII decreased (40.9 ± 23.3 mmHg to 29.2 ± 15.7 mmHg; 82.5 ± 22,2 mmHg to 40.7 ± 19.4 mmHg, respectively). Significant AVR was present in one GrII pts. Adverse events occurred in five pts: LV-wall perforation - two, AV-perforation - one, significant hemorrhage - one, and significant AVR 1 pts. Ten pts required re-interventions: two pts re-BAV, five - surgical valvuloplasty, two pts - hybrid-stage-one-procedure for HLHS, due to borderline LV and hypoplastic aortic annulus diameter, respectively, one child re-BAV at 3 months of age, surgical valvuloplasty when 3.5 years old and Ross-Konno procedure when aged 5 years. In follow-up, seven pts (25%) died (including 5/9 of preterm infants) at 19 days to 12 months post-initial BAV, including two post-hybrid-stage-one-procedure for HLHS. Fisher test showed significant factor of death to be prematurity ($p < 0.02$). In the groups, no significance was noted for body mass <2500 g. In late follow-up, all other pts were in NYHA I, residual TVPG in Doppler echo was x = 36.8 mmHg ± -13.6 mmHg, LVEF– x = 69.9% ±7%, three pts had AVR >2nd degree, and 10 pts ≤2nd degree.
Conclusions: Transcatheter treatment of severe/critical AVS is a life-saving procedure. Prematurity and probably borderline LV are poor prognostic factors in follow-up.

P2616 - RIGHT HEART CATHETERIZATION USING BASILIC VEIN APPROACH INITIAL EXPERIENCE

Nadeem Aslam, Saleem Sadqani, Babar Sultan Hasan
Aga Khan University and Hospital, Paediatric Cardiology, Karachi-Pakistan

Background and Objectives: Cardiac catherization is traditionally performed from groin using femoral vein and/or artery, which involves admission, limb immobilization and significant risk of bleeding and hematoma. Recent studies have shown safety of using arm vessels for cardiac catheterization. In this study we evaluated the feasibility of right heart catheterization using basilic vein.
Materials and Methods: We reviewed all patients undergoing right heart catheterization using basilic vein approach at our hospital

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

from January 2013 to December 2016. Demographic data, indication, procedural and outcome data was analyzed using SPSS version 19.
Results: We reviewed all ~ 27 cases during the study period. Success rate in getting access was 100%. All patients were discharged home same day. Only two patients had small hematoma post-procedure. There was no clinical evidence of venous thrombosis at follow up in outpatient clinic.
Conclusion: Right heart catheterization using basilic vein approach is a promising technique in selected group of patients with shorter procedural time, early ambulation and more patient acceptance.

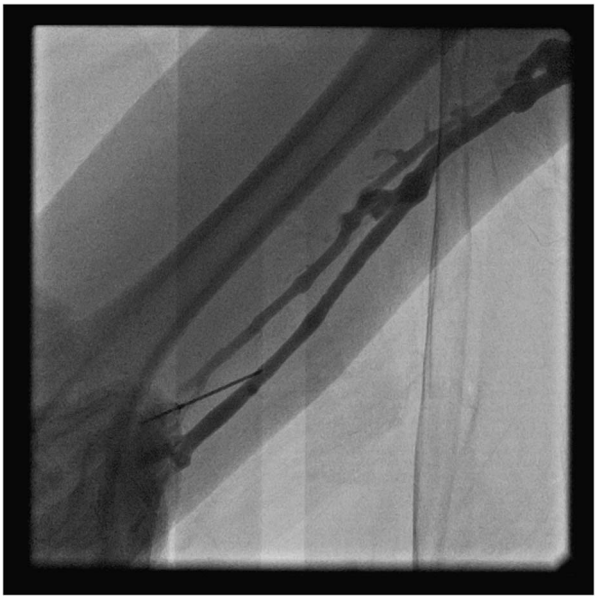

Figure.

P2624 - TRANSCATHETER CLOSURE OF FENESTRATIONS AFTER FONTAN TYPE OPERATIONS EARLY AND LONG TERM RESULTS

Elisaveta Levunlieva[1], Anna Kaneva[1], Lubomir Dimitrov[1], Kiparisia Nenova[1], Stojan Lazarov[2]
National Heart Hospital, Pediatric Cardiology, Sofia-Bulgaria[1]; National Heart Hospital, Pediatric Cardiac Surgery, Sofia-Bulgaria[2]

Fontan type operations are the only surgical palliation with long-term positive hemodynamic effects in patients with single ventricle circulation. Conduit fenestration is a modification which shortens early postoperative adaptation. The presence of a fenester can have negative hemodynamic effect due to persistent right-to-left shunt with resulting hypoxia and paradoxical embolism. Transcatheter closure of the fenestrations improves exercise tolerance and quality of life.
Aim: Assesement of immediate and long-term results of transcatheter closure of the fenestration after Fontan surgery.
Material: Twenty children with single ventricle hemodynamics with completed stages of Fontan operation and subsequent transcatheter fenestration closure.
Methods: In all children the fenester was closed after comprehensive hemodynamic assessment in basal conditions and after temporary occlusion of fenestration. In 15 children the fenestration was closed by Amplatzer septal occlude, in 2 - by Cardioseal device, in 2 - using Figulla Flex II, and in 1 – by Amplatzer vascular plug. The patients were followed for a period of 6 months to 11 years.
Results: After fenestration occlusion oxygen saturation in the systemic circulation increased from $83{,}14 \pm 3{,}58$ to $92{,}58 \pm 3{,}20$ ($p = 0.0001$). Mean cavo-pulmonary pressure (mCPP) and pulmonary vascular resistance (PVR) showed no significant change: mCPP of 11 $28 \pm 1{,}70$ mmHg before occlusion increased up to $11{,}86 \pm 1{,}21$ mmHg ($p = 0.24$). PVR increased from $1{,}21 \pm 0{,}56$ to $1{,}51 \pm 0{,}51$ Wood units ($p = 0{,}15$). There were no procedural or late complications. In 6 of children, development of collaterals with a decrease in systemic oxygen saturation were found. In 5 out of these children, the collaterals were closed subsequently.
Conclusion: Transcatheter closure of fenestration in Fontan type surgery is effective and safe non-surgical treatment option. The accurate selection of patients is essential for good postprocedural results.

P2633 - FEASIBILITY AND SAFETY OF TRANSCATHETER CLOSURE OF ATRIAL SEPTAL DEFECT IN SMALL CHILDREN WEIGHING 10KG OR LESS

Ah Young Kim, Se Yong Jung, Jung Yoon Kim, Jo Won Jung, Jae Young Choi
0Center For Congenital Heart Disease, Severance Cardiovascular Hospital, Yonsei University College of Medicine, Division of Pediatric Cardiology, Seoul-Korea, South

Background: Transcatheter closure of atrial septal defect (ASD) has been accepted as a standard treatment. However, the efficacy and safety of transcatheter closure of ASD in very young and small children have not been clearly defined yet.
Methods: From 2005 to 2015, 124 patients (10.4% of total 1249 patients with device closure) weighing less than 10 kg were included in this study as device group. During same periods, 45 patients (12.8% of total 350 patients with surgical closure) less than 10 kg were included as surgery group. Baseline characteristics, hemodynamic features, comorbidities, success rate and complication rate were compared between two groups.
Results: Age (12.5 ± 5.4 vs 16.8 ± 6.1 months, $p < 0.001$) and weight (8.0 ± 1.8 vs 9.1 ± 1.0, $p < 0.001$) were lower in surgery group. However, hemodynamic features and anatomic details including rim deficiency (75.6% vs 73.4%, $p = 0.563$) and multiple defects (17.8% vs 27.4%, $p = 0.072$) were not different between two groups. Device closure was successfully performed in all children except 4 (3.2%) cases of mitral encroachment by atrial disc. Devices were retracted before detachment in these 4 patients and they underwent subsequent elective surgery. In both groups, there was no major complication. However, minor complication rate (1.6 vs 8.8%, $p = 0.04$) and hospital day (4.0 ± 0.3 vs 11.1 ± 5.4, $p < 0.001$) were significantly lower in device groups. In device group, two cases of transient arrhythmia were occurred. Catch-up growth was observed in both groups after ASD closure.
Conclusion: Transcatheter closure of secundum ASD is technically feasible, safe and effective even in small children weighing less than 10 kg. This study suggests device closure is a viable option in selected group of small children with ASD and there is no need to wait until they grow for transcatheter closure.

P2643 - TRICKS AND TECHNIQUES OF TRANSCATHETER CLOSURE OF CONAL SEPTAL VENTRICULAR SEPTAL DEFECT

Sanjiban Ghosh, Anuradha Sridhar, Muthukumaran Sivaprakasam
Apollo Children's Hospital, Pediatric Cardiology, Chennai-India

Introduction: Conal septum is the part of interventricular septum (IVS) which separates pulmonary valve from aortic valve. This

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

muscular septum forms the supracristal part of IVS. Any ventricular septal defect (VSD) in this septum is known as conal septal VSD or outlet muscular VSD. These defects are located adjacent to the aortic and pulmonary valve and surgical closure is mainstay of treatment. Sometimes, this defect extends upto aortic valve and may produce aortic valve prolpase and aortic regurgitation (AR). Only a few case reports are available in literature about trascatheter closure of these defects. We are describing our experience of transcatheter closure of conal septal VSD.
Method: Total 5 patients were selected for transcatheter closure for conal septal VSD in Apollo Children's Hospital, Chennai in between April 2015 to March 2016. Mean age of the patients was 4 years (1-11 years). One of them had subaortic VSD with outlet muscular extension with mild AVP with no AR. Antegrade approach was used for 3 of them and VSD closure was done using duct occlude-I device. Retrograde technique was used for other 2 patients including the patient with subaortic VSD with outlet extension with AVP and the VSD was closed using duct occlude-II device. Mean follow up period was 9 months (3- 12 months)
Result: There were no major complications noted during the follow up period. None of them had any residual VSD. None of them had any left or right ventricular outflow obstruction or AR.
Conclusion: Conal septal VSD can be successfully closed by transcatheter technique. Proper case selection and proper assessment of the VSD is important for successful closure of this type of VSD. Longer term follow up is required to draw the final conclusion.

P2645 - TRANSCATHETER CLOSURE OF DOUBLY COMMITTED SUBARTERIAL VSD MIDTERM FOLLOW UP

Sanjiban Ghosh, Anuradha Sridhar, Gaurav Kumar, Muthukumaran Sivaprakasam
Apollo Children's Hospital, Pediatric Cardiology, Chennai-India

Transcather closure of ventricular septal defect (VSD) is feasible alternative of surgery. But only a few reports are available in literature on transcatheter closure of doubly committed VSD. VSD device closure are generally not attempted in these VSDs because the device can impinge on the aortic valve cusp which can cause worsening of AR. Fear of producing left and right ventricular obstruction is also high as the VSD is very close to aortic and pulmonary valve. In this article, we are summarizing our experience of transcatheter closure of doubly committed VSD.
Method: Total 8 patients were selected for transcatheter closure for doubly committed VSD in Apollo Children's Hospital, Chennai in between April 2014 to March 2016. Mean age of the patients was 10.4 years (8-13 years). All of them had mild AVP and 5 of them had trivial to mild AR. VSD closure was done by retrograde approach. It was done successfully in 7 patients. AVP appeared to be significant in LV angiogram in one child, and AR became severe after crossing the VSD regradely. That child was referred for surgery. Duct Occluder-II was used for all of them. Mean follow up period was 9.7 months (3- 24 months).
Result: There were no major complications noted during the follow up period. None of them had any residual VSD. None of them had any left or right ventricular outflow obstruction. 5 of them had trivial to mild AR before VSD device closure. None of them had any increase in severity of AR during follow up.
Conclusion: Doubly committed subarterial VSD can be closed by trancatheter technique and AVP with mild AR is not contraindication for device closure. Proper case selection is important. Longer term follow up is required to draw the final conclusion.

P2650 - BALLOON PULMONARY VALVOTOMY IN POST INTRACARDIAC REPAIR OF TOF WITH TRANSANNULAR PATCH WITH BICUSPID VALVE

Sanjiban Ghosh, Anuradha Sridhar, Gaurav Kumar, Muthukumaran Sivaprakasam
Apollo Children's Hospital, Pediatric Cardiology, Chennai-India

Introduction: Reconstruction of Right ventricular outflow tract (RVOT) using transanuular patch (TAP) is a standard technique of intracardiac repair (ICR) of Tetralogy of Fallot (TOF). One of the most popular techniques is TAP with bicuspid valve made of Polytetrafluoroethylene (PTFE). Significant RVOT obstruction is one of the commonest causes of reintervention after TOF surgery. In case of RVOT reconstruction with TAP with bicuspid valve, the PTFE valve can get crumbled or stuck resulting in RVOT obstruction. Surgical management in the form of resection and reconstruction is the standard approach, which is not free of risk and sometimes difficult because of previous surgery. Here, we are reporting our experience of balloon pulmonary valvotomy in post ICR of TOF with TAP with bicuspid valve using high pressure MAX-LD balloon. Patient 1: 2-year-old boy from Bangladesh, asymptomatic, came for routine follow up. He underwent successful ICR for TOF using TAP with bicuspid PTFE valve at the age of 1 year. Echocardiography showed severe RVOT obstruction due to stuck PTFE valve with moderate PR. Cardiac catheterisation showed systemic RV pressure. Pulonary valvotomy was tried first with a low pressure balloon, but it was unsuccessful despite of inflation at maximum pressure. Then pulmonary valvotomy was tried with high pressure Max-LD balloon and it was done successfully. Patient 2: 4-year-old girl from Tamilnadu presented with mild effort intolerance. She underwent surgery for TOF with TAP with bicuspid PTFE valve at 1 year of age. Echocardiography showed severe RVOT obstruction due to stuck PTFE valve with mild RV dysfunction. Diagnostic cardiac catheterisation showed near systemic RV pressure. Pulmonary valvotomy was done successfully with high pressure Max-LD balloon.
Conclusion: High pressure balloon can be successfully used for pulmonary valvotomy in case of severe RVOT obstruction in postoperative cases of TOF. Longer term followup is required to draw the final conclusion.

P2651 - OUTCOME OF NEONATAL CATHETER INTERVENTIONS A SINGLE CENTRE EXPERIENCE

Vinoth Doraiswamy[1], Nageswara Rao Koneti[1], Saileela Rajan[2], Shweta Bakhru[1], Sakshi Sachdeva[1], Nidhi Kaushal[2]
Care Hospital, Pediatric Cardiology, Hyderabad-India[1]; Care Hospital, Pediatric Cardiologist, Hyderabad-India[2]

Aim: To study the indications and complications of all neonatal catheterization procedures done at a tertiary care centre.
Materials and Methods: The records of all neonates (age 1 – 30 days) who underwent catheterization procedures from July 2011 – to December 2016 at our centre were reviewed retrospectively. The indications, vascular access and outcomes were studied.
Results: Of the total 168 patients who underwent neonatal catheterization,74% were male. Median age and weight were 13.5 days (range 1 - 30) and 3.1 kg (range 1.4–5.5) respectively. Clinical presentation include cyanosis (56%), shock (8.7%), recurrent cyanotic spells (7.5%), failure (3.7%), sepsis (5%) and asymptomatic (13.7%). 15% of patients received prostaglandin infusion before procedure. PDA stenting was done in (39%), balloon pulmonary valvotomy (19.6%), balloon atrial septostomy (19.6%), balloon aortic valvotomy (10.7%), pulmonary valve

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

perforation (4.7%), balloon coarctoplasty (5.3%), RVOT stenting (5.3%), coarctation stenting (2.3%), diagnostic catheterization study (1.7%), collateral closure (1.1%), PDA device closure and vertical vein stenting (0.5%). Femoral access was the commonest in all groups. Other unconventional accesses used were: carotid artery (n = 14), axillary artery (n = 22), right internal jugular vein (n = 2) and umbilical vein (n = 5). The complications encountered were transient bradycardia/hypotension (n = 18), transient pulse loss (n = 14), access related hematoma (n = 1), renal failure (n = 3), stent thrombosis(n = 2), stent embolization (n = 1), duct rupture (n = 1) and aortic dissection (n = 3). Overall mortality was 18 (10.7%), with maximum deaths among the PDA stenting group (12/67), followed by pulmonary valve perforation (2/8) balloon coarctoplasty (2/9), balloon aortic valvotomy (1/18) and balloon atrial septostomy (1/18). Among them, 55% were procedure related deaths and the rest were due to associated sepsis or aspiration

Conclusion: This study provides an insight into the common neonatal procedures and their complications at a tertiary centre. The complications are probably attributed to the poor pre-procedure hemodynamics as most of them presented with acidosis.

P2654 - TRANSCATHETER CLOSURE OF MUSCULAR VENTRICULAR SEPTAL DEFECT IN INFANTS WITH HEART FAILURE

Bhargavi Jillella, Sakshi Sachdeva, Saileela Rajan, Sujata Patil, Nageswara Rao Koneti
Care Hospital, Pediatric Cardiology, Hyderabad-India

Introduction: Surgical closure is considered as the gold standard for infants with muscular ventricular septal defect (VSD) presenting with heart failure. We present a single center's experience on transcatheter closure of Muscular VSDs in symptomatic infants.

Methods: Medical records of infants with muscular VSDs.were analyzed between July 2011 to July 2016. There were 25 symptomatic infants with muscular VSDs.

Results: Of the 25 infants, eight were males. The median age at the time of procedure was 7 months (range 2-12 months) and median weight was 5 kg (range 3.3 -10 kg). All the infants presented with heart failure. The VSD was single in 15 and multiple in 10 Infants. The location of the defects were: Mid muscular in 8, anterior muscular in 7, posterior muscular in 5 and apical in 5 infants. Approach was retrograde in 5 cases and antegrade in 20cases. Antegrade route included foramen ovale approach (17). Femoral accesses was taken in 22 cases and 2 cases through internal jugular vein and 1 through carotid route. Procedure was successful in all but one infant. The device deployed were: Lifetech muscular device in 10 cases, Amplatzer muscular device in 9 cases and Amplatzer Duct Occluder II in 6 cases. Complications include transient bradycardia in one and vascular injury in one infant. There was one early mortality. Child with a large muscular VSD and Coarctation of aorta who presented with hemodynamic instability died 12 hours following VSD device closure and balloon coarctoplasty. There was one death 2 weeks following the procedure due to non-cardiac condition

Conclusion: Transcatheter closure of Muscular VSDs in Infants is a feasible in selected group of patients and is a safe alternative

P2668 - SYSTEMIC ARTERIOVENOUS MALFORMATIONS IN CHILDREN EXOTIC CONNECTIONS & INTERVENTIONAL STRATEGIES

Anand Subramanian[1], Usha M K[2], Bharath A P[2], Jayaranganath M[2]
Sri Jayadeva Insitute of Cardiovascular Sciences & Research, Pediatric Cardiology, Bangalore-India[1]; Sri Jayadeva Institute of Cardiovascular Sciences & Research, Pediatric Cardiology, Bangalore-India[2]

Background: Systemic arteriovenous malformations are by and large, uncommon. Most of them are acquired. Most cases of congenital arteriovenous malformations are confined to isolated case reports. We present a series of congenital systemic arteriovenous malformations seen in the pediatric cardiology department at a tertiary care centre with special emphasis on imaging, possible embryological basis and interventional treatment strategies.

Materials and Methods: This is a prospective study undertaken over the last one year. A total of 5 patients were seen. Age of presentation varied from 7 days to 13 years.

Results: Patient characteristics and arterial, venous connections with their management strategies are summarized in the table below.

Conclusions: Systemic arteriovenous malformations, being rare are difficult to diagnose in the pediatric age group. Presentations may range from being asymptomatic to features of cardiac failure. Diagnosis on echocardiography is challenging due to the unusual nature of sites of entry and exit with many being extracardiac. The embryological basis of these unusual communications is yet not well understood. Device closures of most of these may be accomplished successfully after precise identification of the nature of communication.

Table.

AGE	SEX	ARTERY	VENOUS DRAINAGE	SYMPTOMATIC	INTERVENTION
45 day	Female	Anomalous artery from Descending aorta	Portal vein	Abdominal distension, hepatosplenomegaly	4/6 ADO II
13 day	Male	Subclavian artery	Portal vein	Congestive heart failure	6/4 ADO II
5 y	Male	External carotid artery	Internal jugular vein	Pulsatile neck mass	5/4 ADO II
13 y	Female	Axillary artery	Axillary vein	Swelling over shoulder	Coil closure (3 coils)
1 week	Female	LPA	Left atrium	Murmur/asymptomatic	Follow up

P2670 - EARLY FAILING FONTAN ROLE OF CATHETER INTERVENTION

Munesh Tomar[1], Amit Misri[2], Pankaj Bajpai[2], Paramveer Singh[3], Anil Bhan[4]
Associate Director Medanta The Medicity, Pediatric Cardiology and Congenital Heart Diseases, Gurgaon-India[1]; Senior Consultant Medanta The Medicity, Pediatric Cardiology and Congenital Heart Diseases, Gurgaon-India[2]; Fellow Medanta The Medicity, Pediatric Cardiology and Congenital Heart Diseases, Gurgaon-India[3]; Vice Chairman Medanta The Medicity, Pediatric Cardiology and Congenital Heart Diseases, Gurgaon-India[4]

Objective: Aim was to assess the role of catheter based interventions in stabilization of early failing Fontan operation.

Methods and Results: All records of patients (n = 51) who underwent Fontan Sugery from 2011-2016 at our hospital were analysed retrospectively. There were 13(25.4%) females and 38(74.5%) males. Mean age at time of surgery was 10 years (4 years- 33 years). There was one hospital death. The average hospital stay was 15 days (6 days to 35 days). The most important reason for prolonged hospital stay was persistent pleural drainage. Five patients who had prolonged pleural drainage despite all medical management underwent catheter based intervention. Two patients (3.9%) had antegrade flow in Fontan and underwent device closure of antegrade flow. Other two patients (3.9%) were subjected to creation of Fontan fenestration as their PA pressures were found to be higher on post operative catheterization study. Out of these two one patient also had a simultaneous balloon dilatation of distal pulmonary artery at the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

same sitting. One patient (1.9%) had anatomical narrowing at conduit and inferior vena cava (IVC) junction with large thrombus in inferior vena cava. In this child after thrombolysis, stent was deployed at IVC and conduit junction.
Results: All patients had significant reduction in pleural drainage over 24 hours and got discharged within 5 days of catheter intervention.
Conclusion: Prolonged pleural drainage is the most common problem of Fontan Surgery. Responsible factors should be meticulously worked out. Judious use of Catheter based interventions for some of these causes may save the failing Fontan.

P2675 - TRANSCATHETER CLOSURE OF VENTRICULAR SEPTAL DEFECTS USING NIT OCCLUD®LÊ VSD COIL

Marta Flores[1], Jose Manuel Velasco[1], Alberto Mendoza[1], Dolores Herrera[1], Ana T. Caro[1], Enrique Garcia[2], Miguel A. Granados[1], Belen Toral[1], Leticia Albert[1], Felipe Hernandez[3]
12 Octubre Hospital, Pediatric Cardiology, Madrid-Spain[1]; 12 Octubre Hospital, Pediatric Cardiac Surgeon, Madrid-Spain[2]; 12 Octubre Hospital, Adult Cardiac Catheterization, Madrid-Spain[3]

Objective: Investigate the mid-term results of transcatheter ventricular septal defect (VSD) closure with the PFM Nit-Occlud® Lê VSD coil.
Background: In 1988, Lock described the first transcatheter VSD closure using a Rashkind double-umbrella. In 2002, Hajazi used an Amplatzer® device specific for perimembranous VSD (pVSD) closure with successfully results but a high rate of permanent atrioventricular block. For this reason, the use of the Nit-Occlud® Lê VSD coil started without any cases of permanent atrioventricular block in large case studies.
Methods and Materials: Thirty-three patients underwent an attempt of VSD closure with the PFM device between February/2014 and December/2016: 24 perimembranous, 1 Gerbode, 2 muscular and 6 postsurgical residual. Mean age: 7,8 years (4 months-16 years). Mean weight: 31,6 kg (5,8-79). The mean diameter of the VSD was 5 mm (3,5-9) and mean Qp/Qs was 1,65 (1,2-2,8). The Nit-Occlud® Lê VSD coil is made up by flexible nitinol spirals as a left-sided-cone. An intraprocedural transesophageal echocardiography was performed. The follow-up protocol included echocardiography and electrocardiogram on day 1 and 7 after VSD closure and during 1°,3°,6° and 12° month.
Results: The device was successfully placed in 21 of the 24 pVSD, except for 2 cases of Laubry's syndrome and one large defect, and was successfully implanted in all the other type of VSDs. Complete closure rate in pVSD was: 15 immediately closure (15/21 = 71,45%) and 20 after 1 year (20/21 = 95,3%). In the other type of defects there were a complete immediately closure in all cases but one with mild residual leak. As complications, there were 3 cases of transient asymptomatic nodal rhythm.
Conclusions: The Nit-Occlud® Lê VSD coil device can be used successfully for perimembranous, muscular and postsurgical residual VSDs closure. As an important advantage, there was no permanent atrioventricular block. Despite the initial satisfactory results, larger series are necessary.

P2677 - BALLOON COARCTOPLASTY IN INFANTS WITH INTERMEDIATE TERM OUTCOME IT IS WORTH PURSUING

Usha M K[1], Jayaranganth M[1], Anand Subramaniam[2], Bharath Ap[1], Manjunath C N[3]
Sri Jayadeva Institute of Cardiovascular Sciences and Research, Pediatric Cardiology, Bangalore-India[1]; Sri Jayadeva Institute of Cardiovascular Sciences and Research, Pediaric Cardiology, Bangalore-India[2]; Sri Jayadeva Institute of Cardiovascular Sciences and Research, Cardiology, Bangalore-India[3]

Background: Coarctation of aorta carries significant morbidity and mortality in infants and neonates. Balloon coarctoplasty is not recommended as a procedure of choice due to reports of significant restenosis. We have reviewed the data from December 2009 to August 2015 of neonates and infants undergoing balloon coarctoplasty
Material and Methods: All babies with significant coarctation of aorta requiring intervention below one year of age were included. Gradients of more than 20 mmHg with normal LV function or any gradient with anatomic narrowing in presence of LV dysfunction were considered for intervention.
Results: 33 children underwent balloon coarctoplasty. 8 were neonates. M:F::3.8:1(26:7). Median age was 3 months (13days -12mon). LV dysfunction was present in 21(65%) babies.. 28(84%) babies had significant drop in pressure gradients to less than 30%. 3 (9%) babies had drop in pressure gradients between 30% - 50%. Average pressure gradients reduced from 41 + 30 mmHg to 6.7 mmHg. 2(6%) babies had gradients of >50%. There were no procedure death or dissection.
Follow up: 31(94%) babies had immediate success. Two babies died due to non cadiac causes. LV dysfunction resolved in 3 months. 3 babies were lost to follow up. Three babies had recoarctation at 3 - 4 months follow up(10.7%- 3/28). One neonate underwent repeat balloon coarctoplasty and two were referred for surgery. Mean follow up was 6mon(1mon -60 mon). Among 8 neonates seven had successful procedure(88%). One baby is lost to follow up. Among six, three required reintervention (50%), 3 are symptom free.
Conclusion: Residual gradients <30% predicts good long term outcome and >30% suggests need for reintervention. Residual gradients of more than 50% require surgical correction. Immediate success rate is 94%. Recoarctation is 10% in babies above 1 month and 50% in neonates. Recoarctation is unlikely after 1year. LV dysfunction resolves within 3 months.

P2680 - MEDIUM TERM FOLLOW UP OF TRANSCATHETER CLOSURE OF PATENT DUCTUS ARTERIOSUS USING AMPLATZER DUCT OCCLUDER II

Nageswara Rao Koneti, Shweta Bakhru
Care Hospital, Pediatric Cardiology, Hyderabad-India

Background: Limited follow-up data of Amplatzer duct occluder II (ADOII) is available.
Objective: To see the efficacy and medium term results of transcatheter closure of PDA using ADOII.
Materials and Methods: This is a single centre follow-up study of patients underwent PDA closure using ADOII between 2010 and 2013. All patients were followed up and analyzed various parameters by transthoracic echocardiography and CT angiogram in selected cases. The angiograms of the procedure were reviewed and various parameters were analyzed retrospectively to see the cause for left pulmonary artery stenosis.
Results: Total 52 (female n = 31) patients underwent PDA device closure using ADO II. The median age and weight were 24 months (range 7-120) and 10.5 kg (range 5.5-25) respectively. Mean ductus arteriosus diameter was 3.6 2.8 mm. Analysis of angiogram showed type A in 36, type B in 1, type C 8, type D 4 and type E 3 cases. Size of the device used were: 3 × 4:2, 3 × 6:3, 4 × 4:9, 4 × 6:4, 5 × 4:9, 5 × 6:5, 6 × 4:12, and 6 × 6:8. The immediate occlusion rate was seen in 88%, within 24 hours 96% and 100% closure at 6weeks. There

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

were no procedure related deaths. Vascular injury was seen in 1, device embolization in 1, device repositioning in1 and device was removed in 1. The median follow up was 4.8 years. Three cases developed significant left pulmonary artery stenosis confirmed by CT angiogram and cardiac catheterization (1). The analysis of various parameters showed young age, large device and distance between the device to 50% of left pulmonary artery diameter are the predictors of LPA stenosis. One child developed mild coarctation of aorta and became normal during follow-up.
Conclusion: Follow-up assessment is mandatory to see the left pulmonary stenosis in patients after transcatheter closure of Ductus arteriosus using ADOII.

P2685 - TRANSCATHETER CLOSURE OF VENTRICULAR SEPTAL DEFECT IN A CHILD WITH ANATOMICALLY CORRECTED MALPOSITION OF GREAT ARTERIES

Aritra Mukherji[1], Indira Banerjee[1], Audil Mohmad Lanker[1], Suman Paul Chowdhury[1], Debasis Bera[1], Tahmina Karim[2], Amitabha Chattopadhyay[1]
Narayana Superspeciality Hospital, Pediatric Cardiology, Howrah-India[1]; Bangabandhu Sheikhmujib Medical University, Pediatric Cardiology, Dhaka-Bangladesh[2]

Background: Anatomically corrected malposition of great arteries (ACMGA) is an extremely rare form of congenital heart disease characterized by abnormal spatial relation of the great arteries maintaining atrioventricular and ventriculoarterial concordance. Structural defects like ventricular septal defects, atrial septal defects, subaortic and subpulmonary obstructions, juxtaposed atrial appendages are commonly associated with this condition. Till date there are no reports of transcatheter closure of ventricular septal defects in this subset of patients. We present a child with ACMGA who underwent successful transcatheter closure of VSD.
Materials and Methods: SK, a 8 year old girl, had dyspnoea on exertion with stunted growth. Echocardiography revealed a 5 mm upper muscular ventricular septal defect with significant left to right shunt. Angiograms at anteroposterior and 300 right anterior oblique views further corroborated the echocardiographic findings. A soft device in the form of Amplatzer Duct Occluder II (ADO II) was chosen to minimize the risk of possible complete heart block and to avoid subaortic obstruction following placement of a bulky device as prominent subaortic conus is associated. The defect in our patient was splayed on the right ventricular side, limiting the opportunity to close it from the arterial side. After obtaining an arteriovenous loop, a 6 × 4 ADO II was thus deployed from the venous side to successfully close the defect.
Results: The defect was totally occluded with no residual flow across it. Alienation of the device to the interventricular septum was perfect and the patient was in sinus rhythm with no obstruction to any outflow tracts at 6 months follow up.
Conclusions: Vivid understanding of the anatomy, particularly the alignment of the ventricles and the outflow tracts are essential, especially to profile the VSD angiographically. Thorough knowledge of the conduction system in ACMGA is a must before attempting any intervention in such patients.

P2689 - STENTING OF THE DUCTUS ARTERIOSUS IN NEWBORNS WITH DUCTAL DEPENDENT PULMONARY CIRCULATION 7 YEARS OF A SINGLE CENTER EXPERIENCE

Marta Flores[1], Hemir Escobar[1], Ana T. Caro[1], Alberto Mendoza[1], Dolores Herrera[1] Belén Toral[1], Marta Yagüe[1], Jose M. Velasco[1], Miguel A. Granados[1], Lorenzo Boni[2]
12 Octubre Hospital, Pediatric Cardiology, Madrid-Spain[1]; 12 Octubre Hospital, Pediatric Cardiac Surgery, Madrid-Spain[2]

Objetive: describe our experience in ductal stenting on patients with ductal-dependent pulmonary circulation.
Background: Since the early 90 s, ductal stenting has been proposed to maintain ductus patency as an alternative to surgical shunts to ensure a stable pulmonary blood flow. In the last decade, the technique has become a viable alternative as a result of device's and technical improvements.
Methods: We retrospectively analyze 27 patients who underwent cardiac catheterization for ductal stenting in our center from March 2009 to September 2016.
Results: The procedure was successfully completed in 17 patients (65,3%, Table 1). One patient died after anesthetic induction before

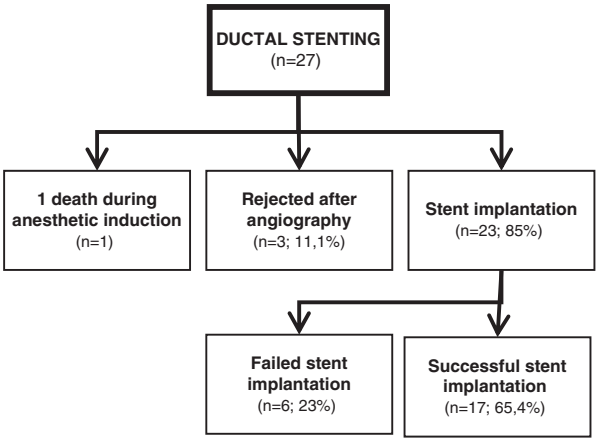

Figure 1.
Flow chart of the total patients

Table 1. Demographic data of patients who underwent successful stent implantation

Demographic data	Value
Age (days), mean (range)	12 (1 – 30)
Weight (kg), mean (range)	3 (2 – 4,2)
Procedure time (minutes), mean (range)	155 (65 – 290)
Diagnosis (n):	
- Biventricular physiology:	12 (70,59%)
Tetralogy Fallot, pulmonary stenosis	4
Double outlet right ventricle, pulmonary stenosis	1
Pulmonary atresia with intact ventricular septum	2
Pulmonary atresia with ventricular septal defect	2
Critical pulmonary stenosis	1
TGA, ventricular septal defect, pulmonary stenosis	2
- Univentricular physiology:	5 (29,41%)
Pulmonary atresia with intact ventricular septum	1
Ebstein´s anomaly	2
Tricuspid atresia	1
Complex congenital heart disease*	1
Ductus arteriosus (mm), mean (range):

- Pulmonary artery side	1,9 (0.8 – 3,8)
Stent (mm), mean (range):	
- Diameter	4 (4 – 4,5)
- Length	13 (8 – 18)
Stent implantation:	
- Via axillary artery (3 or 4Fr sheath)	7 (41,2%)
- Via femoral artery (4Fr sheath)	7 (41,2%)
- Via femoral vein (5Fr sheath)	3 (17,6%)

TGA: transposition great arteries. * Complex congenital heart disease: single right ventricle, common atrioventricular valve, malposition of the great arteries and pulmonary stenosis.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

starting the procedure because of haemodynamic deterioration. There were no other procedure-related deaths. In 3 patients stent implantation were not attempted because of an adverse anatomy at the angiography: bilateral pulmonary artery stenosis (n = 1) and ductal tortuosity (n = 2). In 6 patients, the stent could not be implanted or embolized. These 9 patients were referred for surgery. The freedom from reintervention (surgical shunt n = 1/re-catheterization n = 9) was 126,1 days (2-381). Average time from stent implantation to the first cardiac surgery was 294 days. Four patients required early re-catheterization (<3 months) due to: ductal stenosis (n = 2), incomplete ductal stenting on the aortic side (n = 1), and pulmonary over-circulation (n = 1). Mayor complications occurred in four patients (3 stent embolization and 1 femoral dissection) and minor complications in nine (3 transient arrhythmias, 5 vessel entry thrombosis, 1 intimal left subclavian artery dissection). The number of referred patients for ductal stenting has tripled in seven years. In 2009 half of the procedures failed, while since 2014 all of the ductal stents have been successfully implanted.
Conclusions: Ductal stenting is reasonable, feasible and safe as an alternative to surgical shunt in newborns with ductal-dependent pulmonary circulation. The results are satisfactory after the learning curve.

Table.

	Duration of symptoms	Hepatic Vein cannulated	Succesful	Balloon/ Stent	Follow up
1. 4 yr/F	1 month	Right hepatic vein	Successful	Balloon with stent insertion	Four year asymptomatic
2. 6 yr/M	2 months	Left hepatic vein	Immediate success	Balloon	Improved in 10 days, lost to follow up
3. 8 mon/M	3 days	Right hepatic vein	Successful	Balloon	Died on 6th day with variceal bleed
4.9 y/M	1 month	Left hepatic vein	Successful	Balloon	Two years follow up, asymptomatic
5. 2 yrs/F	5 months	Unsuccessful	Unsuccesful		Died due to variceal bleed
6. 1.5 yrs /M	1 month	Unsuccessful	Unsuccessful		Died within a month
7. 3 yrs/M	4 months	Unsuccessful	Unsuccesful		Died within one week with encephalopathy and sepsis
8. 16 y/M	4 mon	Right hepatic vein/IVC obstruction	Successful	Stent to IVC	Follow up -2 yr Asymptomatic
9. 14 y/F	1 week	Unsuccessful	Sent for surgery		Died due to coagulopathy
10. 9m/F	2 weeks	Right hepatic vein/IVC obstruction	Successful	Balloon with stenting after 2 months	Follow up 12 months

P2692 - INTERVENTIONAL THERAPY IN PEDIATRIC BUDD CHIARI SYNDROME – GRATIFYING OUTCOMES

Usha M K[1], Jayaranganath M[1], Anand Subramaniam[1], Bharath Ap[1], Manjunath Cn[2]
Sri Jayadeva Institute of Cardiovascular Sciences and Research, Pediatric Cardiology, Bangalore-India[1]; Sri Jayadeva Institute of Cardiovascular Sciences and Research, Cardiology, Bangalore-India[2]

Background: Budd- Chiari syndrome (BDCS) is an eponym for hepatic venous out-flow obstruction It leads portal hypertension, hepatic dysfunction and cirrhosis. Establishing patency of the hepatic veins is the most desirable therapy. The outcome for Budd Chiari syndrome is dismal without treatment. Surgical portosystemic shunting carries high morbidity is of palliative nature.
Materials and Methods: Data collected retrospectively and prospectively from January 2012 - December 2016 from hospital records
Results: 10 children presented to our hospital with Budd- Chiari syndrome. Interventional therapy was attempted in all 10 children but was successful in 6 of them. Initial balloon dilatation was done. Stenting was necessary when there was a gradient of more than 2 mmHg and narrowing on angiogram after balloon dilatation. Stent implantation was necessary in 3 children. All children who underwent intervention became completely asymptomatic within 10 days. Longest duration of follow up is 4 years. Among six children with successful intervention four are on follow up and at the end of four years are doing well with normal portal pressures and liver function. The ascites has completely disappeared. Their growth has normalized. All are on anticoagulation. One child died within a week of intervention. It had acute Budd chiari and developed severe variceal bleeding. One child is lost to follow up. One child developed recurrence and required stenting at 3months on follow up. All four children where intervention was not possible were referred for surgery but unfortunately died while awaiting surgery or in immediate postop period.
Conclusion: Hepatic vein angioplasty is the most physiological therapy for Budd –Chiari syndrome. It should be attempted for every child before embarking on surgical options. Long standing obstructions are difficult to intervene. When successful the results are gratifying and intermediate term follow up shows event free survival.

P2727 - UTILIZATION OF THE EDWARDS SAPIEN 3 VALVE IN THE NON AORTIC POSITION IN CONGENITTAL HEART DISEASE

Heike Schneider[1], Verena Gravenhorst[1], Ulrich Kruase[2], Thomas Paul[1], Claudius Jacobshagen[3]
University Goettingen, Pediatric Cardiology, Goettingen-Germany[1]; University Goettingen, Pediatric Cardioloy, Goettingen-Germany[2]; University Goettingen, Cardiology, Goettingen-Germany[3]

Background: Transcatheter pulmonary valve replacement with the MELODY valve has become an important adjunct in the treatment of children and adults wiht failing right ventricular outflow tract conduits. Recently, the MELODY valve has also been succesfully implanted in the tricuspid, mitral and aortic positions, typically within failing bioprosthetic valves. The Edwards SAPIEN 3 has been developed for treatment of calcified aortic valves in elderly patients at high surgical risk. There is limited data on the use of this new third generation valve in other positions.
Materials and Methods: We implanted three Edwards SAPIEN 3 valves transfemorally in the pulmonary position in one adolescent and two young adults with repaired tetralogy of Fallot by for severe pulmonary insufficiency without complications. All had received a transannular patch for reconstruction of the right ventricular outflow tract at previous surgery. The fourth patient had single ventricular physiology and he had undergone a Damus-Kaye-Stansel procedure, partiaaly reconstructed with a Dacron prothesis. The pulmonary portion of the Damus-Kaye-Stansel was severly insufficient in this symptomatic young adult. An Edwarsd. SAPIEN 3 valve could be implanted via the femoraly artery after pre-stenting the pulmonary portion of the Damus-Kaye-Stansel anastomosis.
Results: All four Edwards-SAPIEN 3 valves were not or not more than mildy stenotic or regurgitant at 6, 6, 12 and 15 months, respectively. No stent fractures or endocarditis occured.
Conclusions: The Edwards SAPIEN 3 valve may be an additional alternative to the Melody valve and previous versions of the Edwards Sapien valves through its combination of a smaller sheath size and larger diameter valves.

P2734 - TRANSCATHETER OCCLUSION OF PERIMEMBRANOUS VENTRICULAR SEPTAL DEFECTS BY AN OCCLUTECH DUCT OCCLUDER DEVICE THE FIRST REPORTED CHILDREN

Duran Karabel, Ali Yildirim, Tugcem Keskin, Pelin Kosger, Birsen Ucar, Zübeyir Kilic
Osmangazi University School of Medicine, Pediatric Cardiology, Eskişehir-Turkey

Background: Ventricular septal defects (VSDs) are the most common congenital cardiac malformation. Standard treatment for perimembranous VSD (pmVSD) is open surgery. Transcatheter VSD closure avoids extracorporeal circulatory support and the surgical approach and has benefit of faster recovery, but both methods carry potential risk of atrioventricular block (AVB). Valvular regurgitation was another major consideration in transcatheter closure of pmVSD. We report, firstly, the use of the percutaneous closure of pmVSDs with Occlutech®duct occluder device, as an "off-label" in the five children (Fig. 1).
Materials and Methods: We reviewed, retrospectively, 5 patients with perimembranous VSD who underwent transcatheter VSD closure with device during the last year. The femoral approach was used in all patients. A long sheath was introduced into femoral vein over the arteriovenous circuit wire and advanced through VSD to aorta(Fig 2).
Results: All of patients were successfully treated by transcatheter intervention. Range of pmVSD size was 3.4- 4.5 mm, two of them whose are multipl pmVSD with originating from aneurysmatic tissue. There were used to close defects Occlutech® duct occluder with having a proximal diameters of 6-7 mm(D3), and distal diameters of 4-5 mm(D2) (Fig. 1). There were aortic valve with mild regurgitation in one patient, and trivial residual shunt with multipl pmVSD in another patient. There was no tricuspid regurgitation or AVB after procedure in any patients. Demographic and diagnostic data are summarized in Table 1.
Conclusion: The number of devices used for percutaneous closure of pmVSDs is very limited. The Occlutech® duct occluder, because of it has no right ventricular disc, can not hold aneurysmatic tissues created by tricuspid valve. The risk of developing complete AVB and tricuspid valve failure is low because of it's flexibility and absence of right ventricular disc. However these possible benefits should be supported in larger cohort studies.

P2745 - PERCUTANEOUS CLOSURE OF RIGHT PULMONARY ARTERY TO LEFT ATRIAL FISTULA

Tayfun Ucar, Melih Dogan, Ercan Tutar, Semra Atalay
Ankara University Medical School, Pediatric Cardiology, Ankara-Turkey

Introduction: Right pulmonary artery (RPA) to left atrial(LA) fistula (PALAF) is a very rare cardiovascular anomaly that results in central cyanosis. We report the multiple brain abscesses associated with PALAF and successful closure using Amplatzer Muscular VSD occluder device in a child. Case Report A 8 years old boy was admitted with cough and cyanosis. Physical examination was performed that cyanosis and clubbing fingers were detected. Echocardiography showed elongated left atrium and a communication between RPA and LA. Agitated saline injection showed early appearance of contrast bubbles in the LA within two beats. When the patient complained of blurred vision, the story was

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

deepened and the patient was informed that he had complained of headache for 20 days. Brain tomography was performed and multiple brain abscesses was detected (figure 1). Abscess drainage was performed and brain abscess treatment was completed with antibiotic therapy. After the brain abscess treatment cardiac catheterization was performed. The narrowest part of fistula was 10 mm in balloon sizing (figure 2). A 12 mm Amplatzer Muskular VSD occluder device was deployed at the narrowest site and the fistula was closed successfully (figure 3). Control angiography demonstrated complete occlusion of fistula. After the procedure, arterial oxygen saturation in room air immediately increased from 74% to 95%.

Discussion: PALAF bypasses the capillary bed; the lung loses its filtering function, thus bacteria to pass directly into the systemic circulation, resulting in cerebral abscess. Untreated cases can cause high mortality complications such as systemic thromboembolism, infective endocarditis, brain abscess, aneurysm rupture. Early diagnosis and treatment are very important. In select cases, transcatheter closure appears to be a safe and effective alternative to surgical treatment.

P2746 - THE USE OF STEERABLE GUIDE CATHETER DURING TRANSCATHETER CLOSURE OF ATRIAL SEPTAL DEFECT IN A CHILD WITH INTERRUPTED INFERIOR VENA CAVA CASE REPORT

Duran Karabel, Ali Yildirim, Tugcem Keskin, Pelin Kögger, Birsen Ucar, Zubeyir Kiliç
Osmangazi University School of Medicine, Pediatric Cardiology, Eskişehir-Turkey

Background: Percutaneous closure of trancatheter secundum atrial septal defect (ASD) is the first option for defects with adequate rims. Femoral vein is the conventional access route for the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

transcatheter procedure but congenitally interrupted inferior vena cava may make this route impassable. Our report is the first Turkish study that describes the closure of an ASD with an Agilis steerable guide catheter using the transjugular access.
Case: The patient, 12-year-old girl, was admitted to our department with the complaint of easy fatigability. A transthoracic echocardiogram (TTE) revealed ASD measuring 12-mm in diameter. Infrahepatic interruption of the inferior vena cava with azygous continuation is seen in the TTE and contrast study (Fig. 1). Hence, a 6-Fr sheat was placed into the right internal jugular vein. Attemps at deployment of the device ineffectived while the device removed through the delivery sheat because the exchange guidewire was removed the from inferor pulmonary vein. The 13-mm Amplatzer septal occluder device was loaded and delivered to the left atrium through the 8,5-Fr Agilis steerable curved catheter. Then, the left and right atrial discs were fully opened and the device deployed under fluoroscopy with continuous transesophageal visualization (Fig. 1). A transesophageal echocardiography showed the elimination of any shunt. The patient was discharged home uneventfully at the next day.
Conclusion: Agilis, steerable guide and adjustable curved catheter, used with the transjugular approach proves guidewire advancement into the pulmonary vein and correct engagement of the deployment device. It may be of use in patients with impaired or lost inferior vena cava continuation, such as in interrupted IVC.

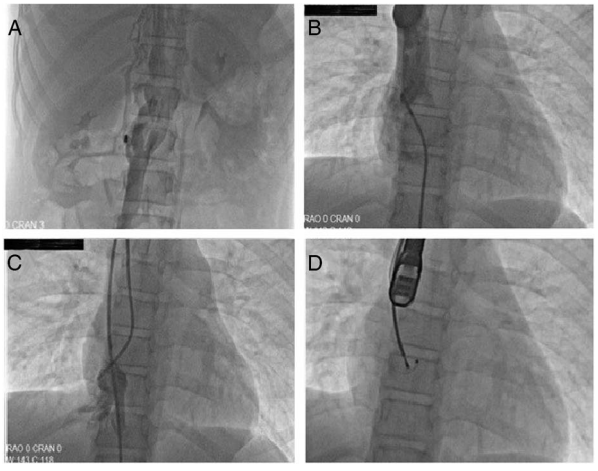

Figure 1.
The angiographic examination shows that interrupted inferior vena cava (a), continuation of inferior vena cava with azygos and superior vena cava, respectively (b,c), Amplatzer septal occluder delivered to the left atrium through the agilis steerable curved catheter (d).

P2747 - STENTING OF THE NATIVE RIGHT VENTRICULAR OUTFLOW TRACT IN THE SYMPTOMATIC INFANT WITH TETRALOGY OF FALLOT

Fernando Ballesteros[1], Alejandro Rodriguez[1], Nuria Gil[1], Isabel Planelles[1], Juan Miguel Gil-Jaurena[2], Ana Pita-Fernandez[2], Jose Luis Zunzunegui[1]
Gregorio Marañón Hospital, Pediatric Cardiology, Madrid-Spain[1]; Gregorio Marañón Hospital, Pediatric Cardiac Surgery, Madrid-Spain[2]

Objective: To assess feasibility, safety and effectiveness of right ventricular outflow tract (RVOT) stenting in symptomatic young infants with Tetralogy of Fallot (TOF).
Methods: Retrospective case note and procedure review of patients undergoing stenting of the RVOT over an 6 year period.
Results: Between 2010 and 2016, 10 patients underwent stent implantation; median age was 45 (range 1–364) days and median weight was 4 (2,2–7) kg. Median procedure time was 56,5 (30–233) min and fluoroscopy time 26,5 (12,6–77) min. There was one procedural emergency surgery. Two patients required ECMO support during the procedure. The pulmonary valve was deemed unsalvageable in all patients but one (median valve diameter 5 mm (range 4–8), median Z-score -3 (range -5 to -0,5). Saturations increased from 77% (50–85%) to 95% (85–98%) ($p < 0.005$). Three further catheter interventions were undertaken (balloon in 1, stent in 2). All patients underwent delayed surgery (complete repair in all of them) at a median of 140 (111–200) days post-stenting. No surgery was compromised by the presence of stents in the RVOT. There were no perioperative deaths. Median Nakata index increased from 80mm2/m2 (50–200) to 126 mm2/m2 (100–251)($p < 0.05$) before surgical repair.
Conclusions: In the symptomatic young infant with TOF, stenting of the RVOT provides a safe and effective management strategy, improving arterial oxygen saturation and encouraging pulmonary artery growth.

P2749 - TRANSCATHETER CLOSURE OF VENTRICULAR SEPTAL DEFECTS USING THE AMPLATZER DUCT OCCLUDER II DEVICE A SINGLE CENTER EXPERIENCE

Vikas Gupta, Mahua Roy, Aakansha Singh, Debasree Gangopadhyay, Lalit Lawankar, Debabrata Nandy, Biswajit Bandyopadhyay, Amitabha Chattopadhyay
Rabindranath Tagore International Institute of Cardiac Sciences, Mukundapur, Pediatric Cardiology, Kolkata-India

Background: Ventricular septal defects (VSD) may be closed surgically, by transcatheter approach or by hybrid procedures depending on the anatomy. We describe a single centre experience of transcatheter closure of VSDs using the Amplatzer Duct Occluder II (ADO II), aiming to evaluate the technical feasibilities and long term safety and efficacy.
Materials and Methods: Between Jan 2011 and Dec 2016, 281 patients between 8 months and 34 years, weighing 6-58 kg underwent percutaneous closure of VSD with ADO II at our institute. Patients with symptoms of left sided volume overload along with estimated Qp/Qs ≥1.5:1 were selected. The choice of ADO II device was based primarily on the size and location of the VSD, ease of the procedure either by arterial or venous approach of deployment, avoidance of an arteriovenous loop in majority of the cases, lower risks of post procedure atrioventricular block and the ease of retrieval in cases of accidental dislodgements. Post procedural echocardiogram substituted angiograms for evaluation of the position of the device, residual shunts, development of aortic regurgitation or tricuspid regurgitation.
Results: The location of the VSDs were: perimembranous -197 (70%), upper muscular- 71(25%), outlet - 11(4%), postsurgical residual- 2(0.7%). Right coronary cusp prolapse was present in 12 (4%) with no aortic regurgitation. In 2 patients, the device embolised but was successfully retrieved. The median duration of follow-up was 32 months. There were no incidences of heart block during the entire follow-up period. None of the patients had any aortic regurgitation post procedure. 2(0.7%) patients had developed mild tricuspid valve regurgitation.
Conclusion: Transcatheter VSD closure with ADO II device can be performed safely and successfully at all age groups with favourable results. In our study, there were no cases of heart blocks or aortic regurgitation. However, long term studies need to be ascertained for further follow up.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

P2755 - TRANSCATHETER PALLIATION IN PULMONARY VENOUS RETURN OBSTRUCTION

Alper Guzeltas, Taner Kasar, Ibrahim Cansaran Tanidir, Selman Gokalp
Sağlik Bilimleri University Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery Center, Pediatric Cardiology, Istanbul-Turkey

Aim: The results of interventional cardiac catheterization for pulmonary venous return obstruction, present either before the surgical procedure or developed due to the procedure itself, were evaluated.
Material and Methods: Clinical and echocardiographic findings of all patients with congenital or acquired pulmonary venous obstruction, requiring transcatheter interventions, were retrospectively analyzed.
Results: Between 2014 and 2016 eight patients underwent nine catheter interventions to relieve the obstruction in pulmonary venous drainage. Five of the patients were male and 3 of them female. The median age was 3.2 months (between 7 days-13 months) and the median weight was 3.3 kg (between 2.6-6.5 kg). Among 8 patients, 5 had single ventricle and 3 had double ventricle physiology. All patients had total anomalous pulmonary venous connection (TAPVC) and five of them had right atrial isomerism with unbalanced complete atrioventricular septal defect. In 5/8 patients preoperative transcatheter vertical vein stenting and in 3/8 patients postoperative pulmonary vein stenting were performed to reveal the obstruction in pulmonary venous return. Only one patient required more than one intervention due to postoperatively developed pulmonary venous obstruction. Two of the patients had developed supraventricular tachycardia that was terminated by medication and one patient had cardiac arrest requiring cardiopulmonary resuscitation during the catheter intervention. There were no procedural mortality.
Discussion: The surgical mortality and morbidity of obstructed TAPVC either after or before surgery is high, especially in patients with low birth weight and unstable hemodynamic condition. Removal of the obstruction may improve outcomes for both preoperative and postoperative patients. Transcatheter stent implantation might be an alternative for treatment of obstructed TAPVC.

P2756 - APPLICATION OF AMPLATZER VASCULAR PLUGS IN VARIOUS CARDIOVASCULAR DISEASES AND CLINICAL CONDITIONS

Ayşe Yildirim[1], Metin Sungur[1], Sinem Altunyuva Usta[1], Aysu Turkmen Karaagac[2], Murat Sahin[1], Omer Ciftci[1], Hakan Ceyran[3], Füsun Guzelmeric[4]
Kartal Koşuyolu Heart Training and Research Hospital, Pediatric Cardiology, Istanbul-Turkey[1]; Kartal Koşuyolu Heart Training And Research Hospital, Pediatry, Istanbul-Turkey[2]; Kartal Koşuyolu Heart Training and Research Hospital, Pediatric Cardiovascular Surgery, Istanbul-Turkey[3]; Kartal Koşuyolu Heart Training and Research Hospital, Anesthesiology and Reanimation, Istanbul-Turkey[4]

Backround: Amplatzer vascular plugs (AVP) are devices designed for the closure of extracardiac, high flow, medium to large vascular structures. The aim of this study is to evaluate the safety and efficacy of AVP's in the occlusion of vessels, defects and leaks at various localizations in several congenital cardiac diseases and clinical conditions.
Results: In the study, 3 to 21 years old 4 male and 7 female patients, to whom AVP's were applied, were included. Emergent application was required for the three of them, whereas the other eight were elective procedures. Our AVP indications were as

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

follows: Aorto pulmonary collateral artery (MAPCA), pulmonary arteriovenous malformations (PAVM), azygos vein occlusion following the Norwood stage II operation, antegrade pulmonary flow occlusion following the modified Glenn operation, abnormal systemic artery and Scimitar vein occlusion in Scimitar syndrome, residual Swiss cheese ventricular septal defect (VSD) occlusion and aortic paravalvular leak (PVL) occlusion. The diameters of occluded vessels were ranging between 4.3 and 14.6 mm. Totally 18 AVP's were used for the 18 vessels: 13 AVP II (6 × 6-22 × 18 mm), 4 AVP IV (7 × 12.5-8 × 13.5 mm) and 1 AVP III (8 × 4 mm). Only one device was used for the closure of target vessel, defect or leak in each patient, with a 100% success rate. No complication was experienced during or after the applications.
Conclusion: There are a large variety of indications for AVP applications. They can be used safely and efficiently for the closure of vessels of different size and structure in various localizations in various cardiac diseases as an alternative to surgery. Complete occlusion can be achieved by a single device in large, abnormally shaped vessels, paravalvular leaks or residual ventricular septal defects.

P2779 - TRANSCATHETER CLOSURES OF SECUNDUM ATRIAL SEPTAL DEFECTS WITH ALTERNATIVE METHODS A SINGLE CENTER EXPERIENCE

Tugcem Keskin[1], Duran Karabel[1], Pelin Kosger[1], Ali Yildirim[2], Birsen Ucar[1], Zubeyir Kilic[1]
Eskisehir Osmangazi University, Department of Pediatric Cardiology, Eskisehir-Turkey[1]; Pediatric Cardiologist, Eskisehir-Turkey[2]

Introduction: The aim of this study is to emphasize successfull transcatheter closures of atypical ASDs with alternative methods.
Methods: 138 consecutive patients between 2010 and 2016 with significant ASD were considered for transcatheter closure with ASD occluder devices; 35 patients with inadequate septum or deficient rims were excluded from transcatheter closure after initial transoesophageal echocardiography.
Results: Procedure was successful in 89 cases (success rate 86,4%), among whom 69 had device deployment from the LUPV. 20 patients (7 male, 13 female; age 3 to 15 years, median 8 years; body weight 11–60 kg, median 25 kg) had deployments from the RUPV (8 patients) and LLPV (12 patients). One patient with interrupted inferior vena cava (IVC) had succesfull transjugular catheterisation closure, assisted with steerable introducer (Agilis NxT Steerable Introducer, St Jude Medical, Maple Grove, Minnesota). Six patients had successfull ASD closure with balloon-assisted technique and 2 patients had successfull ASD closure with Hausdorf sheat technique (Cook, Bloomington, IN) with deficient aortic rims. The diameter of defects and devices ranged between 10-28mm and 11-30mm, respectively of patients with atypical deployments. No severe procedure related complications occurred. At follow up (30 days to 5 years, median 3 years) complete closure was documented in all patients.
Conclusions: RUPV and LLPV techniques are usefull for transcatheter closure of ASD, also successfull closure of ASD can be managed by steerable introducer, Hausdorf sheat and balloon-assisted techniques in cases with deficient aortic rims or interrupted IVC.

P2783 - TRANSCATHETER CLOSURE OF LARGE AORTA TO RIGHT ATRIAL TUNNEL IN A NEWBORN

Stephen Kaine, Michael Bingler, Sanket Shah, Girish Shirali
Children, Division of Cardiology, Kansas City-United States

Background: The aorta to right atrial tunnel is a rare cardiac defect described in infants, children and adults which has been treated most often by surgery. We describe the acute presentation and transcatheter treatment of a large defect in a newborn.
Case Presentation: A 2200 gram, 38 week, twin newborn was admitted to our facility with hemodynamic compromise related to a large aorta to right atrial tunnel measuring 6-8 mm in dimension. The defect was associated with torrential flow such that inotropic and prostaglandin infusions were required to augment systemic cardiac output. Echocardiography and CT angiography defined the anatomy as a posterior-type tunnel arising from the left coronary sinus of Valsalva communicating to the right atrium via an enlarged coronary sinus. The left coronary system was separate from the tunnel. A 3.5 mm restriction in the tunnel was noted posterior to the mitral valve and served as the target region for transcatheter device closure. The tunnel was entered from the aortic side and a 6 mm Amplatzer Vascular Plug 4 device was deployed in the region of vascular restriction posterior to the mitral valve. Flow persisted in the tunnel through the device mesh for several days, but inotropic and prostaglandin infusions were weaned off the day following treatment. Complete occlusion of tunnel flow was documented by echocardiography 6 days after device deployment. The patient developed right external iliac artery thrombus which resolved with 3 months of enoxaparin therapy. The infant was well and without cardiac symptoms six months following catheter treatment.
Conclusion: The aorta to right atrial tunnel is a rare congenital defect which may be amenable to transcatheter closure, even in small infants.

P2786 - TRANSCATHETER DEVICE CLOSURE OF DOUBLY COMMITTED VENTRICULAR SEPTAL DEFECTS

Tran Cong Bao Phung[1], Gemma Penford[2], Tin Do Nguyen[1], Le Trong Phi[1]
Children's Hospital 1, Cardiac Unit, Ho Chi Minh City-Vietnam[1]; Birmingham Children's Hospital, Cardiac Unit, Birmingham-United Kingdom[2]

Background: There remains international debate regarding efficacy and safety of transcatheter closure of doubly committed VSDs (DCVSD). This study reports a 5 year single centre experience with the approach.
Methods: Retrospective review, October 2009 to Jul 2014; 44 patients underwent device closure of DCVSD. Selection criteria: Weight >10 kg, no severe/moderate AR or cusp prolapse, defect <7mm, no other intra-cardiac abnormalities, plus evidence of pulmonary hypertension, left heart volume loading, or trivial/mild AR or cusp prolapse. Technique: Anterograde approach and AV loop, angiographic re-evaluation following sheath placement, echocardiographic evaluation of AR and outflow before and after device release.
Results: Median age 63 months (10-170), weight 18 kg (8-32), defect 3.7mm (2-6). Associated abnormalities: trivial to mild AR; 1 (2.3%), left heart dilation; 10 (22.7%), MR; 3 (6.8%), coronary cusp prolapse: 11 (25.0%). Devices used: PFM Coil: 10 (22.7%), ADO II: 21 (47.7%), PFM Coil and ADOII 13 (29.5%). Post-procedure murmur in 20: residual shunt disappeared on echo <48 hours in 18 (56,2%) the remainder after 6 months. Complications: haemolysis: 1 (2.3%) referred for surgery, embolization: 1 (2.3%), residual shunt 1 (2.3%) referred for surgery, RV outflow obstruction: 5 (11.4%) all resolved <3 months, AR increased: 4 (9.0%) 3 recovered to baseline <1 month, one referred for surgery. Mild LV outflow obstruction: 1 (2.3%) resolved <2 months.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Device closure of DCVSD is a controversial but effective and safe option in selected patients. Coils are associated with a greater incidence of haemolysis than ADOII or Coil & ADOII. Close follow-up is required to identify haemolysis, outflow obstruction and outlet valve competence.

P2793 - TRANSCATHETER DEVICE CLOSURE FAILURE OF ATRIAL SEPTAL DEFECT ASSOCIATED WITH EUSTACHIAN VALVE

Tugcem Keskin[1], Pelin Kosger[1], Duran Karabel[1], Ali Yildirim[2], Birsen Ucar[1], Zubeyir Kilic[1]
Eskisehir Osmangazi University, Department of Pediatric Cardiology, Eskisehir-Turkey[1]; Pediatric Cardiologist, Eskisehir-Turkey[2]

Introduction: Atrial septal defect (ASD) is a common congenital heart defect which needs closure by transcatheter method or surgery. Device closure of ASD is a well-established procedure. We describe transcatheter closure failure of ASD associated with Eustachian valve.
Case Report: A 4-year-old girl was found symptomatic with functional class II. Physical examination revealed a healthy child with height 118 cm, weight 20 kg, pulse rate of 89 bpm, blood pressure of 110/72 mmHg, and respiratory rate was 22 per min. Cardiovascular system examination revealed normal first heart sound, wide fixed second heart sound. Chest X-ray showed mild cardiomegaly. Transthoracic echocardiogram demonstrated right atrial and ventricular enlargement with ASD secundum. Transesophageal echocardiogram measured a 17 mm ASD with 35 mm of total septum and adequate rims. Transcatheter closure was decided and performed with the patient under general anesthesia. Vascular access was obtained via the right femoral vein using 6 F sheath, right and left cardiac catheterization showed a pulmonary arterial pressure of 14 mmHg, Qp/Qs:1.8. The left upper pulmonary vein was entered using a 6 F multipurpose catheter. A 0.035" Superstiff wire was positioned and exchanged for a 9 F delivery sheath. A 22 mm Ceraflex septal occluder (Lifetech Scientific Corp., Shenzhen, China) was loaded on to the delivery system for the deployment from left upper pulmonary vein. Both discs were released however, right atrial disc could not be positioned well, TEE images then revealed a large Eustachian valve in right atrium. Several attempts were made to deploy the device, but were unsuccessful since Eustachian valve was slipped into right atrial disc and transcatheter closure of ASD failed.
Conclusion: Transcatheter closure of ASD in patients with large Eustachian valve may be challenging even with suitable size and adequate rims.

P2796 - TRANSCATHETER INTERVENTIONS IN CONGENITALLY CORRECTED TRANSPOSITION OF GREAT ARTERIES A CASE SERIES

Amitabha Chattopadhyay, Aritra Mukherji, Prabhat Kumar, Indira Banerjee
Narayana Superspeciality Hospital, Pediatric Cardiology, Kolkata-India

Background: Congenitally corrected transposition of great arteries (CCTGA) is a condition where the anatomic right ventricle (RV) assumes the function of systemic ventricle. The natural history of these patients are worse when associated with cardiac defects that increase the volume or pressure load on the already compromised systemic RV. We hereby present three patients of CCTGA with associated lesions who were successfully tackled by trans-catheter modalities.
Materials and Methods: GM, a 10 years old girl presented with NYHA II exertional dyspnoea. Echocardiography revealed CCTGA, an Ebstenoid tricuspid valve with moderate tricuspid regurgition(TR) along with a 7mm perimembranous ventricular septal defect (VSD). To unload the systemic ventricle it was decided to close the septal defect by percutaneous approach. Due to significant TR and massively dilated RV, the VSD was not delineated well on RV angiograms. The VSD was crossed from venous side using an NIH catheter and angiograms were taken in shallow RAO view with catheter tip just at the mouth of the defect. A 12 mm Lifetech Muscular VSD Device was then used to close the defect from the venous side. Post-procedure patient remained in sinus rhythm with no residual shunt and significant decrease in TR. BN, a 3 month old 5 kg baby with CCTGA had severe discrete post-subclavian coarctation of aorta with severe RV dysfunction and thus surgery was not preferred.The coarctation was successfully dilated using a 6mm x 2 cm Mini Tyshak balloon. AC, was a 8yrs old girl with CCTGA and a 3mm PDA. The PDA was closed successfully using a Flipper detachable coil.
Results: In all three patients, there were significant symptomatic improvement with increase in cardiac function and decrease in TR. All remained in sinus rhythm.
Conclusions: Any lesion increasing the volume or pressure load on the already compromised systemic RV in a CCTGA should be promptly corrected, to prevent further damage.

P2804 - EVALUATION OF BALLOON ANGIOPLASTY FOR AORTIC COARCTATION IN DIFFERENT AGE GROUPS A SINGLE CENTER EXPERIENCE

Tugcem Keskin[1], Pelin Kosger[1], Duran Karabel[1], Ali Yildirim[2], Birsen Ucar[1], Zubeyir Kilic[1]
Eskisehir Osmangazi University, Department of Pediatric Cardiology, Eskisehir-Turkey[1]; Pediatric Cardiologist, Eskisehir-Turkey[2]

Introduction: Pediatric patients with different age groups who underwent balloon angioplasty or stent implantation for aortic coarctation were evaluated.
Methods: From January 2006 to 2017, 69 patients with aortic coarctation underwent balloon angioplasty or stent implantation were evaluated. According to age at angioplasty, patients were divided into two groups: Group A (0-3 months, n = 21, 16 male/5 female, weight 2.5-6 kg) and Group B (>3 months, n = 48, 41 male/7 female, weight 6-68 kg).
Results: Mean peak systolic pressure gradient was reduced from 36,1 (15-58) mmHg to 8,4 (1-20) mmHg after balloon angioplasty [n = 21, 21 (100%) native] in group A and mean peak systolic pressure gradient was reduced from 40, 2 (17-74) mmHg to 10,6 (0-31) mmHg after balloon angioplasty or stent implantation [n = 48, 30 (62.5%) native, 14 (29.1%) recoarctation, 4 (8.4%) in-stent restenosis] in group B. There was no difference between groups for early success ($p < 0.001$). One patient required immediate surgery due to aortic dissection in group A. Mean follow-up period was 66 (1-120) months. There was no significant difference in terms of need for surgery between the groups ($p = 0.312$). Recoarctation developed in 9 (42.8%) patient after an average of 15 (0.5-60) months in group A, of which 7 required surgery, 2 required redilatation. Recoarctation developed in 18 (37.5%) patient after an average of 27(1-36) months in group B of which 9 required surgery, 9 required redilatation. Two (2.8%) patients had balloon angioplasty after surgical repair. 14 patients with coarctation underwent stent implantation, of those 4 had in-stent restenosis. During follow-up of 1-5 months, 3 (4,3%) patients died.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Balloon angioplasty and stent implantation are usefull methods for aortic coarctation treatment. Patients should be monitored closely after procedures for recoarctation in all ages.

P2808 - EVALUATION OF SECUNDUM ATRIAL SEPTAL DEFECTS FAILURE RATES RESTRICTING FACTORS A SINGLE CENTER EXPERIENCE

Tugcem Keskin[1], Pelin Kosger[1], Duran Karabel[1], Ali Yildirim[2], Birsen Ucar[1], Zubeyir Kilic[1]
Eskisehir Osmangazi University, Department of Pediatric Cardiology, Eskisehir-Turkey[1]; Pediatric Cardiologist, Eskisehir-Turkey[2]

Introduction: The aim of this study is to emphasize the facts leading to transcatheter closure failures of ASDs or need for surgery.
Methods: 138 consecutive patients between 2010 and 2016 with significant ASD were considered for transcatheter closure with ASD occluder devices; 103 patients found suitable for transcatheter closure, 35 patients with inadequate septum or deficient rims were excluded from transcatheter closure after initial transoesophageal echocardiography.
Results: Procedure was successful in 89 of 103 cases (success rate 86,4%). Failure rate was 13,6% (14 cases, among whom 6 required surgery). Features of failed cases were; 5 inappropriate deployment despite several attempts due to malalignment ASD, 3 device embolization (surgery in 1, catheter retrieval in 2), 2 atrial septal anevrism, 1 Eustachian valve causing indentation into the right atrium resulting in improper positioning of device, 1 thrombus formation in right atrium before deployement, 1 failure despite Hausdorf sheath and balloon-assisted technique and 1 air embolism during prosedure. The diameter of defects and devices ranged between 16-24 mm and 17-30 mm, respectively of patients failed. Thirty five patients were found inappropriate for transcatheter closure (19 male, 16 female; age 2-17 years, median 7,6 years, body weight 14–64 kg, median 29 kg, defect diameter 16-32 mm) among whom 32 required surgery with deficient rims and inappropriate septums, 3 patients were thought to be evaluated for transcatheter closure in fallow-up.
Conclusions: Adequate total septum and sufficient rims, careful case selection, detailed imaging protocols and expertise in techniques are necessary for successful outcomes of transcatheter ASD closure.

P2814 - WHAT IS THE MAIN COUSE OF THE HEMI FONTAN FAILURE

Julita Sacharczuk[1], Aleksandra Morka[1], Tomasz Mroczek[1], Piotr Weryński[2], Magdalena Czerżyńska[1], Janusz Skalski[1]
University Children Hospital, Pediatric Cardiac Surgery, Cracow-Poland[1]; University Children Hospital, Pediatric Cardiology, Cracow-Poland[2]

Introduction: Hemi-Fontan operation is one of the stages of treatment children with single ventricular types of congenital heart defects. Overall mortality after the operation is about 5%. The mail purpose of this study is to identify the most common causes of the failure after hemi-Fontan procedure.
Materials and Methods: Twenty nine children underwent cardiac catheterization during three month after hemi-Fontan procedure between 2014-2016. The results of these evaluations were analyzed for cause and effectiveness of the interventions.
Results: The majority of the study population were children with hypoplastic left heart syndrome (62,1%). Almost all children who underwent cardiac catheterization presented hypoxemia (89,7%) and symptoms of heart failure (72,4%), including fluids in the body cavities and generalized edema (24,1%). Other symptoms were decrease blood pressure in the lower part of the body (2 child) and superior vena cava syndrome (1 child). The most common cause of bad clinical condition after hemi-Fontan operation was left pulmonary artery (LPA) stenosis, which occurred in 79,3% of cases (23). Other causes include narrowing of the superior vena cava (3), stenosis of the distal aortic arch (3), stenosis of the right pulmonary artery (2), thrombus in hemi-Fontan system (3) and thrombus in left pulmonary artery (3). Left pulmonary artery stenting was performed in 18 children with good result in 17 cases (94,4%). Balloon angioplasty of LPA was effective in 53,8% of cases (7/13).
Conclusions: The most common cause of the hemi-Fontan failure is left pulmonary artery stenosis. Percutaneous stenting is an effective method of the pulmonary artery stenosis treatment.

P2834 - PERCUTANEOUS DUCT OCCLUSION IN VERY LOW WEIGHT CHILDREN A SAFE AND FEASIBLE ALTERNATIVE TO SURGICAL APPROACH

Maria Giulia Gagliardi[1], Luciano Pasquini[2], Andrea Dotta[3], Paolo Guccione[1], Cosimo Marco Campanale[1], Fiore Salvatore Iorio[1]
Ospedale Pediatrico Bambino Gesù, Cardiology, Rome-Italy[1]; Ospedale Pediatrico Bambino Gesù, Perinatal Cardiology, Roma-Italy[2]; Ospedale Pediatrico Bambino Gesù, Neonatology, Roma-Italy[3]

Background: Patent Ductus Arteriosus (PDA) is the most frequent cause of heart failure in pre-terms and newborns with co-morbidities in neonatal intensive care units. Nowadays surgical closure is the treatment of choice in very low weight pre-terms but it carries significant morbidities and mortality risks. Catheter closure option can potentially overcomes these limitations. We present our experience in this population.
Materials and Method: From March 2012 to November 2014 we treated 12 newborns below 3Kg (mean weight 2.56, min 1.7, max 3.4 kg) with percutaneous approach. Amplatzer Duct Occluder (ADO) II and ADO II Additional Size were used.
Results: All 12 patients had hemodynamically significant PDA. Eight (66%) were preterms; comorbidities were severe broncodysplasia in 4 (25%), operated of aneurysm of Galeno vein in 1 (8.3%), congenital Rubella in 1 (8.3%), diaphragmatic hernia in 1 (8.3%) and other congenital cardiac defects (ASD and VSD) in 3 (25%). In eight patients (66%) medical therapy with indometacine was previously attempted but in four of them (50%) complications occurred. Eleven patients (92%) received furosemide, three (25%) ACE-Inhibitors therapy and two (17%) sildenafil. We register no mortalities nor morbidities due to catheterization. Nine (75%) received ADO II Additional Size and three (25%) ADO II. Mean fluoroscopy time was 15 minutes and mean contrast volume was 15 ml. No residual shunt at echocardiography was found in all cases. At follow-up (12 months) no deaths were registered. The heart failure therapy was stopped in all patients after procedure.
Conclusions: using currently available technology, percutaneous PDA closure in very low weight newborns is a feasible and safe alternative to surgical procedure. Early and mid-term follow-up is encouraging.

P2843 - PULMONARY ARTERY BANDING BALLOON DILATION PATIENT DESCRIPTION AND OUTCOME

Ana R. Sousa, Inês Mendes, João Rato, Fernando M. Martins, Rui Anjos
Hospital De Santa Cruz, Chlo Epe, Pediatric Cardiology, Carnaxide-Portugal

Pulmonary artery banding (PAB) is used for paliation of congenital heart defects with excessive pulmonary blood flow. The primary

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

aim is to reduce pulmonary blood flow and protect the pulmonary vasculature from irreversible pulmonary hypertension. As the patient grows the obstacle becomes more restrictive causing reduced pulmonary blood flow and progressive cyanosis. In patients who are not candidates to corrective surgery, balloon dilation is an alternative to surgical intervention. We report our results with PAB balloon dilation (PAB-BD) over a ten-year period from 2007 to 2016. During this period 12 patients underwent PAB-BD. The most frequent diagnosis was aortic coarctation and ventricular septal defect(VSD) in 7 patients, followed by apical/multiple VSDs in 4 patients and a univentricular defect in one patient. The mean age at PAB was 58 days(3-238), and the mean post-operative gradient across the PAB was 65 mmHg(35-94), excluding the patient with univentricular defect (gradient of 33 mmHg). PAB-BD was performed at a mean age of 28 months (10-88) and was performed for severe cyanosis in five patients, restrictive/closed VSDs in five patients and severe RV hypertrophy in two patients. Balloons used were high-pressure in nine patients, low-pressure in two patients and in one patient a low-pressure balloon was used followed by a high-pressure balloon. The invasive gradient across the PAB decreased from a mean of 70 mmHg(35-124) to a mean of 46 mmHg(7-90). In patients with cyanosis there was an increase in saturation from a mean of 80,4% (60-87) to a mean of 89,9%(85-93). There were no complications of the procedure. None of the patients with small restrictive/closed VSDs required surgery. One patient died 10 years after the procedure. PAB-BD is a safe and effective procedure, improving saturation in cyanotic patients and avoiding the need for surgical pulmonary artery debanding and VSD closure in patients that evolve to small restrictive/closed VSDs.

P2846 - BALLOON ATRIAL SEPTOSTOMY IN THE CATHETERIZATION LABORATORY FACILITATES UMBILICAL APPROACH

Mairi Macinnes, Brodie Knight
NHS Greater Glasgow and Clyde, Paediatric Cardiology, Royal Hospital For Children, Glasgow-United Kingdom

Introduction: Balloon atrial septostomy (BAS) is routinely performed under ultrasound control and can be performed via femoral (FV) or umbilical vein (UV). FVBAS requires a 7 F introducer for the Miller-Edwards septostomy catheter. FV thrombosis is common after FVBAS. Avoiding this complication is important as FV access facilitates future surgical or interventional procedures. Difficulty crossing the ductus venosus often makes UVBAS impossible. We investigate the use of fluoroscopy to facilitate UVBAS.
Methods: Patients undergoing BAS at <7 days of age by a single operator from 2010 to 2017 were included. Since late 2103 fluoroscopy has been used to facilitate UVBAS. Data were collected on location of procedure, access route, use of fluoroscopy, degree of urgency, radiation dose, and complications.
Results: During the study period a total of 52 BAS were performed. In the pre-fluoroscopy era (PreFE) 25 patients underwent BAS, 12 UVBAS (48%) and 13 (52%) FVBAS. In the post-fluoroscopy era (PostFE) 27 patients underwent BAS, 17 in the catheterization laboratory (63%). In 13/17 (76%) fluoroscopy was used to facilitate UVBAS. This was successful in 12/13 (92%). Fluoroscopy was available but unnecessary in 4 cases. In the one failure, fluoroscopy assisted diagnostic catheter passage via UV to right atrium but BAS was not possible. In the PoFE, UVBAS was successful in 21/27 (78%) and femoral in 6/21 (29%). Of the latter, UV was attempted unsuccessfully without fluoroscopy in 2. PoFE success rate of attempted UVBAS in the last 19 patients was 100%. Fluorography was used less often in urgent than in non-urgent UVBAS (3/9 vs 8/12 respectively). Complication rates were comparable between UVBAS and FVBAS. Fluoroscopy dose was negligible.
Conclusions: Since utilizing fluoroscopy, 78% of BAS have been performed using the UV compared to 48% prior to this, with no increase in complication rate and only minimal radiation.

P2853 - CATHETER BASE CLOSURE OF LARGE PDAS A CASE SERIES

Kamran Mirza Md, Amitabha Chattopadhyay
Narayana Superspeciality Hospital, Pediatric Cardiology, Howrah-India

Back Ground: Patent Ductus Arteriosus (PDA) constitutes 6 to 11% of all heart defects. Surgical repair is a safe, widely accepted procedure with negligible mortality but it is also associated with morbidity, discomfort and a thoracotomy scar. Transcatheter closure of PDA is under continuous phase of evolution as far as technique and the closure devices are concerned. Multiple occluder devices have been studied and used for large PDAs of different shapes and sizes.We describe our single center experience with closure of large PDAs using the different devices depending on the anatomy, morphology and hemodynamics.
Materials and Methods: From July 2015 to December 2016, 25 patients (16 females,9 males) between 2 to 16 years underwent transcatheter closure of large PDAs (ranging from 6mm to 18 mm at PA end). On simultaneous measurements of PA and Aortic pressures, 4 children showed PA pressure >2/3rd of systemic pressure which further came down on oximetry, while the remaining 21 had PA pressure between ½ to 2/3rd of systemic pressure with features of reversibility.PDA delivery systems ranging from 6 F to 12 F were used.The devices used included Atrial Septal Occluder (2), Duct Occluder (14), muscular VSD device (5), vascular plug (1). 3 of the largest PDAs (12 mm ,16mm and 18mm) were closed with Post Infarct Muscular VSD Occluder measuring 20 mm,22 mm and 24 mm respectively.
Results: Transthoracic Echocardiography in immediate post intervention period revealed all devices in situ with no residual flow, aortic or branch pulmonary flow obstruction. Of 25 patients, 20 had moderate LV dysfunction which improved over next 2 to 3 days on inotropic supports, while 5 had mild LV dysfunction which improved eventually over 6 months.
Conclusion: Although surgical repair of large PDA is a safe, widely accepted procedure with negligible mortality, it is associated with morbidity, discomfort and a thoracotomy scar. Transcatheter closure of PDA is a reliable alternative to surgery.

P2858 - VALIDATION OF A US RISK SCORE FOR CARDIAC CATHETERISATION PROCEDURES IN A SINGLE CENTER PORTUGUESE PAEDIATRIC POPULATION

Paulo Éden Santos[1], Ana Correia Costa[1], Tiago Adrega[2], Joana Oliveira Miranda[1], Edite Gonçalves[1], Maria João Baptista[1], Jorge Antunes Moreira[1]
Centro Hospitalar De São João, E.P.E, Pediatric Cardiology, Porto-Portugal[1]; Centro Hospitalar De Baixo Vouga, E.P.E., Cardiology, Aveiro-Portugal[2]

Introduction: In 2016, the Congenital Cardiac Interventional Study Consortium (CCISC) developed and validated a scoring system that predicts the risk of serious adverse events

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(SAE's) for individual paediatric patients undergoing cardiac catheterisation (CRISP: Catheterization RISK Score for Pediatrics). We sought to validate this score in a Portuguese paediatric population and to compare its predictive accuracy with the original score.
Methods: A single-centre retrospective study, embracing patients under 18 years-old undergoing cardiac catheterisation, between January 2013 – January 2017. The area under the receiver operating characteristic curve (ROC) and Hosmer-Lemeshow test were used to assess the test performance and compare it with the original score.
Results: We included 459 patients in the study, median age was 6 years old, 47.3% female and 51,2% percutaneous interventions were performed. There were 17 SAE's (3.7% vs predicted 2.8%) with 0% mortality rate. All SAE's were amenable of immediate correction without morbidity. More experienced centers had SAE rate inferior than expected. The score exhibited good discrimination, with 0.79 area under the ROC curve (CI 0.66 to 0.91 vs original score 0.74) and an appropriate goodness of fit, with a Hosmer-Lemeshow test of 0.62.
Conclusion: The CRISP is useful risk stratification for SAE's in our patients undergoing cardiac catheterisation. Our outcomes are similar to other experienced institutions.

P2863 - TRANSCATHETER CLOSURE OF PERSISTENT FORWARD FLOW FROM THE VENTRICLE TO THE PULMONARY ARTERIES IN FONTAN PROCEDURES

Ana R. Sousa, Inês Mendes, João Rato, Fernando M. Martins, Rui Anjos
Hospital De Santa Cruz, Chlo Epe, Pediatric Cardiology, Carnaxide-Portugal

The Fontan procedure is a palliative surgery performed for the management of patients with complex congenital heart disease that are not amenable to complete biventricular repair. If excessive forward flow from the ventricle to the pulmonary arteries persists after the Fontan procedure, persistent pleural effusions, congestion of systemic veins or progressive ventricular dysfunction may occur. We report our series of transcatheter closure of forward flow from the ventricle to the pulmonary arteries in 5 patients after superior cavopulmonary shunt (n = 1) or complete Fontan procedure (n = 4). The main diagnoses were: double inlet left ventricle and transposition of great arteries (TGA); unbalanced atrioventricular septal defect, TGA and pulmonary stenosis (PS); tricuspid atresia and L-TGA; double outlet right ventricle (DORV) with unbalanced ventricles; and TGA and PS. Indications for closure were persistent congestion with edema in two patients, haemodynamic instability in the acute phase after Fontan procedure in one patient, persistent chylothorax in one patient (with cavopulmonary shunt) and low cardiac output with limited exercise tolerance in one patient. Mean age at the time of intervention was 10 years (1-20). In three patients an Amplatzer duct occluder was used and in two patients an Amplatzer atrial septal occluder. In two patients there was a small residual leak after the transcatheter procedure. No complications were reported. There was symptomatic improvement in all patients. The patient with haemodynamic instability and prolonged intubation was extubated the day after the procedure, two patients with edema reduced diuretics in the weeks following the procedure and one patient with chylothorax removed pleural drainage 5 days after the procedure. Transcatheter closure of ventricle-pulmonary artery communication is a safe and effective treatment for patients with residual flow after cavopulmonary shunt or Fontan procedure with early or late complications due to excessive pulmonary blood flow.

P2872 - ELIMINATING STENT SLIPPAGE USING A NEW COMBINED BALLOON SHEATH ASSEMBLY SYSTEM (NUDEL)

James Yashu Coe[1], Marisha Mclean[1], Cameron Seaman[1], Dion Pepelassis[2], Shreepal Jan[1], Chodchanok Vijarnsorn[1]
University of Alberta, Pediatric Cardiology, Edmonton-Canada[1]; University of Manitoba, Pediatric Cardiology, Edmonton-Canada[2]

Backgound: Percutaneous stent placement is used to treat vascular stenosis through previously placed long sheaths. Stents can slip off the balloon during its passage to the target. The stent must be retrieved, repositioned or remounted prolonging the procedure, some required surgical removal. Despite advances in technology and techniques, this complication persists. We describe our experience with a new method of stent delivery that eliminates stent slippage using an all-in-one stent-in-sheath balloon assembly system.
Material & Methods: The concept was to permit movement as one system (NuDEL, NuMed USA) minimising stent migration over the balloon. It evolved from the initial obturator shape system that was introduced through another short sheath, and did not allow free injection of contrast. The current NuDEL design overcame these drawbacks. The sheath has a hemostatic valve and permitted contrast injection. The BIB balloon has an obturator tip, using a 0.035" wire.
Results: From 2008, 21 patients (age 5.9-25.9 years) underwent 23 procedures to relieve pulmonary artery (PA) stenoses (n = 8), prior to pulmonary valve replacements (n = 12), PA conduit stenosis (n = 1) and coarctation (n = 2). The stent, front loaded on the balloon (8-22 mm) covered by the sheath (12-22 Fr). Pre-mounted stent system was used in 9 cases, covered CPTM stents in coarctation (n = 2) and for relieving proximal left PA stenosis while simultaneously occluding an aorto-pulmonary collateral. Multiple non-sustained arrhythmias (n = 8) occurred during the procedure. One obturator tip dislodged from the catheter. All stents remained on the balloon, and successfully deployed. In one patient where 2 stents were deployed to relieve lobar PA stenosis, one stent embolized proximally into the right hepatic vein, 12 hours after successful deployment.
Conclusion: Stent slippage is eliminated using the all-in-one balloon sheath assembly system, shortening of procedure time. It is ideal to rescue an unexpected arterial tear or perforation.

P2874 - HEART FAILURE IN A NEONATE DUE TO HEPATIC HEMANGIOMA DIAGNOSIS AND MANAGEMENT

Andressa Mussi Soares[1], Paulo José F. Soares[2], Bernardo Mussi Soares[3], Resi Apolinario[4], Saulo Ayub[5], Fabio R. Bortolini[6], Patricia L. Mota[4], Renata B. Pacifico[4], Luiz Daniel F Torres[7], Vitor C. Guerra[8]
Hospital Evangelico, Pediatric Cardiologi, Cachoeiro De Itapemirim-Brazil[1]; Hospital Evangelico, Interventional Cardiologi, Cachoeiro De Itapemirim-Brazil[2]; Escola De Medicina Souza Marques, Medicine, Rio De Janeiro-Brazil[3]; Hospital Evangelico, Neonatologist, Cachoeiro De Itapemirim-Brazil[4]; Hospital Evangelico, Intervencionist Cardiologist, Cachoeiro De Itapemirim-Brazil[5]; Hospital Evangelico, Radiologist, Cachoeiro De Itapemirim-Brazil[6]; Hospital Evangelico, Cardiologist Surgery, Cachoeiro De Itapemirim-Brazil[7]; Sick Children, Pediatric Cardiologist, Toronto-Canada[8]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Introduction: Hepatic hemangioma is a vascular tumor that involves arteriovenous shunt and which can culminate in heart failure in up to 50% of the cases. Death is the outcome in 70% of untreated cases. Cardiac symptoms are worse in younger patients.
Objective: To describe the clinical presentation, diagnosis, and management of a newborn with cardiomegaly, heart failure, anuria, and early hemodynamic instability.
Case Report: A full-term male baby weighing 3,950 g, with respiratory failure and cardiomegaly at chest X-ray, was submitted to mechanical ventilation, inotropic doses and peritoneal dialysis due to hemodynamic instability, tachycardia, signs of heart failure, hepatomegaly, edema, anuria and coagulation disorders. Echocardiography showed inferior dilation of the vena cava and heart chambers, moderate tricuspid insufficiency, and persistent ductus arteriosus. Abdominal ultrasonography revealed hepatic vascular alterations. Abdominal CT scan showed a huge hepatic hemangioma with arteriovenous shunt.The tumor occupied 80% of the liver, which prevented its resection. Due to the newborn's poor hemodynamic status, we decided to coil the tumor fistula by the percutaneous route when the baby was 12 days old. Soon after the procedure, angiography showed reduced shunt, and diuresis began. The coil was well positioned at the right hepatic artery as

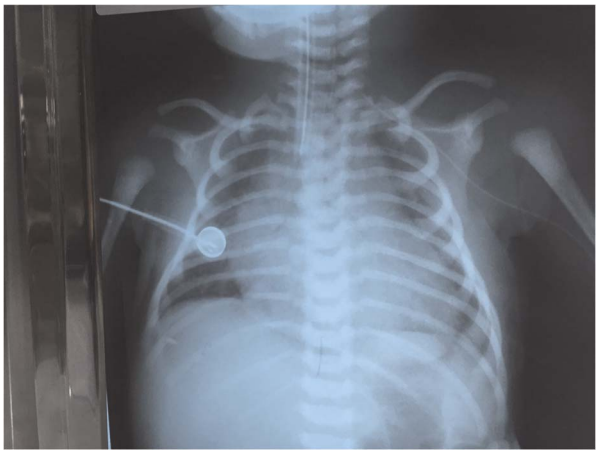

Figure 1.

Figure 2.

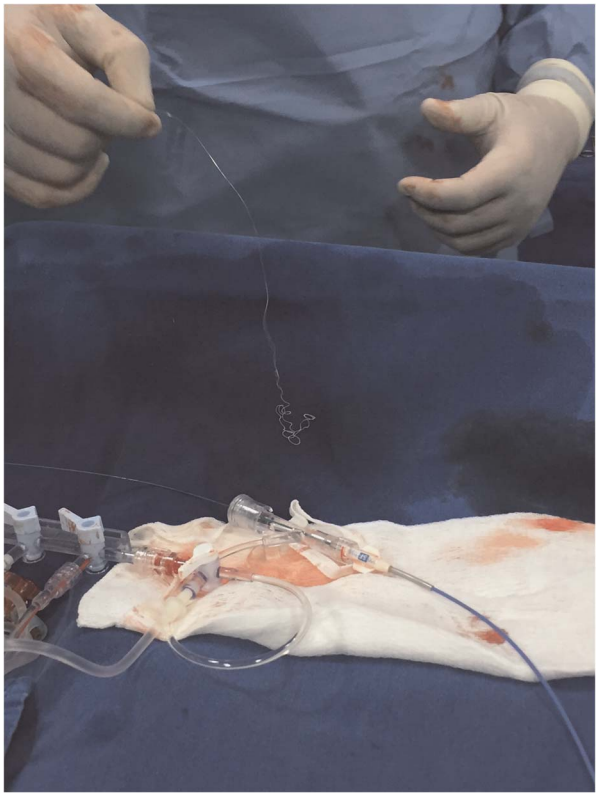

Figure 3.

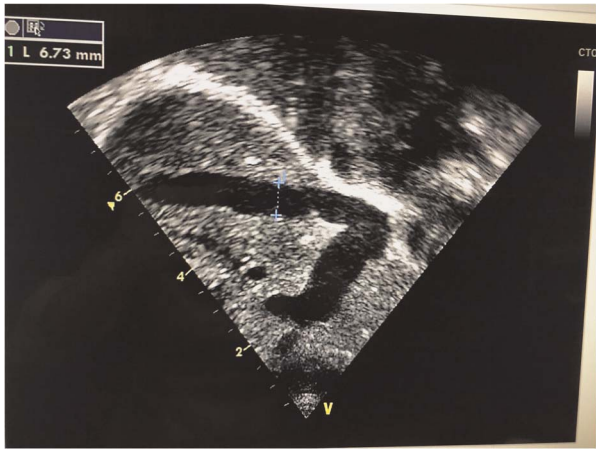

Figure 4.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

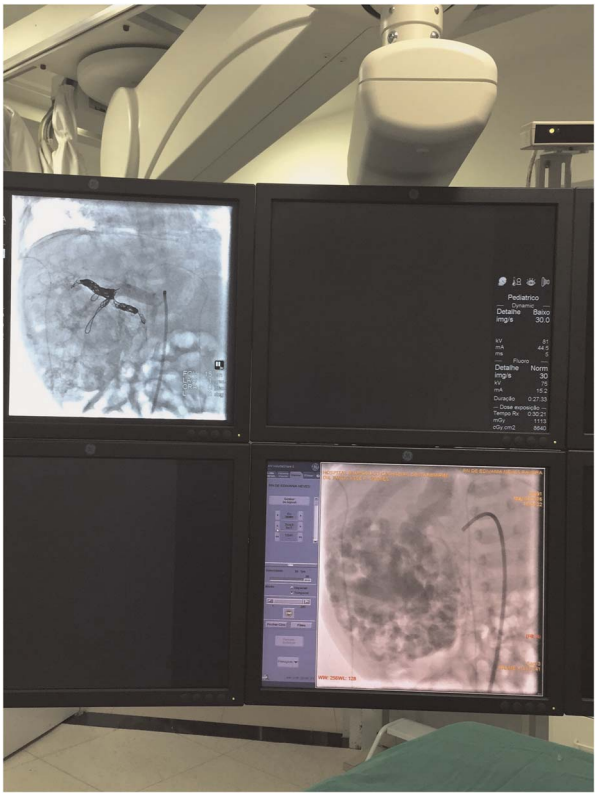

Figure 5.

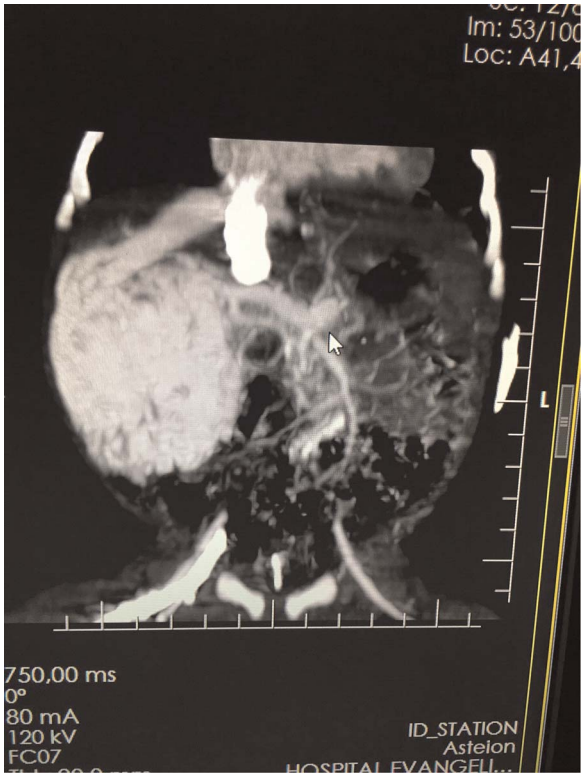

Figure 6.

revealed by post-procedure X-ray examination. Clinical conditions improved gradually, and the patient was discharged from hospital on propranolol. When the patient was six months old, he presented good cognitive and physical development and was being breast-fed. The latest abdominal ultrasonography, conducted at 4 months of age, showed liver with normal size and shape; there were scars in its central portion.

Conclusion: Although hepatic tumors are benign and tend to involute spontaneously, they may lead to heart failure and great morbi-mortality. Hepatic artery percutaneuos embolization was a challenging procedure that probably changed the progress and outcome in this case.

P2880 - RESTENOSIS OF STENT IMPLANTED AORTIC COARCTATION DUE TO NEOINTIMAL HYPERPLASIA

Tugcem Keskin[1], Pelin Kosger[1], Duran Karabel[1], Ali Yildirim[2], Birsen Ucar[1], Zübeyir Kilic[1]
Osmangazi University, Department of Pediatric Cardiology, Eskisehir-Turkey[1]; Pediatric Cardiologist,Eskisehir-Turkey[2]

Introduction: Progressive neointimal proliferation may reduce the size of the stent lumen over time requiring redilatation.
Method: Balloon dilatation was performed in 3 male patients with stent implanted aortic coarctation due to instent restenosis.The age of stent implanted patients were 8, 11, and 16, respectively, post-procedural instent restenosis of patients detected in the second, first and third years of follow-up, respectively. Peak systolic pressure gradients measured before redilatation were 34, 35 and 52 mmHg respectively and the pressure gradients measured after redilatation were 2, 8 and 9 mmHg respectively. Mild proximal arch hypoplasia was present in 11 years old patient, restenosis detected in echocardiography at the first year of redilatation in the same patient requiring control angiography, pressure gradient was found lower than 20 mmHg, patient decided to be monitored with anhypertensive treatment, no redilatation prosedure was performed. Eight-year-old patient is in the 2nd year of redilatation and the 16 year-old patient is in the third year of redilatation, both are still followed with antihypertensive treatment.
Conclusion: Neointimal proliferation may cause restenosis in aortic coarctation. Redilatation is successful in treating restenosis caused by neointimal proliferation.

P2888 - PULMONARY ATRESIA AND INTACT VENTRICULAR SEPTUM – CAN WE STIMULATE THE RIGHT VENTRICLE GROWTH

Monika Pietrzak[1], Maria Hussey[2], Joanna Duliban[3], Agnieszka Grzyb[4], Adam Kolesnik[5], Grazyna Brzezińska-Rajszys[4], Andrzej Kansy[6], Bohdan Maruszewski[6], Joanna Dangel[7]
Medical University of Warsaw, 2nd Department of Obstetrics And Gynecology, Warsawa-Poland[1]; St Peter Hospital, Emergency Medicinie, Guildford-United Kingdom[2]; Medical University of Warsaw, Fetal Cardiology 2nd Department of Obstetrics and Gynecology, Warsaw-Poland[3]; Children's Memorial Health Institute, Cardiology Department, Warsaw-Poland[4]; Warsaw Hospice For Children Foundation, Referral Center For Fetal Cardiology, Warsaw-Poland[5]; Children's Memorial Health Institute, Cardiac Surgery Department, Warsaw-Poland[6]; Medical University of Warsaw, Referral Center For Fetal Cardiology, Warsaw-Poland[7]

Background: Pulmonary atresia with intact ventricular septum (AP&IVS) is a defect which often requires single ventricle treatment. Prenatal pulmonary valve opening and valvuloplasty (FPV) is undertaken to preserve right ventricular size and function allowing for biventricular correction.
Materials and Methods: Echocardiographic examinations and postnatal follow-up of 64 fetuses with AP&IVS were reviewed. Patients were divided in two groups: diagnosed before 2010 year (n = 28). Basing on this results prospective study between 2011-2016 was conducted with the aim to prepare for FPV. There were 36 fetuses, including 9 who underwent FPV, 2 still in utero.
Results: The mean age of diagnosis was 28 + /-6 weeks in the first group, and 23 + /-5 weeks in the second. Heart defect was isolated in 85% of fetuses from 1stgroup and 72% from 2ndgroup.Chromosomal abnormality were in 4% and 14% in respective groups, other organs defects in 11% and 14%. Survival was 46% in the 1st group, only one patient achieved biventricular circulation. In the 2ndgroup survival rate was 66%. 7 patients after FPV have biventricular circulation, with one death after postsurgical complication. Right heart structures measurements during last prenatal exam (RV length, width, and TV annulus) expressed in Z-scores were compared between fetuses who underwent FPV and those who did not. They were significantly bigger in the FPV group: RV length: -1.26 vs. -5.74, RV width -0.41 vs. -4.62, TV annulus 0.81 vs. -2.43. In both groups pulmonary arteries were of normal size.
Conclusion: Prenatal diagnosis of AP&IVS improved with time. Retrospective analysis with majority of SV pathway enables to establish the national program for FPV. Right ventricle grows significantly after FPV. FPV enables biventricular pathway in majority of children.

P2893 - MID TERM FOLLOW UP OF MULTI CENTRE TRIAL OF THE OCCLUTECH® ACCELL® FLEX II SEPTAL OCCLUDER FOR TRANSCATHETER CLOSURE OF SECUNDUM ATRIAL SEPTAL DEFECTS

Amal El-sisi[1], Sonia El-saeidi[1], Rasha Ammar[1], Ziyad Hijazi[2]
Cairo University, Pediatric Cardiology, Cairo-Egypt[1]; Sedra Medical Centre, Pediatric Cardiology, Doha-Qatar[2]

Background: The Occlutech® Flex II ASD is currently used to close wide range of defects.Thrombus formation on atrial septaloccludersis rare, but it is a potential serious complication that could lead to an embolic event. A newer modification of this device (Occlutech® ACCELL® Flex II) has been designed to eliminate/reduce this potential complication. The aim of this study was to determine mid term follow up safety of this device.
Methods: A prospective, single-arm, open label, multi-center non-randomized pilot study in an application for CE mark. Thirty two patients were included in this study from a single center. Procedure protocol was approved by the institutional ethics committee. Patients were followed at 1, 30 and 90 days and six monthly post

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

procedure. Color Doppler echocardiography was performed to quantify residual shunt (trivial shunt: jet width < 1mm;small shunt width 1-2mm; moderate shunt width 2-4mm and large shunt width > 4mm).
Results: Total number of patients enrolled were thirty two patients. 12 males(37.5%).Mean age was 7.5 ± 8.2 yearsand mean weight was 26 ± 23.9 Kg. All procedureswere done under general anesthesia and TEE was used to guide all procedures. Balloon sizing was performed in only three patients. All patients had adequate rims. The mean procedure time was 33.3 ± 14.7 minutes and mean fluoroscopy time was9.2 ± 7.8 minutes. The mean device size used was 18.5 ± 6.9 mm and the mean sheath size used was 10.8 ± 1.6 F. All patients had complete closure of their defects as demonstrated by TTE at 24-hour follow up. Mean follow up period was 3.2 years. No complications were encountered during the procedure or at follow up.
Conclusion: Mid term follow up of the Occlutech® ACCELL® Flex II showed it is a safe and effective device. The ACCELL coating on the device may enhance endotheliazation of the occluder and therefore may minimize the risk of thrombus formation.

P2899 - TRANSCATHETER CLOSURE OF SUPRACRISTAL VENTRICULAR SEPTAL DEFECTS – SHORT TERM OUTCOME

Amitabha Chattopadhyay[1], Snehal Patel[1], Prabhat Kumar[1], Indira Banerjee[1], Aritra Mukherji[1], Audil Mohmad Lanker[1], Mahua Roy[2], Biswajit Bandyopadhyay[2]
Narayana Superspeciality Hospital, Pediatric Cardiology, Kolkata-India[1]; Rabindranath Tagore International Institute of Cardiac Sciences, Mukundapur, Pediatric Cardiology, Kolkata-India[2]

Background: Surgery has been the mainstay for closure of supracristal ventricular septal defects (VSD). Transcatheter closure of supracristal VSDs have not been in vogue due to concerns of damage to the surrounding structures and outflow obstructions, risk of aortic incompetence (AI) from aortic valve damage. We present our series of 10 cases of device closure of supracristal VSDs, with a short term follow up of one year.
Materials and Methods: We followed the standard echocardiographic nomenclature for VSDs, whereby the VSDs which were well beyond the 12 o'clock position on the short axis views, were taken into this study. The VSDs were evaluated from other views as well, conforming to the diagnosis of supracristal VSDs. Cases where the RCC had summarily prolapsed into the VSD were rejected. 4 girls had whiff of preexisting AI, but their parents preferred device closure to open heart surgery, even after adequate counseling. Proper written consent was obtained in each of the cases in their vernacular language. The VSDs were best visualized in RAO 30 degree and Caudal 20 degree views, which we improvised for the supracristal VSDs. The VSDs were crossed from the aorta retrogradely and the ADO II devices were delivered from the aortic side. Meticulous echocardiographic evaluation of the devices were done after positioning them across the defect with special emphasis on the position, stability, possible impingement on the aortic valve and the pulmonary valve and any outflow obstruction.
Results: There was no residual flow, outflow obstructions or AI in any of the cases, on immediate and one year follow up examinations. The whiff of preexisting AI in 4 patients remained so even after a one year follow up.
Conclusion: Device closure of supracristal VSDs is possible in selected cases. Short term outcomes are encouraging, however long term outcomes need to be studied.

P2911 - DEVICE IN DEVICE FOR ASD CLOSURE

Renata Mattos[1], Gabriel Camargo[1], Maritza Anzanello[1], Victor Hugo Oliveira[1], Luiz Carlos Simoes[1], José Geraldo Athayde[2], Alexandre Abla[1], Marilia Domingues[1], Gabriela Mesquita[1], Monica Celente[1]
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil[1]; Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescenteservico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil[2]

Background: The atrial septum defect (ASD) is a common congenital heart disease. Its closure by percutaneous technique is safe, with a shorter hospitalization time, but it is not exempt of complications such as device malposition, thrombosis, endocarditis, residual shunt, arrhythmias, valvular regurgitation, cardiac perforation and sudden death.
Case report: 36-year-old woman with no previous comorbidities and an ASD, measuring 22 mm, occluded with a CARDIA ATRIASEPT 30 device, in August 2013. During follow-up she reported progressive fatigue and palpitations. Transthoracic echocardiogram (TTE) in March 2014 revealed residual shunt with a QP:QS of 2.3, which rised to 3 in November 2014 and 5.6 in a year later. These findings followed worsening of the symptoms. She underwent another catheterization in August 2016. On physical examination, she presented a splitting of S2 and mesosystolic murmur 3 + / 6 + in pulmonary and accessory aortic areas. During the procedure a fixed CARDIA device was detected in the ASD, with its metallic structure intact, but with complete loss of its polyvinyl alcohol membrane. Percutaneous closure of residual shunt was performed with multifenestrated AMPLATZER 35, successfully covering the previous prosthesis. This procedure was guided by three-dimensional transesophageal echocardiography. There was no residual shunt in the follow-up.
Discussion: Complications such as that described in this case are usually treated by surgical techniques. The occurrence of residual shunt through the central portion of the CARDIA ATRIASEPT

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

prosthesis is still poorly described in the literature and its correction by the "intra prosthesis" technique has been shown to be a less invasive option with good results.

P2958 - TRANSCATHETER CLOSURE OF SUBARTERIAL VENTRICULAR SEPTAL DEFECT WITH THE AMPLATZER DUCT OCCLUDER II INITIAL CLINICAL EXPERIENCE

Yun-Ching Fu, Tsung-Cheng Shyu, Ming-Chih Lin, Yeak-Wun Quek, Sheng-Je Lin, Sheng-ling Jan Taichung Veterans General Hospital, Department of Pediatrics, Taichung-Taiwan

Background: Surgical closure of subarterial ventricular septal defect (VSD) is well established but requires open heart surgery with cardiopulmonary bypass. This study aimed to evaluate the feasibility, safety and outcome of transcatheter closure of subarterial VSD with the Amplatzer duct occluder II (ADO II).
Materials and Methods: Between March 2014 and October 2016, a total of 12 patients with subarterial VSD who underwent transcatheter closure with ADO II were enrolled retrospectively. There were 7 males and 5 females. The age ranged from 2.3 to 58.6 years with the median of 7 years. The body weight ranged from 11.5 to 84 kg with the median of 26.3 kg. Echocardiography showed the VSD was supracristal subtype in 8 patients and intracristal subtype in 4. All patients had prolapse of right coronary cusp without subaortic rim. Mild aortic regurgitation was noted in 5 (42%) patients.
Results: Aortography showed VSD size ranged from 0.8 to 5.0 mm with the median of 1.9 mm. Device was successfully implanted in 92% (11/12) of patients. No complication was noted. Complete closure rate was 64%, 64% and 82% at 1-day, 1-month and 3-month follow-up respectively. Three (27%) patients developed new mild aortic regurgitation during follow-up.
Conclusions: The initial experience shows that transcatheter closure of subarterial VSD with ADO II is technically feasible, safe and effective. However, the influence of aortic regurgitation needs long term follow-up.

P2988 - USE OF SYMMETRICAL HYPERIOM PERI MEMBRANOUS VSDO FOR PERVENTRICULAR CLOSURE OF MUSCULAR SEPTAL DEFECT

Justo Santiago, Juan Gallego, Sara Mendoza, Javier Castro, Constanza Bastos
FCV, Cong Heart Dis, Bucaramanga-Colombia

The per ventricular closure of the muscular interventricular septal defects it's use in children with lightweight and it's incrementing with more promising results everytime. The devices used have been occlusors designed for muscular septum, which possess a length of 7 mm. We described a case which is treated with this closure mode through a new device designed for Perimembranous Ventricular Septal Defect in a 3 month old infant with 4,3 kg of weight and history of intrauterine growth retardation whom was diagnosed with the presence of muscular interventricular communication with length of 6 mm which is associated with the presence of aortic coarctation. It was taken to the surgery room and under general anesthesia a correction of aortic coarctation with terminal technical term extended by left lateral thoracotomy, sternotomy sequentially and interventricular communication approach per ventricular puncture was performed and a septal occlude device perimenbranous of 8 mm designed for interventricular communication was placed achieving a complete occlusion of the defect. The device used constitutes a feasible alternative in this patients and we consider the smallest waist length an advantage. Offering a more apt configuration further adapting the diameters of the interventricular septum in this age, which exposes less of the device's material towards the ventricular cavity.

P2993 - UNSATISFACTORY RESULTS OF CRITICAL AORTIC STENOSIS

Eun-Young Choi[1], Hye-Won Kwon, Sang-Yun Lee, Seong-Ho Kim[1], Chang-Ha Lee[2], Su-Jin Park[1], Ji-Seok Bang[1]
Sejong General Hospital, Pediatrics, Bucheon-Si-Korea, South[1]; Sejong General Hospital, Cardiothoracic Surgery, Bucheon-Si-Korea, South[2]

Introduction: Critical aortic stenosis is a rare disease in Koreans. The purpose of this study is to review the critical aortic stenosis cases experienced in a single center during the recent 12 years and to consider the issues to be considered when conducting treatment.
Methods: The period included in the study was from January 2005 to December 2016. We performed retrospective medical record review and image reanalysis for 7 patients.
Results: Seven patients were all male and the median age of first intervention was 11 days (2~15) and the average weight was 2.96 kg (2.4~3.3). The median follow-up period was 75 months (1-119). One patient died suddenly at home during the follow-up period. One patient underwent Ross operation and the remaining patients underwent balloon aortic valvuloplasty or surgical valvotomy. After first intervention, the aortic valve annulus increased by 0.47mm (0.2-0.8), but the coaptation height of aortic valve decreased by 0.44mm (-2.3-1.0). Prior to intervention, only two patients had grade I aortic regurgitation, but after intervention, aortic regurgitation was observed in all patients except one.
Conclusion: After critical aortic stenosis treatment, most patients have various degree of aortic regurgitation. These are mainly due to the prolapsed of the dysmorphic aortic valve leaflet and the decrease of the coapation height of aortic valve.

P2998 - UNDERSTANDING THE HEMODYNAMICS OF THE FETAL AND NEONATAL CIRCULATION AND ITS TRANSITION IN PULMONARY ATRESIA

Juliana Sánchez-P.[1], Alberto García Torres[2], Juan Carlos Briceño T.[1]
Universidad De Los Andes, Biomedical Engineering Department, Bogota-Colombia[1]; Fundación Cardioinfantil, Institute For Congenital Heart Disease, Bogotá-Colombia[2]

Background: Important changes in the circulatory system happen at birth, when gas-exchange function is transferred to the lungs. Modifications of the system ensue for adaptation and survival of the newborn. Patients with pulmonary atresia (PAt) who have a ductus-dependent pulmonary-circulation are at risk as they may fail to make adequate transition to postnatal life. In PAt there is a left-to-right flow through the ductus arteriosus (DA), contrary to normal fetal circulation and most cardiopaties. Since few models have evaluated the hemodynamic effects of the transition to postnatal life, the objective of this study was to develop mathematical models of the circulation of healthy and PAt infants during fetal and postnatal life to understand the changes between these four conditions.
Methods: Lumped parameter models (LPM) of the cardiovascular circulations of healthy-fetal, PAt-fetal, healthy-newborn and PAt-newborn were developed. The main assumption was that oxygen supply and blood flow to vital regions was maintained between

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

models. Models were validated with hemodynamic variables from healthy infants found in literature.
Results: We developed realistic LPM of fetal and neonatal circulations of both healthy and PAt infants, which allow estimation of flow properties that cannot be assessed from clinical measurements and to study the effects of the transition from fetal to postnatal life. The models give point-to-point pressure and flow estimates in all four conditions, confirm the fetal right-heart and newborn left-heart dominance in the healthy models and the importance of DA flow in PAt infants (Table 1).
Conclusions: The proposed LPM are good approximations to assess hemodynamic changes in fetal and neonatal circulations and their transition for healthy and PAt patients. Further development of the model can be useful for assessing the importance of isolated parameters and for simulating the effect of surgical and device interventions to repair congenital heart defects in PAt patients.

Table 1. Stability conditions for each model.

		Fetal (F)			Neonatal (N)		
					CO healthy: 230 mL-min^{-1} kg^{-1}		
		CCO: 540 mL-min^{-1}kg^{-1}			CCO PAt: 460 mL-min^{-1} kg^{-1}		
		Pressure drop, ΔP [mmHg]	Flow, Q [mL-min^{-1} kg^{-1}	Distribution of CCO, %	Pressure drop, ΔP [mmHg]	Flow, Q [mL-min^{-1} kg^{-1}]	Distribution of CO/ CCO, %
Heart hy (H)	Upper systemic circulation	47,9	151,2⋆	28,0%	67,6	151,2⋆	65,7%
	Foramen oval	0,7	113,4	21,0%	Closed		0,0%
	Pulmonary circulation	51,5	102,6^{+}	19,0%	20,7	102,6⋆⋆	100%
	Ductus arteriosus	2,8	221,4	41,0%	Closed		0,0%
	Lower systemic circulation	47,9	270,0	50,0%	67,6	270^{++}	27,2%
Pulmonary atresia (PAt)	Upper systemic circulation	41,9	151,2⋆	28,0%	41,5	151,2⋆	32,9%
	Foramen oval	7,5	437,4	81,0%	8,3	437,4	50,0%
	Pulmonary circulation	49,3	102,6^{+}	19,0%	49,8	102,6⋆⋆	50,0%
	Ductus arteriosus	0,0	102,6	19,0%	0,0	102,6	50,0%
	Lower systemic circulation	41,9	270,0	50,0%	41,5	270^{++}	13,6%

Model Assumptions:
⋆ Blood flow to the upper systemic circulation is equal in all models.
+ Blood flow to the pulmonary circulation is equal in HF and PAtF.
⋆⋆ Blood flow to the pulmonary circulation is equal in HN and PAtN.
++ Blood flow to the lower systemic circulation is equal in HN and PAtN.

Notes:
-CCO: Combined Cardiac Output
-CO: Cardiac Output

P3000 - HYBRID PULMONARY VEIN STENTING IN THE PATIENTS WITH REFRACTORY TO SURGICAL PULMONARY VEIN STENOSIS REPAIR

Jakyoung Yoon[1], *Gibeom Kim*[1], *Eunjung Bae*[1], *Kyungjin Ahn*[1], *Mikyung Song*[1], *Chungil Noh*[1], *Woonghan Kim*[2], *Jaegun Kwak*[2], *Jeong Ryul Lee*[2]
Seoul National University Hospital, Pediatrics, Seoul-Korea, South[1]; *Seoul National University Hospital, Thoracic and Cardiovascular Surgery, Seoul-Korea, South*[2]

Back ground: Pulmonary vein stenosis (PVS) is still frustrating disease with an extremely high mortality, especially in the patient with multiple severe PVS. Hybrid pulmonary vein stenting is a rescue treatment for recurrent and malignant PVS. We performed intraoperative hybrid pulmonary vein stent placement successfully in the 4 patients who had been operated multiple times for severe PVS after total anomalous pulmonary vein return (TAPVR) repair.
Cases and Review: Four patients were identified between 2013 and 2016, who were diagnosed with PVS and underwent hybrid pulmonary vein stenting. We performed hybrid PV stent placement on one patient who had progressive multiple PV stenosis and severe pulmonary hypertension despite recurrent surgical PV widening after cardiac type TAPVR repair. After hybrid stenting with coronary drug eluting stent (DES) and surgical pulmonary vein angioplasty, pulmonary vein stenosis was relieved and pulmonary hypertension was improved. Other two patients was diagnosed mixed type TAPVR (supra-cardiac + cardiac) and had severe multiple PVS despite recurrent surgical repair. These patients underwent twice hybrid pulmonary vein stenting with bare-metal stent (BMS) and pulmonary vein ballooning. Last patient who was diagnosed as functional single ventricle with pulmonary atresia and supra-cardiac type TAPVR developed progressive severe PVS after surgical repair of TAPVR. This patient also underwent hybrid stent placement. Hybrid pulmonary vein stenting resulted in sufficient relief of pulmonary venous stenosis to permit clinical stabilization in all patients. All patients received aspirin and clopidogrel after the operation. Three patients had undergone several elective further catheterizations for pulmonary vein ballooning or large stent insertion after hybrid stenting procedure.
Conclusion: We consider hybrid pulmonary vein stenting is to be a useful treatment modality for recurrent PVS patient to achieve longer freedom of restenosis than repetitive surgical PV widening.

P3006 - ROUTINE TRANSCATHETER CLOSURE OF PATENT DUCTUS ARTERIOSUS IN PREMATURE BABIES

Alain Fraisse[1], Zdenek Slavik[1], Aurelie Chalard[2], Claire Dauphin[2], Giovanni Di Salvo[1], Olivier Ghez[3], Margarita Burmester[4], Stephanie Douchin[5], Helene Bouvaist[5], Patrice Morville[6]
Royal Brompton Hospital, Paediatric Cardiology, London-United Kingdom[1]; Chu De Clermont-ferrand, Cardiology, -France[2]; Royal Brompton Hospital, Paediatric Cardiac Surgery, London-United Kingdom[3]; Royal Brompton Hospital, Paediatric Cardiac Intensive Care, London-United Kingdom[4]; Chu De Grenoble, Paediatric Cardiology, Grenoble-France[5];, Paediatric Cardiology, Reims-France[6]

Background: Few previous studies have reported the feasibility of transcatheter closure of patent ductus arteriosus (PDA) in premature babies. The use of the AMPLATZER DUCT OCCLUDER II ADDITIONAL SIZES (ADO II AS) seems potentially interesting in this patient population. However, the type and size of PDA that can be percutaneously closed with this device in premature babies remains unknown.
Materials and Methods: Since December 2015, 26 premature babies (10 male) underwent transcatheter closure of their PDA in 3 institutions. The last 18 cases were performed consecutively between October 2016 and January 2017 since this procedure has been offered as a first line treatment, regardless of the patient's weight as well as size/type of PDA. With the exception of the 2 initial cases who underwent an additional 3-French arterial access, all catheterisations were accomplished through a 4 French femoral venous access only. The ADO II AS was used in all cases, mainly under echocardiographic guidance.
Results: The median age and weight of patients at the time of transcatheter PDA closure was 29 days (range 8 to 100) and 1250grams (range 823 to 2900 grams). The median diameter of the PDA was 3.5 (1.5 to 5)mm. The ADO II AS was used in all cases. There was one failure, no immediate complications and no residual shunts. During follow-up, no aortic obstruction was demonstrated. Two months after the procedure one patient experienced severe left pulmonary stenosis requiring surgery. Two other patients had mild left pulmonary stenosis with an increased Doppler velocity of 1.6 and 2 m/s, respectively.
Conclusions: Based on this preliminary experience, routine transcatheter occlusion of PDA in premature babies with the ADO II AS is safe and effective. Longer follow-up is needed and larger studies must be performed to confirm that this procedure can be an interesting alternative to surgery.

P3012 - RIGHT HEART CATHETERIZATION USING ANTECUBITAL VENOUS ACCESS IN PATIENTS WITH COMPLEX CONGENITAL HEART DEFECTS

Irfan Levent Saltik, Sezen Ugan Atik, Ayşe Güler Eroğlu
Istanbul University Cerrahpaşa Medical Faculity, Pediatric Cardiology, Istanbul-Turkey

Introduction: The antecubital venous approach is a technique that provides very high comfort of both patient and physician, which is now forgotten but easy to access. In this report, we present the technique and features of the patients with antecubital fossa vein approach.
Technique: The most prominent antecubital fossa vein punctured with a 21-gauge needle. A 0.021 guide-wire was inserted through the needle into the vein. After seeing the tip of the wire in the vena cava superior with free movement, a 4-5 Fr sheath was inserted into the antecubital vein. All manipulations performed by using right Judkins catheter and 0.035-inch hydrophilic guide-wire. Heparin was not routinely given and the sheaths were pulled out at the end of the procedure using manual compression.
Patients: Between January 2014 and December 2016, we performed right cardiac catheterizations through the antecubital fossa veins of nine patients with various clinical indications. Six patients (67%) were male and three patients were female. The median age was 14, 6 years (3, 5 to 24 years) and the median weight was 43 kg (12 to 80 kg). Right arm was used in five patients and left arm in four. All patients except one had complex congenital heart disease with Glenn anastomosis. One patient was operated for sinus venosus ASD, abnormal pulmonary venous return and had total occlusion of VCS. In the five of the patients femoral approach was used concomitantly for additional diagnostic reasons. In two patients abnormal veno-venous collaterals occluded with various devices. Patients whom the diagnostic angiography performed discharged after 3-6 hours.
Conclusion: The antecubital venous approach can be performed easily and safely for diagnostic and theuropatic catheterisation in patients with complex congenital heart defects.

P3040 - LATE STENT REVASCULARIZATION OF ISOLATED PULMONARY ARTERY OF DUCTAL ORIGIN

Thomas Fagan[1], John Messenger[2], David Campbell[3], Dunbar Ivy[4], Jeffery Darst[4]
University of Tennessee Health Science Center, Pediatric Cardiology, Memphis-United States[1]; University of Colorado-Denver, Cardiology, Aurora-United States[2]; University of Colorado-denver, Pediatric Cardiac Surgery, Aurora-United States[3]; University of Colorado-denver, Pediatric Cardiology, Aurora-United States[4]

Background: We report our experience with stent revascularization (SR) of isolated pulmonary artery of ductal origin (IPADO) prior to surgical repair.
Methods: SR involved use of a 4Fr catheter, microcatheter and 0.014" hydrophilic coated wire to traverse occluded ductal tissue with subsequent coronary stent implantation.
Results: Between 5/08 and 5/16, 7 subjects had attempted SR-IPADO. Median age = 12mo (1-61.5), median wt = 8.4 kg (2.7-17.6) and 4 had right IPADO. A premature neonate was kept on PGE for 1 month until SR where the ductus was patent but severely stenotic (1.1mm). Median pulmonary arterial resistance was 5.0units (2.8-8.6). SR was successful in 4/7. A remnant aortic ampulla was present in all and a ductal "beak" (Fig A) leading to the occluded ductus was present in all successful (S) SR but a blunt ending ampulla (Fig D) was found in 2/3 unsuccessful (U) SR. The IPADO distal mean diameters for S-SR increased from average 3.4mm ± 0.64 to 8.9mm ± 0.85 ($p < 0.001$) (Fig B,C) prior to surgical repair. There was significant diffuse branch PA stenosis in 2/7 (1 S-SR; 1 post mBT shunt) and 2/4 S-SR developed in-stent stenosis all requiring intervention prior to surgery. Therapy for mild-moderate PHTN was used in 4/4 S-SR prior to corrective surgery. Surgical repair occurring at median 12.5mo (range 5-19) post SR involved interposition graft in 3 (9, 10 and 14 mm diameter) and 1 direct anastomosis. Surgery was facilitated by having a "virgin" chest. In median follow-up of 39.5mo (6-88) post surgery, only the subject with diffuse PA stenosis remains on therapy for PHTN. 2/3 U-SR remain unrepaired. Pulmonary vein wedge 3DRA imaging/roadmapping facilitated SR in 4/7 (Fig E). Complications of the SR-IPADO procedure include femoral artery thrombus (1/7) and occlusion (1/7).
Conclusion: Stent re-vascularization of IPADO is safe and when successful provides adequate growth of the effected artery and facilitates surgical correction.

NURSING

P1186 - DEVELOPMENT AND IMPLEMENTATION OF A PEDIATRIC CARDIAC INTENSIVE CARE NURSE RESIDENCY PROGRAM NURSE COORDINATORS AND CLINICAL EDUCATORS

Jeff Paurus[1], E. Marsha Elixson[2], Adriana Dobrzycka[3], Rohini Paul[4], Sandra Staveski[5]
Normondale Community College, Continuing Education, Cincinnati-United States[1]; Pediatric Clinical Concepts, Inc., Atlanta-United States[2]; Children, Minneapolis-United States[3]; Narayana Health, Bangalore-India[4]; Cincinnati Children, Cincinnati-United States[5]

Background/ Hypothesis: A sustainable, reproducible Nurse Residency Program (NRP) may address the gap between nurses' academic preparation and their clinical practice in the Pediatric Cardiac Intensive Care Unit (PCICU). However, in order for a NRP to be reproducible and sustainable local expert nursing staff require mentoring to become NRP coordinators and clinical educators.
Materials and Methods: International nursing experts, in collaboration with Children's HeartLink, developed a three one-week NRP through an interactive peer review process including specific coordinator and clinical educator training. Three six-hour coordinator/educator classes focused on teaching/learning methods in both the classroom and in the clinical setting. Training included, but was not limited to, facilitating small group learning, critical thinking, instructional technology, promoting active learning, and concept mapping. Topics that focused on the clinical aspects included the preceptor role, mutual goal setting, providing meaningful and supportive feedback, evaluation conferences, and gaining acceptance of the clinical educator role in the ICU. Coordinators were invited to biweekly teleconferences to discuss program and facility planning issues, as well as to provide ongoing support, coaching, and encouragement.
Results: Six hospital nurses attended the 3 clinical educator sessions with two being prepared for the NRP coordinator role and four as clinical educators during initial NRP implementation. The NRP was subsequently implemented by coordinators and clinical educators with less support from Children's HeartLink volunteers. Some nurses from the leadership group were no longer involved during the second NRP session due to staff turnover or promotion highlighting the need to train adequate local staff in order to sustain the NRP.
Conclusions: A NRP can be reproduced in a resource constrained environment by local expert nursing staff if there is sufficient training and support for selected nursing staff at the onset of the NRP.

P1358 - REGIONAL BRAIN GRAY MATTER VOLUME LOSS IN ADOLESCENTS WITH SINGLE VENTRICLE HEART DISEASE

Nancy Pike[1], Sadhana Singh[2], Bhaswati Roy[2], Mary Woo[1], Rajesh Kumar[2]
University of California, Los Angeles, School of Nursing, Los Angeles-United States[1]; University of California, Los Angeles, Anesthesiology, Radiological Sciences, and Bioengineering, Los Angeles-United States[2]

Background/Hypothesis: Adolescents with palliated single ventricle heart disease (SVHD) show autonomic, mood, and cognitive deficits, indicating brain changes induced functional issues in the condition. Scattered brain injury appears preoperatively and postoperatively in both gray and white matter areas in SVHD. The purpose of this study was to examine regional brain gray matter volume changes in SVHD over controls using voxel based morphometry procedure.
Materials and Methods: Regional whole-brain gray matter volume changes were examined using voxel based morphometry procedure. Two high-resolution T1-weighted images were collected from 18 SVHD adolescents (age: 15.7 ± 1.1 years, male: 10) and 31 healthy controls (age: 16.0 ± 1.1 years, male: 17) using a 3.0-Tesla magnetic resonance imaging (MRI) scanner. Whole-brain high-resolution T1-weighted images were realigned and averaged, gray matter tissue type partitioned, normalized to a common space and modulated, smoothed and compared between groups using ANCOVA (covariates: age and gender; corrected threshold; $p < 0.05$; voxel size, 696 voxels).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: No significant differences in age ($p = 0.35$) or gender ($p = 0.96$) emerged between groups. Multiple gray matter sites, including the bilateral thalamus, caudate, putamen, insular cortices, and left hippocampus showed volume loss in SVHD compared to controls [all regions $p < 0.05$](Figure 1).
Conclusions: Adolescents with palliated SVHD show significant gray matter volume loss in areas that regulate autonomic, mood, and cognitive functions. The pathological mechanisms contributing to gray matter volume loss may include developmental and hypoxia/ischemia induced processes operating in the condition.
Grant Support: This research work was supported by National Institutes of Health R01NR013930 and R01NR016463. Figure 1 Caption: Gray matter loss in brain areas including (a) caudate nucleus, (b) thalamus, (c) putamen, (d) left insula lobe and (e) left hippocampus, in SVHD patients compared to controls.

P1434 - HEMOSTASIS WITH NEW DESIGNED BAND AFTER PEDIATRIC CARDIAC CATHETERIZATION

Yukiko Mimoro[1], Yoko Moede[2], Motoki Takamuro[3], Keiji Haseyama[3], Masato Yokozawa[3]
Hokkaido Medical Center for Child Health and Rehabilitatin, Nursing Depatrtment, Sapporo-Japan[1]; Nursing Department, -[2]; Department of Pediatric Cardiology, -[3]

Backgrounds: Physical restraint after cardiac catheterization make a patient confused. We have used adhesive plaster bandages for hemostasis on which peeling off made patients feel pain. Additionally glue-related dermatitis was significant events. Since 2014 hand-made girdle band, to press groin for hemostasis was introduced and used in preparation. Purpose: To evaluate effect of "Maki-chan", for appropriate pressing the puncture site and reducing dermatitis and pain. Objects: Patients over three years old who received pediatric cardiac catheterization in our ward.
Methods: We manually made a new designed girdle band of cotton with a piece of Velcro and rubber. The band cross just above the puncture site and rubber attached to cotton band can keep effectively press the groin. Before the procedure patients tried it on and recognized fitting and painless. The puncture site was disinfected and dressed by gauze with small adhesive plaster. The folded gauze with about 2 cm thickness compressed the puncture site and Maki-chan was worn on. From medical record during last four years hemostasis effects were compared between large adhesive plaster band and "Maki-chan", with small adhesive plaster.
Results: Large adhesive plaster bandage was used in 119 cases during 2 years. Maki-chan with small plaster was in 113 case during 2 years. No bleeding occurred in both group. Some patients in large adhesive plaster group showed localized dermatitis. Discussions: New band with non-stretchable cotton and folded gauze compress the puncture site effectively. Reducing plastered area could decrease pain and dermatitis. Trying band on before procedure is expected to be effective for preparation, even though just looking at. Preparation with trying band on helped reduction of confusion after procedure.
Conclusions: New band can reduce pain and dermatitis. Preparation with it can lead child's cooperation and strengthen hemostasis.

P1485 - SOCIOCULTURAL BELIEFS AND SOCIAL PRESSURE IN EVERYDAY LIFE OF CHILDREN LIVING WITH CONGENITAL HEART DISEASE IN THE PALESTINIAN WEST BANK

Kawther Elissa[1], Carina Sparud Lundin[2], Åsa Axelsson[2], Salam Kathib[3], Ewa-lena Bratt[4]
Institutes of Health and Care Science, Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden, Faculty of Health Profession, Alquds University, Abu-deis-Palestine[1]; Institutes of Health and Care Science, Sahlgrenska Academy, Gothenburg University, Gothenburg-Sweden[2]; Faculty of Health Profession, Alquds University, Abu-deis-Palestine[3]; Department of Pediatric Cardiology, The Queen Silvia Childrens Hospital, Institutes of Health and Care Science, Sahlgrenska Academy, Gothenburg University, Gothenburg-Sweden[4]

Background: In Palestinian territories, approximately 700 newborns are diagnosed with congenital heart disease (CHD) every year. The advances in early diagnosis, treatment and postoperative care have resulted in increased survival rates. Research focus has shifted from survival to long-term follow up, wellbeing, daily life experiences and psychosocial consequences. Much remains to be learned about everyday experiences of children with CHD in occupied territories since challenging social conditions can have an impact on management and support. The aim of this study was to explore the everyday experiences of children with CHD and of their parents living in the Palestinian West Bank.
Material and Method: We adopted a qualitative descriptive design and analyzed the data using content analysis. A purposeful sample of children aged 8-18 years with CHD ($n = 9$) and their parents ($n = 9$) was selected. All participants were interviewed individually.
Results: Facing barriers and managing challenges was the overall theme that emerged and it consisted of four themes; socio-cultural burden and destiny, challenging physical/structural limitations, self-perceptions and concerns about not standing out and restraints in health care due to the political situation. Facing barriers represented the struggle children and their parents experienced which affected their daily life. Daily life was influenced negatively by socio-economic restraints due to political struggle, societal stereotyping and children's perceptions of their illness. Some considered the illness as a fate and therefore found comfort in their religious beliefs.
Conclusion: The negative impact of sociocultural beliefs and social pressure in everyday life of children with CHD and their parents is related to insufficient knowledge and misunderstanding about CHD in the Palestinian society. In addition, the political situation also contributes to a challenging daily life for children with CHD.

P1555 - SELF REPORTED HEALTH STATUS IN ADOLESCENTS AND ADULTS WITH CONGENITAL HEART DISEASE COMPARED TO HEALTHY CONTROLS

Jennifer Peterson[1], Patricia Chung[2], Nancy Pike[2]
University of California, Irvine, Program in Nursing Science, Irvine-United States[1]; University of California, Los Angeles, School of Nursing, Los Angeles-United States[2]

Background/Hypothesis: Improved life-expectancy in adolescents and adults with congenital heart disease (CHD) comes with need for continued follow-up. Self-reported health status is vital information for ongoing follow-up and clinical decision-making. The Individual's perceived health living with CHD may be related to disease severity. The purpose of this study is to examine self-reported health status in adolescents and adults with repaired or palliated CHD, compared to healthy controls.
Materials and Methods: Cross-sectional, comparative study; CHD participants were recruited from two cardiac centers in Los Angeles and controls from high schools and the community. Self-reported health status was measured using the Short-Form Health Survey (SF-36v2) which includes 8 subscales and two summary scores [physical and mental health scores 0-100; mean 50 ± 10; worse health status <50]. Demographic and clinical data was extracted from medical records. Descriptive and non-parametric statistics, including Kruskal–Wallis test were used to assess CHD severity [single ventricle (SV) and biventricular (BV)] and control group differences.
Results: 303 participants [CHD = 150 (SV = 87, BV = 63)/Controls = 153], ages 14-53 years. Within the CHD group, 55% male, 58% had a single ventricle, 77% had undergone $\geq$ 2 cardiac surgical procedure. CHD group reported significantly lower perceived health status than healthy controls in both physical and mental health [median 47 vs. 58, $p < .001$; 48 vs. 57, $p < .001$], respectively (see Table). SV group reported worse perceived physical and mental health compared to the BV group. Both CHD severity groups had lower mental health. All SF-36 subscales were statistically significant between groups [$p < .05$] except for bodily pain.
Conclusions: Adolescents and adults with SV and BV CHD had significantly lower self-reported health status compared to healthy controls. Interventions are warranted that focus on improving both physical and mental health status in this high-risk population.

P1641 - REFINED ANALYSIS THE CRITICAL EARLY WARNING SCORE FOR CHILDREN WITH CONGENITAL HEART DISEASE AFTER CARDIAC SURGERY

Zhouying Zhuang, Lijuan Fu
Shanghai Children's Medical Center, Cardiovascular Surgery, Shanghai-China

Objective: To divide the level the critical early warning score and time interval to predict the prognosis of children with congenital heart disease after cardiac surgery.
Methods: 607 cases who was living in CICU after cardiac surgery was chosen to make a score by the electronic scoring system once an hour until the children died or transfer out CICU. According to the different outcomes, the children were divided into diffient groups. ROC curve, AUC, Youden index, Hosmer-lemeshow test was used to choose the optimal critical value and diagnosis the effect of the scoring.
Results: ① I-no risk:The mean score was 0 to 2 points and the highest score was 0 to 5 points, the highest score occurred after transferring to CICU about 3-4 days, 2 days after the highest score roll-out CICU. ② II-mild critically ill:The highest score was 6 to 10 points,and the mean score was 3 to 4 points keeping the trend and dynamic score, corresponding to the end for the critically ill. ③ III-moderate critically ill: The mean score was 5 points, the highest score was 11-18 points and keeping the trend of dynamic score is children, dead end, in death risk of interval ④ IV-severe critically ill: The mean score was 6 to 7 points, the highest score was 19 to 39 points, the highest score occurred after transferring to CICU after 2.5 days, 4 hours after result in rescue.⑤ V- extremely critical: The mean score was 8-39 points, the marking, the highest score was 40-57 points and peak appears in the CICU after 2-3 days, 4 hours after the peak,and ending for rescue invalid death.
Conclusion: The 5 risk levels of critical early warning score will help CICU nursing staff to be sensitive early-warning prompt on time and to take the countermeasures.

P1642 - VERIFY THE ELECTRONIC ILLNESS SCORING INFORMATION SYSTEM AND THE PAPER VERSION SCORING TOOLS FOR CHILDREN WITH CONGENITAL HEART DISEASE AFTER CARDIAC SURGERY

Lijuan Fu, Zhouying Zhuang
Shanghai Children's Medical Center, Cardiovascular Surgery, Shanghai-China

Objective: To verify the degree of consistency and efficiency between the electronic illness scoring information system and the paper version scoring tools for children with congenital heart disease after cardiac surgery.
Methods: Two raters using two kinds of evaluation tools 50 cases of children with congenital heart disease surgery in CICU for measuring time each score used at the same time. Intraclass correlation coefficient (ICC) was used to analyze the two scoring tools' consistency degree; Independent samples t-test was used to analyze timeliness.
Results: ① The two scoring tool high degree of consistency: the same raters using two scoring tool for children with the same score the consistent rate of raters respectively A: 94%, B: 96%. ICC were 0.993 (0.988 0.996), 0.990 (0.983 0.995), $P < 0.01$. Two raters used the same kind of tools for children with the same score consistent rate respectively was: print score tools, electronic scoring system, 90% and 100%. ICC were 0.984 (0.972 0.991), 1 (1, 1). ② The timeliness validation results showed: paper score tool

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

54.48 ± 5.93, 5.93 ± 5.28 (s); electronic scoring system: 21.26 ± 3.11, 3.11 ± 3.86 (s), P < 0.01. Both A and B raters used paper score tool ,the time has the difference: respectively 54.48 ± 5.93, 5.93 ± 5.28 (s), P < 0.05; Both A and B raters used electronic scoring system to make a score,and there was no statistically significant difference,the time was: 21.26 ± 3.11, 20.92 ± 3.86 (s), P > 0.05.
Conclusion: The electronic scoring system highly restored the paper version scoring tool, with higher accuracy and less affected by human factors, and it can avoid the artificial errors, In terms of timeliness advantages: a score of time saved nearly 2/3.

P1661 - IMPLEMENTING SAFE PERFUSION PRACTICES IN THE KARDIAS CONGENITAL HEART SURGERY PROJECT IN MEXICO

Gabriela Trejo-Gómez, Orlando Tamariz-Cruz, Hector Díliz-Nava, Alexis Palacios-Macedo Q
American British Cowdry, Cardiovascular Surgery, Mexico City-Mexico

Introduction: Since 2007 the World Health Organization proposed the implementation of safety checklists for all periods of the surgical processes. Considering congenital heart surgery, a special area to be considered is extracorporeal support, also denominated perfusion. We describe the implementation of a pre-perfusion checklist, immediate post perfusion report and a perfusion handoff protocol to the cardiac intensive care unit in the KARDIAS project in Mexico.
Material and Methods: Moment 1: A three phase checklist (as advised by the IQIC project) was integrated to the perfusion record to asses safety prior going into cardiopulmonary bypass.
Moment 2: A report sheet including the main details occurring during the perfusion period was designed. This format is analyzed both by the surgeon and the perfusionist before they leave the operating room. This document includes very concise information including: bypass and aortic clamping duration, water balance, low flow duration, etc. and it's included in the patient's record.
Moment 3: We also designed a postoperative perfusion hand-off protocol, which included a report sheet containing details occurred during perfusion, such as: mean NIRS values, mean hematocrit value during the procedure and hypothermic circulatory arrest duration, but what we consider of utmost importance is the inclusion of an adverse incident report section. This synthetic report is read by the perfusionist in charge of the surgical procedure, in between the surgeon's and anesthesiologist's segments at the hand-off process. Finally this document is included in the medical record of the patient.
Results: We present the three perfusion formats implemented in the KARDIAS project. We also show the perceptions concerning effective communication and process fulfillment of the surgical nurse participating in the handoff process, the receiving intensive care unit nursing staff, anesthesiologists, surgeons and intensive care physicians.
Conclusions: Considering the overall team opinion we propose the implementation of a safe perfusion practice strategy in order to enhance quality.

P1706 - CONTINUING EDUCATION PROGRAM IN THE HOSPITAL SETTING QUALITY IMPROVEMENT INITIATIVE

Ekaterina Anikeeva[1], Georgy Plotnikov[2], Olga Andguladze[3], Ivan Halivopulo[4], Dmitry Borisenko[5]
Federal State Budgetary Institution "Research Institute for Complex Issues of Cardiovascular Diseases", Department of Research And Education, Kemerovo-Russia[1]; Federal State Budgetary Institution "research Institute for Complex Issues of Cardiovascular Diseases", Laboratory of Critical Care, Kemerovo-Russia[2]; Federal State Budgetary Institution "research Institute For Complex Issues of Cardiovascular Diseases", Executive Office, Kemerovo-Russia[3]; Federal State Budgetary Institution "research Institute for Complex Issues of Cardiovascular Diseases", Department of Cardiovascular Surgery, Kemerovo-Russia[4]; Federal State Budgetary Institution "research Institute for Complex Issues of Cardiovascular Diseases", Intensive Care Unit, Kemerovo-Russia[5]

Background: Nurses involvement in quality improvement is limited by specific challenges, related to traditional nursing education that does not always adequately prepare them for their evolving role in today's contemporary hospital setting. Healthcare demands require from educators to use novel teaching frameworks to enhance learners' competency in the clinical settings.
Purpose: To assess the efficiency of the case-based education program in improving the level of knowledge among acute nurse practitioners in the intensive care unit (ICU).
Methods: 33 ICU nurses (the mean age 39 ± 6 years) were included in the study from June, 2015 to July, 2016. The mean total years of the ICU services - 11 ± 6 years. The pretest-posttest model was used to assess the efficiency of the hybrid educational program. Both groups underwent post-test II after each educational phase to assess the retention of knowledge. All nurses were enrolled into 2 groups according to the results of the pre-test. Subjects who gave >50% of the correct answers were included in Group 1 (n = 11) and underwent a lecture-based education. Subjects who received <50% were included in Group 2 (n = 22) and underwent case-based tutorials based on virtual patient.
Results: Both groups showed significant improvement in scores between the pre- and posttests (Group 1 -56.64 ± 3.17; Group 2 - 56.50 ± 0.70) with similar knoweledge retention after 1 year (Group 1 - 54.45 ± 2.42; Group 2 - 55.0 ± .000). No statistically significant difference in mean test scores could be found between 2 groups at each point: 1.4% (95% CI –0.6% to 3.4%) for post-test I, and –0.3% (95% CI –3.9% to 3.3%) for post-test II.
Conclusion: Case-based education using virtual patient provides the potential to teach nurse practitioners with greater flexibility using different learning methods addressed to different learning domains than classroom instruction.

P1763 - PREVENT REGRESSION IN FUNCTION AFTER EARLY CARDIAC SURGERY HELP FIND A WAY

Gwen Bond[1], Bryan Acton[2], Dianne Creighton[3], Karen Penner[4], Sharon Selzer[5], M. Florencia Ricci[1], Charlene Robertson[6]
Glenrose Rehabilitation Hospital, Complex Pediatric Therapies Follow-up Program, Edmonton,-Canada[1]; Saskatoon Health Region, Clinical Health Psychology, Saskatoon, SK-Canada[2]; University of Calgary, Psychology, Pediatrics, Calgary, AB-Canada[3]; Glenway Health Management Ltd., Neurodevelopment, Psychology, Winnipeg, MB-Canada[4]; Regina General Hospital, Developmental Assessment Clinic, Regina, SK-Canada[5]; Glenrose Rehabilitation Hospital, Complex Therapies Follow-up Program, Edmonton, AB-Canada[6]

Background/Hypothesis: The early years (0-5), are recognized as the period of greatest brain vulnerability to adverse events, including those stemming from early complex cardiac surgery. While limited, the research also indicates that children following complex cardiac therapies are at risk of ongoing adverse neurocognitive, behavioral, emotional, and academic outcomes as they progress into their school years. We set out to 1) determine the extent to which regression occurs in pre-academic and academic functioning after life-saving therapies at <6 weeks of age and to 2) develop

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

a practical, workable framework of intervention to prevent regression in the child's developmental trajectory.
Method: We determined a mean lack of expected progression of functional skills and a regression of skills (loss of ability) using the parent-completed Adaptive Behavioral Assessment System II (domain, mean + sd, 10 + 3; delay = < 4). Focus Groups consisting of health care professionals, allied health workers and parents engaged in active dialogue about prevention of regression under the sub-topics of: at the bedside, in follow-up, early childhood, school-readiness, and school age.
Result: Pre-academic and Academic scores were 8.9(3.1), 8.2(3.4) and 6.4(3.3) at 2, 4,and 8 years of age respectively. The proportion of children with delay increased, 4.1%, 9.7%, 32% at these ages relative to peers. The Focus Groups yielded well organized and helpful approaches to intervention.
Conclusion: Lack of progression and regression of skills occurs in children after complex cardiac therapies. Evaluation and intervention for functional deficits for these children requires collaborative care early on in the child's life. This study informs our developing framework to enable all children to have support both before and after school entry. Functional abilities are a very important consideration in developmental evaluations of children assessed for school readiness.

P1766 - IMPACT OF PARTNERSHIP WITH INTERNATIONAL DATABASE AND CARDIOLOGY AND PEDIATRIC CARDIOVASCULAR SURGERY CENTER IN BRAZIL

Ulisses Croti[1], Alexandre Murakami[1], Bruna Cury Borim[2], Patricia Hickey[3], Kathy Jenkins[3]
Faculdade De Medicina De São José Do Rio Preto, Carviovascular Surgery, São José Do Rio Preto-Brazil[1]; Hospital Da Criança E Maternidade, Nursing Education, São José Do Rio Preto-Brazil[2]; Boston Children´s Hospital, Pediatric Cardiology, Boston-United States[3]

Introduction: In Brazil, there is a 65% deficit of congenital heart defects surgical correction. Improving quality of care in Brazilian pediatric cardiovascular surgery services would be facilitated by the establishment of parameters and objective data to evaluate surgical results offered.
Objective: To analyze the evolution of quality of care for children with congenital heart disease after the establishment of the partnership between the International Quality Improvement Collaborative Database (IQIC) for Congenital Heart Surgery in Developing Countries and a Center for Cardiology and Pediatric Cardiovascular Surgery in Brazil.
Methods: Data collection from a single center of cardiology and pediatric cardiovascular surgery in Brazil between 2011 and 2015 independently and with external audit in partnership with an international database. The data include preoperative information, as well as postoperative information.
Results: In the preoperative period, there was a difference in patients with altered nutritional appearance between the years (P = 0.004). There was also a difference regarding mechanical ventilation and inotropic therapy (P = 0.006). In the postoperative period, surgical procedures classified in RACHS-1 risk category show a small variation between groups (P = 0.445), with categories 2 and 3 prevailing. The number of surgical site infections reduced from year to year (P = 0.130), but it was evident bacterial sepsis and other major infections had a significant reduction (P = 0.023 and P = 0.026, respectively). The 30-day postoperative follow-up evolved satisfactorily with a discrete reduction in mortality for both in-hospital (P = 0.172) and 30 day-mortality (P = 0.156).
Conclusion: The five-year analysis showed a positive evolution in the quality of care for children with congenital heart disease after the establishment of the partnership with the IQIC database, mainly in the areas of infection reduction and mortality.

P1849 - VALIDATION OF AN EARLY WARNING SCORING TOOL FOR IDENTIFYING PEDIATRIC CARDIAC AND NON CARDIAC PATIENTS AT RISK FOR CARDIOPULMONARY ARREST

Mary Mclellan, Kimberlee Gauvreau, Jean A Connor
Boston Children's Hospital, Heart Center, Boston-United States

Background: Most inpatient pediatric arrests are preventable by early recognition and treatment of clinical deterioration. Children with cardiac disease have the highest arrest rates however early warning scoring systems had not been validated in this population. The Cardiac Children's Hospital Early Warning Score (CHEWS) was designed and implemented to identify clinical deterioration in this high risk population. The CHEWS was then applied to all inpatients outside of the intensive care units (ICU). Nurses assess patients' CHEWS scores during routine vital signs and follow an escalation of care algorithm: routine care (score 0-2), increased assessment/intervention (3-4), or ICU consult/transfer (≥5).
Objective: This study s objective was to validate the CHEWS in identifying clinical deterioration in cardiac and non-cardiac patients using the previously validated Brighton Pediatric Early Warning Score (PEWS) for comparison.
Methods: A retrospective cohort study reviewed all non-ICU patients at a quaternary academic pediatric hospital. Specificity, sensitivity, area under the receiver-operating characteristic curves (AUROC) and early warning times were calculated for the CHEWS and PEWS in patients that experienced an arrest or unplanned ICU transfer (n = 424) and a randomly selected comparison cohort (n = 1026).
Results: see attached table
Conclusions: CHEWS has excellent discrimination to identify clinical deterioration in cardiac and non-cardiac pediatric patients. CHEWS had a higher AUROC and sensitivity compared to PEWS. CHEWS provided a longer early warning time the PEWS for clinicians to treat patients experiencing clinical deterioration.

Table.

	Cardiac Cohort (n = 312)		Non-Cardiac Cohort (n = 1136)	
	CHEWS	**PEWS**	**CHEWS**	**PEWS**
AUROC*	0.917	0.785	0.902	0.798
Sensitivity score (score ≥3)	95.3%	54.7%	91.4%	73.6%
Specificity (score ≥3)	76.2%	86.3%	67.8%	73.5%
Median early warning time for score ≥3* (hours)	9.25	2.25	11.1	3.8
Median early warning time for score ≥ 5 * (hours)	2	0	8.5	0.6

Validation of CHEWS and PEWS for identifying deterioration in cardiac and non-cardiac patients (*p < 0.001).

P1888 - EFFECT OF AN EDUCATIONAL INTERVENTION ON NURSE'S KNOWLEDGE ABOUT LOW CARDIAC OUTPUT SYNDROME IDENTIFICATION AND MANAGEMENT

Hina Nizar[1], Qalab Abbas[2], Anwar Ul Haque[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Aga Khan University, Nursing, Karachi-Pakistan[1]; Aga Khan University, Pediatrics and Child Health, Karachi-Pakistan[2]

Objective: To determine the effectiveness of a two hour teaching module in increasing pediatric cardiac intensive care nurses knowledge about low cardiac output syndrome (LCOS) identification and management.
Methods: A 2 hour teaching module consisting of a didactic lecture, small group discussion (on case scenarios) on identification and management of pediatric LCOS was designed by an MScN student in collaboration with pediatric critical care physicians. Twenty six cardiac intensive care nurses were included in the study. Their knowledge on LCOS was tested before and after this education intervention. Data was collected on a structured proforma and knowledge was assessed on a self-developed validated tool. Paired T test was used to determine the difference in knowledge.
Results: Mean age of the participants was 35 ± 15 years, 20 participants were males, two were nursing intern, 18 were registered nurses and 6 were critical care technicians, 12 of particiapnts had no formal critical care qualification. Four participants had <1 year experience, 11 had 1-5 years' experience, 5 had 6-10 years' and 11-15 years' of critical care experience. Twenty six participants were basic life support certified and 5 were pediatric advanced life support certified. Mean score of participants increased from 58.41 ± 12.5 to 81.2 ± 18.4 (p value <0.05).
Conclusions: On job focused small group educational intervention is very helpful to increase the knowledge of critical care nurses which can then translate into good patient outcomes.

P1933 - LOW MOLECULAR WEIGHT HEPARIN ADMINISTERED BY SUBCUTANEOUS CATHETER IS A SAFE AND EFFECTIVE ANTICOAGULATION REGIMEN IN SELECTED INPATIENT INFANTS AND CHILDREN WITH COMPLEX CONGENITAL HEART DISEASE

Nadja Pardun, Julia Lemmer, Kristina Belker, Milka Pringsheim, Alfred Hager, Peter Ewert, Cordula Wolf
Deutsches Herzzentrum Munich, Pediatric Cardiology, Munich-Germany

Background/Hypothesis: Intravenous therapeutic unfractionated heparin (IV UFH) is the first-line anticoagulant agent in infants and children with complex congenital heart disease admitted to the hospital. Disadvantages of IV UFH are unpredictable pharmacokinetics requiring frequent phlebotomies and the need for continuous intravenous access. Low molecular weight heparins administered by a subcutaneous indwelling catheter device (SC LMWH) might be an effective alternative.
Objective: To compare the efficacy and safety of SC LMWH with IV UFH in this patient population in a case control study.
Materials and Methods: Demographic data, number of needle punctures, anticoagulation parameters and complications of patients admitted to the pediatric cardiology inpatient unit and requiring invasive anticoagulation were recorded.
Results: Data are depicted in the Table. There was no difference between age, gender, underlying anatomic diagnosis, and the number of treatment days per patient between groups. The number of needle punctures was significantly lower in the SC LMWH as compared to the IV UFH group. Most activated partial thromboplastin times obtained in the IV UFH group were not within therapeutic range, whereas almost half of the SC LMWH group had therapeutic anti-Xa levels. Neither group had a bleeding or thrombotic complication. Minor and transient local reactions, such as redness or a small hematoma, occurred in 46% of patients of the SC LMWH group; there were no major complications, such as bleeding at the site or infection requiring antibiotics.
Conclusion: As compared to the current gold-standard of IV UFH, SC LMWH offers a safe anticoagulation regimen for inpatient infants and children with complex congenital heart disease providing more efficient therapeutic anticoagulation and a reduction in needle punctures, thus causing less pain and anxiety in this pediatric population.

Table.

	IV UFH	SC LMWH	p-value
Nr. of patients (males)	42 (21)	13(5)	
Nr. of treatment days	102	49	
Age (months)	47 ± 32	37 ± 28	NS
Treatment days per patient	2.4 ± 2.6	3.8 ± 2.6	NS
Nr. of indwelling device placements per treatment day	1.0 ± 0.5	0.5 ± 0.4	0.001
Nr. of phlebomoties per treatment day	1.4 ± 1.1	0.5 ± 0.3	0.001
Non-therapeutic level per phlebotomy (%)*	93 ± 16	58 ± 42	0.017

IV UFH: intravenous unfractionated heparin; SC LMWH: subcutaneous low molecular weight heparin; Nr.: number; * activated partial thromboplastin time (PTT) <55 or >85 seconds or anti-Xa level <0,5 or >1,0 U/mL; data shown as meamstandard deviation; p-value: independent t-test.

P1965 - EFFECT OF CARDIAC INTERVENTION ON PARENTING STRESS IN YOUNG CHILDREN WITH CONGENITAL HEART DISEASE IN CENTRAL SOUTH AFRICA THREE MONTH AND SIX MONTH OUTCOMES

Robyn Smith[1], Joanne Potterton[1], Veronica Ntsiea[1], Stephen Brown[2]
University of The Witwatersrand, Physiotherapy, Johannesburg-South Africa[1]; University of The Free State, Paediatrics and Child Health, Bloemfontein-South Africa[2]

Background: Parents of children with congenital heart disease (CHD) are at increased risk of ongoing stress and psychological problems including anxiety and depression. The parenting stress outcomes of children with CHD in South Africa are unknown. The aim was to determine parenting stress in children with CHD following cardiac intervention.
Materials and Methods: Forty-eight consecutive children, 30 months and younger, and their parents were recruited into this observational descriptive study. Parenting stress was assessed using the Parenting Stress Index- Short Form before cardiac intervention, and at three-month and six-month post cardiac intervention. Parenting stress outcomes were compared over time, and variables associated with parenting stress determined.
Results: Baseline data was collected for 40 parents. Sixty percent of parents (n = 24) experienced clinically significant stress prior to cardiac intervention. Levels of parenting stress declined significantly at both three-month ($p < 0.001$) and six-month post-cardiac intervention ($p < 0.001$). More than 31.8% of parents experienced ongoing stress after their child's cardiac intervention. Neurodevelopmental outcome ($p = 0.03$), perceived health-related quality of life ($p = 0.02$), age at first cardiac intervention ($p = 0.03$) and maternal age ($p = 0.04$) were significantly associated with increased levels of parenting stress.
Conclusion: Most parents experienced clinically significant levels of stress prior to their child undergoing cardiac intervention. Parenting stress declined significantly post-cardiac intervention, but a considerable number of parents experienced ongoing stress. Parents should be screened regularly for risk of psychological problems requiring referral for psychological and educational interventions.

P2030 - WHAT WILL WE DO TO THE INFECTION

Xia Lei
The First Hospital of Lanzhou University, Cardiovascular, Lanzhou-China

The totle amount of infected cases in 2014,2015 and 2016 was 78,68,63 respectively in our unit, and the pulmonary infection occupied the biggest part of them. This year one of our main targets is to reduce the infection rate. According to the learning, we have made some measures: 1.To enhance the hands hygiene 2. To shorten the ventilator time 3.To remove tubes after surgery in time. We are going to add more ABHRs,and make a specific staff do the supervision of team members'hands hygiene meanwhile.If the rate is able to be reduced this year, we will do the sharing, making formal procedures for implemention.

P2064 - PAEDIATRIC CARDIAC WARD NURSE LEAD DISCHARGE

Heather Hatter[1], Angela Scarisbrick[2], Lesley Black[1], Victoria Gander[2], Jenny Hamson[1]
Gt Ormond Street, Cardio/respiratory, London-United Kingdom[1]; Gt Ormond Street, Cardio/Respirtory, London-United Kingdom[2]

Background: Delay in discharge, on a busy cardiac day unit was noted by staff from parent's complaints to cause unnecessary waits in discharge home in a timely fashion. This did not lead to individualised family centred care. Staff satisfaction around timely discharge was compromised. As a tertiary paediatric cardiac centre travelling times for families' are complex and usually prearranged.
Methodology: Before the programme started there was a review of discharge waiting times. Following a literature review into nurse led discharge, a team training day was arranged to introduce the concept of nurse lead discharge. This was followed by a ward Quality Improvement project. A pilot for 1 month following training and setting standards was used for all suitable patients. Audit forms with times, the patient experience and nursing experience were collated over this period.
Findings: An audit before the implementation of the program showed that in 36 patients the delay in discharge time was 23 hours and 40 minutes with a mean time of 65 minute delay before implementation of nurse led discharge. Post the implementation there were no delays. Feedback demonstrated that the nurse felt empowered by the process. There was greater parental satisfaction as it reduced the volume of discharges occurring at the same time allowing for one-to-one care to the family being discharged.
Discussion: The audit data showed a high number of suitable patients for this nurse led program and with a significant reduction in the length of stay role in the day ward. A follow up call next day was used to safety net the process and for the nurses to evaluate effectiveness of practice.
Conclusion: This audit and change in discharge has been embedded and extended to other patient groups. This has resulted in increased family and staff satisfaction.

P2067 - A NATIONAL QUALITY IMPROVEMENT PROJECT EVALUATING A COMMUNITY BASED EARLY WARNING TOOL FOR INFANTS WITH CONGENITAL HEART DISEASE

Liz Smith[1], Jo Wray[2], Kerry Gaskin[3], Kathryn Stimson[4], Angie Martin[5], Justine Kidd[6]
Great Ormond Street Hospital, Cardiac Services, London-United Kingdom[1]; Great Ormond Streeet, Orchid, London-United Kingdom[2]; Worcester University, Health, Worcester-United Kingdom[3]; Southampton General, Cardiac Services, Southampton-United Kingdom[4]; Freeman Hospital, Cardiac Services, Newcastle-United Kingdom[5]; Birmingham Childrens Hospital, Cardiac Services, Birmingham-United Kingdom[6]

Aim: To evaluate the effectiveness of an Early Warning Tool (EWT) for use by families and Children's Community Nursing teams (CCNT) in making decisions about infants at home and standardizing escalation.
Innovation: Currently there are no CCNT EWTs validated for infants with complex CHD in the community setting or for joint use with parents/carers. The EWT is part of an national vision to develop robust models to support acute care in the community using a virtual ward environment Development and tool design prototype The design is based on current knowledge and clinical experience of CHD using structured key domains, in a traffic light system, as part of the current Home Monitoring educational program. These key domains form part of a weekly clinical assessment of the infant, with local CCNT and telephone consultation.
Evaluation: • Organisation of key domains into mutually agreed visual formatted tool • Focus group work with parents and stakeholders – acceptability to families, understanding of the tool • Trial of the tool multiple sites: o retrospective clinical record review – triggers correctly o scenario based (table top) with stakeholders and clinical experts – correctly triggers with escalation plan o in the clinical setting – correctly triggers with escalation plan.
Implementation into practice: • The EWT would be part of the current Home Monitoring Programme (HMP).
• Structured education and implementation by a dedicated Cardiac Nurse Specialist • Dissemination at a national level with wider application • Parent and stakeholder reported outcome measures.
Other: • Number of triggered events • Deaths and deterioration events would be reviewed as per trust policy and to ensure quality review of the EWT • Close links with Rapid Response meetings at the unexpected death of a infant and the application of the EWT • Survival rates will be monitored and reported at local cardiac meetings and via national data sets (CCAD 2016) • Collaboration with the national children's CHD review.

P2088 - GREAT EXPECTATIONS LOOKING FOR ANSWERS; PARENTS' EXPERIENCE OF CARING FOR A CHILD WITH AN IMPLANTED LOOP RECORDER

Annette Mc Quillan[1], Angela Scarisbrick[2], Jim Richardson[3], Jayne Price[3]
Great Ormond Street Hospital, Cardiorespiratory, London-United Kingdom[1]; Great Ormond Street Hospial, Cardiorespiratory, London-United Kingdom[2]; St George, Children Nursing, London-United Kingdom[3]

Background: Implantable Loop Recorders (ILRs) are cardiac devices which are increasingly being utilised in the diagnosis and management of unexplained paediatric syncope. Although the efficacy and use of implantable diagnostic devices is increasing, little is known about the impact that ILR's have on the child or family. To date no research has focused on children or parents' experiences; however, anecdotal evidence suggests challenges in adjustment to devices. This qualitative study aims to address gaps in knowledge by exploring parents' 'lived experiences' and concerns in this population.
Method: Semi-structured interviews were conducted with 12 parents (11 mothers, 1 father) of 12 children aged 5-16 years. Interviews were recorded, transcribed verbatim and analysed in

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

line with Interpretative Phenomenological methodology. Data analysis was an iterative process bringing the data together into meaningful inductive themes giving rise to super-ordinate themes.
Results: The impact on families' lives were revealed through three main super-ordinate themes: living with uncertainty; disruptive childhood and the impact of technology. Parents reported feeling reassured and safer by the presence of the ILR. However, the longer the device was in place the greater the anxiety. Informing and educating family members, friends, schools and sport coaches on the management of symptoms and device created additional burden. The child's needs were paramount for parents. Pain, body disfigurement, effect on self-esteem and incidence of bullying were reported. On-going issues with equipment failure created disappointment, anger and frustration.
Conclusion: Despite the perceived advantages of ILR, such as ease of implantation and potential for obtaining a diagnosis, the study identified issues which have a negative impact on children and parents. This study provides evidence to target additional supportive measures to families throughout the child's journey, including providing information to schools.

P2449 - FEEDING DIFFICULTIES IN NEONATES FOLLOWING CARDIAC SURGERY DETERMINANTS OF PROLONGED FEEDING TUBE USE

Elissa Mckean[1], Nadine Kasparian[2], Shweta Batra[1], Gary Sholler[3], David Winlaw[3], Jacqueline Dalby-payne[1]
Sydney Medical School, The University of Sydney and, Department of General Medicine, The Childrens Hospital at Westmead, Sydney-Australia[1]; Heart Centre for Children, The Sydney Childrens Hospitals Network and, UNSW Medicine, The University of New South Wales, Sydney-Australia[2]; Heart Centre for Children, The Sydney Childrens Hospitals Network and, Sydney Medical School, The University of Sydney, Sydney-Australia[3]

Background and Hypotheses: For babies with complex congenital heart disease, achieving adequate growth and nutrition can be a challenge. Previous studies show that up to 1 in 2 neonates are not able to completely feed orally after cardiac surgery and are discharged home with a feeding tube. Feeding difficulties in this population are often multifactorial, with pre-, intra-, and post-operative factors influencing a neonate's ability to feed orally. The aims of this study were to examine the prevalence and correlates of feeding difficulties in infants who underwent neonatal cardiac surgery, and to investigate resource utilisation by infants with feeding difficulties.
Materials and Methods: All neonates who underwent their first cardiac surgery at the Heart Centre for Children, The Children's Hospital at Westmead between January and December 2009 were included. Demographic, pre-, intra-, and post-operative data were collected via electronic medical records. For the purpose of this study, feeding difficulty was defined as the requirement for ongoing tube feeding at time of discharge home or transfer to another hospital.
Results: Twenty-four out of a total of 79 neonates (30%) were discharged home or transferred to another hospital with a feeding tube. Feeding difficulties were associated with the presence of a genetic syndrome ($p < 0.0001$), assisted feeding preoperatively (OR = 4.4, $p = 0.03$), and having a palliative procedure prior to biventricular repair (OR = 5.1, $p = 0.02$). Infants with feeding difficulties had significantly more reviews by speech pathologists (M = 5.9, SD = 7.9), dieticians (M = 5.9, SD = 5.4), and cardiac clinical nurse consultants (M = 1.2, SD = 1.4) compared to those without feeding difficulties.
Conclusions: This study identified factors which can be used in the early identification of infants who are at increased risk of feeding difficulties, to help guide the direction of limited health resources, as well as being focal points for future research and clinical practice improvement.

P2451 - COMPARING RETESTING RATES BETWEEN DIFFERENT SCREENING METHODS FOR CRITICAL CONGENITAL HEART DISEASE DATA FROM 112839 NEWBORNS FROM A STATE IN NORTHEAST BRAZIL

Carolina Freitas[1], Felipe Mourato[2], Lucia Moser[3], Cícera Santos[3], Thiago Tavares[4], Sandra Mattos[5]
Círculo Do Coração De Pernambuco, Enfermagem, Recife-Brazil[1]; Círculo Do Coração De Pernambuco, Científico, Recife-Brazil[2]; Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Informática, Recife-Brazil[4]; Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[5]

Background: screening for critical congenital heart disease (CCHD) with pulse oximetry is a practical strategy. However, many different protocols exist and little differences between them can lead to a great number of retest rates. This can increase the work of already overloaded nursing teams, mainly in developing countries, and lead to decreased efficacy of the method. So, identifying protocols with lower retest rates is important to an efficient population screening for CCHD.
Material and Methods: data obtained from a large population screening program for CHD in Paraíba – a state from northeast Brazil – was utilized. Only the cases with gestational age of 36 weeks or more and complete data for oxygen saturation from the right arm (RA) and one foot were utilized. A total of 112839 cases were included in this study. Five different protocols were included: oxygen saturation (OS) < 95% in both RA and foot or a difference between them >3% (Jegatheesan). OS <95% in either RA and foot or a difference between them >3% (Fouzas). OS <95% in both RA and foot or a difference between them >2% (Granelli). OS <95% in either RA and foot or a difference between them >2% (Ewer) and a foot saturation <96% (Riede). The Cochran's Q test was utilized, and a p-value 0.05 was considered significant.
Results: the protocol with least retest rates was Fouzas (1.04%) followed by Jegatheesan (1,44%), Ewer (1.83%), Granelli (2.10%) and Riede (5,47%). All protocols showed statistical significance between them.
Conclusion: The Fouzas et al protocol produced the lowest retest rate. This finding is important and helpful to optimize the implementation of new screening politics around the world.

P2453 - NOMOGRAMS FOR PULSE OXYGEN SATURATION FROM A POPULATION SCREENING FOR CONGENITAL HEART DISEASE IN NORTHEAST BRAZIL

Carolina Freitas[1], Felipe Mourato[2], Cícera Santos[1], Thiago Tavares[3], Lucia Moser[4], Sandra Mattos[5]
Círculo Do Coração De Pernambuco, Enfermagem, Recife-Brazil[1]; Círculo Do Coração, Científico, Recife-Brazil[2]; Círculo Do Coração De Pernambuco, Informática, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[4]; Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[5]

Background: Pulse oxygen saturation (POS) is a great strategy for screening critical congenital heart disease (CCHD). Nomograms

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

for pre-ductal and post-ductal POS have been described, but several factors like skin color, ambient temperature, altitude, presence of anemia, and others can modify them. Therefore, the analysis of nomograms in a developing country can be useful to optimize the screening for CCHD.
Material and Methods: data obtained from a screening program for CHD in Paraíba – a state from northeast Brazil – was utilized. Only the cases with gestational age of 32 weeks or more and complete data for oxygen saturation from the right arm (RA) and one foot were utilized. The results from pre-ductal and post-ductal oxygen saturation were compared between them by gender and gestational age. Non-parametric tests (Mann-Whitney) were performed to do so.
Results: a total of 114723 cases were analyzed. The median from pre-ductal and post-ductal saturation was 97% ($p5 = 95\%$ and $p95 = 99\%$). The mean for the difference between saturations was 0.8822% (IC: 0.8763 to 0.8880) and more than 95% of the neonates showed a difference minor or equal to 2%. The pre-ductal and post-ductal saturation was higher in term than preterm neonates ($p < 0.01$). Male patients showed a little, but significant, higher pre-ductal ($p = 0.01$) and post-ductal saturation ($p = 0.03$). However, such differences had no clinical significance.
Conclusion: The nomograms obtained in this study are similar to others obtained in developed countries. Therefore, environment and population differences seem to have no impact on obtained nomograms.

P2494 - DEPRESSION AND ITS INFLUENCING FACTORS AMONG MATHERS OF CHILDREN WITH CONGENITAL HEART DISEASE IN KOREA

Ju Ryoung Moon[1], Jinyoung Song[2], June Huh[2], I-seok Kang[2], Ji-Hyuk Yang[3], Tae-Gook Jun[3]
Samsung Medical Center, Cardiac Center, Seoul-Korea, South[1]; Samsung Medical Center, Department of Pediatrics, Seoul-Korea, South[2]; Samsung Medical Center, Department of Thoracic&Cardiovascular Surgery, Seoul-Korea, South[3]

Purpose: Mother of children affected by birth defects suffers from a significant psychological burden across the lifespan, but there have been few studies on this area in Korea. Our purpose was to assess depression among mothers of children with congenital heart disease (MCHD) and to explore factors influencing depression among in Korea.
Method: A total of 182 mothers of affected children aged 0-3 years old and 366 mothers of healthy children (MHC) in the same age took part in the study. Kessler Depression Scale was used to assess maternal depression, and logistic regression models were used to explore the factors influencing depression among MCHD.
Results: Of the mothers, 33.0% reported being mild to moderate depression and 8.5% of the mothers reported severe depression. Also, MCHD were more depressed than MHC. The factors influencing MCHD include; mother's self-efficacy, mother's marital conflict, mother's social support, infant's emotionality, mother's smoking and infant's feeding and eating of daily routine. These variables explained 42.5% of MCHD.
Conclusion: The results of the study suggest that the identified factors for MCHD should be included in an intervention program to reduce the risk of depression.

P2518 - INVESTIGATION AND ANALYSIS OF AIRWAY NURSING IN CHILDREN WITH MECHANICAL VENTILATION

Lijuan Fu, Zhouying Zhuang
Shanghai Children Mendical Center, Heart Center, Shanghai-China

Objective: To understand the pediatric ICU nurses do airway care for children with endotracheal tubes. To find out problems in clinical airway care and provide some recommendations for clinical improvement, and to help to reduce the incidence of nosocomial respiratory tract infection.
Methods: To observe and record the airway care operations in the pediatric ICU of Shanghai Hospital, and have 60 samples for two hospitals. Do statistical analysis on airway care for child ren and assessment of the situation of children before and after airway care.
Results: Statistical data analysis show that the before and after comparison of Sa02, HR, and airway pressure of children with airway care in two hospital is $P < 0.01$which has highly statistical significance. There are also some common problems such as airway care compliance, appropriate suction, time on airway care and consistency between nursing documentations and orders. Nurses are positive in doing airway care according to children needs. There are 50% nurses can assess children conditions during airway care in B hospital. The respiratory therapist will do chest therapy, monitor SaO2, HR, R, airway pressure which are correlated airway care. Most nurses can follow the standards. But nurses in A hospital can't do assessment well, which will be a danger to nursing safety.
Conclusion: Results showed that reasonable frequency should be necessary. Guidelines should contain the frequency of airway care according to patients conditions like SaO2, HR, sputum. Do documentation and add standards of the depth in suction. Strengthen airway care, nursing assessment and sterile concept of operations. Improve the compliance on standards of hand hygiene, masks and sterile gloves wearing. Put an end to risk factors for nosocomial infections, reduce respiratory tract infections rate and improve quality of care.

P2572 - PRELONGED EXTRACORPOREAL MEMBRANE OXYGENATION FOR INFANT WITH PNEUMOCYST CARNII PNEUMONIA

Mihyung Kim[1], Jihyeon Yang[2], Jaehyeon Yu[3]
Chungnam National University, Cardio Vascular Surgery, Daejeon-Korea, South[1]; Chungnam National University, Cardiovasculr Surgery, Daejeon-Korea, South[2]; Chungam National University, Cardiovascular Surgery, Daejeon-Korea, South[3]

The selection of various products of pediatric ECMO oxygenator is impossible for adults. I propose to publish a case of five adults oxygenator replaced for 80 days in an environment that was available for use in ECMO. The patient was admitted to the hospital with fever & cyanosis on the day before admission. He underwent severe acidosis and desaturation and underwent VenoVeno ECMO under severe ARDS and Pneumocyst Carinii Pneumonia diagnosis. In the absence of pediatric ECMO, Maquet PLS was used as the oxygenator and Medtronic 550 was used as the all 1/4 inch line. Method: VenoVeno ECMO was performed by inserting hemocath 14fr into Rt. IJV. To increase the drain flow with desaturation and low flow, Rt. Femoral vein to 8fr. Percutaneous catheter was inserted. We performed open sternotomy at the end of the study because of hemodynamic changes such as decreased blood pressure and hypoxic damage of myocardium. Drain outflow: in RA venous 12fr. Cannular and femoral vein first installed 8fr. Catheter was used as Y shape. Artery inflow: ascending aorta to 8fr. Cannular was inserted and changed to VenoAteriall ECMO. On the third day of ECMO administration, Echo was normal in the finding, and the VV ECMO was determined for longterm management. After insertion of the cannula, it was re-replaced with VV ECMO. Anticoagulation: Nafamostat mesilate 0.3 mg/kg ~ 1 mg/kg(Futhan).Target aPTT 80 sec.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Most oxygen changes since 3weeks later. During the repeated weaning trial, the increase in TB and hemolysis of the infant were severe, resulting in five PLS oxygen changes. During the treatment, the patient could not use the product suitable for the patient, and there was a large inconvenience such as blood volume loss while using adult oxygenators. However, in a limited medical environment, we will have good results and share it together.

P2649 - TRANSITIONS OF CARE IN CONGENITAL HEART DISEASE VARIABLES ASSOCIATED WITH CLINICAL SETBACKS

Tanya Maria Kempton[1], Sheilah Harrison[2]
Nationwide Children, Pediatric Intensive Care Unit, Columbus-United States[1]; Grant Medical Center, Quality & Patient Safety, Columbus-United States[2]

Introduction: Improving outcomes and transitions in care are national initiatives. Hospitalizations in congenital heart disease (CHD) patients are often complex. If variables associated with clinical deterioration can be identified, quality initiatives can prevent "setback" events. In this study, a setback is defined as a clinical deterioration requiring escalation of care within 3 days of transition to step-down unit. The objective was to identify patients at risk for setback and variables associated with changes in clinical status which resulted in return to the cardiothoracic intensive care unit (CTICU). Hypothesis: CHD patients less than 6 months old are at risk for a setback event.
Methods: A retrospective chart review was performed on patients admitted to the CTICU between 01/01/2011 to 12/31/2011 to identify patients transferred to the CTICU within 3 days of transition to the step-down unit. Variables evaluated included diagnosis, age, weight, length of stay, date, time, and reason for setback.
Results: Thirty-seven setback events occurred in 30 patients. Thirteen (35%) were due to post-procedure recovery protocol. In 24 setbacks, occurring in 19 patients, median age was 6.3 months (0-48.7 years); median weight was 6.5 kg (3.1-86.2). Respiratory distress/arrest was the reason for transfer in 19/24 (79%) events with 13/19 (68%) occurring in patients less than 12 months old and 15/19 (79%) in patients less than 8 kg. Four of 19 (21%) patients expired during hospital admission. Median time prior to setback was 30.5 hrs (range 3.9-72.1); 12/24 (50%) events occurred on the weekend; 14/24 (58%) were during off-shift hours.
Conclusions: Children less than 8 kg and less than 12 months are at risk for a setback within 3 days of transfer to step-down unit. Respiratory distress was most frequent clinical reason. Setback events occurred more frequently during off-shift and/or weekends. Further studies of specific variables are needed.

P2705 - IMPROVING EARLY INTERVENTION FOLLOW UP FOR INFANTS WITH CONGENITAL HEART DISEASE

Anne Schmelzer[1], Onimes Capote[1], Ann Hyslop[2], Gil Wernovsky[3], Jo Ann Nieves[4], Nancy Dobrolet[5]
Nicklaus Children's Hopsital, Heart Program, Miami-United States[1]; Neuronetwork Partners, Neurology, Miami-United States[2]; Miami-United States[3]; Nicklaus Children's Hospital, Heart Program, Miami-United States[4]; Rainbow Babies & Children Hospital, Cardiology, Cleveland-United States[5]

Background: Infants with single ventricle palliation are at-risk for developmental delays (DD) related to prematurity, cardiopulmonary resuscitation/support, genetic anomalies, and prolonged hospitalizations. Since 2006, our program has provided interstage care for these infants. Through this program, infants are referred to Florida's Early Intervention (EI), which provides developmental evaluations and therapies to children birth to three.
Method: Using our EMR, infants <6 months who underwent a single ventricle palliation were identified. From January 2012 - April 2015, parents received a prescription for an EI evaluation and were instructed to schedule an appointment at four months. Beginning in May 2015, a neurodevelopmental (ND) nurse coordinator directly submitted an EI/therapy referral and followed up to evaluate parenteral compliance.
Results: Eighty infants were identified that underwent a Norwood, shunt placement, ductal stenting, or pulmonary artery banding. From January 2012 -April 2015, 59 patients were identified at-risk for DD and 46/59 patients met criteria for an EI referral (criteria included: EI locally available, patient alive at four months, parent reachable for follow-up). Nineteen/46 patients (41%) complied with a therapy evaluation after discharge. Seventeen/19 (89%) had therapy recommended, and all 17 patients complied with therapies. Between May 2015 - September 2016, using our new approach, 21 patients were identified at-risk and 19/21 patients met criteria for evaluation. Eighteen/19 patients (95%) complied with therapy evaluation after discharge. Sixteen/18 patients (89%) had therapy recommended, and all 16 patients complied with therapies. Three/19 patients (16%) required a referral resubmission because our ND nurse coordinator recognized the therapy site failed to contact the family. *Conclusion:* Single ventricle infants are at-risk for DD. When evaluated by EI these patients qualify and follow-up with therapies. Developmental care improves with a ND nurse coordinator providing direct referral to EI and follow-up to evaluate parenteral compliance.

P2769 - A CALL TO ACTION – IMPROVING THE HEALTH OF THE WORK ENVIRONMENT IN THE CARDIOVASCULAR OPERATING ROOM

Jason Thornton[1], Francis Fynn-Thompson[2], Jean Connor[3]
Boston Children, Cardiac Intensive Care Unit and Cardiovascular Operating Room, Boston-United States[1]; Boston Children, Cardiovascular Surgery, Boston-United States[2]; Boston Children, Cardiovascular and Critical Care Services, Boston-United States[3]

Background/Hypothesis: The American Association of Critical Care Nurses (AACN) has identified systemic behaviors that maintain patient safety, ensure optimal outcomes, and support excellence in nursing practice. These behaviors are organized into six evidence-based standards: skilled communication, true collaboration, effective decision making, appropriate staffing, meaningful recognition and authentic leadership. AACN developed an electronic survey to provide a quantitative assessment of the health of the work environment (HWE). Scoring guidelines are from Needs Improvement, Good, to Excellent. The survey was electronically mailed to Cardiovascular Operating Room (CVOR) interdisciplinary staff from 2010 to 2015. After receiving an overall score within Needs Improvement in 2015, the unit leadership convened to address areas for improvement.
Methods and Materials: A comprehensive and immediate action plan was designed and implemented over 12 months. An authentic commitment to improve the health of the environment was reinforced by cardiovascular nursing and surgical leadership. Based on a key driver diagram, the ambassador group developed and implemented change initiatives and evidence-based practices. Interdisciplinary staff were re-surveyed in 2016.
Results: Eighteen change initiatives and evidence-based practices were implemented to address the areas for improvement.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

The 2016 survey showed an overall improved score as well as improvement within each of the six standards. The overall score and standard scores improved from within Needs Improvement to Good.
Conclusions: Change initiatives were implemented by a nurse-led interdisciplinary team to foster and sustain a commitment to excellence in the work environment. Targeted initiatives will continue to be implemented to address areas requiring improvement. Our results highlight that maintaining and sustaining a healthy work environment is a continuous process and an activity for which all healthcare team members are accountable. Maintaining a culture of health in the work environment will continue to be a priority within CVOR as it is critical to ensuring optimal patient outcomes.

P2772 - TRACHEOSTOMY FOR CHILDREN ADMITTED FOR CONGENITAL HEART SURGERY

Jason Thornton[1], Courtney Porter[2], Kimberlee Gauvreau[3], Jean Connor[2]
Boston Children, Cardiac Intensive Care Unit and Cardiovascular Operating Room, Boston-United States[1]; Boston Children, Cardiovascular and Critical Care Services, Boston-United States[2]; Boston Children, Cardiology, Boston-United States[3]

Background/Hypothesis: The objective is to describe the prevalence of tracheostomy placement and outcomes for children during admission for congenital heart surgery (2006,2009).
Methods and Materials: ICD-9-CM codes were used to identify patients <18 years of age undergoing both congenital heart surgery and tracheostomy during admission using Health Care Utilization Project Kids Inpatient Database (KID) year 2006 and 2009. Hospital characteristics and patient demographic, clinical and surgical (RACHS-1 risk categories) characteristics, discharge disposition, and inpatient utilization were summarized.
Results: In 2006, 16,891 cases were admitted for congenital heart surgery of which 179 (1.1%) also underwent tracheostomy. In 2009, 18,765 cases were admitted of which 234 (1.2%) underwent tracheostomy. In both years, the rate of tracheostomy varied significantly by region, with the highest percentage observed in the South (33.5% in 2006; 33.5% in 2009). Among those who had both procedures, the rate of in-hospital death decreased from 2006 to 2009 (26.8% and 16.2%, respectively). When comparing 2006 to 2009, the use of Medicaid insurance decreased (64.8% to 58.6) and use of private insurance increased (29.6% to 35.5%). The percentage of patients with prematurity, non-cardiac anomalies, or non-Downs major chromosomal abnormalities increased. In 2006 and 2009, the majority were categorized as RACHS-1 categories 2, 3, and 4 (56% and 38.5%, respectively). The percent of cases categorized as a RACHS-1 category 6 increased from 2006 to 2009 (1.7% to 4.7%). The median length of stay was 132 days (16 to 356) in 2006 and 139 days (12 to 362) in 2009. In 2006, 38% were discharged from a children's hospital. In 2009, 31.6% were discharged from a children's hospital.
Conclusions: Tracheostomy, although rare during congenital heart surgery admission, is associated with high in-hospital mortality and resource use. Despite having a similar rate of tracheostomy and RACHS-1 classifications, the rate of in-hospital mortality decreased by 10.6%.

P2777 - MANAGING CARDIAC INTENSIVE CARE UNIT CAPACITY STRATEGIC SOLUTIONS

Jason Thornton[1], Derek Matheiu[2], Michelle Hurtig[3], Aditya Kaza[4], Roger Breitbart[5], Jean Connor[6], Patricia Hickey[6]
Boston Children's Hospital, Cardiac Intensive Care Unit and Cardiovascular Operating Room, Boston-United States[1]; Boston Children's Hospital, Cardiology, Boston-United States[2]; Boston Children's Hospital, Cardiovascular Inpatient and Ambulatory Programs, Boston-United States[3]; Boston Children's Hospital, Cardiovascular Operating Room, Boston-United States[4]; Boston Children's Hospital, Inpatient Cardiology, Boston-United States[5]; Boston Children's Hospital, Cardiovascular and Critical Care Services, Boston-United States[6]

Background/Hypothesis: For an extended period of time during summer of 2014, the needs of our cardiac patients exceeded the capacity of our physical Cardiac Intensive Care Unit (CICU). In response to this unprecedented demand on resources, an interdisciplinary group was established to develop strategic solutions for CICU capacity management.
Methods and Materials: The interdisciplinary group met regularly with an external consultant to analyze the capacity impact of patients remaining in the CICU for more than 28 days. Using this cohort of 182 long-stay patients, we developed a model to predict ICU length of stay to inform scheduling of cardiac surgical cases. A daily data dashboard was generated to display the daily census, incoming cardiac catheterization and surgical cases, and a prediction of the weekly capacity. In addition, a smaller interdisciplinary admissions group was developed to assess CICU capacity daily and advise on pending admissions and transfers. A brief daily huddle was implemented for the admissions group to review the predictions and dashboard to ensure adequate capacity management. At six months, these strategic solutions were evaluated to determine feasibility and sustainability.
Results: Since May 2015, a brief daily huddle of the admissions group has been held every morning. During each huddle, the predictions from the model and the daily dashboard are used to inform surgical scheduling as well admission and transfer decisions. It has been feasible to update and use the data dashboard and predictions daily. During the summer of 2015, there were zero cardiac surgical patients cancelled or postponed due to lack of CICU bed availability.
Conclusions: The development and implementation of strategic solutions for capacity management in the CICU has resulted in a dramatic reduction in the number of cardiac surgery cancellations or rescheduling. The strategic solutions have been found to be feasible to implement and sustain.

P2799 - COMPREHENSIVE MEASUREMENT OF NURSING PRACTICE IN THE CARDIAC INTENSIVE CARE UNIT USING THE CAMEO

Jason Thornton[1], Courtney Porter[2], Christine Lagrasta[3], Patricia Hickey[2], Jean Connor[2]
Boston Children's Hospital, Cardiac Intensive Care Unit and Cardiovascular Operating Room, Boston-United States[1]; Boston Children's Hospital, Cardiovascular and Critical Care Services, Boston-United States[2]; Boston Children's Hospital, Inpatient Cardiology, Boston-United States[3]

Background/Hypothesis: Efforts to capture nursing workload have focused on describing and quantifying direct care nursing activities. Existing tools do not account for many of the provider-related "invisible" activities that comprise critical thinking, leading to an incomplete assessment of the cognitive workload. Complexity Assessment and Monitoring to Ensure Optimal Outcomes (CAMEO) is a validated instrument that provides a quantitative measurement of cognitive workload required to deliver pediatric nursing care. It includes direct and indirect nursing care activities and incorporates the intellectual processing of data and critical thinking

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

necessary to deliver high-quality, holistic care to patients and families. Complexity is measured using a classification scoring system with I representing stable patients requiring minimal intervention and V representing patients with clinical instability and/or complex care coordination needs. The objective was to assess the contribution of indirect nursing care in the cardiac intensive care unit (CICU).
Methods and Materials: Completed CAMEOs were categorized and summarized by level of complexity. Reported workload for the domains of care coordination, family assessment and support, and education and discharge teaching were calculated by number of reported actions and time required to complete the activity by the CICU nurse.
Results: Among 539 CAMEOs reviewed, 90.4% were categorized as classification III, IV, or V. The number of indirect care activities increased with level of complexity with an average of 3.38 care activities reported for level V. Among three indirect care domains, the most frequently reported activity was identified as care coordination. As level of complexity increased so did the amount of time spent to support these indirect activities with 50.5% of level V care reporting >30 minutes.
Conclusions: To understand true workload of pediatric critical care nursing, both direct and indirect care must be considered. Use of CAMEO for pediatric cardiovascular patients revealed a consistently complex level of nursing care.

P2805 - BALANCING AUTONOMY AND INVOLVEMENT THE ROLE OF THE FATHER IN DECISION MAKING FOLLOWING DIAGNOSIS OF A SEVERE FETAL ANOMALY A QUALITATIVE STUDY

Robyn Lotto[1], Natalie Armstrong[2], Lucy Smith[2]
Liverpool John Moores University, School of Nursing And Allied Health, Liverpool-United Kingdom[1]; University of Leicester, Department of Health Sciences, Leicester-United Kingdom[2]

Background: As the discourse surrounding 'new-fatherhood' has become established in the literature, the experiences of fathers-to-be has increasingly been reported. However, the role of fathers-to-be in the decision-making process following diagnosis of a severe fetal anomaly has predominantly been overlooked. Aims: Drawing on findings from a larger study, this article begins to fill that gap by exploring tensions arising from prioritising maternal identity over paternal/couple identities, and seeks to identify mechanisms through which one can be supported without disempowering the other.
Methods: Data from interviews with parents-to-be and clinicians, and audio-recorded consultations were collated. Analysis was undertaken using a constant comparative based approach.
Findings: Data collated from the fathers' interviews highlighted a sense of being a 'bystander', a role that resonates with men's experience of pregnancy/childbirth more broadly. Whilst maternal identity is reinforced from the physical changes in her body to the legal requirements of her signature on consent forms, the paternal identity exists only when validated by others. "Disenfranchised grief", a grief that is not or cannot be openly acknowledged, was frequently encountered by fathers-to-be. This is reflected in the social expectations of stoicism and hidden grief. Implications for practice: Symbolic procedures can be implemented to support the couple as an entity without disempowering the mother. Examples such as providing opportunities for both parents-to-be to sign consent forms when a termination has been decided upon, engagement of the father-to-be by documenting his name in fetal medicine notes so healthcare professionals can refer to him by name, and practical aspects such as ensuring both parents have access to basic facilities such as bedding and food whilst in hospital. As the 'patient', these items will automatically be provided for the mother, but as a 'visitor' the father, as revealed in many of the experiences recalled in this study, was frequently overlooked.

P2828 - READINESS FOR TRANSFER IN ADOLESCENTS WITH CONGENITAL HEART DISEASE

Åsa Burström[1], Mariela Acuna Mora[2], Sparud-lundin Carina[2], Katarina Hanseus[3], Maria Öjmyr-joelsson[4], Margret Nisell[5], Björn Frenckner[4], Annika Rydberg[6], Philip Moons[7], Ewa-lena Bratt[2]
Karolinska Institutet, Stockholm, Dept. of Pediatric Cardiology, Astrid Lindgren's Children's Hospital, Stockholm-Sweden[1]; University of Gothenburg, Inst. of Health and Care Science, Gothenburg-Sweden[2]; Skanes University Hospital, Dept. Pediatric Cardiology, Skanes, Lund-Sweden[3]; Karolinska Institutet, Stockholm, Dept. of Pediatric Surgery Unit, Astrid Lindgren Children's Hospital, Stockholm-Sweden[4]; Karolinska Institutet, Stockholm, The Red Cross Nursing College, Stockholm-Sweden[5]; Norrlands University Hospital, Dept. of Pediatric Cardiology, Umeå-Sweden[6]; Ku Leuven, Dept. Public Health and Primary Care, Leuven-Belgium[7]

Introduction: Many patients with congenital heart disease (CHD) are in need of lifelong medical follow-up. Transfer to adult care in most cases is determined by the age of the patient. In order to develop interventions that can help the young person in this transfer, it is important to determine their readiness to transfer to this new setting.
Aim: The aims were (i) to describe the level of readiness for transfer in adolescents with CHD, and (ii) to explore the association of transition readiness with age, sex and disease complexity.
Method: In a cross-sectional study, 203 adolescents from four outpatient paediatric cardiology units in Sweden participated (response rate: 34%). The mean age was 15.7 ± 1.2 years and 45% were females. Patients could be included if they met the following criteria: 1) diagnosed with CHD; 2) aged 14-18 years; and 3) under active follow-up at one of the participating centres. The overall transition readiness was measured using the Readiness for Transition Questionnaire (RTQ). The score ranges from 2-8, with higher scores denoting higher level of readiness.
Results: Mean RTQ-score in 14 year olds was 4.6 ± 1.6 ($n = 37$), in 15 year olds 5.1 ± 1.8 ($n = 51$), in 16 year olds 5.2 ± 1.6 ($n = 57$), and in 17 year olds 5.9 ± 1.8 ($n = 68$). Indeed, older participants had a significantly higher RTQ-score ($p = 0.003$). Male patients showed to have a higher RTQ mean score (5.5 ± 1.7) than females (5.0 ± 1.8)($p = 0.05$). Transfer readiness was not associated with sex or complexity of the condition (mild 5.3 ± 1.6; moderate 5.3 ± 1.9; severe 5.2 ± 1.8; $p = 0.98$).
Conclusion: Self-reported overall RTQ increased with age. This information is relevant when setting up intervention studies. There is a natural growth in readiness regardless the complexity of the CHD. Interventions should be able to outstrip the natural evolution. Future studies should further explore transition readiness in terms of patients' and parents' involvement and responsibility of care.

P2850 - SKIN PROTECTION POLICY FOR CRITICAL PEDIATRIC PATIENTS WITH CONGENITAL HEALTH DISEASE HAVING EXTRACORPOREAL MEMBRANE OXYGENATION (ECMO) THERAPY A SUCCESSFUL EXPERIENCE LEAD BY NURSES

Yudi A. Rojas[1], Patricia Monroy[2], Sandra Gómez[1], Nathalie Guiza[1], Luz Dary Salazar[1]
Fundación Cardioinfantil Instituto De Cardiología, Skin Care Program, Bogotá, D.c-Colombia[1]; Fundación Cardioinfantil Instituto De Cardiología, Pediatric/cardiovascular ICU, Bogotá, D.c-Colombia[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Since 2015 The Fundación Cardioinfantil Instituto de Cardiología (FCI-IC) in Bogotá, Colombia implemented the skin protection for all children having extracorporeal membrane oxygenation (ECMO) therapy in the cardiovascular intensive care unit (CICU). The implementation of preventive care strategies was lead by the nurses of the Skin Care Program (SCP) and from the CICU.
Objective: to describe (1) the nursing process of skin care assessment, administration of protective skin strategies, evaluation and following up of outcomes during hospitalization, (2) the characteristics of the pediatric population under care, and (3) the effectiveness of the program in the prevention of pressure ulcers.
Methods: All pediatric patients (2015-2016) with congenital heart disease eligible for ECMO received the standardized skin protection. Parents of patients signed a consent form for care implementation. Each patient was assessed and intrinsic and extrinsic factors were taking into a model a care. The skin areas with high risk were protected with hydrocolloid dressings and other areas were protected with hyper-oxygenated fatty acid esters. Following up of the patients was daily by CICU nurses and each five days by SCP nurses.
Results: Nine children from a total of 1204 admitted to the CICU, with mean age of 9.3 months, six men and three women were included in the cohort of patients having ECMO at the FCI-IC. The most prevalent complication was ventricular dysfunction after surgery. The mean length of stay was of 31 days and the mean time in ECMO was 13 days. There were three (0.3%) pressure injuries (Grade I) in occipital area with epithelialization in 4-5 days. Patients did not have pressure ulcers compared with patients not having ECMO (ulcer rate of 6.6 ×1000).
Conclusion: This study highlights the benefit of the implementation of one standardized policy of skin preventive protection for pediatric patients under high risk.

P2864 - PREPLANNED AND PREPREPARED DISCHARGE RAISED QUALITY

Rachael Broomfield[1], Eleanor Constantinou[1], Ruth Umney[1], Liz Nuttall Collins[1], Ram Awat[2], Liz Smith[3]
Great Ormond Street, Cardiology, London-United Kingdom[1]; Great Omrond Street, Cardiology, London-United Kingdom[2]; Great Ormond Street, Cardiac Services, London-United Kingdom[3]

The cardiac nurse practitioner team took on the management of discharges from the cardiology ward environment in 2011. The flow of patients in any large tertiary cardiac paediatric centre is crucial. This will ensure safety, quality of care and efficiency. Discharge of a patient with agreed clinical safety and who continues to receive high quality and efficiency of care is crucial to patient flow and the ability to ensure more patients access the service. This process is crucial for admission of the next patient requiring planned or emergency cardiac surgery, as part of daily planning strategy.
Method: The unit currently runs at over 87% capacity, which means that each bed day is very precious to the hospital and to the patient. An understanding of the discharge planning is critical to running a service where admissions are as critical as your discharges. The collaborative working of clinical experts is very important and the expertise gained working in this "specialist area " or practice cannot be underestimated. Family expectations and preparation were undertaken as part of a Nurse Led clinic to reward the individual and family. Patient supported outcomes measures were used to measure success. With this development it was obvious from data collection that their were large gaps in service and therefore team developments and wins e.g. assessments, wound reviews, follow up calls and animal reviews.
Results: Data collected shows the development of this service and the ANP role. Data will be presented to support this development. Family reviews will provide balancing measures. The success of this model with a quality improvement connection, has been used in other areas of clinical care.
Outcomes: Outcomes measures are needed to ensure the qualitative and quantitative measures are used to support future developments.

P2881 - PERCEIVED CARDIAC CONSEQUENCES FROM ADOLESCENTS WITH TETRALOGY OF FALLOT AND REVIEW OF CLINICAL DATA

Julie Martin, Mark Gelatt
Children's Mercy Hospital, Heart Center, Kansas City-United States

Introduction: Tetralogy of Fallot (TOF) may have long term consequences with exercise ability, quality of life and need for future cardiac surgery. Adolescents may have perceptions of these consequences which may or may not be valid.
Methods: Adolescents with TOF were asked to completed questionnaires to describe how their congenital heart disease affected their exercise abilities, and to report their perceptions of the need for future surgery and long term consequences. Reported symptomatology and quantitative data obtained from echocardiograms, electrocardiograms (ECG), cardiac stress tests, and cardiac MRIs were reviewed and compared to the responses.
Results: Forty percent of TOF adolescents reported no long term cardiac consequences or effect on their exercise abilities. Exercise limits were perceived with minimal consequence in 37% and moderate consequences in 13%. Despite rarely applied exercise restrictions from providers, 28% of adolescents perceived an exercise restriction was recommended. The most commonly reported complaints were exercise intolerance and fatigue. The majority of echocardiograms revealed normal ventricular function, minimal pulmonary valve stenosis; half revealed moderate right ventricle dilatation and half revealed aortic root enlargement. Nearly 50% of patients, completed Holters, exercise stress test and/or cardiac MRI. No significant rhythm abnormalities were seen on the cardiac tracings. Premature ventricular complexes were infrequently reported. Cardiac MRIs provided qualitative data on the pulmonary valve insufficiency. Possible or more definite need for surgery was reported in 70%. Adolescents reporting greater limitations or concerns for future surgery were more likely to have completed a Holter or MRI with more significant cardiac findings noted.
Conclusions: The quantitative data from the cardiac tests frequently validated the adolescents perceived greater concerns with exercise abilities, need for future surgery or long term consequences.

P3015 - CLINICAL HAND OFF IMPROVEMENT INITIATIVE TO STANDARDIZE INTERDISCIPLINARY PATIENT HAND OFF

Mary Mclellan[1], David Hoganson[2], Amy Delaney[2], Christina Ireland[2], Mariam Irshad[3], Megan Matiasek[4], Anna Fisk[4], Jean Connor[3], Francis Fynn-thomspson[2]
Boston Children's Hospital, Inpatient Cardiology, Boston-United States[1]; Boston Children's Hospital, Cardiac Surgery Department, Boston-United States[2]; Boston Children's Hospital, The Heart Center, Boston-United States[3]; Boston Children's Hospital, Cardiac Intensive Care Unit, Boston-United States[4]

Objective: The Clinical Handoff Improvement (CHAIN) initiative aimed to develop and implement a highly reliable and sustainable

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

standardized patient handoff process across all care areas in the Heart Center to optimize the transfer of accurate information and ensure against handoff-related care failures.
Methods: An interdisciplinary quality improvement team was formed to improve patient handoff. Improvement was guided by evidence-based literature, the hospital's clinical handoff policy and mission, and contributions from clinicians across the Heart Center continuum. The CHAIN working group developed an I-PASS (illness severity, patient summary, action list, situation awareness and contingency planning, synthesis by receiver) tool specific to the cardiac units and handoff process involving team-based face-to-face communication. The initiative was piloted over two months for patient transfers from the Cardiac Intensive Care Unit (CICU) to the Cardiac Inpatient Unit. Phase two included scheduled times for structured handoffs. Evaluation via direct observation and surveys included measuring team compliance of the I-PASS format, duration and efficiency of the handoff, synthesis by the receiving team, and clinician satisfaction.
Results: From August to September 2016, 26 patient handoffs were observed (88% from surgical service and 12% from medical service). Duration of team-based handoff decreased with Phase 2 of the pilot (average of 8 minutes per handoff). Overall, clinician satisfaction from both sending and receiving teams improved with the implementation of scheduled times.
Conclusions: Implementation of a structured handoff initiative was found to be both feasible and successful. The CHAIN working group was able to use the pilot to analyze content and structure of handoff communication. Since the pilot, the standardized team-based patient handoff has been implemented for all handoffs between the CICU and inpatient unit. The pilot provided insight to expand the team-based process to handoffs across the Heart Center.

P3019 - CONCERNING THE CHEWS STAFF AND FAMILY CONCERN CONTRIBUTE TO THE IDENTIFICATION OF HOSPITALIZED CHILDREN AT RISK FOR CRITICAL DETERIORATION

Mary Mclellan[1], Adam Homoki[1], Kim Gauvreau[2], Jean Connor[2]
Boston Children's Hospital, Inpatient Cardiology, Boston-United States[1]; Boston Children's Hospital, The Heart Center, Boston-United States[2]

Background: Early warning scores are used in hospitals to identify patients at risk for critical deterioration. The Children's Hospital Early Warning Score (CHEWS) is the only pediatric early warning score that includes clinician and family concern into the aggregate score. The objective was to determine the validity of 'staff concern' and 'family concern' within CHEWS at identifying children at risk for critical deterioration.
Methods: A retrospective cohort study was used to examine the association between 'staff concern' or 'family concern' and critical deterioration in pediatric cardiac (n = 312) and non-cardiac (n = 1136) inpatients. Odds ratios (OR), sensitivity, specificity, and the area under the receiver operator characteristic curve (ROC) were estimated for the CHEWS domains.
Results: See Table 1 and 2.
Conclusion: 'Staff concern' had the highest discrimination at identifying pediatric critical deterioration. The presence of 'staff concern' and 'family concern' were both statistically significant in patients that experienced critical deterioration compared to control patients. The OR for critical deterioration was three times higher in the cardiac patients compared to the non-cardiac patients when staff concern was present. Staff concern' and 'family concern' are valid CHEWS domains in the identification of hospitalized children at risk for critical deterioration.

Table 1. Odds ratio (OR) for critical deterioration by CHEWS domain.

	Non-Cardiac Sample		Cardiac Sample	
CHEWS Domain	**OR**	**p value**	**OR**	**p value**
Staff Concern	10.37	<0.001	31.4	<0.001
Family Concerned or absent	2.87	<0.001	0.96	0.96
Behavior/Neuro	1.96	<0.001	1.7	0.057
Cardiovascular	1.24	0.02	2.25	<0.001
Respiratory	1.64	<0.001	2.47	<0.001

Table 2. Area under the receiver operating curve (ROC), sensitivity, and specificity of 'Staff Concern' and 'Family Concern or Absent' CHEWS domains.

	Non-Cardiac Patients	Cardiac Patients
Staff Concern		
ROC	0.856	0.890
Sensitivity	83.1%	96.2%
Specificity	88.2%	91.7%
Family Concern or Absent		
ROC	0.766	0.661
Sensitivity	78.1%	64.1%
Specificity	75.2%	68.0%

P3023 - POST ORIENTATION SUPPORT TARGETING EDUCATION AND RESILIENCE PROGRAM (POSTER) FOR NEWLY HIRED NURSES ON AN ACUTE CARE PEDIATRIC CARDIOLOGY UNIT

Mary Mclellan, Jessica Mooney, Christine Donovan, Leanne Mcgonagle, Christine Degray, Adam Homoki, Maeve Giangregorio, Michelle Hurtig
Boston Children, Inpatient Cardiology, Boston-United States

Background: New nurses may have high levels of psychological distress, low resiliency, and role transition challenges resulting in decreased confidence, marginalization, and potential errors. Satisfaction among new nurses improved if they had access to supportive resources and were aware of professional development opportunities. New nurses reported higher levels of security off orientation when they received proactive support including regular check-ins, time set aside for them, and monitoring of their progress.
Methods: the Inpatient Cardiology Education Team initiated the Post-Orientation Support Targeting Education & Resilience (POSTER) Program to support new nurses. All new nurses were enrolled in the POSTER program upon orientation completion. The new nurse's preceptor completes an aggregate POSTER scale (0–36) comprised of clinical practice, education needs, psychosocial support and experience level to identify the level of needed support. The POSTER program provides twice a day structured 'check-in's with the new nurse for 6-12 months depending on need. Each new nurse is matched to a nurse educator as their personal POSTER coach. Coaching sessions are provided initially on a monthly basis and decreased if indicated. The new nurse 'graduates' from the POSTER program into the unit's peer-based mentoring program after mutual agreement with the POSTER coach.
Results: 42 nurses entered the POSTER program in 19 months, less than half (38%) were new graduate nurses. Retention of the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

nurses was 88% (n = 37) for the unit and 95% for the department. Initial POSTER scores ranged from 1-21 with a mean of 7.0, 6.5 for unit-retained nurses and 17 for those who left (n = 5) (p = 0.0001).
Conclusion: The POSTER program had a high retention rate since implementation. The POSTER scale may be helpful in identifying nurses completing orientation that are at risk for leaving their position.

P3045 - IMPROVING COMPLIANCE WITH "SAFE SURGERY CHECKLIST" PROCESS; A MULTIDISIPLINARY IMPROVEMENT PROJECT

Elif Terzioğlu[1], Hisam Alahdab[1], Ayhan Erdemir[2], Yetkin Özer[3], Sertaç Çiçek[4]
Anadolu Medical Center, Clinical Quality and Patient Safety, Kocaeli-Turkey[1]; Anadolu Medical Center, General Surgery, Kocaeli-Turkey[2]; Anadolu Medical Center, Anesthesiology, Kocaeli-Turkey[3]; Anadolu Medical Center, Cardiology and Cardiovascular Surgery, Kocaeli-Turkey[4]

In this study we aimed to improve compliance with Safe Surgery Checklist (WHO) to reduce surgery related complications. Compliance with the checklist in June 2014 was 57%. A multidisciplinary group composed of frontline staff gathered to define the root causes of non-compliance. Individual interviews were also used to gather information. The main root causes were: the documentation process had both manual and electronic phases leading to confusion, the checklists had many questions some of which had no value, leading to frustration and time loss, the use of electronic checklists prevented the optimal practice of time out facing the patient. The group decided on the following interventions: Simplification of the forms and getting rid of the wastes, multiple forms were combined to reduce handoff problems and improve communication, moving to manual forms to prevent variation and establish bedside time out. The interventions led dramatic improvement in compliance from 57% in 2014 to 88% in 2015. The next step was to deep dive into specifics where we recognized that the department of cardiovascular surgery (CVS) needed department specific attention. We conducted education sessions specific to CVS to tackle specific concerns and discuss them. Meanwhile, the Anesthesiologists were given the right not to put patients into sleep until proper Time out was performed. These actions increased compliance of cardiovascular surgeons from 79% to 97%. The overall improvement was sustained at the level of 88% in 2016 by regular reporting and personal feedback to non-compliant practitioners. Conclusion: a multidisciplinary team is essential for defining the root causes and actions for non-compliance. A user-friendly documentation which provides the chance to communicate with the patient and team improves compliance with safe surgery checklist. Working with frontline staff is an essential token to improve compliance. A powerful leadership support is also essential to implement and sustain improvement.

RHEUMATIC

P1100 - ECHOCARDIOGRAPHIC PREVALENCE OF RHEUMATIC HEART DISEASE IN 4515 SUDANESE SCHOLARS EVIDENCE OF HEALTH INEQUITY

Sulafa Ali[1], Sara Eldomi[2], Rabab Abbas[3], Tajudeen Bushari[3], Bahja Abbo[4]
Sudan Heart Center, Ped Cardiology, Khartoum-Sudan[1]; Sudan Heart Center (SHC), Ped Cardiology, Khartoum-Sudan[2]; SHC, Ped Cardiology, Khartoum-Sudan[3]; Niyala Hospital, Pediatrics, Niyala-Sudan[4]

Introduction: Rheumatic heart disease is the commonest cause of acquired heart disease in Sudan with a clinical prevalence of 11 per 1000 in 1992.. Introduction of hand held echocardiography (HHE) enabled the detection of subclinical disease which was found to be several folds higher than clinical prevalence in many countries. We carried this study to measure the echo prevalence and initiate a prevention program.
Methodology: This is a prospective epidemiological study on scholars 10-15 years of age. Phase 1 was conducted in Khartoum (September 2015- February 2016). Phase 2: Conducted in South Darfur, Niyala camps for displaced people (July - September 2016). Echocardiographic (echo) screening using HHE (V scan-GE) was conducted In Khartoum by pediatric cardiology fellows using the World Heart Federation criteria. While in Niyala, a simplified protocol using one echo view performed by trained medical officers was utilized. Suspected cases underwent detailed echo examination using standard echo (SE) machine. Training of health personnel was conducted through lectures and workshops.
Results: In Khartoum a total of 3000 scholars were screened, 8 cases were found to be positive for RHD by HHE. Out of them, only 1 case was confirmed by SE. The echo prevalence of RHD was 0.3 per 1000.In Darfur, a total of 1515 cases were screened. By HHE, 59 cases were positive for RHD. Out of these 34 underwent SE; 29 of whom were found to have RHD; 22 had definite and 7 had borderline disease. HHE sensitivity was 85.2%. The estimated prevalence was 30.7 per 1000. A total of 779 health worker were trained and 50 000 posters and pamphlets were distributed. The striking difference of RHD prevalence in the 2 areas is an indication of health service inequity and the need to mobilize resources to primary health care in remote areas.

P1108 - EPIDEMIOLOGY OF CONGESTIVE HEART FAILURE IN CHILDREN IN A TERTIAIRY AFRICAN CENTRE

Tantchou Tchoumi Jacques Cabral[1], Ambassa Jean Claude[2], Gianfranco Butera[3]
Cardiac Centre Shisong, Electrophysiology, Kumbo-Cameroon[1]; Cardiac Centre Shisong, Cardiology, Kumbo-Cameroon[2]; Policlinico San Donato Irccs, Pediatric Cardiology, Milan-Italy[3]

Background: The aim of the study was to investigate the epidemiology of congestive heart failure in children in St. Elizabeth Catholic General hospital, cardiac centre.
Patients and Methods: This retrospective analysis included 265 patients aged between 5 and 16 years old who consulted in the Cardiac centre from July 2008 through July 2013. Data from patients' records, two-dimensional echocardiographic studies, electrocardiogram were reviewed.
Results: Patients aged between 4 days and 16 years old with a mean age of 8,4 ± 4,5 years. The main symptoms were: tachycardia, growth retardation, cyanosis, cough in patients with congenital heart diseases, shortness of breath, lower limbs and abdominal swelling, orthopnoea in patients with acquired heart diseases. Acquired heart diseases due to post rheumatic valvulopathies were mostly diagnosed in 190 cases (71%), severe mitral regurgitation being the commonest diagnosis. Less were mitral stenosis and combined pathologies (mitral and aortic valves) and HIV cardiomyopathy. In the group of patients with congenital heart diseases, ventricular septal defect defect was the commonest diagnosis. Tetralogy of Fallot, patent arterial duct, atrial septal defect, coartation of the aorta, complex congenital heart pathologies and sickle cell cardiomyopathy were also seen. Corrective and palliative surgery were performed in patients with indication after stabilization.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Post rheumatic mitral valve regurgitation is the pathology the most encountered in children with congestive heart failure having acquired cardiopathies and ventricular septal defect is the pathology the most encountered in children with congestive heart failure having congenital cardiopathies. Due to financial limitation poverty and illiteracy of parents, the follow up of patients is difficult.

P1236 - ADHERENCE TO SECONDARY ANTIBIOTIC PROPHYLAXIS FOR PATIENTS WITH SCREENING DETECTED RHEUMATIC HEART DISEASE

Daniel Engelman[1], Reapi Mataika[2], Joseph Kado[3], Maureen Ah Kee[4], Susan Donath[5], Tom Parks[6], Andrew Steer[7]
University of Melbourne, Royal Children's Hospital, Melbourne-Australia[1]; Colonial War Memorial Hospital, Paediatrics, Suva-Fiji[2]; Fiji National University, College of Medicine, Nursing and Health Sciences, Suva-Fiji[3]; Fiji Rheumatic Heart Disease Control Program, Fiji Group A Streptococcal Project, Suva-Fiji[4]; Murdoch Childrens Research Institute, Clinical Epidemiology and Biostatistics Unit, Melbourne-Australia[5]; University of Oxford, Wellcome Trust Centre For Human Genetics, Oxford-United Kingdom[6]; Murdoch Childrens Research Institute, Group A Streptococcal Research, Melbourne-Australia[7]

Background: Echocardiographic screening for rheumatic heart disease (RHD) can detect subclinical cases, however adequate adherence to secondary antibiotic prophylaxis (SAP) is required to alter disease outcomes. We aimed to investigate the adherence to SAP among young people with RHD diagnosed through echocardiographic screening in Fiji, and to investigate factors associated with adherence.
Methods: Patients diagnosed with RHD through echocardiographic screening in Fiji from 2006 – 2014 were included. Dates of benzathine penicillin G injections were collected from 76 health clinics nationally from December 2011 to December 2014. Adherence was measured using the proportion of days covered (PDC). Multivariate logistic regression analysis was used to identify characteristics associated with any adherence (≥1 injection received) and adequate adherence (PDC ≥ 0.80.
Results: Of 494 patients, 268 (54%) were female and the median age was 14 years. Overall, 203 (41%) had no injections recorded and just 33 (7%) had adequate adherence. Multivariate logistic regression showed increasing age (OR 0.93 per year, 95% CI 0.87-0.99), and time since diagnosis ≥1.5 years (OR 0.53, 95% CI 0.37–0.79) to be inversely associated with any adherence. Non-iTaukei ethnicity (OR 2.58, 95% CI 1.04-6.33) and urban residence (OR 3.36, 95% CI 1.54–7.36) were associated with adequate adherence, whereas time since diagnosis ≥1.5 years (OR 0.38, 95% CI 0.17–0.83) was inversely associated with adequate adherence.
Conclusions: This is the first study to assess adherence to SAP following echocardiographic screening, and the first to utilise the PDC as an adherence measure for RHD. Adherence in Fiji is currently inadequate for individual patient protection or population disease control. Secondary prevention should be strengthened before further screening can be justified.

P1266 - ECHOCARDIOGRAPHIC SCREENING FOR RHEUMATIC HEART DISEASE (RHD) AMONG ASYMPTOMATIC ADULTS 18 25 YEARS OF AGE STUDY FROM A REGION WITH HIGH PREVALENCE OF ECHOCARDIOGRAPHIC RHD IN ASYMPTOMATIC SCHOOL CHILDREN

Anita Saxena[1], S Ramakrishnan[1], Shashi Kant[2], Ambuj Roy[1]
All India Institute of Medical Sciences, Cardiology, New Delhi-India[1]; All India Institute of Medical Sciences, Community Medicine, New Delhi-India[2]

Background: Several studies, including our own, have reported a high prevalence of rheumatic heart disease (RHD) in school children on echocardiographic screening. However the significance of these echocardiographic abnormalities remains ill defined. A long term follow up of such children will be ideal to understand the natural history of mild, subclinical RHD. Screening adults living in the same region may provide some insight into the natural history.
Methods: We carried out a cross sectional survey among asymptomatic adults 18-25 years of age in a pre identified area of northern part of India where an echocardiographic screening among school children had detected a high prevalence of RHD. The demographic data was collected. After a brief history and physical examination, echo Doppler was performed by an experienced cardiologist. A diagnosis of RHD was made using the World Heart Federation criteria (WHF); it was divided into "definite RHD" and "borderline RHD".
Results: A total of 835 adults have been screened over the preceding 6 months. The mean age was 20.6 ± 2.5 years, 406 (48.6%) were males. Clinical examination detected RHD in three cases (clinical RHD: 3.6/1000). Using the WHF criteria, RHD was diagnosed in a total of 13 cases (15.6/1000; 95% CI 9.1-26.4/1000), 5 were diagnosed as definite RHD and 8 as borderline RHD. RHD was significantly more common in females and in families with more overcrowding in the house ($p < 0.01$ for both).
Conclusions: This preliminary work demonstrates that prevalence of RHD is high among asymptomatic adults in this region of northern part of India where an earlier study had shown high prevalence in school children. This data may be useful to understand the natural history of mild, subclinical RHD since it may act as a surrogate marker for long term follow up of children diagnosed to have RHD on screening echocardiography.

P1277 - ECHOCARDIOGRAPHIC PROGRESSION OF SCREENING DETECTED DEFINITE AND BORDERLINE RHEUMATIC HEART DISEASE

Daniel Engelman[1], Reapi Mataika[2], Gavin Wheaton[3], Joseph Kado[4], Samantha Colquhoun[5], Bo Remenyi[6], Andrew Steer[5]
University of Melbourne, Royal Children, Centre For International Child Health, Melbourne-Australia[1]; Colonial War Memorial Hospital, Paediatrics, Suva-Fiji[2]; Women's and Children's Hospital, Cardiology, Adelaide-Australia[3]; Fiji National University, College of Medicine, Nursing and Health Sciences, Suva-Fiji[4]; Murdoch Childrens Research Institute, Group A Streptococcal Research, Melbourne-Australia[5]; Menzies School of Health Research, Global and Tropical Health, Darwin-Australia[6]

Background: Echocardiography is a sensitive test for rheumatic heart disease (RHD) screening, however the natural history of RHD detected on screening has not been established. We aimed to evaluate the progression of screening-detected RHD in Fiji.
Methods: All young people previously diagnosed with RHD through screening, with echocardiograms available for review, were eligible. All baseline echocardiograms were re-reported. Participants underwent follow-up echocardiography. A paediatric cardiologist determined the diagnosis using the World Heart Federation criteria and assessed the severity of regurgitation and stenosis.
Results: Ninety-eight participants were recruited (mean age, 17 years; median duration of follow-up, 7.5 years). Two other children had died from severe RHD. Fourteen of 20 (70%) definite RHD cases persisted or progressed, including four (20%) requiring valve surgery. Four (20%) definite RHD cases improved to borderline RHD and two (10%) to normal. Four of 17 (24%)

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

borderline cases progressed to definite RHD (moderate: 2; severe: 2) and two (12%) improved to normal. Four of the 55 cases reclassified as normal at baseline progressed to borderline RHD. Cases with a follow-up interval greater than five years were more likely to improve (37% vs 6%, $p = 0.03$).
Conclusions: This is the longest follow-up study of screening-detected RHD and demonstrates the natural history is not benign. Most definite RHD cases persist and others may require surgery or succumb. Progression of some borderline cases to severe RHD demonstrates the need for monitoring and individualised consideration of prophylaxis. Robust health system structures are needed for follow-up and delivery of secondary prophylaxis if RHD screening is to be scaled-up.

P1278 - CLINICAL OUTCOMES FOR SCREENING DETECTED AND CLINICALLY DIAGNOSED RHEUMATIC HEART DISEASE PATIENTS

Daniel Engelman[1], Reapi Mataika[2], Maureen Ah Kee[3], Susan Donath[4], Tom Parks[5], Samantha Colquhoun[6], Jonathan Carapetis[7], Joseph Kado[8], Andrew Steer[6]
University of Melbourne, Royal Children, Melbourne-Australia[1]; Colonial War Memorial Hospital, Paediatrics, Suva-Fiji[2]; Fiji Rhd Control Program, Fiji Group A Streptococcal Project, Suva-Fiji[3]; Murdoch Childrens Research Institute, Clinical Epidemiology and Biostatistics Unit, Melbourne-Australia[4]; University of Oxford, Wellcome Trust Centre For Human Genetics, Oxford-United Kingdom[5]; Murdoch Childrens Research Institute, Group A Streptococcal Research, Melbourne-Australia[6]; University of Western Australia, Telethon Kids Institute, Perth-Australia[7]; Fiji National University, College of Medicine, Nursing And Health Sciences, Suva-Fiji[8]

Background: Population-based echocardiographic screening is being considered as a disease control strategy for rheumatic heart disease (RHD) in several countries. However, assessment of the utility of screening is limited by the paucity of data on the clinical outcomes of young people with screening-detected RHD. We aimed to describe the outcomes for a cohort with screening-detected RHD, in comparison to patients with clinically-diagnosed RHD.
Methods: A retrospective cohort study included all young people with screening-detected RHD in the Central Division of Fiji in the primary cohort. Screen-negative and clinically-diagnosed comparison groups were matched 1:1 to the primary cohort for baseline demographic characteristics. Data were collected on mortality, clinical complications and healthcare utilisation from the electronic and paper health records and existing databases. Incident Rate Ratios (IRR) and Kaplan-Meier survival curves were used to compare groups.
Results: Seventy participants were included in each group. Demographic characteristics of the groups were very similar (mean age 11 years, 69% female, median follow-up 7 years). There were nine (13%) RHD-related deaths in the clinically-diagnosed group, one (1%) in the screening-detected group (IRR: 9.6, 95% CI 1.3–420.6) and none in the screen-negative group. Complications of RHD were observed in 39 (56%) clinically-diagnosed cases, four (20%) screening-detected cases and one (1%) screen-negative case. There were significant differences in the complication-free survival curves of the groups ($p < 0.001$). Rates of admission and surgery were highest in the clinically-diagnosed group, and higher in the screening-detected than screen-negative group.
Conclusions: This study provides the first evidence that young people with screening-detected RHD have worse health outcomes than the screen-negative population. The prognosis of clinically-diagnosed RHD in Fiji remains very poor, with very high rates of mortality and complications. These data can inform development of evidence-based screening policy. Implementation of comprehensive RHD control strategies are urgently required for prevention of disease and premature mortality.

P1324 - LONG TERM FOLLOW UP STUDY OF PATIENTS WITH KAWASAKI DISEASE

Sin-Ae Park, Jee Won Park, Kichurl Park, Young Taek Jang
Presbyterian Medical Center, Pediatrics, Jeonju-Korea, South

Background: Kawasaki disease (KD) may result in coronary aneurysm formation and increased risk of cardiovascular complications such as ischemic heart disease. Therefore, the early detection, non-invasive monitoring and long-term follow-up of myocardial ischemia are essential. Purpose of this study is to investigate the long-term prognosis of patients with Kawasaki disease in Korea, and discuss the need for long-term follow-up.
Methods: The subjects were 48 patients among 354 who had been hospitalized due to Kawasaki disease, and who consented to echocardiography and exercise challenge testing. The mean duration from the onset of disease to follow-up testing after rehospitalization was 11.6 years (8.2–17.0). Patients without coronary artery aneurysms at the initial presentation of the disease were classified in group 1, and patients with small aneurysms were in group 2. Test abnormalities and differences between the two groups were analyzed.
Result: There were no significant differences in the results of follow-up echocardiography and exercise challenge testing between the two groups. Although no abnormal findings were noted at follow-up in most patients, a 9-year-old boy in group 2 showed coronary artery dilation. The exercise test indicated normal results in both groups, and echocardiography results were also normal in 100% of cases in group 1 and 93.3% of cases in group 2.
Conclusion: As some patients with coronary aneurysms showed coronary artery dilation, we believe that long-term follow-up may be selectively required in patients with coronary artery complications.

P1325 - ECHOCARDIOGRAPHIC SCREENING OF 3 901 NIGERIAN SCHOOL CHILDREN FOR RHEUMATIC HEART DISEASE PRELIMINARY REPORT

Ekanem Ekure[1], Ogochukwu Sokunbi[2], Nnenna Kalu[3], Akinsanya Olusegun-joseph[4], Oyewole Kushimo[4], Hassan Olaiwola[4], Casmir Amadi[5], Desmond Ikebudu[6], Andrea Beaton[7], Craig Sable[7]
College of Medicine, University of Lagos, Paediatrics, Lagos-Nigeria[1]; Lagos University Teaching Hospital, Nigeria, Paediatrics, Lagos-Nigeria[2]; Lagos University Teaching Hospital, Paediatrics, Lagos-Nigeria[3]; Lagos University Teaching Hospital, Medicine, Lagos-Nigeria[4]; College of Medicine, University of Lagos/lagos University Teaching Hospital, Nigeria, Medicine, Lagos-Nigeria[5]; College of Medicine, University of Lagos, Microbiology, Lagos-Nigeria[6]; Children's National Medical Center, Cardiology, Washington Dc-United States[7]

Background: Echocardiographic screening for Rheumatic Heart Disease (RHD) in Africa has revealed prevalence rates in the range of 0.5–3.9%.
Objective: To determine prevalence of RHD in a large population of Nigerian school children using echocardiography.
Methods: Using portable echocardiography and auscultation, 3,901 school children aged 5years to 16years in Lagos, Nigeria were screened for RHD. Multi-stage sampling of public schools within and outside Lagos metropolis was done to enroll 20 schools. Diagnosis of RHD was based on the 2012 World Heart Federation echocardiographic criteria.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: The 3,901 children screened had mean age of 11.3 ± 2.7 years; 2,085 (53.4%) were females. The majority of them belonged to lower socioeconomic class. There were 35 abnormal echocardiograms. Eight (0.2%) had RHD including 2 cases of definite RHD and 6 cases of borderline RHD giving a prevalence of 2.1/1000 [2.6/1000 in the peri-urban, 1.5/1000 in the urban area). The majority (88%) of children with RHD had mitral valve affectation. Six of the eight children with RHD were males including all the children with definite RHD. Mean age of children with and without RHD were similar (12.1 ± 2.1 years versus 11.3 ± 2.7 years respectively; p = 0.4) Echocardiography detected RHD 4 times better than auscultation [echocardiography 8 (0.2%) versus auscultation 2 (0.05%); p < 0.0001]. All 8 cases of RHD were asymptomatic except for heart murmur in the 2 definite cases. The remaining 27 cases with abnormal echocardiograms had congenital heart diseases.
Conclusion: Prevalence of RHD among school children in Lagos, Nigeria is low compared to other African countries. Mitral valve is the most commonly affected valve. All children with RHD were asymptomatic. To detect one case of RHD among apparently healthy school children in Lagos, Nigeria, 400 children have to undergo echocardiography.

P1340 - MULTI CENTERAL STUDY ON IVIG TREATMENT TO KAWASAKI DISEASE

Lan He, Fang Liu, Guoying Huang
Children's Hospital of Fudan University, Heart Center, Shanghai-China

Objective: To investigate treatment in children with Kawasaki disease by three different dose of IVIG therapies and to seek for a most effective therapy.
Methods: We did a multicenter, prospective, randomized trial at three children's hospitals in Shanghai in acute phase of KD. They were randomly divided into three groups: The group A was given IVIG 2 g/kg once via intravenous infusion, in 12 to 24 hours; the group B was given IVIG 1 g/kg twice via intravenous infusion over two days; and the group C was given IVIG 1 g/kg once via intravenous infusion. All the results were statistically analyzed.
Results: There were 138 cases in Group A, 127 cases in Group B, and 132 cases in Group C. During this groups, we found no difference in age and weight. Also there was no difference in the incidence of IKD, IVIG resistance and coronary arterial lesion. There was no difference in clinical signs and the laboratory datas before treatment. No difference in the febrile period before hospitalized in three groups. After treatment, there was no significant difference in three groups in the time of fever relieving. Also there was no significant difference in the duration of fever. there was no difference in the changes of these laboratory datas. Coronary arterial lesion occurred in 57 patients. No difference was observed in the incidence of coronary arterial lesion in three groups. No difference in the incidence of coronary arterial lesion during the follow up. The length of hospital stay and hospital costs satisfy a linear relationship, we found that the cost of Group C was the lowest while the Group B was the most expensive.
Conclusions: Administration of IVIG in a single dose of 1 g/kg in combination with aspirin can become a preferred treatment regimen for Kawasaki disease.

P1373 - SURGERY FOR RHEUMATIC HEART DISEASE A 5 YEAR (2010–2015) REVIEW FROM NAMIBIA

Tangeni Aula[1], Ndati Agapitus[1], Henning Du Toit[2], Jones Nghaamwa[2], Christopher Hugo-Hamman[3]
Ministry of Health, Cardiology, Windhoek-Namibia[1]; Ministry of Health, Cardiac Surgery, Windhoek-Namibia[2]; Ministry of Health, Paediatric and Congenital Cardiology, Windhoek-Namibia[3]

Methods: Retrospective review of patients in the RHD Registry referred for cardiac surgery between October 2010 and December 2015. Case notes, echocardiograms and surgical reports were interrogated. Data captured using Microsoft Excel, coded and analyzed using STATA 14.0.
Results: Two hundred (200) of 536 patients had 205 valve operations. Females 125 (62.5%). One hundred seventy-one (83.4%) under 40 years and 26.3%, children. Sixteen had previous surgery. Patients had advanced disease; 81% NYHA Class III or IV, atrial fibrillation 74%, 70% pulmonary hypertension. Mitral valve surgery performed in 162; 35 repair and 127 replacement of which 60 bioprosthetic and 67 mechanical valves. Aortic position 72, 51 mechanical and 21 tissue valves. Sixty-six (66) patients double valve surgery (51 mitral-aortic, 15 mitral-tricuspid). Mean follow-up 33.98 months. Thirty-two patients (17%) died, 11 within 30 days. Amongst deaths, 12 only mitral valve, 3 only aortic valve, 11 aortic with mitral, 6 mitral and tricuspid surgery. Nineteen (59.4%) deaths occurred in patients younger than 30 years of age. Sixty month survival; mitral repair 90% vs mechanical 76% and aortic tissue 88% vs mechanical 76%. Of mitral valve repair 15 developed post-op regurgitation and 4 required re-operation. Aortic stenosis occurred in 19% tissue and 7.6% mechanical valves.
Conclusion: A large cohort needed surgery in a country previously unable to care for patients with RHD. Patients are young, very sick and predominantly female. High mortality reflects disease severity. Valve repair is preferred over replacement in RHD however, all aortic and many mitral valves required replacement. Difficulty with anticoagulation increases use of tissue rather than mechanical valves. Survival is improved with tissue valves but risk of stenosis is higher.

P1377 - RHEUMATIC HEART DISEASE IN CHILDREN UNDER FIVE YEARS AT THE UGANDA HEART INSTITUTE

Judith Namuyonga[1], Sulaiman Lubega[1], Isaac Ssinabulya[2], Twalib Aliku[3], Emmy Okello[4], John Omagino[5], Peter Lwabi[1]
Uganda Heart Institute, Paediatric Cardiology, Kampala-Uganda[1]; Uganda Heart Institute, Adult Cardiology, Kampala-Uganda[2]; Uganda Heart Insittute, Paediatric Cardiology, Kampala-Uganda[3]; Uganda Heart Institute, Adult Cardiologist, Kampala-Uganda[4]; Uganda Heart Institute, Cardiothoracicsurgery, Kampala-Uganda[5]

Introduction: Rheumatic heart disease (RHD) is the most serious complication of rheumatic fever that commonly affects children aged 5-15years. Children under five years are more likely to have severe carditis. Unfortunately primary prevention has been given less attention in this age group. We set out to describe case series of children under five years with RHD at the Uganda Heart Institute.
Methods: We conducted a retrospective chart review of children aged less than 5 years with a diagnosis of RHD seen at the Uganda Heart Institute from 2010 to 2016. All echocardiograms were reviewed by a paediatric cardiologist using the 2012 World Heart Federation criteria for the echocardiographic diagnosis of RHD.
Results: RHD was confirmed in 379 children less than 18 years. Seven children (1.8%) were under 5 years with a mean age of 2.5 years, range (2–4.5) years. All had advanced disease with severe mitral valve regurgitation and functional tricuspid valve regurgitation. Eighty five percent had moderate to severely elevated pulmonary pressures. None had congenital heart disease. One child had moderate mitral valve stenosis with no left sided obstructive lesions. We describe one case in detail; 2 year old male presented in congestive heart failure, with pedal oedema, ascites, displaced apex beat and grade3/6 holosystolic murmur at the apex.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Echocardiogram revealed thickened mitral valve leaflets (3.8mm), severe mitral regurgitation with an eccentric jet, and mild tricuspid regurgitation PG 45 mmHg. Unfortunately, he died 2 years after diagnosis.
Conclusion: We share unique cases of RHD in children under 5 years who presented with severe disease at the Uganda Heart Institute. Screening programs should not be limited to school going children or those above 5 years. Genetic studies are recommended to assess the particular strains of group A streptococcus that cause severe disease in these children.

P1467 - IMPROVING DELIVERY OF SECONDARY PROPHYLAXIS TO PEOPLE LIVING WITH RHD IN FIJI ISLANDS

Elizabeth Kennedy[1], Emele Naiceru[2], Ana Ramaka[3], Laisiana Matatolu[2], Maciu Silai[2], Frances Matanatabu[2], Maureen Ah Kee[2], Dr Samantha Colquhoun[4], Dr Sai Boladuadua[2], Dr Joseph Kado[5]
Cure Kids New Zealand, Wellness Unit, Suva-Fiji[1]; Ministry of Health And Medical Services, Wellness Unit, Suva-Fiji[2]; Ministry of Health and Medical Services, Divisional Health Office, Lautoka-Fiji[3]; Murdoch Childrens Research Institute, Centre For International Child Health, Melbourne-Australia[4]; Fiji National University, Pediatrics, Suva-Fiji[5]

Rheumatic Heart Disease (RHD) is a significant public health problem in Fiji Islands. Episodes of acute rheumatic fever (ARF) are often unrecognised and cases of RHD often present in severe stages. The Fiji Islands RHD Control and Prevention Project is delivering a four year Project led by Fiji Ministry of Health and Medical Services. The Project has implemented a series of interventions aimed at improving adherence by 1) improving knowledge of the disease among patients and carers 2) improving knowledge of health professionals regarding secondary prophylaxis treatment and importance of patient counselling 3) providing support to patients and carers. The Project piloted models of care at eleven sites with the planned wider roll out across the country. Stakeholder workshops and patient/carer interviews were conducted in the design and interim phases. The effectiveness of interventions were evaluated via the national rheumatic fever information system which records Benzathine penicillin adherence data. Qualitative and quantitative data were gathered and analysed for training, media campaign and patient and carer support activities. Support groups were conducted at health centres and led by nurses using educational flip charts followed by open discussion. The Project has reached over 600 patients and carers through support group activities. Approximately 45% of the nurse workforce were trained in 2016. Preliminary adherence data is showing an average of 20% improvement in adherence among ARF/RHD patients at pilot sites over a 12 month period and a multi- media campaign aimed at non-adherent patients was launched in 2016. The Project, has the potential to contribute to the development of a model of chronic disease care that can be applied in other high RHD prevalence countries.

P1518 - A RARE CASE OF LARGE PERICARDIAL EFFUSION WITH FIBRINOUS APPEARANCE IN ACUTE RHEUMATIC FEVER

Maria Cristina Ventura Ribeiro[1], Fabiana Aragão Feitosa[1], Tereza Arraes Pinheiro[1], Isabella Marques Lira[1], Aline Borges Maciel[1], Larissa Ribeiro Bruscky[2], Cleusa Lapa Santos[1]
IMIP, Pediatric Cardiology, Recife-Brazil[1]; IMIP, Internal Medicine, Recife-Brazil[2]

Background: Acute rheumatic fever is a non-suppurative complication that occurs following beta-hemolytic streptococci group A infection. Cardiac involvement may be in the form of pancarditis by involving each three layers of the heart. Pericardial involvement is mostly in the form of benign and mild pericadial effusion. Rarely, severe pericardial effusion and tamponade may occur.
Case Report: The authors describe a 13-year-old-girl who was diagnosed with rheumatic fever a year ago and was not using Penicilin for secondary prophylaxis. She was admitted to the hospital with fever and joint pain two days ago and shortness of breath 24 hours ago. On physical examination, she had a severe general condition, dyspneic, hypocorax, swollen ankle and hepatomegaly. Heart rate was 132bpm. In the thoracic auscultation, cardiac sounds were rhythmic and hypophonetic with a systolic murmur in the mitral region. Chest radiography revealed a considerable cardiomegaly and water bottle appearance. On the electrocardiogram, she presented sinus rhythm with signs of left ventricle enlargement and altered ventricular repolarization. The echocardiogram revealed severe mitral regurgitation and a large pericardial effusion with fibrinous strands traversing the pericardial space. She underwent venous corticotheraphy for ten days and then continued with oral doses. Oxacilin antibiotic was also started but was suspended nine days after. She evolved with excelente improvement of her symptoms and her echocardiogram nine days after revealed almost no pericardial effusion.
Conclusion: The authors draws attention to the uncommom presentation of the pericardial effusion in this case with large effusion and the aspect of the bundle of fibrinous strands in the pericardial space and for the good result with corticotheraphy, not requiring pericardial drainage.

P1574 - TRIPLE VALVE REPAIR IN YOUNG RHEUMATICS

Ganapathy Subramaniam Krishnan[1], Balakrishnan K. R.[2], Arul Narayanan[3], Venkataswamy K.[3]
Malar Hospital, Cardiac Surgery, Chennai-India[1]; Fortis Malar Hospital, Cardiac Surgery, Chennai-India[2]; Fortis Malar, Cardiology, Chennai-India[3]

Rheumatic heart disease is a significant problem in developing countries and afflicts young children, in whom valve replacement is clearly not a good option. We present our experience in managing 5 young patients with aortic, mitral and tricuspid regurgitation who underwent repair of all the three valves. 5 young patients, all of them female between the age group 11 – 18 years were operated for aortic, mitral and tricuspid regurgitation. The aortic annulus was less than 16mm in all the patients(11–16), the mitral annulus had a mean size of 26 mm(23–31), the tricuspid regurgitation was moderate in all with moderate pulmonary artery hypertension. The method used was leaflet placation, bicuspidisation, leaflet extension and thinning of leaflets in pts with aortic regurgitation. Mitral valve was repaired by anterior leaflet chordal shortening by artificial chords or cusp level chordal shortening and the PML was extended by autologous pericardium and a partial posterior annuloplasty. Tricuspid valve was repaired by sectoral annuloplasty along the anterior posterior area of the annulus. The mean cross clamp time was 110 minutes and bypass time was 140 minutes. Del Nido cardioplegia with moderate hypothermia was used in all. 3 patients no AR, two had mild + AR, 4 patients had no MR. The Post op course was uncomplicated in all the patients and all the patients could be shifted out of ICU by 3rd day and discharged by 6 days. Triple valve repair provides satisfactory outcome atleast in the short term. Leaflet extension of all three leaflets or aortic valve with PTFE membrane mitral valve pathology with anterior leaflet prolapse and restricted posterior leaflet motion have the best result.

P1601 - THROMBOSPONDIN 2 PREDICT WHETHER CHILDREN WITH KAWASAKI DISEASE RESPOND TO TREATMENT WITH INTRAVENOUS IMMUNOGLOBULIN

Shuai Yang[1], Ruixia Song[1], Xiaohui Li[2]
Capital Institute of Pediatrics, Department of Cardiovascular Diseases, Beijing-China[1]; Children's Hospital Affiliated To Capital Institute of Pediatrics, Department of Cardiovascular Diseases, Beijing-China[2]

Object: The present study was to investigate the predictive value of thrombospondin-2(TSP-2) in assessing the response to intravenous immunoglobulin (IVIG) in children with acute Kawasaki disease (KD).
Methods: 61 children with KD were recruited as KD group, and healthy children (n = 32) and febrile children (n = 32) were used as control groups. ELISA was used to measure plasma TSP-2 and TSP-1 levels.
Results: Compared with the control groups, the plasma TSP-2 and TSP-1 levels in acute KD were significantly elevated (TSP-2: 30.56 ± 11.32 vs 21.35 ± 8.82 vs 16.37 ± 2.86ng/ml, P > 0.001; TSP-1: 10271.33 ± 7538.38 vs 7174.31 ± 4807.37 vs 3660.51 ± 2671.90ng/ml, P < 0.001). The plasma TSP-2 level in the IVIG non-responders (13/61) was significantly higher than the responder group (48/61) (38.59 ± 12.12 vs 28.39 ± 10.17ng/ml, P = 0.003). When using an receiver operating characteristic (ROC) curve to analyze the predictive effect of TSP-2 on non-responsiveness to IVIG treatment, the area under the curve(AUC) was 0.776(95% CI: 0.640 to 0.913; P = 0.002). When the cutoff value for TSP-2 was 31.76 ng/ml, the sensitivity was 76.90%, the specificity was 70.80%.
Conclusion: The plasma TSP-2 level was elevated in acute KD and predicted the therapeutic response of children with KD to IVIG with high sensitivity and specificity, which could help guide clinical decisions and lead to better early treatment to prevent complications.

P1633 - EFFICACY OF FOUR SCORING SYSTEMS IN PREDICTING INTRAVENOUS IMMUNOGLOBULIN RESISTANCE IN CHILDREN WITH KAWASAKI DISEASE IN A CHILDREN'S HOSPITAL IN BEIJING NORTH CHINA

Wei Yao[1], Ruixia Song[2], Xiaohui Li[3]
Graduate School of Peking Union Medical College, Capital Institute of Pediatrics, Beijing, China, Cardiovascular Medicine, Beijing-China[1]
Department of Cardiovascular Diseases, Childrens Hospital Affiliated to Capital Institute of Pediatrics, Beijing, China, Cardiovascular Medicine, Beijing-China[2]; Childrens Hospital Affiliated to Capital Institute of Pediatrics, Beijing, China, Cardiovascular Medicine, Beijing-China[3]

Objective: To evaluate the predictive efficacies of four existing scoring systems for intravenous immunoglobulin (IVIG)-resistance in Kawasaki disease (KD) in hospitalized children with KD in Children's Hospital affiliated to Capital Institute of Pediatrics, Beijing, China.
Study Design: We retrospectively analyzed 1569 cases with KD treated at our children's hospital from January 2010 to December 2015. Age, gender, clinical manifestations, and pretreatment hematologic indicators were recorded. Scores were assigned using four existing scoring systems: Egami, Kobayashi, San Diego, and Formosa system. A four case table test was used to determine prediction efficacies.
Results: There were 63 IVIG-resistant cases (41 males, 22 females; average age, 2.5 years). Nine cases were classified as high risk for IVIG resistance by Egami, and this system had a sensitivity and specificity of 14% and 86%, respectively. Ten cases had Kobayashi high-risk scores, and this system had a sensitivity and specificity of 16% and 85%, respectively. The San Diego system assigned 60 cases as high-risk, and the sensitivity and specificity of this system was 95% and 3%, respectively. Finally, 27 cases had Formosa scores in the high-risk category, and the sensitivity and specificity were 43% and 47%, respectively.
Conclusions: None of the evaluated systems to assess risk for IVIG resistance displayed the combination of sensitivity and specificity necessary for screening. Our analyses show that the four scoring systems have limited utility in predicting IVIG-resistance among patients with KD in our population.

P1657 - CHARACTERISTICS OF RHEUMATIC HEART DISEASE IN MANITOBA CANADA A 10 YEAR RETROSPECTIVE STUDY

Tara Corkery[1], Maria-elena Lautatzis[1], Stasa Veroukis[1], Ilan Buffo[2], Reeni Soni[2], Daryl Schantz[2], Dionysios Pepelassis[2]
University of Manitoba, Department of Pediatrics, Winnipeg-Canada[1]; University of Manitoba, Variety Children's Heart Centre, Winnipeg-Canada[2]

Objective: As previously reported, Acute Rheumatic Fever (ARF) remains a significant health problem between the First Nation children of Manitoba. The aims and objectives of this study are to determine the characteristics of Rheumatic Heart Disease (RHD) present in children affected by the disease in the Province of Manitoba, Canada.
Methods: Retrospective study conducted at the Variety Heart Centre, Winnipeg, MB, Canada. Children with discharged diagnosis of ARF were identified through the Children's Hospital of Winnipeg medical records and the Electronic Echocardiography data based at the Variety Heart Centre.
Results: Over a 10-year study period (2000-2010), a total of 42 [male:23, female: 19, median age 9.6 years (min 3.9 max14.9)] patients meeting the Jones criteria for ARF and evidence of RHD are included in this study. Echocardiographic follow up period more than 12 months was the major criterion for enrolment in the study: [median 4.99 years (max 11 and min 1.45 years)]. Marked RHD at presentation defined as moderate or severe mitral (13 and 11 cases) or aortic (2 and 1 cases) insufficiency. Moderate or severe insufficiency affecting both of the valves was observed in 3 patients. Moderate or severe mitral valve insufficiency at follow up was present in 6 and 4 patients respectively, with similar aortic valve findings in 2 patients from each group. Four (4) patients required either mitral or aortic prosthetic valve. Decreased function at presentation was detected in 2 patients and remained decreased in one of them even after valve replacement. There were no deaths related to RHD.
Conclusion: RHD remains a significant health problem between the First Nation children of Manitoba. Therefore, a strategy of primary prevention of ARF based on health education, improvement of social conditions, access to care, early diagnosis and effective treatment of the disease should be implemented.

P1771 - A CASE OF INFANTILE RUPTURED MITRAL CHORDAE TENDINEAE COMPLICATING INCOMPLETE KAWASAKI DISEASE

Osamu Matsuo[1], Kei Honda[1], Kouichi Yatsunami[1], Koji Fukae[2]
Kumamoto City Hospital, Pediatric Cardiology, Kumamoto-Japan[1]; Kumamoto City Hospital, Pediatric Cardiac Surgery, Kumamoto-Japan[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Infantile ruptured mitral chordae tendineae is a rare disease causing acute cardiopulmonary failure. We encountered a patient with concomitant ruptured mitral chordae tendineae with incomplete Kawasaki disease with no main symptoms other than fever, which declined spontaneously.
Case Presentation: The patient was a 7-month-old girl who developed fever (38-39 °C) of unknown origin. The fever persisted for 6 days and then declined spontaneously (36-37 °C). There were no other main symptoms of Kawasaki disease and no flare was noted in the BCG region. The amount ingested and the urinary volume decreased from about 12 days after the development of fever, and the patient was brought to our hospital on day 14. Gallop rhythm and heart murmur were heard. Echocardiography was performed, and severe mitral regurgitation due to ruptured chordae tendineae and coronary arterial dilation (Z-score: RCA, 3.51; LMCA, 5.40; LAD, 5.31) were observed. In laboratory data, increases in C-reactive protein and brain natriuretic peptide, anemia, thrombocytosis, and hypoalbuminemia were observed. Based on the coronary arterial lesion and laboratory data, the patient was diagnosed with valvular impairment complicating incomplete Kawasaki disease. The inflammatory reaction persisted and was treated with intravenous immunoglobulin and steroids, followed by mitral annuloplasty. The postoperative course was favorable and the coronary arterial lesion improved.
Conclusion: Serious valvular impairment, such as ruptured mitral chordae tendineae, occurs even in cases of incomplete Kawasaki disease, i.e., in the absence of the main symptoms of Kawasaki disease, and in which fever declines spontaneously.

P1784 - EPIDEMIOLOGY OF ACUTE RHEUMATIC FEVER AND KAWASAKI DISEASE IN HAWAI'I BETWEEN 2009 AND 2015

Colin Petko[1], Tristan Knight[2], Venu Reddy[3], Marian Melish[2], Andras Bratincsak[4]
Hawaii Permanente Medical Group, Pediatric Cardiology, Honolulu-United States[1]; Department of Pediatrics, John A Burns School of Medicine, University of Hawai'I, Pediatrics, Honolulu-United States[2]; Department of Pediatrics, John A Burns School of Medicine, University of Hawai'I, Pediatric Cardiology, Honolulu–United States[3]; Kapi'Olani Medical Specialists, Hawai'I Pacific Health, Pediatric Cardiology, Honolulu–United States[4]

Background: Kawasaki disease (KD) is currently estimated to be the most common cause of acquired heart disease in children in the developed world, while rheumatic fever (RF) is the most common cause of acquired heart disease in the developing world. Historically, Hawai'i has had a higher incidence of both conditions compared to the continental United States but recent Hawaii specific demographic data are lacking.
Methods: A data base review using discharge ICD 9 diagnosis codes was conducted to identify all patients between 0-18 years of age who were hospitalized for acute RF or KD at two nonmilitary children's hospitals between 2009 and 2015. Only the initial hospitalization was counted. Basic information included age at diagnosis, gender and ethnicity. Hawaii census data were used to calculate incidences.
Results: There were 336 total KD hospitalizations (mean age 2.6 years, 49% male, 82% <5 years), the overall average annual incidence was 17/100000 <18 years of age and 47/100000 <5 years of age. Incidence was highest among Asian children <5 years (52/100000), whereas Caucasian children <5 only had an incidence of 9/100000. There was no noticeable seasonality. For RF, the average incidence was 5/100000 <18 years of age (mean age 11.5 years, 60% male). Of these, 80% were of Hawaiian/Pacific Islander ethnicity, giving an incidence of 41/100000 in this subpopulation and 67% of patients were between 10-16 years at diagnosis.
Conclusion: Between 2009 and 2015, the overall incidence of KD and RF was 2 to 2.5 times higher than described historically in the continental US but similar compared to historic cohorts in Hawaii. Asian children under 5 years are at particular risk for KD and older children of Hawaiian/Pacific Islander ethnicity predominated in the RF cohort, confirming epidemiologic data from previous decades.

P1859 - KAWASAKI DISEASE ANALISIS OF FACTORS ASSOCIATED WITH CARDIOVASCULAR LESIONS

Maria Dolores Zambrano[1], Carles Bautista[1], Sergi Cesar[1], Ariadna Ayerza[2], Lorenzo Jimenez[2], Joan Sanchez De Toledo[1]
Sant Joan De Déu Barcelona Children´s Hospital, Pediatric Cardiology, Barcelona-Spain[1]; Miguel Servet Hospital, Pediatric Cardiology, Zaragoza-Spain[2]

Introduction: Kawasaki disease (KD) is the most common cause of acquired heart disease in childhood. Clinical and laboratory features along with treatment strategies have been associated with development of cardiovascular lesions. This study aims to determine the incidence of cardiovascular lesions and to analyze clinical, laboratory and treatment factors associated with the development of cardiovascular lesions.
Material and Methods: Patients diagnosed with KD in two University Tertiary Hospitals (Barcelona and Zaragoza) between 2013 and 2015 were retrospectively analyzed. The Japanese Society of Pediatric Cardiology clinical guidelines were used for diagnosis and classification. Demographics, clinical and laboratory variables and the presence of cardiovascular abnormalities were collected. Data are presented as median (IQR). SPSS® was used for the analysis of statistical data.
Results: Fifty-eight children were included, 35 (60.3%) males, aged 24 months (12-48). Thirty-two (55.2%) were complete; 19 (32.8%) incomplete and 7 (12.1%) atypical forms of KD. Cardiovascular abnormalities were found in 18 (30.5%): mitral regurgitation 11 (19%), myocardial dysfunction 3 (5.2%), pericardial effusion 3 (5.2%) and coronary aneurysms 8 (13.6%). Patients with more than 7 days of fever had more coronary aneurysms (75% vs 38% $p = 0.06$), although it was not statistically significant. Incomplete and atypical presentations associated more cardiovascular abnormalities compared with complete KD (37.5% - 62.5% vs. 0%, $p < 0.01$) specifically coronary aneurysms (38.9% - 38.9% vs 22.2%, $p < 0.05$).There was no relationship with laboratory features. Children with delayed IVIG treatment (10 days after KD onset) had more coronary aneurysms (50% vs 12% $p = 0.02$).
Conclusion: Duration of fever, type of presentation of KD and the time of administration of IVIG are proposed as markers of cardiovascular risk and coronary aneurysms.

P1896 - DEMOGRAPHIC CLINICAL AND ECHOCARDIOGRAPHIC FEATURES OF 871 PATIENTS WITH RHEUMATIC HEART DISEASE THE RHEUMATIC HEART DISEASE REGISTER

Noha Karadawi[1], Fouada Omer[2], Laila Elmahdi[1], Intisar Ibrahim[2], Sulafa Ali[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Jaffar IBN Ouf Children Specialized Hospital, Sudan Heart Center, Cardiology, Khartoum-Sudan[1]; Sudan Heart Center, Cardiology, Khartoum-Sudan[2]

Background: Rheumatic Heart Disease (RHD) is an important public health problem in Sudan with prevalence of 10:1000. A Register was established in order to monitor RHD-related health outcomes towards achievement of World Heart Federation objective of 25% reduction in mortality of under 25yrs by 2025. Data collected from register will periodically be analyzed to better understand impact of RHD on various states of Sudan and thus enable effective planning of services and management of resources.
Materials & Methods: A Register was initiated in two hospitals (Jaffar Ibn Ouf Children's Specialized Hospital and Sudan Heart Center) since January 2006. All patients with clinical/echocardiographic evidence of RHD were included. Their demographic data, clinical/echo findings, and contact details were recorded. Data covered period January-2006 to October-2016.
Results: 871 patients were reviewed (54% Male). Age ranged 4 to 25 years. Highest incidence (55%) was observed in 10 to 15 years old. 26% of registered population was from Darfur, 25% from Kurdufan, 12% from Al Jazirah, while Northern and Eastern areas showed less affection (Figure-1). Subsequent comparison of cases/100,000 on basis of state's population (Table-1) revealed that White Nile had highest RHD rate per capita (3.1/100,000), followed by Kurdufan (2.8/100,000), then Sinnar (1.8/100,000),

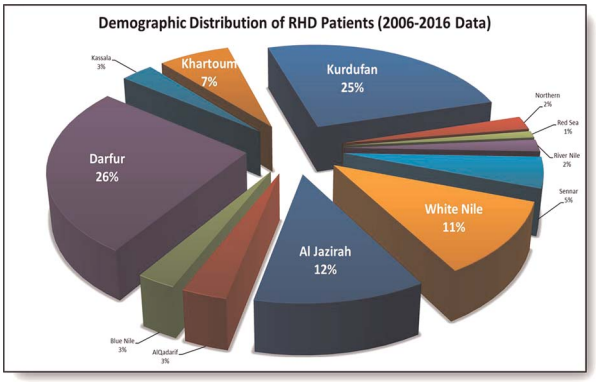

Figure 1.

Table 1. Demographic Distribution of Patients with Severe form of RHD

State	No. of Cases	Percentage
Kurdufan	76	29.3%
Darfur	67	25.9%
White Nile	21	8.1%
Khartoum	19	7.3%
Al Jazirah	16	6.2%
Al Qadarif	9	3.5%
Kassala	9	3.5%
Blue Nile	8	3.1%
Northern	6	2.3%
Sennar	5	1.9%
River Nile	3	1.2%
Red Sea	2	0.8%
Others	18	6.9%
	259	100%

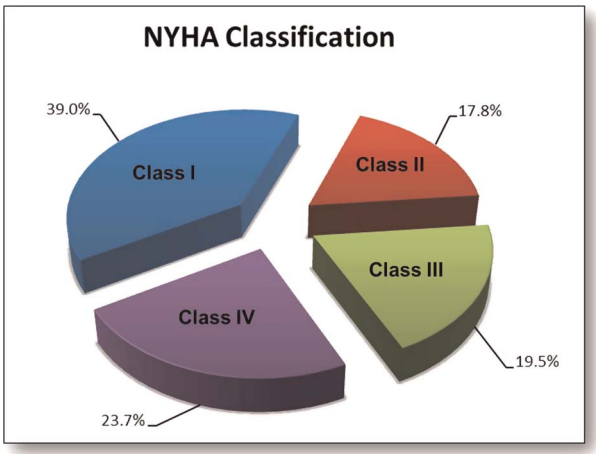

Figure 2.

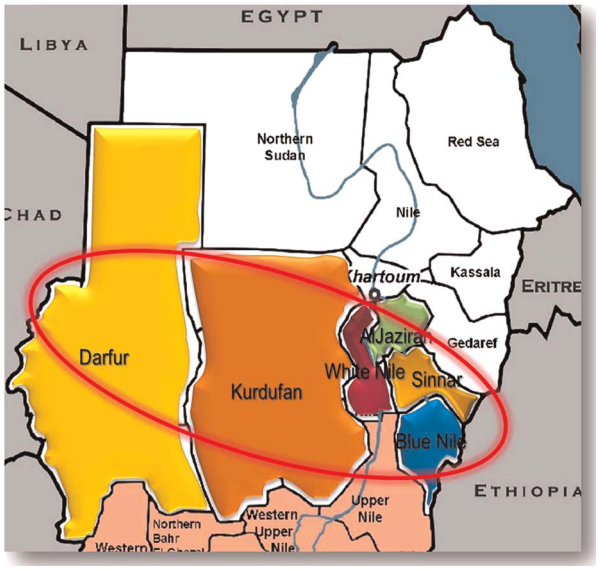

Figure 3.

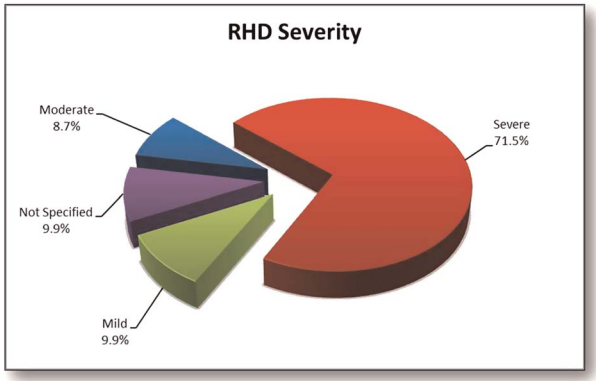

Figure 4.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

then Darfur (1.7/100,000). The study revealed an apparent RHD belt extending from Darfur to Blue Nile (Figure-2). Echo revealed mitral regurgitation (MR) in 78.1%, isolated aortic regurgitation (AR) in 2.7%, and >2 lesions in 15.4% (Table-2 and Figures 3 & 4). In terms of demographic distribution of 259 patients with severe RHD, 29.3% were from Kurdufan, 25.9% from Darfur, and 8.1% from White Nile (Table-3).
Conclusion: There is an apparent RHD belt extending from Darfur to Blue Nile. RHD patients having severe valve affection were mostly from Kurdufan and Darfur. Presentation is late with the severe disease form as it is not caught at acute phase.

Table 2. Residency Distribution Vs RHD Cases per 100,000

State Residency	Population	No. of Cases	Cases per 100.000
White Nile	1,730,588	54	3.12
Kurdufan	4,327,396	120	2.77
Sennar	1,285,058	23	1.79
Darfur	7,515,445	125	1.66
Al Jazlrah	3,575,280	56	1.57
Blue Nile	832,112	13	1.56
Other States	11,628,121	5 to 15	<1.5
Overall	30,894,000	478	1.55

Table 3. Valve Lesions Percentages of RHD patients

Valve Lesions	No. of Cases	Percentage
MR	256	31.9%
AR	22	2.7%
MS	16	2.0%
TR	0	0.0%
MR/AR	293	36.5%
MR/ MS	37	4.6%
MR/TR	41	5.1%
AR/MS	6	0.7%
AR/TR	6	0.7%
MS/TR	2	0.2%
More than 2 lesions	124	15.4%
	803	100%

P1913 - KAWASAKI DISEASE ITS MANIFESTATION AFTER SIMULTANEOUS IMMUNIZATION WITH MEASLES RUBELLA VARICELLA AND PNEUMOCOCCAL VACCINE SUGGESTING ITS POSSIBLE ASSOCIATION WITH MEASLES VACCINATION

Daisuke Matsubara, Takaomi Minami, Shun Suzuki, Kensuke Oka, Koichi Kataoka, Takanori Yamagata
JICHI Medical University, Pediatrics, Tochigi-Japan

Background: Although some previous reports suggested the possible association between vaccination and Kawasaki disease (KD), a recent population-based study showed vaccines did not increase, but rather decreased the incidence of KD shortly after vaccination. We report a pediatric patient: KD manifested just after simultaneous immunization with measles-rubella, varicella, and pneumococcus vaccine. Vaccination, especially measles vaccination, was suggested to be associated with KD ocurrence.
Case: A 14-month-old Japanese girl had a fever the day after concomitant inoculation with measles–rubella (MR) (first dose), varicella (first), and pneumococcal (fourth) vaccination. On day 2, rash appeared around the previous BCG inoculation site. On day 4, her condition met 4/6 KD diagnostic criteria (CRP 4.24 mg/dL, WBC 18200 /μL). On day 5, on meeting 5/6 KD criteria, she was diagnosed with complete KD. KD manifestations resolved with decreases in CRP/ WBC. However, rash around the BCG inoculation site was still evident, which became a crust on Day 11. Aspirin was solely administered. Antibody analysis on Day 6 showed: rubella(-), VZV(-), and EBV(-), and importantly, measles IgG(-)/IgM(+). Ferver did not recur. Ultrasound revealed no coronary artery sequelae throughout her course.
Discussion and Conclusion: KD appeared just after concomitant immunization with MR, varicella, and pneumococcal vaccine. Rash around the previous BCG site is pathognomonic for KD; this strongly suggests this patient had KD. Fever due to MR vaccination usually occurs on day 3 to 12 after inoculation, when viral multiplication occurs within the host. In this patient, fever occurred much earlier (day 1), reducing the possibility of fever due to live-vaccination. The measles IgG(-)/IgM(+) obtained on Day 6 suggested that the measles virus inoculation may have caused, or at least been associated with, KD. Further monitoring may be needed to clarify the association between measles vaccination and KD.

P1947 - VASCULITIS RESULTING IN GIANT CORONARY ARTERY ANEURYSMS AND SYSTEMIC MULTIPLE ANEURYSMS IN A FIVE MONTH OLD INFANT

Chen Chu, Fang Liu
Children's Hospital of Fudan University, Heart Center, Shanghai-China

Background: Systemic vasculitis is a group of diseases characterized by the inflammation of blood vessels. Among the primary vasculitis, Kawasaki disease is common and occurs almost exclusively in childhood. It predominantly affects medium-sized arteries, most commonly the coronary arteries. Vasculitis predominantly affecting large vessels in childhood is Takayasu arteritis, which mostly involves the aorta and its major branches and can also affects some medium-sized arteries.
Materials and Methods: A five-month-old infant had recurrent fever for more than one month. The echocardiography indicated giant coronary artery aneurysm with continuous progress. The MRI imaging presented systemic multiple aneurysms, including aneurysms of subclavian, axillary, brachial, abdominal aorta, iliac and Superior mesenteric arteries, and dilated carotid, radial, femoral and celiac trunk arteries. The child was successively treated with high-dose intravenous immuneglobulin, glucocorticosteroid pulse, cyclophosphamide pulse and TNF-α antagonist (infliximab). However finally he died.
Results: An autopsy was performed with the parental consents. The autopsy indicated that the child died because of the rupture of coronary artery aneurysm and pericardial tamponade. Different types of blood vessels were sampled and histopathological examination confirmed vasculitis of large- and medium-sized arteries, and normal small-sized arteries.
Conclusions: The child was finally diagnosed with large- and medium-size vessel vasculitis, inclining to Kawasaki disease. Although we have tried multiple medications, the severity of coronary arteries aneurysms finally determined the prognosis of the disease.

P1997 - THE USEFULNESS AND SERIAL CHANGES IN NEUTROPHIL TO LYMPHOCYTE RATIO AND PLATELET TO LYMPHOCYTE RATIO IN KAWASAKI DISEASE

Hwa Jin Cho[1], *Yun Hee Kim*[1], *In Su Choi*[2], *Jae Sook Ma*[3]
Chonnam National University Hospiral, Department of Pediatrics, Gwangju-Korea, South[1]; *Chonnam National University Hospiral, Epartment of Pediatrics, Gwangju-Korea, South*[2]; *KK Hospital, Epartment of Pediatrics, Gwangju-Korea, South*[3]

Background: Kawasaki disease is an inflammatory Condition which needs to be distinguished from other infectious diseases. The white blood cell count and its subpopulations in the peripheral blood are classic indicators of inflammation. Neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) are useful as systemic inflammatory markers and prognostic indicators of adverse cardiovascular events and cancers. Also, they may provide additional information to conventional markers for predicting IVIG resistance in patients with KD. The aim of the study is to evaluate usefulness of NLR and PLR in diagnosis of Kawasaki among other infectious disease causing fever. Also, serial changes of NLR and PLR in Kawasaki disease throughout the disease course.
Methods: Ninety six children with Kawasaki disease and 41 controls were retrospectively enrolled. Their leukocyte, neutrophil, lymphocyte counts and platelet counts were recorded serially, before IVIG (D0), 2 days after IVIG (D2), 14 days (D14) and 56 days (D56) after IVIG treatment.
Results: Leukocyte [$p = 0.002$], neutrophil [$p = 0.001$], and platelet [$p < 0.001$] counts were significantly higher in Kawasaki disease patients compared to controls. NLR [$p = 0.02$] was also significantly higher in Kawasaki disease, however, there was no significant difference regarding PLR [$p = 0.291$]. On serial measurement of NLR and PLR in patients with Kawasaki disease, NLR dropped significantly and continuously after IVIG treatment. (D0 vs D2, D0 vs D14, D0 vs D56, all p values are <0.001). On the other hand, PLR significantly increased after IVIG treatment (D0 vs D2, $p < 0.001$), then dropped afterwards (D0 vs D14, D0 vs D56, all p values <0.001)
Conclusion: Neutrophil to lymphocyte ratio values was useful in diagnosing Kawasaki disease from other infectious diseases however, unlike other studies, platelet to lymphocyte ratio was not as useful. In addition, NLR significantly and continuously drops after IVIG treatment.

P2077 - DOPPLER ECHOCARDIOGRAPHY FOR SUBCLINICAL RHEUMATIC HEART DISEASE EVALUATION OF A COMPUTERISED DIAGNOSIS OF THE MITRAL VALVE APPARATUS

Eva Costa[1], *Diana Veiga*[1], *Nelson Martins*[1], *Malik Saad Sultan*[2], *Manuel João Ferreira*[1], *Miguel Coimbra*[2], *Sandra Mattos*[3]
Enermeter, Sistemas De Medição, Lda, Medical Imaging, Braga-Portugal[1]; *University of Porto, Faculty of Sciences, Porto-Portugal*[2]; *Unidade De Cardiologia E Medicina Fetal, Real Hospital Português De Beneficência Em Pernambuco, Recife-Brazil*[3]

Background: Rheumatic Fever and Rheumatic Heart Disease remain a major burden among children in developing countries. Echocardiography with colour flow Doppler is key to early diagnosis, especially in subclinical cases. Jones criteria revision recently included echocardiography screening as an important criterion for diagnosis. However, the technique requires time and experienced operators, which are scarce resources in the affected areas. A computer-aided analysis of the echocardiography images could, potentially, reduce the cost of screening, and spread diagnostic accessibility for a larger number of patients. Ongoing developments on the semi-automatic mitral regurgitation jet detection are presented. These results are part of a major project (NORTE-01-0247-FEDER--003507-RHDecho, co-funded by PORTUGAL2020) which also aims to track the mitral valve leaflets on brightness mode echocardiography.
Materials and Methods: The implemented algorithm starts by finding a region containing the left atrium, given an input from the user (centre of the chamber). Then, the colour patterns which are congruent with reflux are automatically selected as mitral regurgitation candidates. A paediatric screening campaign was conducted by the Non-governmental organization *Círculo do Coração* at the state of Paraíba, Brazil. A total of 979 frames (apical 4 chamber view and parasternal long axis view) from 20 patients showing echocardiographic findings of mitral valve insufficiency were manually annotated and used to validate the proposed methods.
Results: Overall, results for colour pattern detection are promising (sensitivity = 0.92 false detection rate = 0.10), but further developments are required for left atrium delineation (sensitivity = 0.82, false detection rate = 0.25).
Conclusions: The proposed computational algorithms present promising results to be part of an impactful tool for the early diagnosis of subclinical rheumatic heart disease. The collaboration between doctors and engineers can, potentially, revolutionize the way diagnosis of such serious diseases is made.

P2095 - PHYSICIANS HEALTH CARE WORKERS AND THE PUBLIC HOW TO TEACH ABOUT ARF AND RHD

Alyaa Kotby
Ain Shams University, Pediatrics, Cairo-Egypt

Control of Acute Rheumatic fever (ARF) and Rheumatic heart disease (RHD) entails the development and implementation of a comprehensive strategy for teaching physicians, health workers and the public. Undergraduate teaching of ARF and RHD to medical students and nursing staff should be implemented not only in moderate and high risk communities but also in low risk countries since resurgence of RF can occur due to changing epidemiological and virulence factors. A two level approach should be adopted in physician training. The first should give the basic knowledge of how to identify and treat streptococcal throat infection, suspect and investigate RF and RHD. The target physicians include all general practitioners, family doctors, pediatricians and cardiologists. Second level training is for physicians in specialized referral centers for management of notified cases of ARF and RHD. Physicians and health care workers should be guided by the local community guidelines tailored for management in their community. Complete collaboration between the ministries of Health and Education and advocacy insures a continuous awareness campaign for the public. Campaigns include all stakeholders with government representatives, politicians, teachers, religion figures, pharmacists, football players, singers and actors. Films, cartoons and stories with local heroes are used to increase the awareness and compliance. Multimodal approaches to convey the information in a culturally appropriate manner should use verbal and popular media available in each community. Continuous information is sent in simple terms till the whole community is talking about ARF and RHD. Universal teaching will ultimately lead to universal end of ARF and RHD.

P2103 - STRENGTHENING CARDIOVASCULAR CARE WITHOUT SPECIALISTS INTRODUCTION OF HANDHELD ECHOCARDIOGRAPHY TO FACILITATE IMPROVED DIAGNOSIS OF PEDIATRIC HEART FAILURE IN A LOW RESOURCE SETTING

Isaac Ottim[1], *Amy Scheel*[2], *Alyssa Dewyer*[2], *Craig Sable*[2], *Mark Okwir*[3], *William Oyang*[4], *Isaac Ssinabulya*[5], *Chris Longenecker*[6], *Emmy Okello*[5], *Twalib Aliku*[7], *Andrea Beaton*[2]
Lira Regional Referral Hospital, Cardiology, Lira-Uganda[1]; *Children, Cardiology, Washington DC-United States*[2]; *Lira Regional Referral Hospital, Internal Medicine, Lira-Uganda*[3]; *Lira Regional Referral Hospital, Pediatrics, Lira-Uganda*[4]; *Uganda Heart Institute, Cardiology, Kampala-Uganda*[5]; *Case Western Reserve University, Medicine, Cleveland, OH-United States*[6]; *Gulu Regional Referral Hospital, Cardiology, Gulu-Uganda*[7]

Background: Heart failure (HF) is an important cause of morbidity and mortality in Ugandan children. Access to cardiovascular care is limited. The objective this study was to determine the pattern of pediatric heart failure diagnosis prior to and after introduction of handheld echocardiography.
Materials and Methods: Inclusion criteria included age $\geq$ 5 years and at least 1 of 10 pre-determined signs of HF. An attempt was made to capture all eligible patients in the outpatient, inpatient, and emergency departments. In phase 1 (4-months) final diagnosis was made according to clinical evaluation. In phase 2 (currently in month-2) handheld echocardiography used by local healthcare providers was introduced to facilitate improved diagnostic accuracy.
Results: To date (phase 2 ongoing), 847 patients have been enrolled. Of these, 86 (10%) are children (11.7 ± 4.0 years; 57% female). The most frequent pediatric enrollment criteria include dyspnea (80), high provider suspicion of CV disease (70), and tachycardia (42). Phase 1 enrolled 65 children with 54 (83%) having a final diagnosis of HF (2-pericardial effusion, 1-hypertensive HF, 6-congenital, 27-rheumatic, 2-other valvular, 16 HF NOS). Phase 2 has enrolled 21 patients with 9 (43%) having a final diagnosis of HF (1 pericardial effusion, 3 rheumatic, 4 dilated cardiomyopathy, 1 right-sided HF). Echocardiography appears to improve diagnostic specificity for HF (86% vs. 43% of suspected children), though not yet statistically significant ($p = 0.15$).
Conclusions: Approximately 10% of patients presenting at a Ugandan regional hospital with possible HF are children. Preliminary data suggests that echocardiography improves the specificity of this diagnosis. Further data collection and analysis is needed to fully understand the epidemiology of pediatric HF and to determine the impact of handheld echocardiography to improve diagnostic accuracy and outcomes in Uganda and other low-resource settings.

P2104 - LONGITUDINAL OUTCOMES OF UGANDAN CHILDREN IDENTIFIED WITH LATENT RHEUMATIC HEART DISEASE THROUGH SCHOOL BASED SCREENING

Andrea Beaton[1], *Emmy Okello*[2], *Twalib Aliku*[3], *Joselyn Rwebembera*[2], *Grace Mirembe*[4], *Amy Scheel*[1], *Alyssa Dewyer*[1], *Chris Longenecker*[5], *Craig Sable*[1], *Peter Lwabi*[2]
Children's National Medical Center, Cardiology, Washington DC-United States[1]; *The Uganda Heart Institute, Cardiology, Kampala-Uganda*[2]; *Gulu Regional Referral Center, Cardiology, Gulu-Uganda*[3]; *The Joint Clinical Research Center, Medicine, Lubowa-Uganda*[4]; *Case Western Reserve University, Cardiology, Cleveland OH-United States*[5]

Background: The importance of echocardiographic screening for latent rheumatic heart disease (RHD) is not known. Longitudinal data on these populations are limited. We report a large series of children with latent RHD and establish a consistent reporting framework to improve interpretation and generalization of data.
Materials and Methods: Children diagnosed with latent RHD (2010-2015) were enrolled in the Ugandan RHD Registry. Baseline echocardiograms were blindly re-reported (2012 WHF criteria) with subsequent echocardiograms reported in series. Definite RHD was sub-classified by severity. Progression and regression were precisely defined. Penicillin prophylaxis was recorded as a continuous variable when possible.
Results: Echocardiographic inclusion criteria was met by 227 out of 303 children (mean follow-up 2.9 years, SD 2.7 years): 164 borderline RHD (9 borderline-A, 135 borderline-B, 20 borderline-C), 43 with mild definite RHD (33 definite-A, 3 definite-C, 7 definite-D) & 20 with > mild definite RHD (14 definite-A, 3 definite-B, 3 definite-C). Seventy-six (46%) children with

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

borderline RHD regressed, 72 (44%) were stable, and 16 (10%) progressed. Eighteen (42%) children with mild definite RHD regressed, 13 (30%) were stable, and 12 (28%) progressed. Outcomes were notably worse for children with >mild definite RHD, with only 2(10%) showing regression, 11 (55%) stable with moderate-to-severe RHD, and 7 (35%) with progression, including 3 deaths.
Conclusions: There is a large degree of heterogeneity in outcomes among children with latent RHD. Further analysis of this data is needed to determine the impact of penicillin prophylaxis, socioeconomic and demographic variables, and disease categorization on the trajectory of latent RHD. It is clear that children with greater than mild definite RHD should be considered missed clinical cases, as outcomes for these children are poor, and similar to published data on clinical RHD cohorts.

P2198 - A PROTOCOL FOR A SYSTEMATIC REVIEW OF THE DIAGNOSTIC ACCURACY OF HAND HELD ECHOCARDIOGRAPHY FOR THE DETECTION OF RHEUMATIC HEART DISEASE IN SCHOOL AGED CHILDREN AND ADOLESCENTS

Lisa Telford[1], Liesl Zühlke[2], Eleanor Ochodo[3], Mark Engel[1]
University of Cape Town, Dept of Medicine, Cape Town-South Africa[1]; University of Cape Town, Dept of Paediatrics, Red Cross War Memorial Childrens Hospital and Dept of Medicine,Cape Town-South Africa[2]; Stellenbosch University, Centre For Evidence-Based Health Care Faculty of Medicine and Health Sciences, Cape Town-South Africa[3]

Background: Hand-held echocardiography presents an opportunity to address the need for cost-effective methods of diagnosing rheumatic heart disease (RHD) in developing countries where the disease carries high morbidity and mortality. Studies have demonstrated moderate sensitivity as well as high specificity and diagnostic odds for detecting latent RHD. We describe a protocol for systematic review of published primary diagnostic test accuracy studies to evaluate the evidence for this portable technology in diagnosing suspected RHD.
Methods/Design: Electronic search strategies will be conducted among various data sources including PubMed, Scopus, ISI Web of Science and EbscoHost. Primary observational studies of diagnostic accuracy of hand-held echocardiography versus standard echocardiography will be selected. Data extraction will be undertaken by two reviewers independently, to assess the methodological validity and quality of each study against QUADAS-2 criteria. Also, information relating to metrics of diagnostic accuracy and demographics will be extracted. Forest plots of sensitivity and specificity as well as a scatter plot in Receiver Operating Characteristic (ROC) space will be used to investigate heterogeneity of studies. If possible, a meta-analysis will be conducted to produce summary results of sensitivity and specificity using the Hierarchical Summary Receiver Operating Characteristic (HSROC) method. Subgroup analyses will include age, gender, geographical location and expertise of echocardiographic interpreter. Finally, a sensitivity analysis to investigate the effect of studies with a high risk of bias will be undertaken.
Discussion: This will be the first scientifically rigorous and comprehensive systematic review in the field, and may feed into evidence-based guidelines. Upon completion of this review, a paper will be submitted to a leading journal in the relevant field. Likewise, should the findings of this review warrant a change in clinical practice, a one page summary report will be disseminated among leading clinicians and healthcare professionals in the field. [Prospero Registration: CRD42016051261]

P2208 - ECHOCARDIOGRAPHIC FINDINGS OF CHILDREN DIAGNOSED WITH KAWASAKI DISEASE AND THEM EPIDEMIOLOGICAL AND CLINICAL FEATURES IN A REFERENCE HOSPITAL IN BOGOTÁ 2009 2014

Victor Manuel Huertas Quiñones[1], Tatiana Patiño Patiño[2], Liliana Jurado Salcedo[2], Gabriel Fernando Diaz Gongora[3], Roy Sanguino Lobo[4], Paola Martinez Riveros[2]
Pediatric Cardiology and Professor- Fundacion Cardioinfantil Instituto De Cardiologia. Universidad Nacional De Colombia., Pediatric Cardiology, Bogota-Colombia[1]; Post Graduate Student - Universidad Nacional De Colombia, Pediatrics, Bogota-Colombia[2]; Pediatric Cardiology and Professor - Universidad Nacional De Colombia., Pediatric Cardiology, Bogota-Colombia[3]; Pediatric Cardiology - Fundacion Homi Hospital De La Misericordia, Pediatric Cardiology, Bogota-Colombia[4]

Background: Describe the echocardiographic findings, epidemiological and clinical features of patients diagnosed with Kawasaki disease (KD) in the period between 2009 and 2014 in a reference institution in Bogotá, Colombia.
Materials and Methods: This is an observational, cross-sectional study. Statistical analysis was made using Microsoft Excel 2010 and SPSS-22. The study population was obtained from the database of echocardiograms, reviewed the medical records and tabulated the information.
Results: Patients was 58, 6 patients didn´t accomplish inclusion criteria, total universe 52. 51.9% (27/52) female. The mean age of presentation was 33.4 months (interquartile range IR 36). Clinical features for the diagnosis of KD: 86.5% (45/52) of the patients had fever more than 5 days, 67.3% (35/52) had complete presentation. Clinical laboratory criteria: PCR elevation over than 30 mg/dl was found in 80% of the patients, high aminotransferases in 55%, leukocytes >15.000: 48%, normochromic normocytic anemia 36.5%, thrombocytosis 42.3%, albumin <3 g/dl 52%. The echocardiographic findings were: coronary artery aneurysms 9 patients (17.3%), coronary ectasia 2 cases (3.8%), and 78% of the patients had no pathological changes in the coronary arteries. Treatment: 92.3% (48/52) received acetylsalicylic acid, 100% received immunoglobulin. Regarding the risk factors for the development of coronary aneurysms, it was evidenced that in this cohort of patients studied the sex, complete presentation, hematocrit > 35% and leukocytosis > 12000 had a significant correlation.
Conclusions: KD is one of the most frequent vasculitis in childhood, predominantly involves the coronary arteries, but may also affect other large and medium-sized blood vessels; the etiology and pathophysiology have not yet been completely elucidated. However, their presentation suggests an interaction between genetic predisposition and environmental factors that may have infectious origin. It is a challenge for the pediatrician because the non-specific symptoms, but especially because early diagnosis and early initiation of treatment prevents the development of potentially fatal complications.

P2216 - FIFTY CASES OF CONTINUOUS INTRAVENOUS INFUSION OF CYCLOSPORINE A FOR PATIENTS WITH INTRAVENOUS IMMUNOGLOBULIN RESISTANT KAWASAKI DISEASE

Takaomi Minami[1], Daisuke Matsubara[1], Kensuke Oka[1], Shun Suzuki[1], Sadahiro Furui[1], Tomoyuki Ishii[2], Tatsuya Anzai[1], Koichi Kataoka[1], Tomoyuki Sato[1], Takanori Yamagata[1]
Jichi Medical University, Department of Pediatrics, Shimotsuke-Japan[1]; Matsue Red Cross Hospital, Department of Pediatrics, Matsue-Japan[2]

Background: Cyclosporin A (CsA) has been used to treat patients with intravenous immunoglobulin (IVIG)-resistant Kawasaki

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

disease (KD); however, the major administration route of CsA reported in the literature has not been IV but oral. We reported 50 cases demonstrating the effects of continuous IV infusion of CsA (CICsA).
Materials and Methods: Fifty patients with KD (33 boys and 17 girls; age range, 3–110 months) who did not respond to repeated IVIG (≥4 g/kg) were enrolled. All the patients were started on CICsA (3 mg/kg/day; optimal serum level, 300–500 ng/mL) and then subsequently switched to oral CsA (4–6 mg/kg/day) approximately 1 week after their fever had subsided.
Results: Thirty-six of the 50 patients (72%) became afebrile within 24 h after CICsA treatment (range, ≤24 h to 7 days; median, 24 h). The CsA concentration at the time of defervescence was 220–570 ng/mL (median 373 ng/mL). The patients who were treated with CICsA before day 9 had no coronary artery aneurysm (CAA); however, one case of CAA (medium sides) was observed in a patient who had already experienced CAA on admission at day 10. There was no adverse effect of hypertension or hyperkalemia. The duration of CICsA was 4–27 days (median 8 days), and the total duration including internal use was 6–138 days (median 21 days). The serum C-reactive protein (CRP) and soluble interleukin-2R (sIL-2R) levels were significantly lower 3–5 days after CICsA (CRP: 13.1 to 4.4 mg/dL; sIL-2R: 2587 to 1638 U/mL, $p < 0.01$). The white blood cell count was not significantly changed from 16750 to 14048/μL, whereas the lymphocyte count was significantly changed (3021 to 4720/μL, $p < 0.01$).
Conclusions: CICsA was effective against IVIG-resistant KD, especially when the treatment was initiated before day 9, without serious adverse effects. Therefore, CICsA might be a good therapeutic option for treating IVIG-resistant KD.

P2241 - THE BURDEN OF RHEUMATIC HEART DISEASE IN AN ETHIOPIAN POPULATION FROM THE GONDAR REGION

Daniel Lyon Fink[1], Yossy Machluf[2], Samuel Menahem[3], Rivka Farkash[4], Giora Weisz[4], Yoram Chaiter[2]
Shaare Zedek Medical Center, Pediatric Cardiology, Jerusalem-Israel[1]; Israel Defence Forces, Medical Corps, Tel Aviv-Israel[2]; Monash University, Pediatric Cardiology, Melbourne-Australia[3]; Shaare Zedek Medical Center, Cardiology, Jerusalem-Israel[4]

Background/Hypothesis: The prevalence rate of rheumatic heart disease (RHD) in Africa is 5-10/1000 school children. Little is known for the Gondar region, Ethiopia. The mass immigration of the Jewish population from the Gondar region to Israel created an opportunity for further investigation.
Materials/Methods: This cross-sectional study utilized a database of all recruits from a North-East Israel National Service Recruiting Center which included the medical history, physical examination findings together with cardiologist review and echocardiographic findings (if referral required).
Results: The study population included 113,694 recruits aged 16 to 19 years which were screened over a 22 year period. Of them, 140 recruits had a history of rheumatic fever (prevalence rate: 0.12%), although none from an Ethiopian background (n = 1,719). The prevalence of valvar disease confirmed echocardiographically in Ethiopian recruits was 0.76% compared with a rate of 0.93% among all recruits ($p = 0.5$). However, the prevalence among Ethiopian recruits was higher ($p < 0.01$) in those who had migrated to Israel aged 12 years or over (2.1%, n = 287), compared to those who migrated at a younger age (0.27%, n = 742) or were born in Israel (0.72%, n = 690) (as a group 0.49%, n = 1432).
Conclusions: These findings suggest that an Ethiopian teenage population from the Gondar region may have had a rate of clinically evident and echocardiographically confirmed RHD of 1.6% (2.1% {prevalence of valvar heart disease assumed to be secondary to RHD + background prevalence}– 0.49% {background prevalence presumed not related to RHD}), high even for Africa despite no apparent past history. The data also implies that this central African population had no genetic predisposition to RHD as those immigrating before 12 years of age or born in Israel had a lower prevalence of valvar disease than the local population.

P2279 - PERICARDITIS IN CHILDREN EXPERIENCE OF A MOROCCAN UNIVERSITY HOSPITAL

Nadia El Idrissi Slitine[1], Ouidad Louachama[1], Mariam Makkaoui Alaoui[1], Fatiha Bennaoui[1], Ghizlane Draiss[2], Noureddine Rada[2], Fadel Maoulainine[1]
Nicu, Mother and Child Hospital, Med Vi University Hospital, Marrakesh Medical School, Cadi Ayyad University, Pediatrics, Marrakesh-Morocco[1]; Pediatrics A, Mother and Child Hospital, Med Vi University Hospital, Marrakesh Medical School, Cadi Ayyad University, Pediatrics, Marrakesh-Morocco[2]

Objective: To describe the profile and the outcome in children with acute pericarditis.
Methods: The medical files of all patients with a diagnosis of acute pericarditis admitted in the pediatrics department in Med VI University Hospital of Marrakech, during January 2015 to November 2016 were analyzed retrospectively for their etiology, presentation, management, and prognosis.
Results: The total number of patients was 8: 6 boys and 2 girls with a mean age of 10.75 (range: 5 years to 14 years). The predominant symptoms were chest pain, tachypnea, and fever. Chest radiograph and echocardiogram were performed in all cases. Cardiomegaly was a constant character in all patients. Echocardiography was performed between the first and twentieth days of hospitalization, 6 children had pericardial effusion, and 2 had cardiac tamponade. The etiology of pericarditis was as follows: purulent or bacterial pericarditis in 4 (50%) cases, tuberculosis in 2 (25%) cases, and rheumatic fever in 2 (25%) cases. 2 patients (25%) underwent pericardiocentesis and 1 child required pericardiotomy. Echocardiographic follow up performed in less than one month showed: 1 case of dry pericarditis, 2 cases of small pericardial effusion and 4 cases were normal. There was no constrictive pericarditis. All patients had a good evolution. However, one patient had an acute pulmonary edema that was resolved. Median duration of evolution towards the disappearance of clinical signs after treatments was 32.5 days (interquartile range 5 to 60 days).
Conclusions: Management of pediatric pericarditis is influenced by the cause of the pericarditis. It may involve supportive care, pain control, and antibiotic therapy, as well as pericardiocentesis or pericardiectomy if demanded. The tuberculosis and rheumatic pericarditis remain frequent in our context.

P2281 - REGIONAL VARIATION IN THE MANAGEMENT OF KAWASAKI DISEASE; PRELIMINARY RESULTS FROM AN ONGOING GLOBAL SURVEY

Audrey Dionne[1], Sarah Deferranti[1], Nagib Dahdah[2], Surjit Singh[3], Jane Newburger[1], Davinder Singh-grewal[4], David Burgner[5]
Boston Children, Pediatric Cardiology, Boston-United States[1]; Chu Sainte-justine, Pediatric Cardiology, Montreal-Canada[2]; Post Graduate Institute of Medical Education And Research, Pediatric Allergy and Immunology, Chandigarh-India[3]; The Children, Pediatric Rheumatology, Sydney-Australia[4]; Murdoch Children, Pediatric Infectious Disease, Melbourne-Australia[5]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Intravenous immunoglobulin (IVIG) significantly reduces coronary artery complications in Kawasaki disease (KD) and are universally accepted for the treatment of KD. However, other interventions are used inconsistently and differences in practice exist across nations and institutions.
Methods: Cross-sectional study on the management of patients with KD using a standardized online survey (SurveyMonkey).
Results: The survey has been completed to date by 188 physicians from 26 countries and 15 pediatric subspecialties. IVIG was used as initial treatment by 91% of physicians. Physicians from countries with lower Human Development Index (HDI) were less likely to treat patients with normal coronary arteries ($p = 0.004$), despite no difference in belief that all patients should be treated ($p = 0.35$). Cost of IVIG and limited availability of immunomodulating therapy were the most common barriers to treatment. Steroids were used more often in Europe and South-America ($p < 0.001$), and anti-TNFα therapies in countries with lower HDI ($p = 0.04$). Risk scores were used by a third of physicians to guide decisions about additional therapies, more often in Asia and Europe ($p = 0.01$). The majority of physicians defined treatment failure as persistent or recrudescent fever 24 hours after the end of IVIG infusion. Persistent fever and increasing coronary artery dimensions were the most important factors in decision to retreat. Treatment of refractory cases consisted of IVIG (82%), steroids (83%) and anti-TNF agents (55%) in the majority of cases. Steroids were used more often in Europe and South-America ($p < 0.001$); and anti-TNFα in Asia and Europe ($p = 0.02$) as well as countries with lower HDI ($p = 0.02$).
Conclusions: Management of patients with KD varies significantly. Medical and economic resources explain some variations in treatment, but country of origin also significantly affects management decisions, irrespective of economic status. Physicians who manage patients with KD are invited to complete the anonymous on-line survey and contribute to this research. https://www.surveymonkey.com/r/internationalKDsurvey.

P2294 - THE EFFECT OF TYPE AND SEVERITY VALVES'S ABNORMALITIES TO NUTRITIONAL STATUS IN CHILDREN WITH RHEUMATIC HEART DISEASES IN SOETOMO HOSPITAL SURABAYA

Taufiq Hidayat, Alit Utamayasa, Mahrus A. Rahman, Teddy Ontoseno
Airlangga Uniersity-Soetomo Hospital, Cardiology Division Pediatric Deaprtment, Surabaya-Indonesia

Background: Children with rheumatic heart disease most likely demonstrate poor nutrition due to wasting of body fat and skeletal muscle. Evidence for cardiac cachexia maybe seen in different type and severity of valve abnormalities.
Objective: To examined the association between the type and severity of valves abnormalities with nutritional status in RHD children.
Methods: A cross sectional study was done at Paediatric Cardiology Outpatient Clinic of Dr.Soetomo Hospital, Surabaya in period of 2013-2016. Nutritional status was classified into undernourished (underweight and severe underweight), normal and overnourished (overweight and obesity) based on weight for age. Valve abnormalities was studied from echocardiography. Statistical analysis using comparative statistic and a value of $P < 0.05$ considered significant.
Result: A total of 50 children were evaluated [23 (46%) boys; median age 11 (range: 6-15) years]. Nutritional status of undernourished, normal and overnourished were 15 (30%), 27 (54%) and 8 (16%), consecutively. Valve abnormalities at presentation were mitral regurgitation (MR) 43 (86%), aortic regurgitation (AR) 19 (38%) and tricuspid regurgitation (TR) 22 (44%) children. Severity of valves regurgitation were severe MR 22 (44%), severe AR 5 (10%), and severe TR 4 (8%). There were no association between type of valve abnormalities and nutritional status, MR ($P = 0.287$), AR ($P = 0.861$), TR ($P = 0.807$). However, only severity of MR have significant association with nutritional status [MR ($P = 0.022$), AR ($P = 0.628$) and TR ($P = 0.595$)].
Conclusion: Severity of mitral regurgitation associates with nutritional status, but the type of valve abnormalities do not associate with nutritional status.

P2305 - REACTIVATION OF RHEUMATIC FEVER IN RHEUMATIC HEART DISEASE IN INDONESIA COMPARISON BETWEEN CHILDREN AND YOUNG ADULTS

Aulia Putri Dewita, Oktavia Lilyasari, Poppy S. Roebiono, Felix Chikita Fredy, Radityo Prakoso, Anna Ulfah Rahajoe, Indriwanto Sakidjan, Yovi Kurniawati, Ganesja M. Harimurti
Universitas Indonesia-National Cardiovascular Center Harapan Kita, Cardiology and Vascular Medicine, Jakarta Pusat-Indonesia

Background: Rheumatic heart disease (RHD) remains one of the largest preventable burdens of disease in the world. Whereas repeated episodes of rheumatic fever (RF) become an important mechanism for worsening of RHD. The proportion of the disease remains high in the developing countries, associated with lack of access to medical facilities, infrastructure and education for preventive programs.
Objectives: This study aimed to evaluate the pattern of RF reactivation in in the established RHD among Indonesian children and young adult.
Methods: This retrospective study was conducted at National Cardiovascular Center Harapan Kita, Jakarta, as the tertiary cardiovascular center in Indonesia from January 2012 to December 2015. RF reactivation was based on revised Jones criteria and 2002-2003 WHO criteria.
Results: Among patients with RHD, there were 84 children with median age of 12.5(2-17) years, 103 young adults with median age of 24(18-30) years, 88(47.0%) male and 99(52.9%) female. Reactivation of RF was found in 39(20.8%), and significantly higher in children 28(33.3%) than in young adults 11(10.6%), $p < 0.001$. The number of patient treated with phenoxy methyl penicillin as secondary prevention was only 51(27.2%) patients, where 34 (40.4%) were children and 17(16.5%) were young adults ($p < 0.001$). Twenty five (13.4%) patients were hospitalized with severe congestive heart failure and 42(22.5%) patients with pulmonary hypertension.
Conclusion: The number of cases with reactivation of RF was higher in the children age group and the coverage of secondary prevention was still low. Secondary prevention should be more encouraged since it remains the most practical solution to reduce the worsening of RHD in the developing countries.

P2310 - CLINICAL PROFILE RHEUMATIC HEART DISEASE AT SOETOMO HOSPITAL SURABAYA

Teddy Ontoseno, Taufiq Hidayat, Alit Utamayasa, Mahrus A. Rahman
Cardiology Division Pediatric Department, Airlangga Univerity-Soetomo Hospital, Surabaya-Indonesia

Background: Rheumatic Heart Disease (RHD) affected 19 per 100.000 children in developing countries. There are only few

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

systematically collected data on diseases characteristic in Dr. Soetomo Hospital, Surabaya.
Objective: To describe the clinical profile of pediatric patient with RHD.
Methods: Demographic data, and clinical details regarding RHD in pediatric cardiology outpatients clinic Dr. Soetomo Surabaya Hospital from June 2014 to June 2016 were collected. Missing information obtained directly from the patients' parents or guardians.
Results: Among total of 50 patients, majority were school aged (6-11 years old) with median age 10.86 years (ranged 6–15 years). Female to male ratio was 1.17 :1. Most patients lived outside Surabaya 27 patients (54%), 33 patients (66%) were referral patients. At the first time of diagnosis, there were 14 patients (28%) with ARF (Acute Rheumatic Fever) and 36 patients (72%) with RHD. Major clinical manifestations were carditis 13 patients (26%), followed by polyarthritis migrains 1 patient(2%) and chorea 1 patient(2%). Minor clinical manifestations were fever 7 patients (14%), arthralgia 2 patients(4%), positive CRP 30 patients(60%), elevated ESR 34 patients(68%). Supportive evident positive ASTO titer 22 patients(44%). From electrocardiography findings, only 1 patient had prolonged PR interval, and 2 patients had axis deviation. The most common valve lesions were severe MR 20 patients(40%) followed by moderate MR 17 patients(34%). Most of them 27 patients(54%) had normal nutritional status.
Conclusions: Carditis was the most common major clinical manifestation in previous ARF and mitral regurgitation was the most common valve lesion in patient with RHD.

P2371 - A SYSTEMATIC REVIEW OF THE PREVALENCE OF GROUP A STREPTOCOCCAL DISEASE IN AFRICA

Dylan Barth, Annesinah Moloi, Mahmoud Werfalli, Bongani Mayosi, Mark Engel
University of Cape Town, Medicine, Cape Town-South Africa

Introduction: The prevalence of group A streptococcal (GAS) disease is estimated at >18.1 million cases with an incidence of >1.78 million cases py. While GAS is a significant cause of mortality and morbidity on the global scale, the burden of GAS disease in Africa is not known.
Methods: We conducted a comprehensive literature search in a number of databases, using an African search filter to identify published studies of GAS prevalence amongst symptomatic patients. Two reviewers independently selected articles meeting pre-specified criteria and extracted data on a standardised data extraction form. Statistical analysis included the identification of data sources, documenting estimates, and the application of the random-effects meta-analysis model to aggregate prevalence estimates 95% CI for GAS. We applied Freeman-Tukey transformation to account for between study variability. The I^2 statistic was used to determine the extent of variation in effect estimates due to heterogeneity (H0).
Results: Of 128 articles identified, 27 met the inclusion criteria. Meta-analysis revealed a pooled prevalence of 23% (95% CI, 20–27%). Regional pooled prevalences were similar between Western, 25% (95% CI, 23–27%) and Northern Africa, 26% (95% CI, 21–31%). Central and Eastern Africa had the lowest pooled estimate of 5% (95% CI, 2–11%) and 16% (95% CI, 8–27%) respectively, while Southern Africa had the highest pooled estimate of 32% (95% CI, 20– 46%). Two articles reported on molecular characterisation of isolates with 92 *emm*-types documented; the most dominant subtypes were *emm*44, 48 and 65.
Conclusion: The prevalence of GAS is high in Africa. Efforts focused on the primary prevention of GAS pharyngitis are therefore warranted. Data on molecular strain characterization of GAS in Africa is largely non-existent and thus there is a need for further studies such as AFROStrep to inform current prevention efforts including vaccine development.

P2403 - THE NEW ZEALAND FAMILIAL ECHO STUDY REVEALS HIGH PREVALENCE OF RHEUMATIC HEART DISEASE AMONGST PARENTS AND SIBLINGS OF CHILDREN WITH RHEUMATIC FEVER ECHOCARDIOGRAPHY SHOULD BE OFFERED TO FIRST DEGREE RELATIVES

Rachel Webb[1], Nicola Culliford-semmens[2], Elizabeth Tilton[2], Ross Nicholson[3], Rob Doughty[4], Diana Lennon[5], Briar Peat[6], Nigel Wilson[2]
University of Auckland, Paediatrics, Auckland-New Zealand[1]; Starship Children's Hospital, Paediatric And Congenital Cardiac Services, Auckland-New Zealand[2]; Middlemore Hospital, Paediatrics, Auckland-New Zealand[3]; University of Auckland, Medicine, Auckland-New Zealand[4]; University of Auckland, Population Child and Youth Health, Auckland-New Zealand[5]; Middlemore Hospital, Medicine, Auckland-New Zealand[6]

Background: The risk of Rheumatic Heart Disease (RHD) in relatives of Acute Rheumatic Fever (ARF) patients is poorly defined. This study aimed to determine the prevalence of RHD in first degree relatives of ARF patients using echocardiography and family history, and to explore the feasibility of using echocardiography for enhanced case detection.
Methods: Between 2014 – 2016, 70 cases of ARF were recruited from Auckland, New Zealand (NZ). Family composition and family history of ARF/RHD were determined via structured questionnaire. Parents and siblings ≥4 years were offered echocardiography. Echocardiograms were interpreted according to WHF 2012 criteria. Abnormal scans were read by a panel of 3 cardiologists.
Results: 70 cases and families were recruited. The median age of cases was 11 years (range 4 – 15 years). 55/70 (79%) were of Pacific Island ethnicity and 15/70 (21%) were New Zealand Maori. 132/166 (80%) of eligible siblings and 94 parents underwent echocardiography. Siblings: Echocardiography detected 2 with Definite RHD and 7 with Borderline RHD. 1 additional sibling had known RHD following an ARF episode. Parents: Echocardiography detected 3 with Definite RHD and 3 with Borderline RHD. 2 additional parents had known prior RHD. Prevalence of RHD for parents and siblings is shown in Table One. Overall, the prevalence of RHD (Definite + Borderline) in siblings was 75 per 1,000 (95% CI 40 – 134 per 1,000) and in parents was 83 per 1000, 95% CI 41 – 158 per 1,000.).
Conclusions: We report 8% prevalence of RHD in parents and siblings of ARF cases in New Zealand. These findings support the concept that susceptibility to ARF has a heritable component. In adequately resourced healthcare systems, first degree relatives should be offered echocardiography when a family member is diagnosed with ARF.

Table 1. Prevalence of RHD in parents and siblings of 70 children with ARF

	Borderline RHD		Definite RHD		Total RHD (Definite + Borderline)	
	Rate	Prevalence	Rate	Prevalence	Prevalence	95% CI
Siblings	7/133	53 per 1000	3/133	23 per 1000	75 per 1000	40–134 per 1000
Parents	3/96	31 per 1000	5/96	52 per 1000	83 per 1000	41–158 per 1000

P2470 - PREVALENCE OF POSITIVE RAPID ANTIGEN GROUP A STREPTOCOCCUS TEST IN CHILDREN AND ADOLESCENTS IN A STATE FROM NORTHEAST BRAZIL

Raimundo Amorim[1], Alexandre Falcão Filho[2], Ana Abath[2], Thamine Hatem[1], Felipe Mourato[3], Renata Gomes[4], Sandra Mattos[5]
Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[1]; Círculo Do Coração De Pernambuco, Caduceus, Recife-Brazil[2]; Círculo Do Coração De Pernambuco, Científico, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Estatística, Recife-Brazil[4]; Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[5]

Background: Group A streptococcus (GAS) is deeply associated with sore throat that can lead to acute rheumatic fever and rheumatic carditis. Prevalence of asymptomatic carriers (AC) in Brazil has been reported from 0.8–1.6%. This statistic may vary with the quality of health care provided. Antibiotic therapy with penicillin is effective and low cost, but in 2015 and 2016, Brazil faced shortage of the drug caused by global raw material destocking. This study aims to determine the prevalence of AC through rapid antigen group A streptococcus test (RAGAST) in a poor state in Northeast of Brazil.
Materials and Methods: Analysis of data of 1,648 children over age four and adolescents evaluated in the Heart Caravans, an active search for heart disease that takes place once a year in 13 cities of state of Paraiba, in northeast of Brazil. All patients were submitted to RAGAST using Quidel QuickVue+ kit. Prevalence data was analyzed each year and compared with other variables such as age, social and economic status and diagnosis of rheumatic fever.
Results: We found a high prevalence of positive tests each year, varying from 14.3% in 2014, to 4.3% in 2015 and 21.9% in 2016 ($p < 0.01$). During this time, variables associated with higher prevalence were male gender (p 0.032), age (p 0.034), brown ethnicity (p 0.041) and access to public water supply system (p 0.018).
Conclusions: A high prevalence of GAS AC was demonstrated in the studied population. A reduction in prevalence was observed between 2014 and 2015, with a greater increase between 2015 and 2016. We theorize that the lack of appropriate antibiotic therapy between 2015 and 2016 may explain such a rise. The Heart Caravan intervention in 2014 may have contributed in decreasing prevalence between 2014 and 2015.

P2534 - RISK FACTORS AND IMPLICATIONS OF PROGRESSIVE CORONARY DILATATION IN CHILDREN WITH KAWASAKI DISEASE

Ming-Tai Lin, Chia-Hui Wu, Ming-Yu Liu, Mei-Hwan Wu
National Taiwan University Hospital, Pediatrics, Taipei-Taiwan

Background: Kawasaki disease (KD) is an acute systemic vasculitis of childhood, which may lead to cardiovascular morbidity and mortality. Progressive coronary dilatation at least two months has been known associated with worse late coronary outcomes in the KD patients with medium or giant aneurysms. However, its risk factors and occurrence in the KD patients without medium or giant aneurysms were less studied.
Method: We retrospectively enrolled 169 KD patients from a tertiary medical center (2009-2013). Medical records were reviewed. Echocardiography was followed at the acute KD phase and 3-4 weeks, 6-8 weeks, 6 months and 12 months after disease onset. Progressive coronary dilatation was defined for those with progressive enlargement of coronary arteries in three consecutive echocardiograms.
Results: Maximal coronary Z-score of 31 KD patients (31/169, 18.3%) were more than +2.5 at the acute phase KD. 16 patients (16/169, 9.5%; M/F:9/7) had coronary aneurysms one month after KD onset and 5 (5/169, 3.0%) of them satisfied the definition of progressive coronary dilatation. By using multivariate logistic regression, we found initial maximal coronary Z-score $\geqq +2.5$ [odds ratio (OR): 5.24, $P = 0.020$] and hypoalbuminemia [OR: 4.83, $P = 0.035$] were two independent risk factors of coronary aneurysms. Both factors were also significantly associated with progressive coronary dilatation. IVIG unresponsiveness was borderline associated only with the development of coronary aneurysms one month after disease onset ($P = 0.058$).
Conclusions: 3% of KD patients had progressive coronary dilatation, which was associated with the aneurysm persistence one year after KD onset. Initial coronary dilatation and hypoalbuminemia were independently associated with the occurrence of progressive coronary dilatation. Such patients may need closer cardiac monitoring and adjuvant therapies besides immunoglobulin.

P2540 - PATTERN OF RHEUMATIC HEART DISEASE AMONG CHILDREN YOUNG ADULTS AND ADULTS IN INDONESIA

Andi Mahavira, Oktavia Lilyasari, Poppy S. Roebiono, Aulia P. Dewita, Anna U. Rahajoe, Indriwanto Sakidjan, Radityo Prakoso, Ganesja M. Harimurti
National Cardiovascular Center Harapan Kita, Department Cardiology and Vascular Medicine, Faculty of Medicine Universitas Indonesia, Jakarta-Indonesia

Background: Rheumatic heart disease (RHD) continues to be a major public health problem in the developing countries. The aim of this study was to investigate the pattern of RHD among Indonesian children, young adults, and adults whom hospitalized at the tertiary center in Indonesia.
Methods: This retrospective study was conducted at National Cardiovascular Center Harapan Kita, Jakarta, Indonesia. The data were retrieved from the hospital database in one year period.
Results: Total of 64 patients, 34.4% males and 65.6% females were included in this study. Patients were divided into 3 groups, 21 (32.8%) children (<18 years old), 18 (28.1%) young adults (18-30 years old), and 25(39.1%) adults (>30 years old). The most common clinical presentation was congestive heart failure found in 66.7% children, 88.9% young adults, and 13(5%) adults. There was not significantly different in this clinical presentation between groups ($p = 0.05$). The most valve disease findings among children group were isolated mitral regurgitation (85.7%), followed by both mitral and aortic regurgitation (9.5%). There were 72.2% patients with isolated mitral regurgitation and 16.7% with isolated mitral stenosis in young adults group. While in adults group, 68% with mitral stenosis, 16% patients with combination of mitral stenosis and regurgitation. These valve disease findings was significantly different between groups ($p = 0.000$). Among children group, there was 47.6% patients only treated medically and 33.3% whom underwent surgical mitral valve repair. In young adults, mitral valve replacement and mitral valve repair performed in 33.3% each. Medical treatment only, mitral valve replacement and mitral valve repair were done in 32%, 40%, and 20% respectively in adults group. These procedures were also not significantly different between groups ($p = 0.051$).
Conclusions: The RHD patterns in our institution, apart from type of valve involvement, there was no difference of clinical presentation and method of treatment between children, young adults, and adult patients.

P2682 - TWO YEAR FOLLOW UP OF RHEUMATIC HEART DISEASE DIAGNOSED THROUGH ECHOCARDIOGRAPHIC SCREENING IN MALAWI AFRICA

Amy Sims Sanyahumbi[1], Craig Sable[2], Andrea Beaton[2], Danielle Guffey[3], Melissa Karlsten[1], Peter Kazembe[4], Charles Minard[3], Mina Hosseinipour[5], Daniel Penny[1]
Baylor College of Medicine/Texas Childrens Hospital, Pediatric Cardiology, Houston-United States[1]; Childrens National Medical Center, Pediatric Cardiology, Washington, D.C.-United States[2]; Baylor College of Medicine, Clinical Research Institute, Houston-United States[3]; Baylor College of Medicine, Pediatrics, Lilongwe-Malawi[4]; University of North Carolina Project, Infectious Disease, Lilongwe-Malawi[5]

Background: In asymptomatic children, screening echocardiography (echo) may diagnose latent rheumatic heart disease (RHD). World Heart Federation has standardized categorization of "definite", "borderline", or no RHD by echo findings. Progression of screening-diagnosed RHD is not known. In 2014, we screened 1450 schoolchildren in Lilongwe, Malawi and diagnosed 39 with borderline and 11 with definite RHD.
Objective: Evaluate 2-year RHD evolution amongst those diagnosed through screening.
Methods: 2-year follow-up echos were performed on participants with definite and borderline RHD. Echos were read by primary, secondary, then third readers if there was disagreement. We compared initial and follow-up diagnosis and compared penicillin adherence, age, gender, number in home, and household income among those with disease advancement versus stable disease. Comparisons used Fisher's exact and Wilcoxon rank sum tests. If children did not come to follow-up appointments, they were traced using location information provided at enrollment.
Results: Of 39 with borderline RHD, 1 was lost to follow-up (2.6%), 1 progressed to definite (2.6%), 19 remained borderline (48.7%), 17 (43.6%) regressed to normal, and 1 was re-classified as mitral valve prolapse (2.6%). Of 11 with definite RHD, 6 (54.5%) remained definite, 4 regressed to borderline (36.4%), and 1 regressed to normal (9.1%). Only 5 of 11 (45%) with definite RHD had penicillin adherence >80% for the previous year. There was no difference in adherence, gender, age, household income, or number in household between those with definite RHD that regressed and those who did not ($p > 0.05$), or between those with borderline who regressed and those that did not ($p > 0.05$). Retention rate was 98%.
Conclusions: A strength of our study was a high retention rate. At 2 years, more patients had disease regression than progression similar to previous cohorts, but longer follow-up is required to predict true disease evolution.

P2764 - EFFECTIVENESS OF A NURSE LED MECHANICAL VALVE ANTICOAGULATION PROGRAM FOR RHEUMATIC HEART DISEASE PATIENTS IN HAITI

Benjamin Meza[1], Owen Robinson[2], Ketly Altenor[3], Julia Von Oettingen[3], Chris Carpenter[3], Ric Bonnell[3], Marie-michele Sainvil[3], James Wilentz[4], Gene F. Kwan[5], Jean-louis Romain[6]
University of Miami, Dept. of Pediatrics, Miami, FL-United States[1]; Haiti Cardiac Alliance, Haiti Cardiac Alliance, Burlington, VT-United States[2]; Kay Mackenson Clinic, Kay Mackenson Clinic, Montrouis-Haiti[3]; Icahn MT. Sinai School of Medicine, Mt. Sinai Heart, New York, NY-United States[4]; Boston University Medical Center, Dept. of Cardiology, Boston, MA-United States[5]; Zanmi Lasante/Partners in Health, Zanmi Lasante/Partners in Health, Mirebalais-Haiti[6]

Introduction: Rheumatic heart disease (RHD) disproportionately affects young people in low- and middle-income countries (LMIC) where health systems for chronic care are weak. Mechanical valves are more durable than bioprosthetic valves, but require long-term anticoagulation. In LMICs, bioprosthetic valves are often chosen given concerns about the feasibility of long-term anticoagulation.
Hypothesis: Nurse-led management allows effective anticoagulation in Haiti.
Methods: A nurse-led anticoagulation program was established in Haiti. 25 RHD patients with mechanical valves (7 female, median age 19 years) were followed from 9/2013 through 12/2016. All patients live in impoverished communities: 15 urban, 10 rural. Valve position was mitral only (17), aortic only (3), or mitral and aortic (5). We trained patients to use donated portable machines (Coagusense Inc., Fremont, CA) to measure their International Normalized Ratio (INR). On a defined schedule, their INR values were checked and self-reported by phone to supervising nurses. Warfarin dose was titrated by standardized protocol. Physician support was available. Time in therapeutic range (TTR) was calculated using the modified Rosendaal method.
Results: In 907 INR samples, median TTR was 50.1% (Interquartile Range [IQR] 30.6% - 61.7%) (Table 1). Time below and above therapeutic range was 35.2% (IQR 27.9% - 46.8%) and 14.7%, (IQR 7.1% - 20.9%), respectively. INR was within 1.0 of target 95.0% (IQR 94.1% - 98.6%) of the time. One patient died unrelated to anticoagulation due to severe dilated cardiomyopathy. Twenty-four participants reported no anticoagulation-related complications (severe bleeding, thromboembolism, endocarditis, or valve dysfunction). INR test results were reported to the nurse a mean of 4.3 days after the protocol-specified date.
Conclusion: Nurse-led, protocol-driven anticoagulation of patients with mechanical valves can be successfully and safely managed in a low-income country. Health systems including physician-nurse task shifting can be implemented to facilitate long-term care of patients with RHD in whom surgery with mechanical valve replacement is required.

Table 1.

Patient #	Age	Sex	Valve Position	Low INR Limit	High INR Limit	Months in Program	Total Tests	% of Days In Range	% of Days Out Of Range (1.0 or less)	% of Days Out Of Range (more than 1.0)

P2837 - CARDIAC ABNORMALITIES IN CHILDREN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Houda Ajmi[1], Rim Letaief[1], Sameh Mabrouk[1], Mehdi Slim[2], Saida Hassayoun[1], Minyar Tfifha[1], Noura Zouari[1], Jalel Chemli[1], Essia Boughzela[2], Saoussen Abroug[1]
Sahloul University Hospital, Pediatric Department, Sousse-Tunisia[1]; Sahloul University Hospital, Cardiology Department, Sousse-Tunisia[2]

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterised by disturbances in innate and adaptive immune mechanisms. Manifestations affecting the skin, joints, kidney and cytopenia are commonly detected in this disease. However cardiac involvements are often subclinical and then misdiagnosed unless they results in severe disorders that could be life-threatning.
Objective: The aim of the study was to assess the systolic and diastolic function of the left ventricle (LV) in SLE children without clinically evident cardiovascular disease, using pulsed Doppler echocardiography.
Methods: We conducted a transversal study in the department of Pediatrics of Sahloul hospital-Sousse. Children and adolescents with SLE and no cardiac symptoms were included in our study. They were examined for cardiac involvement by physical examination and echocardiography.
Results: We collected 4 cases of SLE (2girls, 2 boys). Echocardiographic examination revealed mild tricuspid valve regurgitation in all patients, and moderate mitral valve regurgitation in one patient. Pulmonary arterial hypertension was found in one case (systolic pulmonary hypertension = 30 mmHg). Pericardial effusion was found in one patient. Indexes of LV systolic were correct with ejection fraction (EF) between 59% and 68% and fractional shortening (FS) between 33% and 46%. Peak early diastolic filling velocity (E) was >1,2 m/s in 2 cases and ratio of early-to-late diastolic filling velocity (E/A) was >1 in all cases and >2 in 2 cases. Deceleration time (DT) was long in 2 patients (243ms, 239ms) and low in one case (136ms). Late filling velocity (A) and isovolumic relaxation time (IRT) were low (>60ms) in 2 cases. Patients demonstrated significantly high E'/A' (>1) in all cases.
Conclusion: We conclude that asymptomatic diastolic dysfunction is common in children with SLE, most likely representing myocardial involvement. Routine cardiac evaluation by echocardiography can be recommended in the follow-up of children with SLE in order to detect silent cardiac abnormalities.

P3032 - LONG TERM OUTCOME OF GIANT CORONARY ARTERY ANEURYSM IN KAWASAKI DISEASE

Hong Ryang Kil, Yun Jin Lee, Eun Joo Kim
Chungnam National University, Pediatrics, Daejeon-Korea, South

Purpose: In childhood Kawasaki disease (KD), giant coronary artery aneurysm (CAA) is associated with significant mortality and morbidity associated related to ischemic heart disease. The aim of this study was to investigate the incidence, treatment modalities and clinical course of ischemic cardiac sequelae in KD patients with giant CAA.
Methods and Results: The medical records of children with KD with giant CAA admitted to Chungnam National University Hospital, Konyang University Hospital and Soonchunhyang University Cheonan Hospital from 1993 to June 2016 were retrospectively analyzed. Giant CAA defined as internal diameter >8mm or Z score of coronary artery diameter >10. The subject included 22 patients, who male patients were predominant (90.9%). One patient diagnosed as KD with giant CAA by chance during the evaluation of cardiac murmur. The mean age at diagnosis was 38 ± 32 months and the average follow-up period was 7.4 ± 7.6 years. Four patients (18%) were treated with thrombolytic therapy for acute coronary syndrome at 1 month to 21 months after KD onset and one of them died. The catheter or surgical coronary artery intervention to alleviated coronary ischemia were performed at 1 year to 16 years after onset in three patients (13.6%). The overall all ischemia event free survival rates were 78.6%, 69.9% and 46.6% at 5, 10 and 20 years after the onset of KD, respectively. The age and coronary artery diameter at diagnosis were related to ischemic events but it was not statistically significant.
Conclusion: KD patients with giant CAA were suffered form significant myocardial ischemia in long-term follow up. Age and initial diameter of CAA are related to myocardial ischemia but not significant. The treatment modality including warfarin and antiplatelet therapy was not directly associated with myocardial ischemia. The national multicenter and prospective studies would be suggested in future.

SURGERY

P1003 - COMPARISON WITH TWO TYPES OF PALLIATIVE PROCEDURES FOR TETRALOGY OF FALLOT THE MODIFIED BLALOCK TAUSSIG SHUNT AND THE RIGHT VENTRICULAR OUTFLOW PATCH

Yih-Sharng Chen, Shu-Chien Huang, Heng-Wen Chou, Chung-I Chang, Chen Yih Sharng Chen
National Taiwan University Hospital, Cardiovascular Surgery, Taipei-Taiwan

Background: When infants with TOF/pulmonary atresia or low body weight not amenable to initial complete correction, palliative procedure will be performed first. Systemic or right ventricular to pulmonary connection can be established with Modified Blalock–Taussig shunt (MBTS) or surgical right ventricular outflow tract (RVOT) patch enlargement.
Methods: A 7-year retrospective study of TOF cases under 6 month old with palliative procedure without initial total correction in our institute between March 2007 to April 2015 was conducted. Cases were classified into two groups; group I included patients that had mBT shunt o central shunt, while group II included cases that had transannular RVOT patch augmentation. We compared age and body weight at the time of palliative surgery, age at the time of total correction, numbers of operations between palliation and total correction, and pulmonary growing rate of two groups.
Results: Thirty-six patients fulfilled the study criteria. There were 29 cases (80%) in group I, and 7 cases (20%) in group II. All patient tolerated surgical repair but 4 patient expired after operation due

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

to sepsis, heart failure, hypoxic-ischemic encephalopathy. Median weight at the time of palliative surgery($p = 0.007$) in group I and group II is 2.9 kg(mean, 3.13 ± 0.96; range, 1.8 to 6.2 kg) and 2.3 kg(mean, 2.25 ± 0.26; range, 1.7 to 2.5 kg). Numbers of operations between palliation and total correction in group II is zero. In group I, 9 of 29 patients had one time operation between palliation and total correction. We observed no statistically significant difference in pulmonary artery growing rate (mm2/days).
Conclusions: Transannular RVOT patch augmentation with cardiopulmonary bypass can be performed safely and effectively in lower age and body weight infants as palliative procedure. It also can decrease the number of operations between palliation and total correction. Long-term follow up is needed to evaluate future difference in different techniques.

P1009 - IMPACT OF SOCIAL DISADVANTAGE ON LONG TERM OUTCOMES IN CHILDREN UNDERGOING CARDIAC SURGERY

Edward Justo[1], Benjamin Reeves[2], Robert Ware[3], Janelle Johnson[4], Tom Karl[5], Nelson Alphonso[6], Robert Justo[4]
University of Queensland, Paediatric Cardiology, Brisbane-Australia[1]; Cairns Hospital, Paeadiatric Cardiology, Cairns-Australia[2]; University of Queensland, Biostatistics, Brisbane-Australia[3]; Lady Cilento Children, Paediatric Cardiology, Brisbane-Australia[4]; All Children, Paediatric Cardiac Surgery, St Petersburg-United States[5]; Lady Cilento Children, Paediatric Cardiac Surgery, Brisbane-Australia[6]

Background: Population based registries report 95% 5-year survival in children undergoing surgery for congenital heart disease. The Australian indigenous population is at risk from social disadvantage, inequitable access to healthcare and inadequate follow-up. This study investigates paediatric outcomes and influencing factors in this at risk population.
Methods: All children with acquired or congenital heart disease who underwent cardiac surgery between May 2008 and August 2014 were studied. Demographic information, diagnosis and comorbidities, treatment and outcome data were collected at time of surgery and at cardiac follow-up. Socio-economic Indexes for Areas-2001 was used to quantify socioeconomic status of patients.
Results: 1528 children with mean age 3.4 ± 4.6 years were studied. 123 (8.1%) were identified as indigenous patients. Assessment of socioeconomic status demonstrated that 64 (52.7%) indigenous patients were in the lowest third of the population, compared to 456 (28.2%) of the non-indigenous population ($p = < 0.001$). There was no difference in the Basic Aristotle scores between populations ($p = 0.20$) The indigenous population had a significantly higher Complex Aristotle score (indigenous 9.4 ± 4.2 vs non-indigenous 8.7 ± 3.9, $p = 0.04$). Rate of long-term follow-up did not differ between groups (indigenous 93.8% vs. non-indigenous 95.6%, $p = 0.17$). No difference was noted in 30 day mortality (indigenous 3.2% vs non-indigenous 1.4%, $p = 0.13$). 6-year survival for the entire cohort was 94.9% with cox analysis demonstrating increased 6-year mortality in the indigenous group (indigenous 8.1%% vs non-indigenous 5.0%; hazard ratio = 2.10; $p = 0.03$). Freedom from surgical re-intervention was 79.5% for all patients and did not differ between groups (hazard ratio = 1.40; $p = 0.11$). When long-term survival was adjusted for socio-economic status and Complex Aristotle Score, no significant difference in outcomes between the populations was demonstrated ($p = 0.19$).
Conclusion: Despite equitable access to cardiac medical care, the indigenous population experienced a higher late mortality, which may be explained by complex socioeconomic issues.

P1021 - CASE REPORT AORTO VENTRICULAR TUNNEL

Humberto Rodriguez[1], Jesus Figueroa[1], Jose Antonio Quibrera[2], Luis Cordova[3], Thomas Disessa[4]
Hospital Pediatrico De Sinaloa, Surgery, Monterrey-Mexico[1] Hospital Pediatrico De Sinaloa, Cardiology, Culiacan-Mexico[2] Hospital Pediatrico De Sinaloa, Antehesiology, Culiacan-Mexico[3] Novick Cardiall Alliance, Cardiology, Louisville-United States[4]

One day old male, product of a 39 week uncomplicated gestation, labor and, delivery to 19 yr.old female was noted to have respiratory distress characterized by intercostal retractions and nasal flaring shortly after birth. On physical assessment, a systolic murmur, III/IV and an intense second heart sound, were detected. Chest x-ray demonstrated cardiomegaly ; echocardiogram revealed an atrial communication with a left to right shunt, a ductus arteriosus with bidirectional flow, and a direct communication between the left ventricle (LV) and a dilated right sinus of Valsalva. There was anterograde flow into the aorta in systole and retrograde flow into the ventricle in diastole. Despite treatment with diuretics, the baby developed refractory cardiac failure. The baby was scheduled for surgery. The procedure was performed with aortic cross-clamping, cardioplegia, ligature of both cavae and a right atriotomy. We observed a tissue like bump over the right sinus of valsalva to the anterior left ventricular outflow tract (LVOT). We opened this tissue and found a communication between Aorta and LV, Aortic valve was complete and without problems, right coronary artery was normal size; and then it was closed along its anterior wall with a Goretex patch using a double running suture; same patch was used to close LVOT, use running suture over aortic annulus and close the Aorta. We close the remnant tissue over the patch. The ASD and the atriotomy were repaired. The aortic clamp and caval ligatures were released. Heart rate returned to sinus rhythm with the aid of dobutamine, epinephrine and milrinone. Cardiopulmonary bypass time was 55 min. and the aortic cross-clamping, 43 min. Post-op management included iv fentanyl, mechanical ventilation and continued administration of inotropic drugs. Over the second day post-op the baby.

P1024 - MITRAL VALVE REPLACEMENT FOR A PATIENT LESS THAN TWO YEARS OF AGE WITH MITRAL REGURGITATION AND EVOLVING POST REPAIR MITRAL STENOSIS

Justine Iris Yap
University of The Philippines - Philippine General Hospital, Pediatric Cardiology, San Fernando-Philippines

We present a case of a one year and nine-month old girl who was diagnosed by echocardiography to have congenital mitral regurgitation at four months of age after presenting with a murmur and heart failure symptoms. Despite being maintained on medications, the mitral regurgitation became progressively worse, associated with rapid enlargement of the left-sided chambers, prompting mitral valve repair at 14 months old. Although intra-operative transesophageal echocardiography showed only moderate mitral regurgitation, serial echocardiographic studies done on the 3rd month and 6th month post-repair showed rapidly evolving mitral stenosis, associated with recurrence of heart failure symptoms. She therefore underwent mitral valve replacement, seven months after the first repair, using a 19mm bioprosthetic aortic valve. This case report highlights the surgical aspects of repairing a congenitally incompetent mitral valve, and the challenging dilemma of choosing between mitral valve repair versus replacement in the very young pediatric patient. Key words: Congenital mitral regurgitation, Mitral valve Repair, Mitral Valve Replacement.

P1035 - NEONATAL CARDIAC LUPUS MYOCARDITIS FLAIL TRICUSPID VALVE AND NORMAL RHYTHM

María-Teresa González-lópez[1], Ramón Pérez-Caballero-Martínez[1], Ana-María Pita-Fernández[1], Juan-Miguel Gil-Jaurena[1], Teresa Álvarez-Martín[2]
Gregorio Marañón Hospital, Pediatric Cardiac Surgery, Madrid-Spain[1]; Gregorio Marañón Hospital, Pediatric Cardiology, Madrid-Spain[2]

Background: Neonatal cardiac lupus is a rare, passively acquired autoinmune disease. Congenital atrioventricular block is the most common cardiac abnormality found. We describe the first case of flail tricuspid valve due to papillary muscle rupture following in utero myocarditis associated with maternal anti-Ro and anti-La antibodies in absence of atrioventricular block. We discuss the pathophysiology and management in this unique scenario.
Case: We present a patient who was first detected in utero myocarditis. The mother was identified as antibody positive for lupus (anti-SSA/Ro and anti-SSB-La). Dexametasone was started. Fetal echocardiography showed signs of acute myocarditis, with involving of both the chordal and subvalvar apparatus. Normal rhythm was maintained. At 34th week, an emergent caesarean was performed. Following birth, echocardiography showed a flail tricuspid valve due to anterior papillary muscle rupture and severe tricuspid regurgitation. Treatment was initiated (dopamine, milrinone, hydrocortisone and immunoglobulin). Anti-SSA/Ro and anti-SSB-La were positive in the neonate. He was extubated on the 5th day after birth. Symptoms of heart failure improved (tricuspid regurgitation unchanged). He was discharged at home on day 25 after birth on medical treatment. At 2 months of age (weight 3.6 kg), he underwent tricuspid valve repair (7/0 polytetrafluoroethylene neochordae was placed onto the anterior leaflet with attachment to the papillary muscle; no associated annuloplasty; total cardiopulmonary bypass 46 minutes; aortic cross-clamping time 23 minutes).
Results: No postoperative complications were detected. He was discharged on the 26 postoperative day. At 20-month follow-up,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

he is progressing well, with normal-sized right ventricle and mild tricuspid regurgitation.
Conclusions: The spectrum of cardiac manifestations associated with anti-SSA/Ro and SSB/La antibodies is expanding. The recognition of flail tricuspid valve as the final event of an underlying myocardial auto-immune inflammatory process may be added as manifestation of neonatal lupus. The management of heart failure in the neonate is mandatory for a proper timing for surgery.

P1037 - TRAINING ANIMAL MODEL PROGRAM FOR VIDEO ASSISTED REPAIR OF CONGENITAL HEART DEFECTS IN PEDIATRIC PATIENTS INITIAL EXPERIENCE

María-Teresa González-lópez[1], Ramón Pérez-Caballero-Martínez[1], Ana-María Pita-Fernández[1], Juan-Carlos De-Agustín-Asensio[2], Juan-Miguel Gil-Jaurena[1]
Gregorio Marañón Hospital, Pediatric Cardiac Surgery, Madrid-Spain[1]; Gregorio Marañón Hospital, Pediatric Surgery, Madrid-Spain[2]

Background: Minimally invasive cardiac surgery has grown in adult population. However, its application to congenital heart disease in pediatric patients remains limited. In this scenario, alternative minimally invasive approaches have recently been used, but taking a step forward on a video-assisted repair is still unclear. We present the initial experience of a pioneering training animal model program for video-assisted repair in congenital heart defects in pediatric patients. We discuss the preliminary results in this complex scenario.
Patients and Methods: Phase 1. The ovine model (total number: 8) was used for a progressive training of the pediatric cardiac surgeons under the supervision of expertise pediatric surgeons in videothoracoscopy. Training areas: thorax access (three working ports), dissection and handling of great vessels and adjacent structures (in vivo); right atriotomy, creation of atrial septal defects (ASD) and direct closure (post-mortem). Material: camera (0° y 30°-angled; KarlStorz material), trocars (5-11 mm) and additional surgical material. Phase 2. Patients. Initially, 4 pediatric pacientes (table) with ASD underwent minimally invasive video-assisted repair (submammary mini-thoracotomy, two working ports and peripheral cannulation).
Results: Direct closure was performed uneventfully in all them. Intraoperative extubation was performed in 3. One significative postoperative complication was presented in the patient #4 (reperfusion injury of right lower limb secondary to cannulation, resolved with decompressive fasciotomy). At follow-up (11 + /-2 months, range 8-13), all remain with optimal functional class with no residual defects.
Conclusions: Although the small size of pediatric patients constitutes the main limiting factor for a video-assisted repair, the use of animal models for training in these techniques may be useful. This training in close partnership with expertise pediatric surgeons in thoracoscopic techniques is a key point for acquiring novel surgical skills for those surgeons dedicated to congenital heart defects, improving the presented preliminary results in pediatric patients in a future..

Table 1. Anthropometric and surgical features of the pediatric patients.

	Gender	Age (years)	Weight (kg)	CPB time	AO-Cross clamping time
#1	Male	12	36	145	70
#2	Male	13	46	157	41
#3	Male	12	23	102	23
#4	Female	10	50	135	52

CPB: Cardiopulmonary bypass time.

P1039 - MULTICENTER QUALITY IMPROVEMENT PROJECT TO PREVENT STERNAL WOUND INFECTIONS IN PEDIATRIC CARDIAC SURGERY PATIENTS

Cathy Woodward[1], Richard Taylor[1], Minnette Son[1], Roozbeh Taeed[1], Marshall Jacobs[2], Lauren Kane[3], Jeffery Jacobs[4], S. Adil Husain[5]
University of Texas Health Science Center San Antonio, Pediatrics, San Antonio-United States[1]; Johns Hopkins School of Medicine, Cardiac Surgery, Baltimore-United States[2]; Baylor College of Medicine, Congenital Heart Surgery, Houston-United States[3]; Johns Hopkins All Children's Hospital, Cardiovascular Surgery, St. Petersburg-United States[4]; University of Texas Health Science Center San Antonio, Cardiothoracic Surgery, San Antonio-United States[5]

Background: Children undergoing cardiac surgery are at risk for sternal wound infections (SWI) leading to increased morbidity and mortality. Single center quality improvement initiatives have demonstrated decreased infection rates utilizing a bundled approach. The project's purpose was to determine the efficacy of a protocolized approach to decrease SWI.
Methods: Pediatric cardiac programs joined a collaborative effort to prevent SWI. Programs implemented the protocol, collected compliance data and provided data points from local clinical registries using Society of Thoracic Surgery Congenital Heart Surgery Database harvest-compliant software or from other registries.
Results: Nine programs prospectively collected compliance data on 4198 children. Days between infections were extended from 68.2 days (range 25-82) to 130 days (range: 43-412). Compliance was 76.7% the first quarter and 91.3% the final quarter. Ninety (1.9%) children developed a SWI pre protocol and 64 (1.5%) post protocol, $p = 0.18$. The 657 (15%) delayed sternal closure (DSC) patients had a 5% infection rate with 18 (5.7%) year one and 14 (4.3%) year two. For DSC patients there was a trend towards increased risk for SWI by 1.046 for each day the sternum remained open, $p = 0.067$. Single dose bolus pre-op antibiotics administered 0- 60 minutes pre incision resulted in less infections than when administered outside 0-60 minutes, 3.7% v. 1.9%, $p = 0.025$.
Conclusions: A multicenter QI project to reduce pediatric SWI's demonstrated an extension of days between infections and a decrease in SWI's. Administration of pre-op antibiotics within the recommended time was associated with decreased infection rates.

P1055 - A COMPLICATED CASE OF INFECTIVE ENDOCARDITIS COMPLICATING COMPLETE HEART BLOCK POST SURGERY A CASE REPORT

Raania Amaani, Niken Rachma Sayekti, Raditya Dewangga, Amiliana M. Soetanto
Faculty of Medicine University of Indonesia, Cardiology, Jakarta-Indonesia

Introduction: Infective endocarditis (IE) is a serious infection with high morbidity and mortality. Three most frequent and severe complications of IE are heart failure, paravalvular complication, and embolic events. This is a case of severe complicated IE having complete heart block (CHB) post-surgery.
Case Report: A 45 years old man, admitted to emergency unit with dyspnea, intermittent fever since months ago and signs of right heart failure. His past medical history included severe aortic regurgitation. Electrocardiogram revealed AF with some episodes of non-sustained VT. TTE showed dilation of all heart chambers, severe tricuspid regurgitation with multiple-mobile vegetation, severe aortic regurgitation with vegetation at aortic valve. Blood culture showed S.epidermidis, non positive result for major

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

criteria. Diagnosis of definite IE was then established. Urgent heart surgery was then performed. Surgical findings revealed ruptured of the right sinus of Valsalva with fistula connecting to tricuspid annulus. Further, evacuation of vegetation, reconstruction of tricuspid and aortic annulus, and repairing ruptured sinus-of-Valsalva were done. Post surgery, the patient condition was relatively stable, however ECG revealed CHB. Pacemaker had been implanted to obtain adequate heart rate.
Discussion: Diagnosis of definite IE was based on the Modified Duke's Criteria. One major criteria was the echocardiography features of vegetation and fistula. Three minor criteria include AR as predisposing heart condition, fever, and positive blood culture not met major criteria. Complication of IE including fistula and large vegetation is the indication for urgent surgery as stated in 2016 ESC guidelines of IE management. TAVB was occurred due to structural deterioration affected AV node or wide surgical manipulation. Urgent surgery and immediate permanent pacemaker implantation improved early outcome.
Conclusion: IE remains a serious problems which can lead to severe complication and even mortality. Thus, appropriate treatment should be started immediately to have better clinical outcome.

P1060 - THE PROTECTIVE ROLE OF HYPOXIA INDUCIBLE FACTOR IN CHRONIC HYPOXIA INDUCED RIGHT VENTRICULAR REMODELING

Lei Qi, Sen Zhang, Kai Ma, Qiumin Chen, Fengpu He, Shoujun Li
Fuwai Hospital, Peking Union Medical College, Center of The Cardiac Surgery, Beijing-China

Objective: Generally, chronic hypoxia (CH) is a crucial factor in the development of congenital heart disease (CHD), especially in cyanotic congenital heart disease (CCHD). Clinically, right ventricular remodeling (RVR) is one of the most important determinants of longevity with certain CHD patients and CH-induced RVR correlates with an even worse aftermath. So improved understanding of molecular pathways such as hypoxia inducible factor (HIF) that modifies RVR may provide important clues toward novel therapies for CHD and RVR treatment.
Methods: Adult male Wistar rats (4wk) were placed in a chamber maintained at 10% O2 for 4 weeks. The chamber was constantly flushed with room air to maintain low (<0.5%) CO2 concentrations. A Real-time control system monitored O2 levels and injected 100% N2 as needed to maintain 10% ± 0.5% O2. Normoxic animals were kept in normal air (21% O2). Every single day of the hypoxic exposure, rats were weighed and injected daily with Dimethyloxalylglycine (DMOG) (100 mg/kg i.p.), which was diluted in five times the volume of sterile saline, or injected with an equal volume of sterile saline. In addition, we explored the response of myocardial erythropoietin and its receptor to hypoxic exposure.
Results: By comparison between the experimental group and the control group, treatment with DMOG attenuated myocardial fibrosis, apoptosis, and oxidative stress, which lead to enhanced RV contractile function. As an endpoint of HIF-dependent cardioprotection, a novel pathway in which nuclear factor kappa B links HIF-1 transcription was defined.
Conclusions: DMOG is a competitive inhibitor of hypoxia-inducible factor (HIF)-hydroxylated prolyl hydroxylase and has been shown to play an important role against ischemia-reperfusion myocardial injury. And this study supports a role for HIF-1 stabilizers in the treatment of RVR by improving the level of expression of VEGF, HO-1 and Glut-1. In addition, RVR follows a linear relationship with increased RV afterload.

P1063 - DYSLEXIA SENSORY INTEGRATION AND ACADEMIC PERFORMANCE IN MEXICAN CHILDREN WITH CONGENITAL HEART DISEASE

Almudena March
Instituto Nacional De Pediatria, Congenital Heart Surgery, Mexico City-Mexico

The aim of this work is to find out if there is a relationship between Congenital heart disease(CHD), reading and writing difficulties (dyslexia), academic performance and sensory integration in children between the ages of 6 and 12 years old.
Materials and Methods: We had 30 participants : 15 children with Congenital Heart Disease, and 15 children with other pediatric diseases, but no chronic. The DST-J test for dyslexia detection in children, was administered to both groups and compared with their individual academic achievement. All the parents answered the Sensory Integration Questionnaire. None of the children had been diagnosed with a neurological or genetic disease. The DST-J test has been tested and validated with mexican children.
Results: For the data analysis we used the SPSS program and obtained a Pearson coefficient for each group and variables of the DST-J test related with the report card from the school in which each child is attending; specifically spanish, math and the general average of all the academic subjects. Concerning the Sensory Integration Questionnaire, 33.3% of the children with congenital heart disease have problems, compared with 13.3% of the other pediatric group. Regarding the incidence risk for dyslexia, the congenital heart disease group was 30% risk while the pediatric group 20%, with the same score for non risk children. The highest correlation between the predictive value for incidence of dyslexia and the subtests of the DST-J test was reverse digit, that was also highly correlated with the academic performance average marks. An intervention program was proposed considering the individual and group results. More studies need to be done comparing with normal population and bigger samples of children with complex congenital heart defects.

P1067 - CUSTODIOL SINGLE DOSE IS COMPARABLE TO BLOOD CARDIOPLEGIA FOR MYOCARDIAL PROTECTION IN CONGENITAL CARDIAC SURGERY

Jaime Alkon[1], Frank Scholl[2], Jianli Niu[3], Kevin Tayon[4], Steven Bibevsky[2]
Joe Dimaggio Children's Hospital, Pediatric Cardiology, Hollywood-United States[1]; Joe Dimaggio Children's Hospital, Pediatric Cardiac Surgery, Florida-United States[2]; JDCH, Pediatric Cardiac Surgery, Florida-United States[3]; JDCH, Pediatrics, Florida-United States[4]

Background: Custodiol used for myocardial protection due to single dose administration. We investigated single dose Custodiol myocardial protection versus intermittent blood cardioplegia in congenital cardiac surgery.
Methods: single-center retrospective review of prospectively collected data. One hundred twenty-seven patients <12 months undergoing biventricular congenital cardiac repair under cardiopulmonary bypass (CPB) were randomized to single dose Custodiol (n = 101) or blood cardioplegia (n = 26). Demographic, preoperative variables and postoperative (24 hours and discharge) echocardiography cardiac function were compared.
Results: same baseline patient's STAT mortality categories and score. Average CPB time (Custodiol: 90.7 ± 51.3 minutes vs blood cardioplegia: 82.6 ± 45.1 minutes, P = 0.46) and aortic cross-clamp time (Custodiol: 57.5 ± 33.1 minutes vs blood cardioplegia: 53.8 ± 34.3 minutes, P = 0.62) were similar. Patients on

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Custodiol were younger (101.3 ± 56.6 days), lower weight (4.8 ± 1.3 kg), compared with 143.6 ± 81.4 days and 5.4 ± 1.6 kg blood cardioplegia ($p < 0.05$). Left ventricle Ejection Fraction pre-operative (blood cardioplegia: 69.6 ± 14.6% vs. Custodiol: 73 ± 9.5%, $p = 0.15$), post-operative at 24 hrs (blood cardioplegia: 64.7 ± 10.6% vs. Custodiol: 65.1 ± 13.7%, $p = 0.89$), and post-operative at discharge (blood cardioplegia: 66.3 ± 8.5% vs. Custodiol: 67.7 ± 10.7% $p = 0.54$) were similar. The pre-operative right ventricle (RV) function by fractional area change (FAC) was lower in blood cardioplegia than Custodiol (blood cardioplegia: 43.4 ± 12.9% vs. Custodiol: 49.1 ± 8.2%, $p < 0.05$) although both normal (>40%).The FAC (24 hours and discharge) was 41.4 ± 12.7% and 41.9 ± 9.9% for blood cardioplegia, compared with 50.1 ± 9.1% and 50.9 ± 8.5% for Custodiol ($P < 0.001$).
Conclusions: Single dose Custodiol is convenient and as safe as blood cardioplegia for myocardial protection in congenital cardiac surgery with better RV function preservation.

P1072 - TRANSPOSITION OF GREAT ARTERIES WITH AORTOPULMONARY WINDOW (OPERATIVE VIDEO OF ARTERIAL SWITCH OPERATION)

Amit Mishra[1], Hemang Gandhi[2], Pranav Sharma[1], Hardik Patel[1]
UNMICRC, CVTS, Ahmedabd-India[1]; UNMICRC, Cardiac Anesthesia, Ahmedabad-India[2]

Background: Transposition of the great arteries with aorto-pulmonary window is a rare congenital cardiac anomaly. An arterial switch operation with repair of the aortopulmonary window is the preferred operation in this subset. As the tissue between the great arteries is missing, it is considered to be a complex operation. The purpose of the video is to demonstrate our simple yet highly effective surgical technique for arterial switch operation for this rare complex cardiac defect.
Methods: The video will demonstrate Arterial switch operation with minor modification in excision of branch pulmonary arteries is all that is needed in approaching this complex subset. The moiety of tissue resulting from the absence of an aortopulmonary window was naturally covered by the proximal and distal neoaortic flap tissue. The operative technique used in the 4 cases.
Results: Four patients of ages 28 days, 35 days, 40 days, and 6 months were successfully operated. One patient expired on postoperative day 21. In this case, advanced age of presentation, severe pulmonary artery hypertension, and sepsis possibly caused the death. The remaining 3 patients are off medication now and are being regularly followed up.
Conclusions: In our experience early diagnosis and an arterial switch operation have been crucial in getting a favorable outcome in planning of this complex congenital heart disease.

P1073 - A NEW SURGICAL TECHNIQUE FOR CLOSURE OF APICAL MUSCULAR VENTRICULAR SEPTAL DEFECT

Amit Mishra[1], Ritesh Shah[2], Hardik Patel[1], Nilesh Oswal[3]
UNMICRC, CVTS, Ahmedabad-India[1]; UNMICRC, Cardiac Anesthesia, Ahmedabad-India[2]; UNMICRC, Pediatric Cardiology, Ahmedabad-India[3]

Objective: Ventricular septal defect (VSD) is among the most common congenital heart diseases encountered in pediatric cardiac patients. Apical muscular VSD constitutes nearly 2% of defects, which may or may not be associated with other congenital heart defects. The purpose is to present our innovative and simple surgical technique using custom-made low-profile polytetrafluoroethylene (PTFE) single disc device for closing multiple apical muscular and isolated apical muscular VSD.
Method: Between January 2010 and July 2016, 34 patients with isolated or multiple apical muscular VSDs with or without associated heart diseases underwent operation at our institute. The apical VSD was closed using our custom-made low-profile single disc polytetrafluoroethylene device. The operative technique and the technique used to prepare the single disc device will be presented.
Results: Thirty four patients of ages ranging from 3 months to 8 years underwent operation over 6 years. One 8-month-old patient with transposition of the great arteries with multiple VSDs died after 35 days due to severe pulmonary artery hypertension and sepsis. Another newborn infant with infracardiac total anomalous pulmonary venous connection with a 4-mm apical VSD also died after 3 days because this VSD could not be identified. All other patients are doing well on follow-up.
Conclusions: The technique described by us has the advantage of apical single/multiple VSD closure through the left ventricle without left ventriculotomy. Our technique is simple and cost-effective.

P1074 - THREE DIMENSIONAL PRINTING MODEL IN DOUBLE OUTLET RIGHT VENTRICLE UTILITY OF PATIENT SPECIFIC PATCH BAFFLE FOR INTRAVENTRICULAR REPAIR

Ignacio Juaneda[1], Ernesto Juaneda[2], Hector Diaz[1], Victor Defago[3], Santiago Garlot[4], Gabriel Massano[4], Javier Courtis[5], Alejandro Peirone[6], Sergio Luchino[7]
Hospital De Niños., Congenital Heart Surgery., Cordoba-Argentina[1]; Hospital De Niños., Pediatric Cardiology., Cordoba-Argentina[2]; Hospital De Niños., Pediatric Surgery and Biomodel Unit., Cordoba-Argentina[3]; Hospital De Niños - Universidad Nacional De Cordoba., Biomodel Unit., Cordoba-Argentina[4]; Instituto Oulton, Medical Diagnostic Imaging Center., Cardiology., Cordoba-Argentina[5]; Hospital De Niños, Cordoba., Pediatric Cardiology., Cordoba-Argentina[6]; Instituto Oulton, Medical Diagnostic Imaging Center., Radiology., Cordoba-Argentina[7]

Background: Three-dimensional (3D) engineered replicas of different anatomical structures have been used extensively in different fields of medicine over the past years and are rapidly gaining interest in congenital heart surgery for surgical planning. We report a 6 year old patient with double outlet right ventricle, subtype Fallot, who underwent biventricular surgical repair with intracardiac baffle, right ventricle outflow tract augmentation and pulmonary valve comisurotomy after surgical planification with assistance of a 3D printed heart and patch model.
Material and Methods: Transthoracic echocardiogram, cardiac catheterization and computed tomography angiography (CTA) with 3D reconstruction of intracardiac anatomy were performed to plan surgical strategy for repair. Subsequently, 3D heart model and virtually created baffle patch were printed to asses repair suitability and strategies of baffle construction. Both the 3D printed heart and patch model were sterilized for intraoperative use to precisely cut the Dacron patch for baffle construction for intraventricular repair.
Results: The 3D heart model accurately depicted the ventricular septal defect position (VSD) relative to important adjacent structures, including the outflow tracts, aortic and tricuspid valves. Virtual planning, simulation and 3D printing of patch model were useful for Dacron patch trimming for baffle construction. Post-operative predischarge transthoracic echocardiogram revealed appropriate VSD baffling, without obstruction.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Three-dimensional printed heart model of the intracardiac anatomy and patch simulation and printing using CTA data can provide valuable information for preoperative planning in DORV subtype Fallot repair. 3D printed patch templates are useful to simplify and increase accuracy for complex procedures.

P1075 - EMPOWERING THROUGH EDUCATION: SINGLE VENTRICLE CONSIDERATIONS FOR NON CARDIAC PROCEDURES

Angela Hartley[1], Sara Holst[1], Ram Kumar Subramanyan[2], Usha Desai[3]
Children's Hospital Los Angeles, Cardiac Operating Room, Los Angeles-United States[1]; Children's Hospital Los Angeles, Cardiothoracic Surgery, Los Angeles-United States[2]; Mission Viejo Hospital, Cardiac Operating Room, Mission Viejo-United States[3]

Each year in the United States, 1 in 20,000 live births results in an infant born with complex single ventricle disease1. Surgical palliation of these defects usually involves three procedures. The first performed soon after birth, second at about six months and the third by three years. With advances in their management, many children are surviving beyond the third stage of palliation. Such an increase in life expectancy has resulted in an additional need for non-cardiac interventions including PICC lines, GI, ENT and radiologic procedures. The operating room nurse requires additional understanding of the physiologic and anatomic differences in patients with single ventricle physiology to maintain safety during non-cardiac surgical procedures. The objective is to empower the nurse through education to utilize their critical thinking skills. To achieve optimal safety, this education will aid in the integration of single ventricle considerations with high quality nursing standards. Increased knowledge and awareness will provide the nurse with confidence to administer individualized care to ensure a safe patient outcome.

P1086 - SINGLE VENTRICLE PALLIATION AMONG DEVELOPING WORLD CONGENITAL HEART SURGERY PROGRAMS A REPORT FROM THE INTERNATIONAL QUALITY IMPROVEMENT COLLABORATIVE

David Schidlow[1], Kimberlee Gauvreau[2], Km Cherian[3], Xinwei Du[4], Mahesh Kappanayil[5], R Krishna Kumar[5], Ana Miriam Lenz[6], William Novick[7], Craig Sable[1], Kathy Jenkins[2]
Children's National Health System, Children's National Heart Institute, Washington DC-United States[1]; Boston Children's Hospital, Cardiology, Boston-United States[2]; Frontier Lifeline Hospital, Cardiothoracic Surgery, Chennai-India[3]; Shanghai Children's Medical Center, Thoracic and Cardiovascular Surgery, Shanghai-China[4]; Amrita Institute of Medical Sciences and Research Centre, Pediatric Cardiology, Kerala-India[5]; Juan P. Garrahan Pediatric Hospital, Critical Care Medicine, Buenos Aires-Argentina[6]; University of Tennessee Health Science Center and William Novick Global Cardiac Alliance, Surgery, Memphis-United States[7]

Objectives: Surgical care for congenital heart disease in the developing world is increasingly available. We describe patient characteristics, surgeries, outcomes, and risk factors for mortality among patients undergoing single ventricle palliation (SVP) procedures in this setting.
Methods: We identified SV diagnoses and Glenn or Fontan operations from a multicenter developing world database (32 programs in 20 countries) in 2010-2014 collected for quality improvement purposes. Clinical information and outcomes were summarized for each procedure. Multivariate models were used to identify risk factors for in-hospital mortality.
Results: Among 2,543 cases, there were 5.2% Stage 1 (S1), 5.9% pulmonary artery band (PAB), 7.2% systemic-to-pulmonary shunt (SPS), 26.5% Fontan, and 53.4% Glenn. Two-thirds had SV diagnoses: 19.8% tricuspid atresia, 16.5% double-inlet ventricle, 5.9% hypoplastic left heart syndrome, and 5.9% pulmonary atresia/intact ventricular septum. One-third had potential 2 V anatomy, including 14.0% double-outlet right ventricle and 9.1% transposition of the great arteries. SVP surgeries represented <1-15.6% of a program's congenital heart surgical volume. Overall survival was 89.3%, but mortality was considerable among initial palliations (S1 51.5%, SPS 24.6%, PAB 12.0%). In contrast to developed countries, a large proportion (61.3%) of initial palliations (S1, SPS, PAB) were performed after 1 month of age, and malnourishment and infections were common among them (47.0% and 19.8%, respectively). In addition to type of surgery, independent risk factors for death included age (≤ 30 days odds ratio (OR) 2.7, 31 days-1 year OR 1.9, $p < 0.005$), major medical illness (OR 2.2, $p = 0.003$), major non-cardiac structural anomaly (OR 2.1, $p = 0.009$), and low weight or body mass index for age (OR 1.8, $p < 0.001$).
Conclusions: We report outcomes from SV procedures performed in developing word settings, including strategies to perform Glenn or Fontan procedures in complex 2 V patients. Surgeries in neonates were rare, and malnutrition was common and increased the risk of death.

P1095 - UNUSUAL PRESENTATION OF AORTIC ARCH ANOMALY IN MONOZYGOTIC TWINS

Ramiro Marcos Pellicciari, Andres Javier Rosso, Mariana Alejandra Lopez Daneri, Hyon Ju Choe, Manuel Garrido, Pablo Ariel Navarro, Nicolas Vernetti, Pablo Morgillo, Willy Conejeros Parodi
Hospital De Niños Ricardo Gutierrez, Cardiovascular Surgery, Buenos Aires-Argentina

Anomalous origin of the innominate artery from the pulmonary artery is an extremely rare congenital heart disease that has been scarcely reported. Twin number 1, (11 month-old), presented with significant asymmetry in upper left side of the body, cervical hemivertebrae, scoliosis, and inspiratory and expiratory stridor. A two-dimensional ultrasonography and color doppler evidenced dilated left cavities without intra-cavitary pathology, right aortic arch and a continuous flow vessel communicating left subclavian artery with the pulmonary artery. Multislice CT angiography with 3D reconstruction demonstrated a right aortic arch and anomalous innominate artery emerging from the trunk of the pulmonary artery, and hypoplastic ipsilateral internal carotid artery resulting in an asymmetric intracranial flow. The angiographic procedure revealed significant circulation steal from the pulmonary artery trunk to the innominate artery resulting in a decrease on the left side cerebral blood flow. In twin number 2, an echocardiogram showed right aortic arch, severe stenosis at the origin of the left pulmonary artery with a gradient of 50 mmHg. CT angiography confirmed right aortic arch causing compression of the right main

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

bronchus, causing an upper lobe chronic atelectasis, and left pulmonary artery with significant stenosis in the origin and abnormal length, with unapparent upper lobe branch. In twin number 1, resection of the left innominate artery with end-to-side anastomosis to the aortic arch and aortopexy was performed. In twin number 2, left pulmonary artery augmentation with pericardium patch and aortopexy resolved the chronic atelectasis. Both patients had good clinical outcome.

P1106 - ANALYSIS OF LONG TERM OUTCOMES OF CHILDREN CONGENITAL HEART DISEASE COMPLICATED WITH SEVERE PULMONARY ARTERIAL HYPERTENSION AFTER SURGERY

Mengpei Cheng, Hong Gu, Qiangqiang Li, Chen Zhang, Dan Zhang, Wangui Zhao, Qian Liu
Anzhen Hospital, Pediatric Cardiology, Beijing-China

Purpose: To analyze the survival status of children out of indication and to discuss the indication through follow-up on children with severe pulmonary hypertension associated with unrestrictive left-right shunt congenital heart disease.
Methods: Hemodynamic data and other information are collected from children with severe pulmonary arterial hypertension associated with congenital heart disease and treated in Anzhen hospital from January 2005 to June 2016. The survival analysis and log-rank test are executed as well as ROC curve.
Results: The object of observation is 59 children (aged 8.4 ± 5.2 years), 27 males and 32 females included, with major cardiac malformations of unrestrictive left-right shunt congenital heart disease, and follow-up time of 4-127 months (mean 69.3 ± 33.5 months). 12 children belong to Group PVRI $<$ 6 wood*U*m2 (6 male and 6 female), 3 lost to follow up, and none patient with postoperative PAH. Comparatively, 47 patients belong to Group PVRI $\geq$ 6wood*U*m2 (21 male and 26 female), 15 lost to follow up, and most of whom still suffered pulmonary arterial hypertension (one of them died 10 months after surgery) except 4 patients. According to postoperative living quality, the prognosis of Group PVRI $\geq$ 6wood*U*m2 with the rate of no positive event 86.6% in 3-year, 79.2% in 5-year and 22.5% in 10-year was significantly worse than group PVRI $<$ 6wood*U*m2 (Log-rank test $p = 0.0496$). Moreover, PVRI may further rise if surgeries are operated on the children out of indication. ROC curve demonstrates that PVRI is a sensitive indicator to predict post-operative pulmonary arterial hypertension(AUC 0.90), with the sensitivity of 84.2%, the specificity of 80.0%, as the boundary point of PVRI 8.15 wood*U*m2.
Conclusion: 1. long-term surgical outcomes is better in Group PVRI $<$ 6wood*U*m2 than in Group PVRI $\geq$ 6wood*U*m2. 2. PAH may progress in long-term post-operative follow-up if PVRI is too high before surgery. 3. Radical surgery is not recommended when PVRI is higher than 8.15 wood*U*m2.

P1109 - ACQUIRED VON WILLEBRAND SYNDROME IN INFANTS WITH AORTOPULMONARY SHUNT

Gesa Wiegand[1], Vanya Icheva[2], Ulrich Budde[3], Michael Hofbeck[2]
University Children's Hospital, Pediatric Cardiologyl, Tuebingen-Germany[1]; University Children's Hospita, Pediatric Cardiologyl, Tuebingen-Germany[2]; Medilys Laborgesellschaft Mbh, Hemostaseology, Hamburg-Germany[3]

Background: The acquired von Willebrand syndrome (aVWS) was first described in 1968 by Simone and colleagues in patients with autoimmune diseases. The aVWS is very rare in children, most frequently being described in connection with congenital heart defects including aortic stenosis, PDA, VSD and pulmonary hypertnsion. The aVWS often results in increased bleeding tendency. Until now, there are no reports describing aVWS in infants with aortopulmonary shunts.
Patients and Results: Between 07/15-07/16 we evaluated 11 infants younger than 3 months with univentricular hearts and aorto-pulmonary shunt (9x Blalock-Taussig-Shunt, 1x central aorto-pulmonlary shunt, 1x Sano-Shunt (from the systemic right ventricle to the pulmonary artery)) and tested for avWD. The shunt operation was performed between day 5.-180. (median 8d), the blood samples were collected between days 18-260 after surgery (median 32d). In all 11 patients we identified avWD with a reduction/loss of the largest VWF multimers.
Discussion: Despite the limited number of patients, we can presume that nearly 100% of the patients with aortopulmonary shunt present aVWS. Its pathogenesis is explained by the increased activation of the VWF under the influence of the turbulent flow within the shunt. The activated VWF is bound to its specific receptors located on the platelets and on the activated endothelial cells, and undergoes an ADAMTS 13 mediated proteolysis, which leads to the loss of large multimeres. First results show that the VWF swiftly normalizes shortly after suppression of the shunt dependent lung perfusion and switching to a cavopulmonary (Glenn) connection.
Conclusions: So far none of our patients demonstrated an increased bleeding tendency in everyday life. However, we must consider this anomaly as a potential cause of increased blood loss during cardiac catheterizations and operations. Knowledge of the existence of an avWS is therefore necessary for introduction of the replacement therapy with FVIII/VWF products.

P1112 - MONOCUSP VALVE PLACEMENT DURING COMPLETE REPAIR OF TETRALOGY OF FALLOT WITH TRANSANNULAR PATCH DOES NOT HAVE BENEFITS AT 1 YEAR FOLLOW UP

Rohit Loomba[1], Nikki Singh[1], Todd Gudausky[1], Peter Kouretas[1], Michael Mitchell[2]
Children, Pediatric Cardiology, Milwaukee-United States[1]; Children, Pediatric Cardiolgoy, Milwaukee-United States[2]

Background: A monocusp valve (MV) may be placed in the right ventricular outflow tract (RVOT) during complete repair of tetralogy of Fallout (TOF) using a transannular patch (TAP). There is limited data regarding outcomes of those with a MV and no data directly comparing those with and without a MV. This study compares 1-year follow-up data of children having undergone complete repair of TOF utilizing TAP with and without MV.
Materials and Methods: Children who underwent complete repair of TOF using TAP at the Children's Hospital of Wisconsin between the years 2000 and 2016 were identified. Clinical and surgical data was collected. Echocardiographic data from the pre-operative period, at time of discharge, and 12 months after repair was collected. Clinical, surgical, and echocardiographic data was then compared between those with and without monocusp.
Results: A total of 48 patients were included in this analysis, 30 (63%) with MV. There was no difference in preoperative characteristics. Peak RVOT gradient was greater in those with a MV (82.1 vs 67.0 mmHg, $p = 0.007$) although no difference was noted in preoperative PI. MV was surgeon dependent. Bypass time, cross clamp time, extubation in the operating room, and chest closure did not differ. Duration of mechanical ventilation, chest tube drainage, or postoperative hospital stay did not differ. Those without a MV were more likely to have moderate or severe PI at

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

the time of discharge (83% vs 23%, p = 0.001) although there was no difference in peak RVOT gradient. At 1 year follow-up there was no longer a difference in PI and there was no difference in peak RVOT gradient. Need for reintervention and mortality at 1 year were also similar.
Conclusion: MV does not decrease PI, reintervention, or mortality at 1 year follow-up. A larger study with longer follow-up is warranted.

P1116 - COMPLETE REPAIR OF TETRALOGY OF FALLOT IN THE NEONATAL VERSUS NON NEONATAL PERIOD A META ANALYSIS

Rohit Loomba, Matthew Buelow, Ronald Woods
Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-United States

Background: The surgical intervention of tetralogy of Fallot has evolved from a palliative intervention to a goal of complete repair. Optimal timing for complete repair, however, is not clear. For those who are asymptomatic, delayed complete repair in the first year of life is reasonable. For those who are symptomatic it is unclear if a staged palliation, including a neonatal shunt followed by complete repair outside of the neonatal period or complete repair within the neonatal period is preferable. We conducted a meta-analysis comparing neonatal and non-neonatal repair.
Materials and Methods: Several databases were queried to identify studies comparing neonatal and non-neonatal repair for tetralogy of Fallot. Manuscripts were reviewed for quality and bias with favorably scored manuscripts being included in the final analysis. A meta-analysis was conducted using the Mantel-Haenszel approach. Several perioperative and postoperative variables were compared.
Results: A total of 8 studies with 3,858 patients were included in the analysis. Of these patients, 19% underwent neonatal complete repair. Those who underwent neonatal complete repair had longer intensive care unit stays and longer total hospitalization. Neonatal repair was also associated with increased likelihood of need for transannular patch, delayed sternal closure, significant postoperative arrhythmias, and mortality.
Conclusion: Neonatal complete repair of tetralogy of Fallot is associated with increased morbidity and mortality. For those who are asymptomatic, complete repair should be deferred until outside of the neonatal period.

P1118 - TIMING OF FONTAN COMPLETION IN CHILDREN WITH FUNCTIONALLY UNIVENTRICULAR HEARTS AND ISOMERISM THE IMPACT OF AGE WEIGHT AND PRE FONTAN ARTERIAL OXYGEN SATURATION

Rohit Loomba[1], Peter Frommelt[1], Robert Anderson[2], James Tweddell[3]
Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-United States[1]; Newcastle University, Pediatric Cardiology, Newcastle Upon Tyne-United Kingdom[2]; Cincinnati Children's Hospital, Pediatric Cardiology, Cincinnati-United States[3]

Background: Isomerism, or heterotaxy, impacts morbidity and mortality after various stages of univentricular palliation. Timing of Fontan completing in these patients based on preoperative factors has not been investigated previously. The aim of this study was to determine the impact of preoperative factors on various outcomes including length of hospital stay and duration of chest tubes.
Materials and Methods: A cross-sectional study was conducted. Patients with isomerism having undergone Fontan at the Children's Hospital of Wisconsin between 1998 and 2014 were identified. Preoperative, operative, and postoperative data was collected on these patients. Linear regression analysis was conducted to determine preoperative characteristics associated with various postoperative outcomes. Receiver operator curve analysis was also performed to determine the sensitivity and specificity of age and pre-Fontan arterial oxygen saturation in predicting increased length of hospitalization and increased duration of chest tubes.
Results: Younger age and lower pre-Fontan arterial oxygen saturation were associated with increased length of hospitalization while younger age, lower pre-Fontan arterial oxygen saturation, interrupted inferior caval vein, and worse pre-Fontan atrioventricular valve regurgitation were associated with increased length of chest tubes.
Conclusions: Age, arterial oxygen saturation, pulmonary arteriovenous malformations, interruption of the inferior caval vein, and atrioventricular valve regurgitation should all be taken into consideration when timing Fontan completion in patients with isomerism. Arterial oxygen saturations between 82 and 84% with an approximate age of 3 years appear to be a time at which it is reasonable to consider Fontan in patients with isomerism.

P1121 - ARTERIAL SWITCH SURGERY A 4 YEAR EXPERIENCE OF A SMALL CARDIAC CENTER IN BRAZIL

Karla Loureiro Loss[1], Juliana Pacheco[2], Danielle Rocha Lopes[1], Ernani Vassoler Rodrigues[3], Rafael Aon Moyses[4], Isabela Salgado[1], Carla Del Caro[1], Roberto San Thiago Pereira[1], Vitor Torres[1], Sonia Andrade Rabello[1]
Hospital Infantil E Maternidade Dr Alzir Bernardino Alves, Pediatric Cardiology, Vila Velha-Brazil[1]; Dresden International University, Health Care Sciences, Dresden-Germany[2]; University of São Paulo, Faculdade De Educação, São Paulo-Brazil[3]; Hospital Infantil E Maternidade Dr Alzir Bernardino Alves, Cardiac Surgeon, Vila Velha-Brazil[4]

Background/Hypothesis: The typical survival rate for infants with transposition of the great arteries (TGA) is greater than 90%. We aimed to evaluate the long term survival of all patients with TGA that underwent the arterial switch operation (ASO) at our small cardiac center in Brazil.
Material and Methods: Between April 2012 and October 2016, 28 consecutive patients who underwent ASO for TGA at Hospital Infantil e Maternidade Dr Alzir Bernardino Alves were included in this retrospective study. The median weight was 3.3 kg, median age 14.5 days, 21 were male and 7 female. Following parameters were evaluated: use or non-use of custodiol for cardioplegy, size of the post operative care team (small, 4 physicians or large, 8 physicians), simple TGA (TGA with intact ventricular septum) and complex TGA (TGA with ventricular septal defect or others anomalies) For statistics analisys were used the Kruskal-Wallis test, the Cox hazard proportion and Kaplan Meier curve.
Results: Overall mortality was 28.5% (8 patients), however, in the period after July 2014 we operated 18 patients with only one death (5.5%). The comparison between small team vs large team and between with versus without custodiol was statistically significant ($p < 0.05$), showing the improvement on mortality rate with the large team and with custodiol. Accordingly with Cox hazard proportion the non-admission of the custodiol represented a major risk factor to mortality ($p < 0.05$). Associated heart disease and coronary anomaly showed no significant difference for survival.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Analyzing the patient's death during the period, 5 occurred on the first 24 postoperative hours (PO), 2 in the first 5 days and 1 in the 14th PO. We have 20 live patients in clinical follow-up.
Conclusions: The observed survival rate was 71.5%, with significant improvement after the first 2 years. The increase of post operative team and the use of custodiol were the key to achieve the observed survival improvement.

P1122 - DETERIORATION OF FUNCTIONAL ABILITIES AND STROKE IN CHILDREN SURVIVING THE FONTAN PROCEDURE

M. Florencia Ricci[1], Billie-jean Martin[2], Ari Joffe[1], Gonzalo Garcia Guerra[1], Gwen Bond[1], Charlene Robertson[1]
University of Alberta, Paediatrics, Edmonton-Canada[1]; University of Alberta, Surgery, Edmonton-Canada[2]

Background/Hypothesis: Children surviving complex cardiac surgery are at risk for developmental delays. We hypothesized deterioration of functional abilities (DFA) is not uncommon after the Fontan procedure, and often due to stroke. Objectives: To determine the frequency of 1) DFA post-Fontan 2) post-Fontan stroke among those with and without DFA.
Materials/Methods: As part of The Western Canadian Complex Pediatric Therapies Follow-up Program (CPTFP), from 1996-2016, 187 children prospectively registered in the CPTFP underwent a Fontan operation at Stollery Children's Hospital. At age 2 and 4.5 years, surviving children received multidisciplinary assessment, and the Adaptive Behavior Assessment System-II general adaptive composite (GAC) was determined. DFA was defined as a 1 SD decrease in GAC in comparison to pre-Fontan scores. Stroke diagnosis was ascertained through retrospective chart review. Frequency of DFA and stroke are presented as percentage of assessed survivors. T-tests and chi-square tests compared groups.
Results: Results are obtained for 156/181 survivors (64% male, 52% classic hypoplastic left heart syndrome). DFA occurred in 38/156 (24.4%), and stroke occurred in 16/156(10.3%). Mean (SD) post-Fontan GAC in all children with stroke was 77.4 (22.3) vs. 89.6(18.7) in those without stroke ($p = 0.01$). Evidence of post-Fontan stroke was found in 9/38 (23.7%) of children with DFA, vs. 7/118 (6%) of children without DFA ($p = 0.002$). Mean (SD) GAC decline among children with DFA was greater in those with stroke [25 (9.6)] than in those without [20 (6)], though the difference was not statistically significant ($p = 0.16$).
Conclusion: Almost 25% of children surviving the Fontan procedure show DFA, which has major implications for their functioning later in life. Evidence of post-Fontan stroke is more commonly found among those with DFA; however, stroke is not the only event leading to DFA. The next step is to determine potentially modifiable predictors of DFA.

P1128 - IS THE PRESENCE OF END DIASTOLIC FORWARD FLOW SPECIFIC FOR A RESTRICTIVE RIGHT VENTRICULAR PHYSIOLOGY IN A REPAIRED TETRALOGY OF FALLOT

Yoshiki Mori[1], Tomotaka Murakami[1], Nao Inoue[1], Sachie Kaneko[1], Yasumi Nakashima[1], Masaaki Koide[2]
Seirei Hamamatsu General Hospital, Division of Pediatric Cardiology, Hamamatsu-Japan[1]; Seirei Hamamatsu General Hospital, Department of Cardiovascular Surgery, Hamamatsu-Japan[2]

Background: The presence of end-diastolic forward flow (EDFF) has been regarded as a r-RVP, but conflicting results have been reported regarding the effects of r-RVP on the clinical outcome in patients with r-TOF.
Objectives: We hypothesized that the EDFF by Doppler was not specific for the diagnosis of r-RVP.
Methods: Sixty-two consecutive patients aged 15.7 ± 11.6 years who underwent cardiac catheterization were studied. The patients were divided according to the presence of EDFF (group 1: EDFF + , group 2:EDFF-) and right ventricular (RV) size (group A: small RV, group B: large RV [> 150 ml/m2]). We compared clinical and hemodynamic variables between the groups.
Results: The EDFF with at least 3 consecutive and >30 cm/sec velocity was present in 23 of 62 patients (39.6%). Group 1($n = 23$) had higher right atrial pressure (RAP), pressure gradients between the RAP and pulmonary diastolic pressure (PDP), and atrial natriuretic peptide (ANP) levels than group 2. Four patients (17.4%) in group 1 and 89.7% in group 2 had a normal RAP range (a wave < 10 mmHg). There were no differences in the RV volume and ejection fraction (EF), left ventricular (LV) volume, LVEF, B-type natriuretic peptide (BNP) levels, cardiothoracic ratio, QRS duration and severity of pulmonary regurgitation (PR) between groups 1 and 2. Group A had a better RVEF, LVEF and smaller LV size than group B. The RAP in subgroup 1 A was higher than that in the other 3 subgroups. Subgroup 1B had a similar RAP as group 2, and had lower PDP and more severe PR than the subgroup 1 A.
Conclusions. Patients with the presence of an EDFF are associated with an increased ANP, but not BNP. The presence of EDFF may not be specific for r-RVP. A more accurate definition is necessary to determine how the r-RVP effects the clinical outcome in r-TOF.

P1137 - COMPARISON OF SEPTAL LEAFLET DETACHMENT VERSUS CHORDAL DETACHMENT TECHNIQUES IN CLOSURE OF HARD TO EXPOSE VENTRICULAR SEPTAL DEFECTS

Agnieszka Boron[1], William Decampli[2], Sukumar Suguna Narasimhulu[3], Mark Ruzmetov[2], Michael Obrien[2], Alicia Kube[2], Carlos Blanco[3], Kurt Piggott[3], Harun Fakioglu[3], Kamal Pourmoghadam[2]
University of Central Florida College of Medicine, Pediatric Cardiac Surgery, Orlando-United States[1]; Arnold Palmer Hospital for Children, Pediatric Cardiac Surgery, Orlando-United States[2]; Arnold Palmer Hospital for Children, Pediatric Cardiac Intensive Care, Orlando-United States[3]

Purpose: Different techniques have been used for exposure of ventricular septal defect (VSD) margins when there is crowding of the anatomy by tricuspid valve (TV) subvalvar apparatus. The aim of this study was to compare surgical outcomes, for the two techniques of TV leaflet detachment (LD) and the rarely described TV chordal detachment (CD) for hard-to-expose VSDs.
Methods: All patients undergoing transatrial VSD repair at our institution were identified from our database. Follow-up echocardiography and patient data were obtained from medical records. Between 1/2005-12/2015, 121 isolated perimembranous VSDs were repaired. Among these, 24 patients had LD, while 13 underwent CD, and 84 had regular VSD repair (reference group).
Results: There was no significant difference between the groups in age, weight, postoperative length-of-stay (LOS), inotropic score, genetic/syndromic abnormalities, pre- or postoperative gastric surgery, time-to-extubation, and discharge medication. The CPB and cross-clamp times were significantly higher in LD group, when compared with reference group (Table). Return to second CPB run occurred in 5 reference group patients, 1 LD, and no CD

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

patient; these differences were not significant. Two patients (reference group) required pacemaker insertion. No operative deaths occurred. Follow-up echocardiograms were available for 76 patients at a mean of 2.6 years (1 month-11 years). TV regurgitation was rated as none or trivial in 59 (78%) and mild in 17 (22%). There was no difference in presence of residual VSD, or degree of TV regurgitation amongst the three groups. There was no reoperation for TV regurgitation. Two patients (reference group) underwent reoperation due to residual VSD, 1 and 3 years after initial surgery.
Conclusions: Tricuspid valve LD and CD techniques provide a viable and safe alternative to closure of hard-to-expose VSDs while maintaining appropriate TV function. Their use in our series did not lead to increased TV dysfunction at midterm echocardiographic assessment.

Table 1. Comparison between septal and chordal detachment and the reference group.

Variables	CD group (N = 13)	LD group (N = 24)	Reference group (N = 84)	CD/LD (P value)	LD/ Reference (P value)	CD/ Reference (P value)
Age (median, IQR, d)	174 (117-575)	187 (128-590)	140 (87-199)	0.23	0.34	0.70
Weight (median, IQR, kg)	6 (4.9-9.6)	6 (4.4-11)	5 (3.9-6.7)	0.23	0.24	0.96
CPB (mean +/-SD, min)	108+/-23	115+/-29	102+/-33	0.42	0.04	0.30
CCT (mean +/-SD, min)	67+/-17	70+/-20	60+/-24	0.46	0.03	0.22
LOS (median, IQR, d)	5 (4-7)	5 (4-11)	5 (4-7.5)	0.81	0.71	0.95

CCT = cross clamp time, CD = chordal detachment, CPB = cardiopulmonary bypass, LD = leaflet detachment, LOS = postoperative length-of-stay.

P1139 - PREDICTING FEASIBILITY OF BIVENTRICULAR REPAIR IN UNBALANCED ATRIOVENTRICULAR SEPTAL DEFECT

Ignacio Lugones[1], Fernanda Biancolini[2], Ana De Dios[2], Biancolini Julio[2], German Lugones[3]
Elizalde Children Hospital, Cardiac Surgery, Buenos Aires-Argentina[1]; Elizalde Children Hospital, Pediatric Cardiology, Buenos Aires-Argentina[2]; Centre For Natural Sciences And Humanities, Federal University of Abc, Sao Pablo-Brazil[3]

Background: Unbalanced forms of atrioventricular septal defect continue to be challenging and present poor surgical outcomes. Echocardiographic indicators such as atrioventricular valve index, right ventricle/left ventricle inflow angle and size of the ventricular septal defect have been identified as relevant discriminators that may guide surgical strategy.
Methods: A new variable we called "indexed ventricular septal defect" is described, which reflects the size of the defect in relation to the atrioventricular valve diameter. We outline a geometrical description of the echocardiographic features of atrioventricular septal defect and derive an equation relating the new index with the atrioventricular valve index and the right ventricle/left ventricle inflow angle. In the light of that equation we discuss the interdependence between variables and employ data of the inflow angle presented in a study held by the Congenital Heart Surgeons' Society to set limits on the new index.
Results: For moderately unbalanced forms (modified atrioventricular valve index between 0.2 and 0.39), indexed ventricular septal defect can guide surgical decision-making: a) under 0.2, biventricular repair is strongly recommended; b) between 0.2 and 0.3-0.35, biventricular repair can be achieved depending on other factors; c) between 0.3-0.35 and 0.5-0.55, other strategies must be considered; and d) above 0.5-0.55, univentricular palliation must be followed.
Conclusions: Combined use of indexed ventricular septal defect and atrioventricular valve index can significantly narrow the grey zone of unbalance and guide surgical approach.

Table. Indexed VSD as a function of mAVVI and RV/LV inflow angle.

mAVVI/α	80°	90°	100°	110°	120°	130°	140°	150°	160°	170°
0.02	0.25	0.14	0.07	0.04	0.03	0.02	0.01	0.01	0	0
0.05	0.32	0.21	0.14	0.10	0.07	0.05	0.03	0.02	0.01	0

0.30	0.55	0.45	0.37	0.31	0.25	0.20	0.15	0.11	0.07	0.03
0.32	0.56	0.46	0.38	0.31	0.25	0.20	0.16	0.11	0.07	0.03
0.34	0.57	0.47	0.39	0.32	0.26	0.21	0.16	0.12	0.08	0.04
0.36	0.57	0.48	0.40	0.33	0.27	0.21	0.17	0.12	0.08	0.04
0.38	0.58	0.48	0.40	0.33	0.27	0.22	0.17	0.12	0.08	0.04

Different combinations of values of mAVVI and RV/LV inflow angle (α) are entered to obtain the respective inVSD in the uAVSD group. This number represents the size of the VSD indexed to the diameter of the AVV.

P1142 - PSEUDO ANEURYSM ERODING INTO THE CHEST WALL FOLLOWING AORTO PULMONARY SHUNT

Ashish Katewa[1], Balaswaroop Sahu[2], Yogesh Sathe[3]
Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiothoracic Surgery, Naya Raipur-India[1]; Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiac Anaesthesiology, Naya Raipur-India[2]; Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiology, Naya Raipur-India[3]

Background: Pseudo-aneurysms of ascending aorta,following surgery for congenital heart defects are exceedingly rare. Their usual location is at the aortic cannulation site. We present a first-ever case of pseudo-aneurysm following a central aorta-pulmonary shunt.
Material & Methods: An 11 year-old boy presented with acute onset pain and swelling near the sternal head of his right clavicle. Past medical history included a Tetralogy of Fallot (TOF) diagnosed in infancy, with central aorto-pulmonary shunt placement at age 6 years performed at another hospital. Computed Tomography delineated a large pseudo-aneurysm measuring 12X10 cm, arising from the ascending aorta and protruding under the upper end of sternotomy scar after eroding into the first rib, medial clavicular head and sternal manubrium. Emergency surgical correction was scheduled with a plan of concomitant repair of TOF.
Results: Cardiopulmonary bypass(CPB) was instituted using the right femoral artery and vein and cooling to 16 degrees C to achieve total circulatory arrest (TCA). Re-sternotomy was performed and the wall of pseudo- aneurysm was breached. The aorta-pulmonary shunt graft was found floating within the clots and altered blood. The defect in the ascending aorta measured 8X5 cm, and was repaired with a Polytetra fluroethylene (PTFE) patch. CPB was resumed after transferring the cannulae centrally, followed by complete intracardiac repair for TOF. The postoperative course was uneventful, requiring 12 hours of mechanical ventilation and hospital stay of 6 days.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: This is an extremely rare and previously unreported complication of a central aorta-pulmonary shunt. The aneurysm was contained by the surrounding structures initially, but increased in size gradually to erode into the chest wall. CPB using femoral cannulation, deep hypothermia and TCA is recommended to avoid fatal exsanguination during re-sternotomy for a large pseudo-aneurysm of ascending aorta.

P1167 - A NOVEL SYNTHETIC HYBRID CARDIOVASCULAR PATCH PROMOTES VIABLE TISSUE REGENERATION IN THE LARGE VESSELS

Shintaro Nemoto[1], Hayato Konishi[1], Ryo Shimada[1], Hideaki Yamada[2], Jun Sakurai[2], Atsuko Onishi[3], Kazuteru Kohno[3], Masaya Ito[3]

Osaka Medical College, Thoracic and Cardiovascular Surgery, Takatsuki-Japan[1]; Fukui Warp Knitting Co., Ltd., Production Development, Fukui-Japan[2]; Teijin Limited, New Healthcare Business Development, Hino, Tokyo-Japan[3]

Background/Hypothesis: Vascular wall regeneration has been attempted using various types of biodegradable materials containing stem cells, but the results have been disappointing. The aim of this study was to investigate whether vascular wall regeneration could be promoted by a unique synthetic cardiovascular patch (OFT patch).
Materials & Methods: The OFT patch is made with an extensible warp-knitted fabric composed of a combination of biodegradable (poly-L-lactic acid: PLLA) and non-biodegradable (polyethylene terephthalate: PET) yarn. The fabric is coated with gelatin to seal its porosity. The in vitro mechanical properties of the OFT patch were compared with those of commercial polytetrafluoroethylene (PTFE) and bovine pericardial patches. Part of the vascular wall of either the canine inferior vena cava (IVC) or descending aorta was replaced with an OFT patch. After 1, 3, 6, and 12 months, the patch was removed for histological examination.
Results: The OFT patch had excellent tensile strength, suture retention strength, and bending resistance that were equivalent to those of the two commercial patches. Furthermore, needle hole leakage from the OFT patch was far less than that from the PTFE patch. Microscopic examination revealed optimal tissue regeneration characterized by layered smooth muscle cells and collagen fibers induced in both the IVC and aorta after replacement. Interestingly, tissue connections developed across the OFT patch with neo-arterioles, along with disappearance of gelatin. There was a minimal inflammatory reaction, no calcium deposition on the patch yarn, and no aneurysmal or stenotic changes in patch-implanted regions.
Conclusions: The OFT patch had favorable mechanical properties and resulted in optimal tissue regeneration in the early stages after implantation in large vessels. Since the non-biodegradable portion is program-designed to expand to quadruple its initial size, the OFT patch would not interfere with vascular wall ingrowth as the biodegradable PLLA portion is absorbed.

P1171 - STAGED COMPLETE REPAIR WITHOUT HOMOGRAFT USE IN PATIENTS WITH PULMONARY ATRESIA–VENTRICULAR SEPTAL DEFECT AND MAJOR AORTOPULMONARY COLLATERAL ARTERIES

Akio Ikai[1], Junichi Koizumi[1], Ryoichi Kondo[1], Takayuki Hagiwara[1], Satoshi Nakano[2], Shin Takahashi[2], Kotaro Oyama[2], Hitoshi Okabayashi[1]

Iwate Medical University, Cardiovascular Surgery, Morioka-Japan[1]; Iwate Medical University, Pediatric Cardiology, Morioka-Japan[2]

Objective: Repairing pulmonary atresia–ventricular septal defect (PAVSD) and major aortopulmonary collateral arteries (MAPCAs) remains challenging, particularly without the use of a homograft. Here, we evaluated our surgical strategy, which consists of primary unifocalization with an autologous pericardial patch and staged complete repair using a handmade expanded polytetrafluoroethylene (ePTFE) tri-leaflet valve conduit.
Methods: Since 2007, eleven consecutive patients with PAVSD and MAPCAs underwent primary unifocalization. The median patient age and body weight were 7.3 months (2–116 months) and 7.3 kg (2.7–16.2 kg), respectively. All patients underwent primary unifocalization using tissue-to-tissue anastomosis. The central pulmonary artery was absent or diminutive in all cases; therefore, it was created using an autologous pericardial patch with a target diameter of at least 10 mm. The pulmonary blood flow source was established using a modified Blalock-Taussig shunt in 9 cases, a central shunt in 1 case and a right ventricle-pulmonary artery shunt in 1 case. The mean number of MAPCAs was 3.8.
Results: There was 1 operative death due to congestive heart failure after unifocalization. Post-unifocalization cardiac catheterization showed that the mean pulmonary artery (PA) resistance was 2.4 wood units and the mean PA pressure was 16.1 mmHg (13–24) under mean Qp/Qs = 1.05. Nine patients underwent staged complete repair within an average of 7.1 months after unifocalization. One patient is awaiting complete repair. The median body weight was 9.5 kg (6.8-17.6 kg). The median ePTFE conduit diameter was 16 mm (16–20 mm). The mean intraoperative right ventricle/systemic artery pressure ratio was 0.53 (0.4–0.71). Post-repair cardiac catheterization showed that the mean right/left ventricular pressure ratio was 0.58 (0.4–0.97).
Conclusions: Primary unifocalization was performed completely, even without a homograft. Acceptable right ventricular pressure was obtained. A sufficiently large handmade valve conduit to avoid early reoperation could be applied during the planned staged complete repair.

P1179 - PROPOSING GUIDELINES AND EVALUATION OF TWO STAGE ARTERIAL SWITCH AS A TREATMENT STRATEGY IN THE MANAGEMENT OF DELAYED PRESENTATION OF TRANSPOSITION OF THE GREAT ARTERIES WITH A REGRESSED LEFT VENTRICLE

Mohammad Asim Khan[1], Salman Ahmeald Shah[2], Faiz Rasool[1], Masood Sadiq[3]

The Children's Hospital, Paeds Cardiac Surgery, Lahore-Pakistan[1]; TH Children's Hospital, Paeds Cardiac Surgery, Lahore-Pakistan[2]; The Children's Hospital, Paeds Cardiology, Lahore-Pakistan[3]

Background and Objectives: Management of transposition of the great arteries with intact ventricular septum (TGA/IVS) is currently an arterial switch operation (ASO) performed in the first 2 weeks of life. Two stage ASO is one form of treatment in infants with TGA presenting late. But the guideline on how to train LV is not clear in literature.
Methods: From December 2009 to January 2016 total of 33 patients with TGAIVS presented late and were selected for a two stage ASO. Serial echocardiography was used to assess the increased thickness of LV posterior wall. A stage II ASO was done a few weeks later. Retrospective review of patient charts was done. Data was formulated into a structured database and statistical analyses were performed with the statistical package SPSS for Windows.
Results: 33 patients underwent Stage I. 10 patients underwent isolated PAB, 17 patients underwent PAB and BTS and in 6 patients PDA stenting was done. Stage I had an in hospital

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

mortality of 22%, while the interval mortality between both stages was 14%. Initial increased mortality was probably due to acute volume loading of the RV due to unrestrictive atrial communication, hence we modify to do PA band only in the presence of large ASD, and to shunt only selected patients. The mean interval between the two stages was 3 ± 1 weeks.16 patients have undergone a successful Stage II ASO. Stage II mortality was zero. All patients had remarkably rapid recoveries and short hospital (6 ± 2 days) stay.
Conclusion: Early experience indicates that in a developing country like Pakistan with a rapid two stage arterial switch is an acceptable treatment option. Patients who survived Stage I and the interval period have excellent results with Stage II.

P1180 - DIFFICULTIES AND POSIBLE SOLUTIONS IN ESTABLISHING PEDIATRIC CARDIAC CARE IN A DEVELOPING COUNTRY

Mohammad Asim Khan[1], Masood Sadiq[2]
The Children's Hospital, Paeds Cardiac Surgery, Lahore-Pakistan[1]; The Children's Hospital, Paeds Cardiology, Lahore-Pakistan[2]

Background: Establishment of pediatric cardiac services in developing countries is a major challenge. Once established, it is even bigger a challenge to cater for the needs of very large populations. In Pakistan with population of 190 millions, about 4000 babies require urgent open heart surgery each year.
Objectives: To analyze difficulties and propose solutions, in establishing a pediatric cardiac program in a developing country.
Methods: The Children's Hospital Lahore is the only public sector children's hospital in the country where we established a congenital cardiac program and neonatal interventions and open-heart surgeries are being performed. It is a multidisciplinary hospital, with all the support facilities. In a developing country, there are numerous challenges like paucity of centers and personnel, limited resources, overcrowding, illiteracy, and infection control.
Results: Pediatric cardiac program at CH started in 1999. The problems faced include recruitment of trained staff and equipment and lack of resources for ongoing financial needs. So far we have performed surgery on >5000 children, with an overall mortality of 7% in the year 2015. The cost for an open heart surgery is about US $1200 and for a closed heart surgery is US $250. This is still too much for a poor patient. The current waiting list for routine open heart surgery is over 3 years.
Conclusions: Despite improved infrastructure and skills, the logistics, affordability, staffing, late presentation, nutritional status, infection, and unfavorable economics continue to negatively influence the overall results. With continued determination and philanthropic support, establishment of pediatric cardiac program is still possible in a developing country.

P1197 - MANAGEMENT OF PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM FOR OLDER PATIENTS A SINGLE CENTER EXPERIENCE FROM CHINA

Xiaomin He, Jinghao Zheng, Zhongqun Zhu, Botao Gao, Guocheng Shi, Huiwen Chen, Zhiwei Xu, Jinfen Liu
Shanghai Children's Medical Center, Shanghai Jiao Tong University School of Medicine, Department of Pediatric Cardiothoracic Surgery, Shanghai-China

Background: Despite surgical treatment of the pulmonary atresia with intact ventricular septum (PAIVS) has been improved, the clinical outcomes of PAIVS patients with older ages were still deficient with related studies. In the present study, we summarized the experiences and evaluated the clinical outcomes of PAIVS patients with ages over 6 months for the first surgery in our heart center.
Methods: Between January 2006 to June 2016, 45 cases of PAIVS with ages over 6 months finished definitive repairs were reviewed. The patients were received definitive repairs, including biventricular repair, 1.5 ventricular repair and univentricular palliation without or with initial intervention. Median follow-up time was 5.3 years (range, 0.5 to 10.6 years), and survival, risk factors for death, and clinical status after definitive repairs were assessed.
Results: A total of 3 patients died (6.7%, 3/45) during follow up. Fontan procedure made up a large proportion of the older PAIVS patients (42.2%, 19/45), while only a few patients received biventricular repair (22.2%, 10/45) since the growth potential of RV was limited in the older patients. The medium-term (10 years) survival rates of biventricular, 1.5 ventricular and univentricular palliation were 100.0%, 93.3%, and 81.2%, respectively ($P > 0.05$). Moreover, multivariate analysis indicated that there were no independent predictors had the statistical difference as risk factors for death because of the low mortality in the present study. At latest follow-up, most patients had well clinical status after definitive repairs, while re-operation rate was 10.0% (1/10) after biventricular repair, 14.3% (2/14) after 1.5 ventricular repair and 20.0% (3/15) after univentricular palliation.
Conclusion: Favorable clinical outcomes of older PAIVS patients that managed with different definitive repairs were found in our retrospective study. In addition, the choice of optimal definitive repairs for the older PAIVS patients could also be achieved with a low mortality.

P1199 - SURGICAL OUTCOME OF CONGENITAL HEART DEFECTS WITH SEVERE PULMONARY HYPERTENSION IN INFANTS

Khurshid Saitazizov[1], Bakhtiyor Khalmukhamedov[2], Botir Ismatov[2], Qosim Zaripov[3], Nariman Islamov[2]
Tashkent Pediatric Medical Institute/ Republic Specialized Scientific Center of Pediatrics, Cardiac Surgery, Tashkent-Uzbekistan[1]; Tashkent Pediatric Medical Institute, Cardiac Surgery, Tashkent-Uzbekistan[2]; Republic Specialized Scientific Center of Pediatrics, Anaesthesia Dpt, Tashkent-Uzbekistan[3]

Background: Congenital heart diseases with large left-to-right shunt often complicated with severe pulmonary hypertension. It is an important determinant of morbidity and mortality in patients without educate surgical treatment especially in infants.
Methods: one hundred forty five patients with congenital cardiac septal defects and pulmonary arterial hypertension operated to close their septal defects. All the patients checked by Chest X-ray, EchoCG, ECG, selectively performed the cardiac catheterization and lung biopsy. Before and after surgery the PA pressure was compared to systemic by needle puncture measurement.
Results: Thirty-four patients died in the hospital after operation. 6 of them were under 6 months and others above 1 year. There were no later deaths in follow-up. Hemodynamic changes after operation included a significant decrease in pulmonary artery pressure (mean pulmonary artery pressure, 28.3 ± 2.4 mm Hg versus 58.45 ± 1.69 mm Hg before repair). The follow-up period was from 3 months to 4 years (mean 1.3 ± 0.6 years).
Conclusion: Studies from developed countries have shown that in term infants, young age is not a risk factor for adverse postoperative outcome after surgical closure of septal left-to-right defects. The main reason of the positive result is educate time for surgery and the level of cardiology service diagnostic developing. The data presented in this study show that operations to close cardiac septal defects in the presence of severe pulmonary hypertension are effective, but must done during first 6 monthes.

P1206 - CASE REPORT PRIMARY REPAIR TETRALOGY OF FALLOT AND MAJOR AORTO PULMONARY COLLATERAL ARTERIES WITH SUSPECTED NOONAN SYNDROME IN DR. SOETOMO TEACHING HOSPITAL SURABAYA INDONESIA

Erdyanto Akbar, Arief Rakhman Hakim, Heroe Soebroto, Paul Tahalele, Puruhito Puruhito
Soetomo General Hospital, Airlangga University, Cardiothoracic and Vascular Surgery, Surabaya-Indonesia

Background: Tetralogy of Fallot (TOF) is a complex congenital heart disesase including four abnormalities; ventricular septal defect (VSD), pulmonary stenosis (PS), right ventricular hyperthrophy (RVH), and overiding aorta. Cyanotic heart defect can develop Aorto-pulmonary collateral (APCA) to supply underperfused pulmonary bed. Genetic syndromes can occur in 20% of patients with TOF. Noonan syndrome is a common genetic disorder characterized by facial anomalies, congenital heart defect, short stature, webbed neck, chest deformities and cryptochidism. In developing country, diagnosed genetic syndromes associated with heart defect hasn't been covered by health insurance, yet the outcome of the primary repair still unknown.
Objective: To report the outcome primary repair tetralogy of fallot and major aorto-pulmonary collateral arteries with suspected Noonan Syndrome.
Case Report: A 11 years old boy admitted with cyanosis since birth, dispnea on effort, growth delay, learning problems, scoliosis, micropenis, hypertelorism, exopthalmos, facial dysmorphism, cryptochidism, and major aorto-pulmonaries collaterals. The patient undergone an echocardiographic study and it shows VSD malalignment with overiding aorta 48%, critical pulmonary stenosis, size of pulmonary arteries is favorable for primary repair. Cardiac

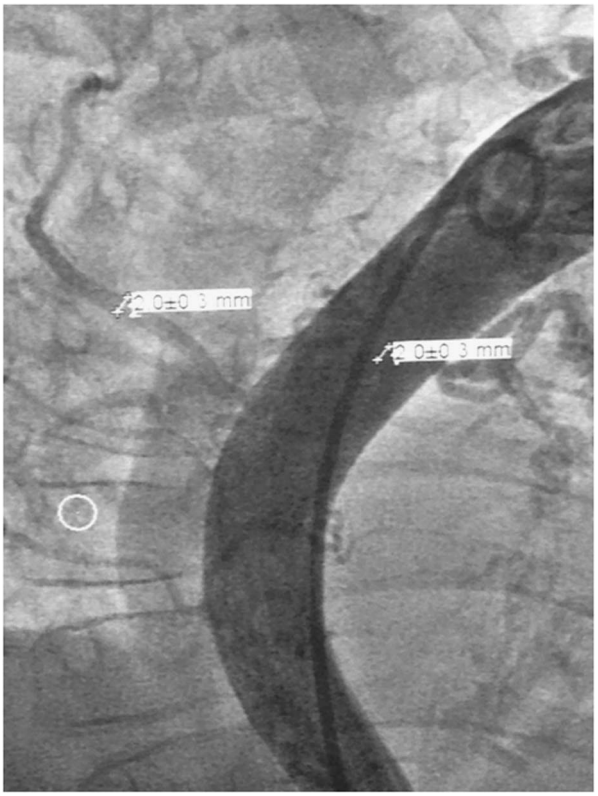

Figure 2.

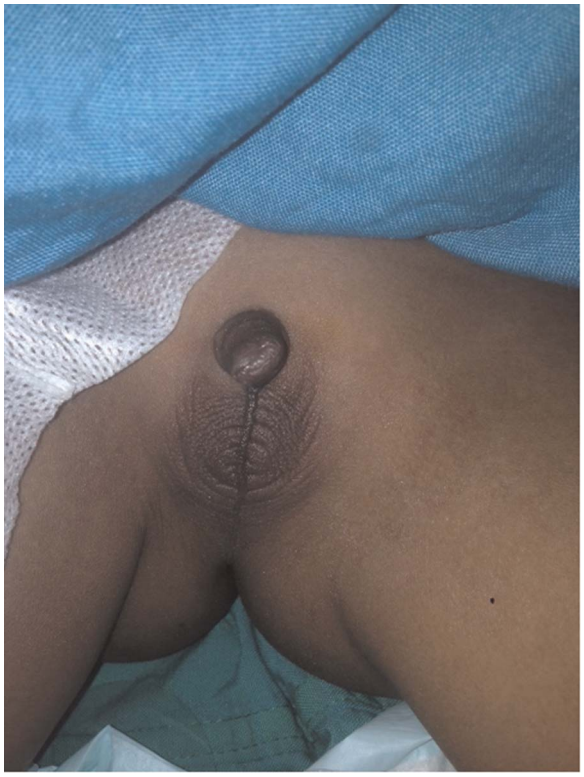

Figure 1.

Figure 3.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

catheterization shows classic fallot with normal coronary arteries and major aortopulmonary collateral arteries (MAPCA) arising.
Surgical Technique: The patient underwent percutaneous coil embolization just before surgery and then median sternotomy was done and aortic cross-clamping are achieved, right atriotomy was performed and there provided exposure to malalignment VSD. A longitudinal pulmonary arteriotomy is made to expose infundibular stenosis. Infundibulectomy was performed and reconstruct MPA with pericardial patch. The VSD is closed using PTFE patch. The patient transferred to ICU afterward.
Result: Post operative echocardiography shows good outcome, and the patient was discharged after 15 days.
Conclusion: Primary Repair TOF with MAPCAs and suspected Noonan Syndrome was done successfully.

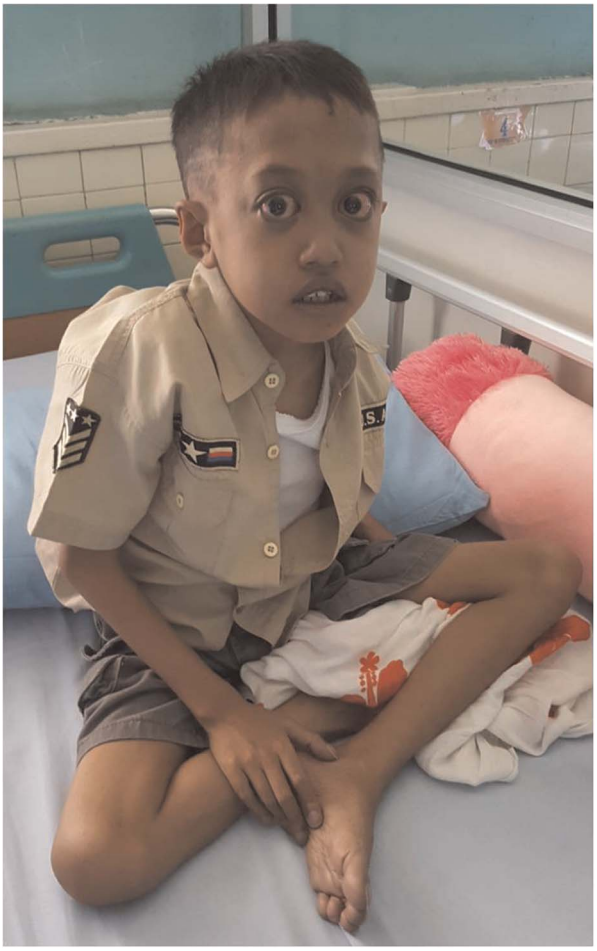

Figure 4.

P1220 - OUTCOMES OF HEPATIC VENOUS REDIRECTION FOR PULMONARY ARTERIOVENOUS MALFORMATIONS FOLLOWING KAWASHIMA PROCEDURE IN LEFT ATRIAL ISOMERISM

Mariko Kobayashi, Toshihide Asou, Yuko Takeda, Noritaka Ota, Hiroshi Okada, Yasuko Onakatomi, Hidetsugu Asai
Kanagawa Children's Medical Center, Cardiovascular Surgery, Yokohama-Japan

Background: The development of pulmonary arteriovenous malformation (PAVM) after Kawashima procedure (TCPS) in left atrial isomerism (LAI) frequently induces desaturation, and then the redirection of hepatic vein to the pulmonary circulation (TCPC) improves oxygen saturation (SO2) with PAVM's regression. However, the degree of the improvement has not been unclearly delineated, and in addition, the effective timing of the conversion to TCPC remains unclear. The aim of this study is to examine the changes in SO2 and the occurrence of PAVM after TCPS and to propose the appropriate timing of the TCPC conversion.
Methods: Twenty-two patients with LAI achieving TCPC were reviewed. Antegrade pulmonary flow was completely interrupted during surgery of TCPS. Mean age at TCPS and TCPC were 6.6 ± 3.7 months-old and 1.5 ± 0.3 years-old, respectively. The ages at TCPS and TCPC of the patients with LAI are not different from those of patients with other types of univentricular physiology in our institute. PAVM was diagnosed by contrast echocardiography, catheterization or pulmonary angiographic findings as follows; 1) contrast agent return into the left atrium within 2-4 beats, 2) spongy pattern of pulmonary vasculartur, and 3) less than 92% of SO2 in pulmonary venous blood. Data of SO2 were collected at discharge from hospital, visit to outpatient clinic after TCPS, at catheter examinations before TCPC, and 1 year later after TCPC.
Results: SO2 decreased from $88.5 \pm 4.5\%$ to $79.1 \pm 10.1\%$ during the interval of 8.4 ± 4.2 months after TCPS and conversely increased to $92.3 \pm 3.7\%$ following conversion to TCPC ($p < 0.01$). The occurrence rate of PAVM was 77.3% about 8 months after TCPS and successfully decreased to 38.1% one year after TCPC ($p < 0.01$).
Conclusions: PAVM occurred with significant reduction SO2 even in the short interval of 8 months after TCPS. To prevent severe hypoxia and maintain oxygen level appropriately, therefore, TCPC would be performed within 1 year after TCPS.

P1221 - MID TERM SURGICAL OUTCOMES OF PARTIAL ATRIOVENTRICULAR SEPTAL DEFECT

Mariko Kobayashi, Toshihide Asou, Yuko Takeda, Noritaka Ota, Hiroshi Okada, Yasuko Onakatomi, Hidetsugu Asai
Kanagawa Children's Medical Center, Cardiovascular Surgery, Yokohama-Japan

Background: Relatively high reoperation rate (17 to 25%) has been reported after repair of partial atrioventricular septal defect (pAVSD) mainly due to left AV valve regurgitation (LAVVR). We have developed a simple method with special focus on complete closure of the cleft. The purpose of the present study was to assess the outcomes of repair of pAVSD using this technique.
Methods: We reviewed 61 patients with including 5 with intermediate AVSD. Age and body weight were 3.8 ± 3.8 years old and 13.3 ± 9.9 kg, respectively. There were 16 patients with Down syndrome and 9 with polysplenia. At surgery wide coaptation zone was obtained with complete cleft closure up to the chordal attachment. Associated cardiovascular lesions included patent ductus arteriosus (4), coarctation of the aorta (2), ventricular septal defect (2), partial anomalous of pulmonary venous drainage (2), Cor triatriatum (1), and Lutembacher syndrome (1). Pacemaker (PM) was implanted in 2 patients with polysplenia before pAVSD repair. Median follow- up was 6.7 years (0.4-12.7 yeas).
Results: Median stays in ICU and hospital were 1 days (1~22 days) and 5 days (3~68 days), respectively. There were no hospital and three late deaths with non-cardiac causes in patients with polysplenia. Survival rate was $96.0 \pm 2.8\%$ at 5 years. Freedom from reoperation was $96.0 \pm 2.8\%$ at 5 years. Three patients (4.9%), who had complete repair at the age of less than 60 days old, underwent

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

reoperation for subaortic stenosis, residual atrial septal defect, and LAVVR. The other two patients with polysplenia had PM implantation for SSS after repair.
Conclusions: Mid-term outcomes of complete repair of pAVSD using a newly developed method was excellent. The creation of wide coaptation zone with complete cleft closure up to chordal attachment might be effective to prevent late LAVVR.

P1225 - RESTRICTIVE ENLARGEMENT OF PULMONARY ANNULUS AT SURGICAL REPAIR OF TETRALOGY OF FALLOT A COMPARATIVE 10 YEAR FOLLOW UP STUDY

Jana Logoteta[1], Lars Dullin[1], Mona Salehi Ravesh[1], Abdullah Al Bulushi[1], Ines Kristo[1], Carsten Rickers[1], Jan Hinnerk Hansen[1], Tim Attmann[2], Jens Scheewe[2], Hans-heiner Kramer[1]
University Hospital Schleswig-holstein, Department of Congenital Heart Disease and Paediatric Cardiology, Kiel-Germany[1]; University Hospital Schleswig-Holstein, Department of Cardiovascular Surgery, Kiel-Germany[2]

Background: Since 1996 our center follows a uniform strategy of restrictive enlargement of the pulmonary annulus (PV) at surgical repair of tetralogy of Fallot (ToF). A transanular patch (TAP) is only used if the z-score of the PV is < -2. We sought to determine whether this strategy leads to reduction of pulmonary insufficiency (PI) and re-operation rate in the long-term compared to a nationwide contemporary cohort that has not been operated using a uniform strategy.
Methods: 87 ToF patients (repair 1996-2006) were included in the study (Group 1). Echocardiographic, ECG and cardiac MRI data were collected. 172 ToF patients from the Competence Network for Congenital Heart Disease served as the controls (Group 2).
Results: Follow Up time since repair was not different between groups (12.9 (7.7-18.8) vs. 13.1 (5.2-16.9) years, $p = 0.9$) while TAP rate was significantly lower in Group 1 (32.2% vs. 62.8%, $p < 0.001$). In Group 1 more patients were in NYHA class 1 ($p < 0.01$), QRS was narrower (132 ± 22 ms vs. 144 ± 21 ms, $p < 0.001$), moderate or severe PI was less common ($p < 0.001$), CMR derived volumes were smaller (EDVi: 103 ± 21 vs. 120 ± 30 ml/m^2, $p < 0.001$; ESVi: 52 ± 15 vs. 59 ± 19 ml/m^2, $p = 0.03$) and regurgitation fraction was lower (21 ± 14 vs. 29 ± 16%, $p < 0.01$). 10 year freedom from re-operation of the PV was significantly higher in our cohort (92% vs. 87%, $p = 0.015$).
Conclusion: In long-term follow up restrictive enlargement of the PV reduces the rate of pulmonary insufficiency and limits the amount of right heart dilatation. The re-operation rate of the PV is significantly lower compared to a contemporary cohort.

P1231 - CHALLENGE IN MANAGEMENT OF PATIENTS WITH FUNCTIONALLY UNIVENTRICULAR HEART IN INDONESIA

Pribadi Wiranda Busro
National Cardiac Centre Harapan Kita Hospital, Pediatric Cardiac Surgery Unit, Jakarta Selatan-Indonesia

Management of patients with functionally univentricular heart has evolved during recent years. Usually patient underwent stages operation to achieve "normal" functional heart towards Fontan circulation. In our countries with large population and scattered around many islands, it is still difficult to manage patients with heart diseases. Especially for stages operation, while economy still a big problem for young family. Centre performing complex procedures on a regular basis is very few in Indonesia including Fontan Procedures. Harapan Kita is the biggest center for doing pediatric cardiac center in Indonesia. From 1998 to 2016 there were 661 childrens underwent BCPS operation, meanwhile only 171 (26%) of those patients had Fontan operations. There are a few reasons why only small number of patients had Fontan completion. Previously, government did not give fully support for operation, but for recent years it is covered by government insurance although only for selective population. That is why, the number of Fontan operation is increasing for the last four years. But some patients had long time to wait for Fontan completion, thus it will compromise the condition of the heart to have Fontan operation. Careful selection of patients and optimal timing of intervention remain cornerstones of successful outcomes. But only relatively few patients will fulfill all of Fontan criteria. While, however, the 'limits' of Fontan inclusion criteria continue to be challenged, it remains the case that preoperatively impaired ventricular function and elevated mean pulmonary arterial pressure (greater than 15 to 20 mmHg) still have an adverse impact on surgical outcomes in contemporary series.

P1248 - POLYMERIC BIOABSORBABLE VASCULAR GRAFT IN MODIFIED FONTAN PROCEDURE – TWO YEAR FOLLOW UP

Leo Bockeria[1], Thierry Carrel[2], Alex Kim[1], Konstantin Shatalov[1], Vladimir Makarenko[3], Martijn Cox[4], Oleg Svanidze[5]
Bakoulev CCVS, Congenital Heart Disease, Moscow-Russia[1]; University Hospital Bern, Cardiovascular Surgery, Bern-Switzerland[2]; Bakoulev CCVS, CT & Mri, Moscow-Russia[3]; Xeltis Bv, Research & Development, Eindhoven-The Netherlands[4]; Xeltis Ag, Medical Affairs, Zurich-Switzerland[5]

Background/Hypothesis: The bioabsorbable graft material is designed to allow patient's own cells to infiltrate and replace the material by a process called Endogenous Tissue Restoration (ETR) leading to natural tissue growth. After implantation the graft is gradually replaced with the native tissue, developing into a fully functioning blood vessel. This study evaluated safety and performance of a novel bioabsorbable vascular graft in pediatric patients with univentricular congenital malformation, undergoing hemodynamic correction with an extracardiac cavopulmonary conduit.
Materials and Methods: Five patients with single ventricle congenital malformation have been enrolled in the study from October 2013 to February 2014. In all patients the bi-directional Glenn anastomosis have been previously performed. The patients' age at the time of implantation were ranged 4–12 years while 60% ($n = 3$) were males. Total follow-up was 26–31 months with scheduled visits at 1, 3, 6, 9 and 12 months after surgery for the first year and yearly thereafter. The device performance evaluation has been performed by transthoracic ultrasound, and optional CT-scan and MRI were performed at several timepoints in all patients.
Results: All 5 patients have been successfully recovered from the procedure and completed 24 months follow-up. No device related adverse events were reported to date. Ultrasound and MRI studies have demonstrated anatomical (conduit dimensions) and functional (blood flow velocity and pattern, absence of thrombosis) stability of the grafts in all patients at up to 31 months.
Conclusions: The study device demonstrated an adequate hemodynamic performance at up to 31 months follow-up. The clinical study outcomes suggest that this bioabsorbable polymer technology has the potential to improve cardiac and vascular surgical procedures by reducing implant-related complications. Longer follow-up, however is needed to fully assess effectiveness of bioabsorbable vascular grafts. This represents the first step towards development of more complex bioabsorbable devices such as heart valves.

P1249 - HYBRID PULMONARY VALVE IMPLANTATION IN TETRALOGY OF FALLOT

María-Teresa González-lópez[1], Ramón Pérez-Caballero-Martínez[1], Fernando Ballesteros-Tejerizo[2], Alejandro Rodríguez-Ogando[2], José-luis Zunzunegui-Martínez[2], Ana-María Pita-Fernández[1], Juan-Miguel Gil-Jaurena[1]
Gregorio Marañón Hospital, Pediatric Cardiac Surgery, Madrid-Spain[1]; Gregorio Marañón Hospital, Pediatric Cardiology, Madrid-Spain[2]

Background: Transannular patch repair of tetralogy of Fallot (TOF) often results in significant right ventricular outflow tract (RVOT) dilation and distortion, along with free pulmonary regurgitation (PR). Pulmonary valve replacement (PVR) is indicated in this group of patients at any point of the follow-up. The surgical and trans-catheter options of PVR continue to expand, but hybrid approaches have not been described in this scenario. We present two cases of a novel approach of hybrid PVR and early outcomes.
Patients/Methods: CASE 1. Male, 2.5 year-old. He was referred to our center following complete TOF transannular repair (6 months of age). A residual ventricular septal defect (VSD), moderate pulmonary stenosis and nodal rhythm were found. He underwent VSD closure, left pulmonary artery (PA) patching, implantation of Melody valve (expanded to 16 mm; four interrupted sutures) and definitive epicardial leads. Cardiopulmonary bypass time 155 min; aortic cross clamping time 58 min. CASE 2. Female, 2 year-old. She underwent palliation procedure (5 months of age): transannular patch and right ventricular (RV) hypertrophy resection. The VSD was left open due to severe hypoplasia of PA branches). Two months later, left PA stent was implanted. One year later, normal-sized PA branches were noted. She underwent VSD closure (pericardial patch) and implantation of Melody valve (expanded to 14 mm). Cardiopulmonary bypass time 154 min; aortic cross clamping time 56 min.
Results: Both patients had an uneventful postoperative course. At follow-up (12 + /-2 months), they remain asymptomatic with optimal functional class. Last echocardiography has showed good RV function, normal PV function and good-sized PA branches.
Conclusions: This novel approach may offer potential benefit in treating complex TOF patients. It provides a reasonable alternative to surgical PVR when any additional surgical procedure is needed at an early age, allowing a more adequate matching to the RVOT size as well as subsequent balloon expansions.

P1258 - EUGENY MESHALKIN (1916–1997) THE PIONEER OF THE WORLD HEART SURGERY (THE FIRST IN THE WORLD CLINICAL SUCCESSFUL CAVAPULMONARY CONNECTION) – IN MEMORIAM

Igor Kotelnikov[1], Yuri Gorbatykh[2], Alexsander Karaskov[2]
Gruppo San Donato, Cardiac Surgery Department, Milan-Italy[1]; Siberian Federal Biomedical Research Center, Congenital Heart Diseases Department, Novosibirsk-Russia[2]

Last year it was 100th Anniversary of Eugeny Meshalkin, the pioneer of the world heart surgery. He graduated from high medical school in Moscow just before the Second World War. He was drafted into the army as a military front surgeon for 5 years. In 1946 Meshalkin entered to a clinic in Moscow headed by Aleksandr Bakulev. This clinic became the first center of cardio-vascular surgery in Russia. In 1952 Meshalkin became a chief of the division of cardio-vascular surgery. He performed more than 200 cardio-vascular operations a year. On 3 April 1956 Meshalkin did the first successful operation of cavopulmonary anastomosis for a 15 years old patient with tetralogy of Fallot. He published a paper in the Russian journal "Experimental Surgery" (N 6, 1956) which summarized the experience of 24 operations of cava - pulmonary anastomosis performed from April to October 1956. Three patients died. Meshalkin described the technique of the operation in detail. Twenty three anastomosis were "end to end" and one was end of pulmonary artery to side of vena cava. Meshalkin was the first in the world who used mechanical suture for dividing vena cava. He performed postoperative angiography of the shunt. Only two years later on February 25, 1958 William Glenn was the first in North America to perform a successful cavopulmonary shunt, and it became known by his name. Francis Robicsek wrote in his paper "An epitaph for cavopulmonary anastomosis" (the Annals of Thoracic Surgery vol 34, N2, 1982) that the patient Meshalkin operated on April 3, 1956 undoubtedly represents the first successful clinical case of cavopulmonary anastomosis reported in surgical literature. Harris Shumacker, who dedicated a lot of works to developing this operation, confirmed the priority of Meshalkin in his book "Evolution of Cardiac surgery" in 1992.

P1259 - WHEN THE CHILD BECOMES A YOUNG ADULT UNCOMMON SCENARIOS FOR AORTIC VALVE REPAIR

María-Teresa González-López[1], Ana-María Pita-Fernández[1], Ramón Pérez-Caballero-Martínez[1], Alejandro Rodríguez-Ogando[2], Constancio Medrano-López[2], Juan-Miguel Gil-Jaurena[1]
Gregorio Marañón Hospital, Pediatric Cardiac Surgery, Madrid-Spain[1]; Gregorio Marañón Hospital, Pediatric Cardiology, Madrid-Spain[2]

Background: Aortic regurgitation (AR) can be developed over the time following surgical repair of several congenital heart defects. Aortic valve repair needs to be highly considered in this group of young patients. We present 2 uncommon scenarios of aortic valve repair and short-term results.
Patients and Methods: CASE #1. Female, 17 year-old. She underwent surgical closure of subarterial ventricular septal defect (VSD) (Laubry-Pezzi syndrome) at 4 years of age. At long-term follow-up, significative intolerance to exercise was detected. Moderate-to-severe AR and small residual VSD was noted. Left ventricular ejection fraction (LVEF) was 60%. On the operative field, severe fusion of the right and left coronary leaflets with severe retraction of right coronary leaflet were noted. Commissurotomy and shaving of the left coronary leaflet were performed followed by a complete excision of the right coronary leaflet. A right neo-leaflet

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(equine pericardial patch, glutaraldehyde-free, continuous suture) was created and the VSD was closed. Cardiopulmonary bypass time 104 min; aortic cross clamping time 71 min. CASE #2. Male, 17 year-old. He underwent arterial switch operation (Lecompte maneuver) in the neonatal period due to transposition of the great arteries (TGA). At long-term follow-up, severe AR was detected with preserved LVEF. A valve-sparing procedure (David operation) was performed, following the transection of right pulmonary artery for an optimal exposure of the aortic root. Cardiopulmonary bypass time 187 min; aortic cross clamping time 95 min.
Results: Both patients had an uneventful postoperative course. At follow-up (14 + /-2 months), they remain asymptomatic with optimal functional class. Last echocardiography has showed good LV function with no AR.
Conclusions: A repair-oriented strategy for the aortic valve has excellent short-term results in complex congenital patients. Although these procedures are technically demanding, they remain a promising management option in these uncommon scenarios.

P1268 - BEATING HEART AORTIC ARCH REPAIR

Juan-Miguel Gil-jaurena[1], María-Teresa González-López[1], Ana Pita[1], Ramón Pérez-Caballero[1], Dorotea Blanco[2], Constancio Medrano[3]
Hospital Gregorio Marañón, Pediatric Cardiac Surgery, Madrid-Spain[1]; Hospital Gregorio Marañón, Neonatology, Madrid-Spain[2]; Hospital Gregorio Marañón, Pediatric Cardiology, Madrid-Spain[3]

Introduction: The strategies for aortic arch repair (AAR) in neonates/infants have evolved notoriously. Simultaneous cerebro-myocardial perfusion (beating-heart technique) is the most recent modification, although not widely performed. We present our preliminary results by using this strategy.
Methods: Since 2013 we included this technique as the standard approach, gathering 44 patients in four years. Median age 50 + /-27 days (range 1-270); median weight 3.7 + -1.4 kg (range 2.1-7). Hypoplastic aortic arch (HAA) was associated with cor triatriatum (3), ventricular septal defect (VSD,10); interrupted aortic arch (3), transposition of great arteries (5), atrial septal defect (ASD, 3) partial atrioventricular septal defect (AVSD, 1), hypoplastic left heart syndrom (HLHS, 7), double-outlet right ventricle (2), severe aortic stenosis (2) and as isolated defect (8). Coronary perfusion (25 °C) was maintained through a cardioplegia delivery system Y-connected to the aortic cannula. Hence, heart-beating AAR was performed. When intracardiac repair was required, antegrade cardioplegia was delivered via the same catheter used for myocardial perfusión, simply switching the three-way stopcock.
Results: 32 patients had intracardiac lesions: left atrium membrane resection (3), VSD closure (9), arterial switch operation (5), ASD closure (3), partial AVSD repair (1), Norwood-Sano procedure (7), comprehensive-procedure following hybrid-approach (2) and aortic commisurotomy (2). Average cardiopulmonary bypass time 168 + /-73 minutes (range 93-312). Myocardial ischemia time median 30 + /-11, (range 0-160). The heart was not arrested in12 patients: 8 isolated hypoplastic arch, 2 Glenn, 1 Banding, 1 perventricular VSD closure. Selective cerebral perfusion median 35 + /-9 minutes (range 18-53). No cases of operative mortality were detected. No neurologic adverse events occurred. 30-day mortality was 4.5% (n = 2, following extra-corporeal-membrane-oxygenation).
Conclusions: Selective/independent cerebro-myocardial perfusion in aortic arch pathology is a safe/feasible technique, with low rates of adverse events. Heart-beating AAR should be recommended due to the reduction of the myocardial ischemia time, although comparative results with classical techniques need to be addressed.

P1269 - SURGERY OVER STENTS. NEW CHALLENGES TO FACE

Juan-Miguel Gil-Jaurena[1], José-Luis Zunzunegui[2], Ramón Pérez-Caballero[1], Ana Pita[1], María-Teresa González-López[1], Constancio Medrano[2]
Hospital Gregorio Marañón, Pediatric Cardiac Surgery, Madrid-Spain[1]; Hospital Gregorio Marañón, Pediatric Cardiology, Madrid-Spain[2]

Objectives: Complex cases undergo step surgical and percutaneous procedures, including stent deployment. Concerns arise on stent removal at latest surgery. We describe our experience in this issue.
Methods: 83 stents in 68 patients were partial or totally removed at surgery. Univentricular heart was diagnosed in 30 patients. Stents were previously deployed in: ductus (14), right ventricle outflow tract (RVOT, 20), atrial septal defect (ASD, 6), right pulmonary artery (RPA, 9), left pulmonary artery (LPA, 23), inferior vena cava (IVC) 5, superior vena cava (SVC, 3) ascending aorta (AAo, 2) and pulmonary veins (1). Surgical procedures performed: 14 transplants, 10 Fontan, 4 Glenn, 2 comprehensive repair (Norwood + Glenn), 1 Glenn take-down, 13 conduit replacement, 8 Fallot, 6 Rastelli, 1 ventricular septal defect closure (VSD), 1 iatrogenic aorto-pulmonary window, 1 Ross-Konno, 1 double switch, 1 hypoplastic aortic arch and 1 unifocalization.
Results: Ten ductal stents were clipped. Nineteen stents in RVOT, six ones in ASD, five in RPA, thirteen in the LPA, three in IVC and one in the ascending aorta were completely removed. Five stents in RPA, three in SVC, one in AAo and thirteen in the LPA were split and partially retrieved. Handling the stents in ductus, RVOT and ASD was fairly seamless. On the contrary, stent removal in the ductus (for the two comprehensive cases), RPA, LPA, SVC, IVC, aorta or pulmonary veins required short periods of deep hypothermia with circulatory arrest, adding length and morbidity to the procedure.
Conclusions: surgery over stents is increasing in complex, step procedures. Univentricular hearts are most prevalent. Congenital Transplant surgery faces new challenges. Stent removal at the time of surgery may require deep hypothermic circulatory arrest.

P1274 - A RARE CASE OF SITUS INVERSUS TOTALIS VENTRICULAR SEPTAL DEFECT WITH INFUNDIBULAR PULMONARY STENOSIS

Gopi Nallaiyan
Devadoss Multispeciality Hospital, Paediatric Cardiac Surgery, Madurai-India

Introduction: 4 years old male child (12 kg) was admitted with complaints of Breathlessness on exertion for the past 6 months. On Investigation, he was found to have Congenital Heart Disease, Situs Inversus Totalis, Perimembranous VSD with Severe Infundibular PS.
Surgical Strategy: We took certain precautions for ease of doing surgery in Situs Inversus Totalis like - Positioning the patient in the centre of the operating table. - Taking the Arterial and Venous lines little high up for the ease of the movement of the surgeon toward the left side of the patient. - Canulation from right side of the patient. - Main procedure after arresting the heart from left side of the patient. - Decannulation and Closure from the right side of the patient.
Procedure Performed: Trans atrial- Trans Pulmonary Infundibular muscle bundle resection and closure of VSD with 0.6mm PTFE patch.
Conclusion: Cardiac surgery in Situs Inversus Totalis is no different from others, provided we take certain precautions and follow few simple surgical strategies..

P1280 - OPTIMAL TIMING FOR SUREGERY ON AORTIC VALVE INSUFFICIENCY IN PEDIATRIC PATIENTS INSIGHT ABOUT PREOPERATIVE INDICES TO PREDICT POSTOPERATIVE RECOVERY OF LEFT VENTRICULAR GEOMETRY

Tanomo Ono, Masaki Nii, Mizuhiko Ishigaki, Keisuke Sato, Jyun Yoshimoto, Sung-Hae Kim, Norie Mitsushita, Yasuhiko Tanaka
Shizuoka Children, Pediatric Caldiology, Shizuoka-Japan

Background: Though indexed end-systolic LV dimension (ESDI) < 25 mm/m2 is reported to be an optimal timing to maintain LV function after surgery for chronic aortic valve insufficiency (AI) in adults, we have paucity of data describing the optimal timing for aortic valve repair (AOVR) on pediatric AI.
Objectives: The aim of this study is to establish the cut-off values of ESDI and indexed end-diastolic LV dimension (EDDI) to determine the optimal timing for AOVR on pediatric AI.
Methods: 36 consecutive pediatric AI (moderate 8, severe 28) who had biventricular physiology and underwent AOVR between January 2001 and December 2015 were enrolled. 24 were male. Age at AOVR was 10.4 + /- 4.7 (mean + /- S.D.). All patients didn't receive any intervention within 1.5 year before AOVR. Aortic valve replacements were done on 16, Ross procedure on 11, and aortic valve plasty on 9. When ESDI became < 25 and EDDI <40 after AOVR, they are classified as normalized group (N). The others are considered as dysfunctional group (D). Preoperative ESDI and EDDI were compared between two groups.
Results: Preoperative ESDI is significantly smaller in N than D (28.1 + /- 6.5 vs 41.9 + /- 15.4, p = 0.002), and the cut-off value differentiating two groups is 39.9 (area under curve [AUC]: 0.811). Preoperative EDDI is also significantly smaller in N than D (46.1 + /- 9.6 vs 66.1 + /- 18.3, p = 0.006) and cut-off is 51.6 (AUC: 0.869). Preoperative ejection fraction was not different between the groups. By multiple logistic regression analysis, preoperative ESDI <40 predicts normalization of LV geometry after surgery (N = 88% [22/ 25], D = 27% [3/ 11], odds ratio = 1.42 [95% confidential interval; 1.07-2.13], p = 0.03).
Conclusion: Preoperative ESDI <40 would predicts improvement of LV geometry after surgery for pediatric AI.

P1281 - STAGED REPAIR OF PULMONARY ATRESIA VENTRICAL SEPTAL DEFECT AND MAJOR AORTO PULMONARY COLLATERAL ARTERIES WITH SEVERE HYPOPLASIA OR ABSENCE OF PULMONARY ARTERIES

Aleksandr Morozov[1], Ruben Movsesian[2], Vadim Lubomudrov[3], Evgeny Grekhov[1], Andrey Tzytko[2], Alexey Shikhranov[2], Nikolay Antsygin[2]
Federal Almazov North-West Medical Research Centre, Department of Pediatric Cardiac Surgery, St.Petersburg-Russia[1]; Children's City Hospital №1, Department of Pediatric Cardiac Surgery, St.petersburg-Russia[2]; Chest Disease Hospital, Department of Pediatric Cardiac Surgery, Al-kuwait-Kuwait[3]

Background: Surgical management of pulmonary atresia, ventrical septal defect and major aorto-pulmonary collateral arteries with severe hypoplastic or absent pulmonary arteries is still a challenge. We evaluated the results of staged surgical treatment in such challenging patients.
Methods: From 2000 to 2015, 32 consecutive patients with pulmonary atresia, ventrical septal defect and major aorto-pulmonary collateral arteries were surgically treated. Primary complete repair was done only in 4 patients, another underwent staged procedures. Treatment of 28 staged patients began with systemic-to-pulmonary shunt only, unifocalization and systemic-to-pulmonary shunt or palliative right ventricular outflow tract reconstruction and depending on the distribution of pulmonary blood flow. Among all staged patients, 22 had severe hypoplastic pulmonary arteries (median Nakata index 46,7 mm/m2, range 13,1-135,4 mm/m2), and 6 had inconfluence or absence of pulmonary arteries.
Results: 10 staged patients (36%) subsequently underwent complete repair with ventricular septal defect closure (median 2,5 surgical procedures, range 2-4). The median of the pulmonary artery pressure to the systemic blood pressure ratio at the final stage of repair was 0.66 (range 0.44-1.00). Duration of the full surgical course ranged from 6,6 to 69,2 months (median 15,7 months). Overall hospital mortality in staged group was 14,3% (3 patients died after staged procedures and 1 – after complete repair). Subsequently, 3 patients underwent interventional catheterizations (dilation or/and stenting of pulmonary arteries), and right ventricle – pulmonary artery conduit was replaced in 1 case.
Conclusion: Staged surgical approach can be used in pulmonary atresia, ventricular septal defect with severe hypoplastic or absent pulmonary artery and major aortopulmonary collateral arteries with acceptable results.

P1282 - OUTCOMES OF AORTIC VALVE REPAIR IN NEONATES AND INFANTS

Sanae Yamauchi[1], Shigemitsu Iwai[1], Yuji Tominaga[1], Yosuke Kugo[1], Futoshi Kayatani[2], Kunihiko Takahashi[2], Hisaaki Aoki[2], Hiroaki Kawata[1]
Osaka Medical Center and Resesrch Institute For Maternal and Child Health, Cardiovascular Surgery, Izumi-Japan[1]; Osaka Medical Center and Resesrch Institute For Maternal and Child Health, Pediatric Cardiology, Izumi-Japan[2]

Background: To investigate the outcomes in neonates and infants who underwent aortic valve repair.
Materials and Methods: Five patients, aged <1 year, who underwent aortic valve repair between 2012 and 2016, were evaluated. The primary diseases were critical aortic stenosis in 2 cases, aortic stenosis + coarctation of the aorta in 1, left isomerism + aortic atresia in 1, and truncus arteriosus in 1. The median age and body weight at the time of surgery were 40 days (range: 21–202 days) and 3.3 kg (range: 2.6–5.2 kg), respectively. In all cases, aortic valve repair was conducted after bilateral pulmonary artery banding as the initial surgery; in 3, transcatheter aortic valvotomy was performed before aortic valve repair. The surgical procedures for aortic valve repair were leaflet extension + commissure plication in 2 cases, closure of the aortic valve leaflet hiatus + commissure plication in 1, commissurotomy in 1, and truncal valve remodeling in 1.
Results: Follow-up evaluations were performed between 1 and 23 months post-surgery (median: 19 months). One patient died 1 month after surgery from an unrelated condition; the remaining 4 survived. The mean (± SD) flow velocity in the aortic valve was reduced from 3.4 ± 1.1 m/s to 2.8 ± 0.7 m/s after surgery. Two patients required further aortic valve repairs. One patient required suture of the commissure aortic valve 2 months after the initial repair. In another case, the transcatheter aortic valvotomy was performed twice, and Ross-Konno procedure was performed at 8 months after the initial repair. At the latest examination, the left ventricular function was maintained, and B-type natriuretic peptide decreased (pre-surgery: 965 ± 704 pg/ml, post-surgery: 87 ± 103 pg/ml).
Conclusions: The outcomes of the aortic valve repairs were fairly favorable. The results suggest that additional transcatheter aortic valvotomy and/or valve repair after the initial repair was useful to increase the options for future procedures, including Ross-Konno procedure and aortic valve replacement.

P1291 - MULTI DISCIPLINARY FOUR PRONGED TEAM COMMUNICATION THROUGHOUT THE OPERATIVE DAY FOSTERS BETTER UNDERSTANDING FOR COMPLEX PATIENTS AND IMPROVES OUTCOMES

Alistair Phillips[1], Nicole Berndsen[1], Veena Sivarajan[1], Courtnay Caufield[2], Maureen Davis[2], Lorraine Lubin[3], Robert Wong[3], Stephen Robert[4], Pooja Nawathe[4], Vincent Olshove[1]
Cedars-Sinai Medical Center, Surgery, Los Angeles-United States[1]; Cedars-Sinai Medical Center, Nursing, Los Angeles-United States[2]; Cedars-Sinai Medical Center, Anesthesia, Los Angeles-United States[3]; Cedars-Sinai Medical Center, Pediatrics, Los Angeles-United States[4]

Background: A team that communicates openly, defines patient goals, and utilizes a consistent management approach; can reduce care variability, errors and improve outcomes. Well-executed transitions of care improve patient safety and outcomes. Using several tools can help drive understanding. The four important processes we use are: (1) Pre-brief – outlines the conduct of the surgical procedure and expectations, (2) Pre-Op Huddle – Pre-defined worksheet with goals of the Surgeon, Anesthesia, Perfusion, and ICU, performed the morning of surgery, (3) Post-Op-Debrief (POD) – Review the Huddle sheet in the operating room, and define any changes or discrepancies, and (4) Team handoff performed in the ICU.
Method: In 5/1/15, we enhanced our process to include intensive care team in the Huddle and post-huddle process. The Huddle sheet was changed and the huddle was moved to the PICU conference room. The ICU team ran the post-huddle starting in 5/1/15. We compared the entire process (1) Pre-brief, (2) Huddle, (3) Post-Huddle and (4) handoff; pre and post changes. Real-time audit of all forms, with observations of huddles by independent observers and using event monitoring to determine any clinically significant events.
Results: Two surgical groups November 2014 through April 2015 (n = 19) and May 2015 through April 2016 (n = 26). In all patients there was complete documentation of allergies, patient weight, anesthesia plan, and perfusion plan. Surgical plan (100% vs. 96%) and nursing plan (95% vs. 92%) was almost always complete.
Conclusions: A team approach to care had a tremendous effect on patient outcomes, by improving communication of the entire team. We found there was a significant reduction of overall issues immediately in the ICU. By having the ICU team more involved (moving the Huddle to the ICU and having the ICU team run the post-huddle) there was a greater acceptance.

Table 1.

	Group 1	Group 2	p-value
Dosing Weight Documented	0%	50%	<0.001
Post-Op Debrief Completed	5%	92%	<0.001
ECMO Plan Determined in post-Op Debrief	5%	88%	<0.001
ICU Plan Defined in the post-Op Debrief	11%	77%	<0.001
Significant Clinical Disturbances	2.3 ± 1.7	0.7 ± 1.6	0.003

P1295 - EVALUATION OF PERICARDIAL MITRAL VALVE RECONSTRUCTION FOR PEDIATRIC PATIENTS

Masakazu Nakao[1], Guangyu Zhu[2], Munirah Binte Ismail[2], Jooh Hock Yeo[2]
KK Women, Paediatric Cardiothoracic Surgery, Singapore-Singapore[1]; Nanyang Technological University, School of Mechanical and Aerospace Engineering, Singapore-Singapore[2]

Objective: Mitral valve or left sided atrioventricular valve is often involved in structural congenital heart diseases in pediatric patients. The size of commercially available prosthetic valves limits the usage of valve replacement in this group of patients. We hypothesize that pericardial reconstruction of mitral valve with newly developed mold by our group is a feasible option.
Methods: The finite element computer models of a reconstructed mitral valve were created. The leaflet coaptation area and stress distribution on the leaflets were analyzed. Bovine pericardium was prepared based on the computer model. It was hand-sewn to the pigs' hearts as well as the silicon test-rig. Valve motions were observed and recorded with the video camera.
Results: Von Mises stress on the leaflets ranged from 0.47 to 0.85 MPa. The highest stress distribution was observed in the commissure at the chordae. From the video recording on the pigs'

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

hearts, the mitral valve closed rapidly with native-like coaptation and revealed small amount of leakage. The silicon test-rig confirmed similar findings.
Conclusions: The computer model of reconstructed mitral valve showed acceptable performance. Pericardial reconstruction of mitral valve showed similar appearance and performance to the native valves. Although further evaluation is necessary, this has a potential to be a feasible option for pediatric patients.

P1301 - SURGICAL REPAIR OF SUPRAVALVULAR AORTIC STENOSIS SURGICAL RESULTS AND 44 YEARS FOLLOW UP

Eva María Aguilar Blanco, Raul Sánchez Pérez, Juvenal Rey Lois, Álvaro González Rocafort, Luz Polo López, Ángel Aroca Peinado
Hospital Universitario La Paz, Cirugía Cardiaca Infantil Y Cardiopatías Congénitas Del Adulto, Madrid-Spain

Objective: Supravalvular aortic stenosis is defined as left ventricular outflow tract obstruction distal to the aortic valve. Hospital results and long-term follow up of the surgical repair were analyzed and different technical options were compared.
Methods: Between 1972 and 2016, 34 patients younger than 18 years were operated in our department; 70% of whom were male, ranging in age from 0.5 to 15 years (average age, 7 ± 4 years). 23 patients (67.6%) had Williams-Beuren syndrome. Preoperatively, 79.4% patients were asymptomatic. Among the 34 patients, 30 (88.2%) had localized type and 4 diffuse type obstruction. Preoperative peak gradient was 88 ± 33 mmHg and mean gradient was 49 ± 23 mmHg. Left ventricular ejection fraction (LVEF) was conserved in all of them.
Results: Single-sinus repair was performed in 13 patients, two-sinus in 16, and three-sinus in 1. In the remaining four patients, an aortoplasty of a diffuse form was carried out. There was one hospital death. Within the follow-up period ranging from 0.5 to 44 years (medium 21 ± 12 years) one late death happened in the 42nd year and 9 patients had one additional operation (27.3%). Currently the peak gradient is 20 ± 12 mmHg and mean gradient is 13 ± 16 mmHg. LVEF was preserved in 94% (32). There was no statistical significance ($p = 0.17$) in additional operation between the single-sinus technique and the others.
Conclusion: Hospital death and late survival were excellent, with a small numbers of additional operations, no association was found depending on the surgical technique used. Surgical indication should be considered in asymptomatic patients with peak gradients > 50 mm Hg or average gradients > 30 mm Hg with ventricular hypertrophy.

P1303 - EARLY OUTCOMES OF THE ARTERIAL SWITCH OPERATION IN CHILDREN OF MORE THAN 1MONTH OF AGE

Schin Talwar[1], Intekhab Alam[2], Shivkumar Choudhary[2], Balram Airan[3]
All India Institue of Medical Sciencess, CTVS, New Delhi-India[1]; All India Institue of Medical Sciences, CTVS, New Delhi-India[2]; All India Institue of Medical Sciences, CTBS, New Delhi-India[3]

Objectives: Though results of arterial switch operation (ASO) in children presenting early have been encouraging, late presenters continue to pose a challenge. This study aims therefore aims to evaluate out the early results ASO in such children more than 1month of age.
Methods: Records of 488 patients undergoing ASO from January 01, 2005 till April 30, 2016 at All India Institute Of Medical Sciences (AIIMS), New Delhi, India, were analysed. They were divided in 3 groups, Group A (TGA with intact ventricular septum (IVS)), Group B (TGA with VSD) and Group C (Taussig- Bing Anomaly).
Results: Of the 488 children reviewed, records of 470 were available. A total of 268 (57%) had associated VSD, 183 (37.9%) were had intact IVS and 24 (5.1%) presented with DORV. Other associated conditions found were left ventricular outflow obstruction (10/470, 2.1%), coactation of aorta (3/470, 0.6%), right ventricular outflow obstruction (3/470, 0.6%), pulmonary stenosos (2/470, 0.4%), aortopulmonary window (1/470, 0.2%), total anomalous pulmonary venous drainage (1/470, 0.2%) and hypoplastic aortic arch (1/470, 0.2%). Overall early hospital was 11.7% (55/470). In Group A, B & C early hospital mortality was 10.7% (19/178), 13.1% (35/268) and 4.2% (1/24) respectively. ECMO was instituted in 8.9% (42/470) patients. Requirement of ECMO was significantly higher ($p < 0.005$) for children having IVS (38/42 i.e, 90.5%) as against children having VSD (4/42 i.e, 9.5%).. On detailed evaluation of the possible incriminating risk factor for deaths, in such children, presence of associated conditions such as arch abnormalities, presence of CoA, pre-operative infections were found.
Conclusion: In a developing countries, late presentation of TGA is not uncommon. However acceptable results can be obtained in these patients.

P1305 - A RANDOMISED CONTROLLED TRIAL COMPARING RIGHT VENTRICULAR FUNCTION BETWEEN TRANS RIGHT ATRIAL VERSUS TRANS RIGHT ATRIAL RIGHT VENTRICULAR APPROACH FOR TETRALOGY OF FALLOT REPAIR

Balram Airan[1], Sachin Talwar[2], Abhishek Anand[2], Siva Ramakrishnan[3]
All India Institue of Medical Sciencess, CTVS, New Delhi-India[1]; All India Institue of Medical Sciences, CTVS, New Delhi-India[2]; All India Institue of Medical Sciences, Cardiology, New Delhi-India[3]

Background: We compared the immediate pre and postoperative right ventricular functional status byTrans Annular Plane Systolic Exertion (TAPSE) between trans-right atrial (RA) versus trans-right atrial/right ventricular (RA/RV) approach for TOF repair.
Methods: 50 consecutive paediatric patients between ages of 01 year to 15 years undergoing intracardiac repair of TOF between July 2015 and June 2016 were randomized in two groups based on the approach for repair, namely; trans- RA and trans-RA/RV.
Results: Both groups were well matched in terms of age, body surface area and preoperative saturation, bypass time and aortic cross clamp times, ionotropic score, post-operative ICU stay and hospital stay. However Trans RA/RV group had significant mediastinal drain (169 ± 163 ml vs 90.6 ± 58.7 ml, $p < 0.05$), pleural effusions (8 vs 2 patients, $p < 0.05$) but had better relief or RVOT gradient. There was no difference in incidence of post-operative arrhythmias in either group till the first month of follow-up. Preoperative TAPSE for trans RA and trans RA/RV were similar (1.49 ± 0.29 vs 1.66 ± 0.34, $p > 0.05$) and so was the post-operative TAPSE at discharge (1.52 ± 0.30 vs 1.43 ± 0.32, $p > 0.05$) and at one month post operatively (1.6 ± 0.27 vs 1.43 ± 0.032, $p > 0.05$).
Conclusions: Both trans-RA and trans RA/RV approaches provide a safe palliation for patients with TOF. The right ventriculotomy should not be avoided if required for adequate infundibular resection and can be safely done without fear of producing excessive arrhythmias and early right ventricular dysfunction.

Objectives: To assess the outcome of different surgical techniques in patients with congenitally corrected transposition of the great arteries (CCTGA).
Material and Methods: 66 out of 133 patients diagnosed with CCTGA underwent surgery between January 1998 and February 2016. Group 1 (Anatomic repair): 20 patients (25.3%); mean age: 44.6 months. Surgical techniques: Double switch in 10 patients; Senning /Mustard + Rastelli in 8 patients; Hemimustard + Switch, 1 patient; Hemimustard + Nikaidoh, 1 patient. Mean follow-up time: 56 ± 42 months. Group 2 (Traditional surgery): 46 patients (58.2%); mean age: 58.17 months. Surgical techniques: ventricular septum defect (VSD) closure + Left ventricle conduit-pulmonary artery (LV-PA), 33 patients. VSD closure, 10 patients. Tricuspid valve replacement, 3 patients. Mean follow-up time: 104 ± 95 months. The variables evaluated were: tricuspid insufficiency, ventricular dysfunction, complete AV block, aortic insufficiency and reoperations.
Results: Group 1: Improvement in tricuspid regurgitation: 42.8% of cases during follow-up. Ventricular dysfunction: 47% at immediate post-operative time; 50% of them recovered at late follow-up. Two patients developed AV block (with permanent pacemaker). Mild aortic insufficiency: 60%; reoperations, 29.4%. Early mortality rate: 15%; 120-month survival rate: 84%. Group 2: Tricuspid regurgitation: 41%; ventricular dysfunction:28.26%. AV block: 26%: 5 at immediate post-operative time and 9 at late follow-up. Aortic insufficiency: 19.5%. Reoperations: 31.4%. Early mortality rate: 19.5%; 120-month survival rate: 79%.
Conclusions: Outcome of traditional surgery is satisfactory, although there is a tendency for progression towards tricuspid insufficiency and AV block with requirement of permanent pacemaker. Anatomic repair shows improvement of tricuspid regurgitation during follow-up, with low rate of complete AV block, but a greater risk of ventricular dysfunction at immediate post-operative time, and intermediate and long-term mild aortic insufficiency. Reoperation rate was similar in both groups.

P1314 - EARLY RESULTS OF MINITHORACOTOMY USE FOR DUCTUS ARTERIOSUS CLOSURE IN VERY LOW BIRTH WEIGHT PRETERM INFANTS

Pedro Rafael Salerno[1], Juliana V. O. Salerno[2], Geyse Marinho Falcão[3], Rebeca Carlström[3], Lúcia Maria V. O. Salerno[4], Carolina V. O. Salerno[5], Pablo César Lustosa[1], Ahylson Roberto Correia[1], Neize Maria Gondim De Souza Montenegro[6], Daniel Cunha[7]
Esperança Hospital, Cardiovascular Surgery, Recife-Brazil[1]; Fcmpb, Student, João Pessoa-Brazil[2]; Unicap, Student, Recife-Brazil[3]; Esperança Hospital, Pediatric Cardiology, Recife-Brazil[4]; Ufpe, Student, Recife-Brazil[5]; Esperança Hospital, Neonatal Intensive Care, Recife-Brazil[6]; Esperança Hospital, Anesthesiology, Recife-Brazil[7]

Background: Ductus arteriosus' (DA) functional closure occurs 12-15 hours after birth, and permanent closure 5-7 days later. Studies show that 58,8% of very low birth weight neonates have patent ductus arteriosus (PDA), and if left open longer than usual it can cause severe complications such as pulmonary edema, necrotizing enterocolitis, heart and renal failure, systemic hypotension, and cerebral blood flow alterations. Recent studies suggest initial pharmacological treatment, and if unresolved, proceed to surgical intervention, but other findings point out lower immediate mortality of patients treated surgically right after PDA diagnosis. Our objective is to analyze the immediate mortality of infants submitted to surgical closure of the DA.
Material and Methods: From March 2001 to December 2015 the Esperança Hospital of Recife's medical records of 32 very low birth weight preterm neonates with PDA were analyzed. Corrected gestational age varied from 24 to 36 weeks (m = 29 weeks) and weight ranged from 400 to 1,000 g (m = 743,1 g). Surgery performed under general anesthesia, hemodynamic monitorization with noninvasive arterial pressure, pulse oximetry and continuous EKG. The DAs were resected through 2 cm minithoracotomies on the 4th left posterior intercostal space. Metallic clips used according to the DA's size (LT300 or LT400 Ethicon®). After clipping, there was an improvement in the systemic arterial pressure and disappearance of the fremitus.
Results: After the surgical procedure, only one patient (3,1%) needed pulmonary drainage due to a pneumothorax. None of the patients presented surgical site infection. Immediate surgical mortality was of one patient (3,1%).
Conclusion: Although surgical procedures may be high risk for very low birth weight premature infants, DA closure through minithoracotomy had minor morbidity and mortality. Future studies are needed to analyze late results.

P1316 - FONTAN OPERATION FOR 150 CONSECUTIVE CHILDREN WITH HYPOPLASTIC LEFT HEART SYNDROME WITHOUT EARLY MORTALITY

Katarzyna Januszewska[1], Sebastian Kintrup[1], Anja Lehner[2], Kanrad Wisniewski[1], Sabrina Lueck[1], Hans Gerd Kehl[3], Christoph Schmidt[4], Edward Malec[1]
University Hospital Muenster, Division of Pediatric Cardiac Surgery, Muenster-Germany[1]; University Hospital Munich, Department of Pediatric Cardiology, Munich-Germany[2]; University Hospital Muenster, Department of Pediatric Cardiology, Muenster-Germany[3]; University Hospital Muenster, Department of Anaesthesiology,Muenster-Germany[4]

Background: The operative results of the multistage reconstructive surgery for children with hypoplastic left heart syndrome (HLHS) are improving in the recent years and more patients reach the last stage surgery. The goal of the study was to analyze the hospital results of the Fontan operation for children with HLHS.
Material and Methods: Between September 2007 and August 2016, 150 children in the mean age of 37.6 ± 15.6 months and weight of 12.4 ± 1.9 kg with HLHS underwent Fontan operation, and were operated on by the same surgical team in two institutions. 112 patients after bidirectional Glenn anastomosis underwent extracardiac conduit (EC) on beating heart (only 8(7.1%) children required aortic cross-clamp for intracardiac procedures), and 38 children after hemi-Fontan operation underwent lateral atrial tunnel (LT) Fontan procedure. The medical records were retrospectively analyzed.
Results: The hospital survival was 100%. The mean intubation time was 7.2 ± 6.2 hours, mean stay in the intensive care unit was 3.9 ± 9.2 days and the mean hospital stay was 17.7 ± 13.2 days. The mean cardio-pulmonary bypass time (EC: 45.1 ± 14.0 vs. LT: 62.1 ± 17.1 min; $p < 0.001$), mean aortic cross-clamping time if needed (EC: 24.4 ± 6.7 vs. LT: 32.2 ± 7.6 min; $p = 0.016$) and mean intubation time (EC: 5.1 ± 7.4 vs. LT: 9.3 ± 5.9 h; $p = 0.002$) were shorter in the EC group. Children after hemi-Fontan procedure required during Fontan operation significantly

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

more often tricuspid valve repair or replacement in comparison with children after Glenn anastomosis (LT: 9(23.7%) vs. EC: 8 (7.1%); p = 0.013).
Conclusions: Fontan operation in children with HLHS can be performed nowadays without hospital mortality and with low morbidity rate, regardless of the operative technique. The extracardiac conduit Fontan operation can be performed with shorter cardio-pulmonary bypass time and without cardioplegic cardiac arrest on beating heart, which can have impact on the myocardial performance in the late follow up.

P1318 - EXTUBATION IN THE OPERATING ROOM FOR CHILDREN AFTER FONTAN OPERATION

Sebastian Kintrup[1], Daniela Kiski[2], Christoph Schmidt[3], Andreas Brünen[3], Andrea Orth[2], Edward Malec[1], Katarzyna Januszewska[1]
University Hospital Muenster, Division of Pediatric Cardiac Surgery, Muenster-Germany[1]; University Hospital Muenster, Department of Pediatric Cardiology, Muenster-Germany[2]; University Hospital Muenster, Department of Anaesthesiology, Muenster-Germany[3]

Background: Early extubation is beneficial for the Fontan circulation. The goal of the study was to assess the impact of the extubation on the operating table in comparison with the early extubation in the first hours after Fontan operation (FO) on the early postoperative course.
Materials and Methods: Between 2013 and 2016, 114 children (mean age, 3.8 ± 2.3) with univentricular heart underwent FO in our institution. 60 patients were extubated in the operating room (ORE) and 54 in the intensive care unit (ICUE) in a median time of 195 min (range, 30-515 min) after FO. The medical records (191 parameters) were retrospectively analyzed.
Results: One patient needed a reintubation because of respiratory insufficiency (laryngospasm) (ORE: 1/60 vs. ICUE: 0/54; p = 0.958). The hospital survival was 100% and the mean hospital stay was 17.5 ± 6.8 days, without differences between the groups. The results are presented in the table.
Conclusion: Extubation in the operating room after Fontan operation is feasible, safe and can be routinely performed. The adaptation for the Fontan circulation is faster and needs less therapeutic interventions in children with immediate extubation after surgery.

Table.

	ICUE (N = 54)	ORE (N = 60)	p-value
Heart rate [bpm]*	120.3 ± 5.96	106.5 ± 3.99	<0.001
Blood pressure [mmHg]*			
arterial systolic	93.5 ± 6.43	90.6 ± 2.09	0.024
arterial diastolic	53.6 ± 4.33	49.6 ± 1.38	<0.001
central venous	11.4 ± 1.42	10.4 ± 0.66	0.001
Urine output [ml/kg/h]*	4.8 ± 0.96	3.7 ± 0.78	<0.001
Blood gas analysis 2-3 h after FO			
pH	7.300 ± 0.47	7.364 ± 0.04	<0.001
pCO_2	42.67 ± 7.35	38.25 ± 4.73	0.005
pO_2	86.28 ± 34.20	100.22 ± 40.30	0.048
$SatO_2$	91.58 ± 10.57	93.50 ± 10.46	0.041
Cumulative dopamine support [h]	12.77 ± 11.68	9.75 ± 11.28	0.033
Crystalloid fluid therapy [ml/kg/24 h]	73.76 ± 46.09	54.11 ± 31.19	0.019
Total amount of effusions [ml/kg]			
6 h after FO	11.1 ± 6.72	6.5 ± 3.68	0.024
24 h after FO	31.5 ± 18.13	19.1 ± 9.12	0.001
48 h after FO	49.5 ± 26.10	37.9 ± 17.48	<0.001
Antibiotics therapy [days]	5.77 ± 4.63	4.74 ± 3.36	0.037

*bpm - beats per minute; *mean value of every hour recorded parameters during the first 24 h after FO.

P1321 - BETTER IMMEDIATE RESULTS OF JATENE PROCEDURE BEFORE 15 DAYS OF LIFE

Pedro Rafael Salerno[1], Juliana V. O. Salerno[2], Assiane Anceles Da Rocha[3], Emily Ferreira De Araújo Lima[3], Lúcia M. V. O. Salerno[4], Carolina V. O. Salerno[5], Catarina Cavalcanti[6], Thaysa Meneses[7], Anuska Elizabeth L. L. Da Gama[7], Ricardo C. Lima[8], Ricardo Lins[9]
UPE, Cardiac Surgery, Recife-Brazil[1]; Fcmpb, Student, João Pessoa-Brazil[2]; Unicap, Student, Recife-Brazil[3]; UFPE, Cardiology, Recife-Brazil[4]; UFPE, Student, Recife-Brazil[5]; UPE - Procape, Pediatric Cardiology, Recife-Brazil[6]; Esperança Hospital, Pediatric Cardiology, Recife-Brazil[7]; UPE - Procape, Cardiovascular Surgery, Recife-Brazil[8]; UPE - Procape, Cardiovascular Surgeon, Recife-Brazil[9]

Background: Transposition of the great vessels (TGV) is the most frequent congenital cyanotic cardiopathy in the first year of life. There is ventriculoarterial discordance resulting in parallel pulmonary and systemic circulations responsible for a state of hypoxia observed by central cyanosis. It is fatal unless mixing of oxygenated and deoxygenated blood occurs through patent ductus arteriosus (PDA), atrial or ventricular septal defect (ASD and VSD). The initial results of the Jatene procedure were investigated in infants with TGV.
Methods: A retrospective study from July 2008 to March 2015 analyzed 23 patients' medical records who underwent Jatene procedure at Esperança Hospital of Recife or PROCAPE. Exclusion criteria included age over 32 months, coarctation of the aorta, pulmonary stenosis or hypertension, and Taussig-bing syndrome. Age ranged from 4 days to 32 months (m = 101,2 days) and weight from 2,700 to 5,100 g (m = 3,400 g). Associated with TGV 12 patients had ASD and PDA (52,2%), 10 had VSD, ASD and PDA (43,5%) and only one had ASD and pulmonary artery banding (4,3%). The Jatene procedure is performed under general anesthesia with 8oC intermittent cardioplegia. The aorta and pulmonary artery are detached from their native roots, reattached to the opposing root, and the coronary arteries are transplanted from the aorta to the neo-aorta.
Results: Hospitalization period varied from 13 to 180 days (m = 37,1 days). Ten patients presented low cardiac output syndrome (43,4%), seven had renal failure with a need for peritoneal dialysis (30,4%), and seven were deceased (30,4%). Infants over 15 days had higher morbimortality rates as well as patients with ASD and VSD compared to those with ASD and PDA.
Conclusion: The Jatene procedure is a definitive treatment for TGV and has better results when done early, before 15 days of life.

P1334 - NURSE DRIVEN REMOVAL OF CHEST TUBE DRAIN

Siti Laura Mazalan[1], Rajeena Selvi Karuppiah[2], Rasimah Abu Talib[2], Fardilawati Mohamed Noor[2], Vikneswary Sathasevam[2]
National Heart Institute, Cardiothoracic Surgery, Kuala Lumpur-Malaysia[1]; National Heart Institute, Pediatric Ward, Kuala Lumpur-Malaysia[2]

Background: National Heart Institute nurse driven in removal of chest tube because all our patient post cardiac surgery has chest drain. Common chest drains that in place after cardiac surgery are such as pericardial, mediastinal or pleural chest tubes. Our main objective of this study is to present the best available evidence related to the Paediatric ward nurses in removal of chest drains. Secondary objective is to enable the registered nurse to remove chest drain with safety standard applied and developing their competency skill.
Materials/Method: This is a retrospective observational study to audit inpatient Paediatric General Cardiac ward nurses in removal

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

of chest drain at Day 4 post-operative for patient above 1 year. The sample was collected from October 2013 to December 2014, which consist of 182 patients audited in removal of chest drain and total of 313 chest drains were removed. 243 chest drains was removed by the specialized cardiac nurses and another 70 chest drains was removed by surgeon. Audit form was used to collect the data. Training were conduct by Surgeon and Senior Nurse Mentor with workshop, bedside teaching and hand on. Inclusive and exclusive criteria were developed for removal of chest drain to prevent any complications and to ensure patient safety.
Results: From the data collected shows 243 chest drains were removed by ward nurses. 11 cases (3.7%) developed complication such as pneumothorax. 232 (95%) were successfully removed chest tubes without any complication.
Conclusion: Chest tube removal can be successfully performed by the specialized cardiac ward nurses with minimal complication. The advantage is reduce waiting time for surgeon for chest tube removal. Therefore it enhance early mobilization and recovery of Paediatric patient. Structured training in removal chest drain, assess and reassessment is very important element to be conduct in order to develop competent staff.

P1338 - LONG TERM OUTCOMES OF ISOLATED TOTAL ANOMALOUS PULMONARY VENOUS DRAINAGE REPAIR IN NEONATES AND INFANTS A 41 YEAR EXPERIENCE FROM A SINGLE INSTITUTION

Matthew Yong[1], Nima Yaftian[1], Johann Brink[1], Terry Robertson[2], Luigi D'orsogna[3], Robert Weintraub[4], Yves D'Udekem[1], Christian Brizard[1], Igor Konstantinov[1]
Royal Children's Hospital, Cardiac Surgery, Melbourne-Australia[1]; Women's and Children's Hospital, Cardiology, Adelaide-Australia[2]; Princess Margaret Hospital, Cardiology, Perth-Australia[3]; Royal Children's Hospital, Cardiology, Melbourne-Australia[4]

Background: Outcomes of surgery for total anomalous pulmonary venous drainage (TAPVD) has improved. However, surgery in the neonatal period and the development of postoperative pulmonary venous obstruction (PVO) is associated with high mortality.
Methods: A retrospective review was conducted for all neonates and infants (n = 214) undergoing surgery for isolated TAPVD (1973-2014). Multivariate analysis was performed.
Results: Preoperative PVO occurred in 112 (52%) patients. There were 91 (43%) supracardiac, 45 (21%) cardiac, 60 (28%) infracardiac and 18 (8%) mixed TAPVD. Median age was 18 days (1day-1 year). There were 17 (7.9%) early deaths. Risk factors for early mortality were prolonged cardiopulmonary bypass (CPB) time ($p = 0.005$) and neonatal age at surgery ($p = 0.048$). Era of surgery was not a risk factor. Early mortality for infants (n = 81) and neonates (n = 133) was 2.5% and 11%, respectively ($p = 0.021$). Hospital mortality according to era was 12% (6/49) (infant 9.1%, 1/11; neonates 13%, 5/38) during 1973-1988; 8.2% (5/61) (infants 4.8%, 1/21; neonates 10%, 4/40) during 1989-1998; and 5.7% (4/70) (infants 0%, 0/36; neonates 8.8%, 4/34) during 1999-2008 and 5.9% (2/34) (infants 0%, 0/13; neonates 10% 2, 2/21) during 2009-2014. There were 10 (5%) late deaths. Survival at 10 and 20 years was 88 ± 2.2% (95% CI:82-91%). Reoperation for postoperative PVO was required in 22 (10%) patients. Risk factors for reoperation were prolonged CPB time ($p = 0.015$), lower operative weight ($p = 0.003$) and an episode of postoperative pulmonary hypertensive crisis ($p = 0.005$). Freedom from reoperation at 10 and 20 years was 90 ± 2.2% (95% CI:85-93%) and 86 ± 3.2% (95% CI:78-91%), respectively. All survivors were asymptomatic at a mean of 13 ± 9 years (1 month-42 years) after surgery.
Conclusions: While isolated TAPVD repair in infants can be performed without mortality, it is associated with high mortality in neonates that remained unchanged over long study period. Survival beyond 1-year of age is associated with excellent long-term outcomes.

P1342 - INHALED NITRIC OXIDE WITH A NASAL CANNULA AND USE OF PHOSPHODIESTERASE INHIBITOR TO FACILITATE WEANING FROM INHALED NITRIC OXIDE FOR CHILDREN AFTER CONGENITAL CARDIAC SURGERY

Masahide Chikada[1], Hirokuni Ono[1], Takeshi Miyairi[1], Syouta Kita[1], Kentaro Aso[2], Yoshimitsu Tuzuki[2], Masanori Mizuno[2], Yousuke Osada[2]
St.Marianna University Hospital, Cardiovascular Surgery, Kawasaki-Japan[1]; St.Marianna University Hospital, Pediatrics, Kawasaki-Japan[2]

Objective: Inhaled nitric oxide is effective for critical pulmonary perfusion. After extubation, inhaled nitric oxide is usually discontinued and rebound pulmonary hypertension is the problem. The purpose of this study was to evaluate inhaled nitric oxide with a nasal cannula and use of phosphodiesterase inhibitor in facilitating its problem.
Methods: Inhaled nitric oxidewas administered in the case with critical pulmonary perfusion (central venous pressure >20 mmHg or pulmonary hypertensive crisis) during the operation or in the early postoperative period. In ten cases, inhaled nitric oxide could not be discontinued before extubation. In these cases, inhaled nitric oxide with a nasal cannula was continued after extubation and phosphodiesterase inhibitor was also used. Patients ranged in age from 2 months to 2.5 years and weighed from 2.5 kg to 12.7 kg. Four cases were after bidirectional Glenn anastomosis, three case were after total cavopulmonary connection and three cases were after patch closure of ventricular septal defect.
Results: There was no hospital death. No rebound pulmonary hypertension occurred in any cases. The time to discontinuation of inhaled nitric oxide after extubation raged from 2 days to 26 days. The dose of inhaled nitric oxide ranged from 1 to 10 ppm. Phosphodiesterase inhibitor (sildenafil in four cases or tadalafil in three cases) was administered before or after extubation. The dose of sildenafil ranged 0.5 mg/kg to 1.5 mg/kg and the dose of tadalafil was 1 mg/kg. No toxic side effect was observed in any cases.
Conclusion: Inhaled nitric oxide with a nasal cannula and use of phosphodiesterase inhibitor can facilitate weaning from inhaled nitric oxide for children after congenital cardiac surgery with critical pulmonary perfusion.

P1349 - ARTERIAL SWITCH OPERATION IN PATIENTS WITH TRANSPOSITION AND LEFT SIDED AORTA

Sachin Talwar[1], Saurabh Gupta[2], Pradeep Ramakrishnan[3], Robert Anderson[4], Shivkumar Choudhary[3], Balram Airan[3]
All India Institue of Medical Sciencess, CTVS, New Delhi-India[1]; All India Institue of Medical Sciences, Cardiology, New Delhi-India[2]; All India Institue of Medical Sciences, CTVS, New Delhi-India[3]; Institute of Genetic Medicine, Newcastle University, CTVS, Newcastle-United Kingdom[4]

Background: The arterial switch operation (ASO) has evolved as the treatment of choice for infants with transposition. The procedure

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

is technically challenging when the aorta is left-sided, and requires surgical expertise and precision for a good surgical outcome. We review here our experience with such patients.
Methods: We carried out the arterial switch procedure in 20 patients diagnosed as transposition with left-sided and anterior aorta, diagnosed between January, 2002, and October, 2013. Hospital records were analyzed for segmental anatomy, associated cardiac anomalies, the coronary arterial patterns, aortic cross clamp and cardiopulmonary bypass times, and specific surgical techniques used for transfer of the coronary arteries and reconstruction of great arteries. We recorded the outcomes in terms of in hospital survival and left ventricular function at most recent follow up.
Results: Age at the time of operation ranged from 3 days to 18 months (median- 75 days), and weight ranged from 3 kgs to 8.8 kgs (median -3.85 kgs).All patients survived the operation.We did not perform the LeCompte manouvrein 9 patients. Mean cardiopulmonary bypass time was 157.5 ± 24.9 minutes, (median 161 minutes); mean aortic cross-clamp time was 101.2 ± 23.8 minutes, (median 102 minutes). One patient died on the second postoperative day due to sudden onset of ventricular fibrillation. Follow-up ranged from 23 to 31 months(mean 28.04 ± 2.32 months, median 28.4 months). At last follow-up, all 19 survivors are in NYHA class I, and none require cardiac medications. Serial echocardiograms have revealed normal biventricular function and no residual defects.
Conclusion: With appropriate technical modifications, patients with concordant atrioventricular and discordant ventriculo-arterial connections with left-sided aorta can undergo successful anatomical repair.

P1350 - A SINGLE STAGE SURGICAL REPAIR OF INTERRUPTED AORTIC ARCH PROXIMAL AORTO PULMONARY WINDOW TYPE 1 WITH AORTIC ORIGIN OF THE RIGHT PULMONARY ARTERY

Marcin Zaradzki[1], Tsvetomir Loukanov[2]
University Hospital Heidelberg, Department of Cardiac Surgery, Heidelberg-Germany[1]; University Hospital Heidelberg, Department of Pediatric Cardiac Surgery, Heidelberg-Germany[2]

Introduction: The combined deformation consisting of an interrupted Aortic Arch, a proximal aorto-pulmonary window type 1, aortic origin of the right pulmonary artery, intact ventricular septum and patent ductus is a rare and surgically challenging disorder. We present single-stage-repair and successful perioperative management of such a patient.
Case Description: The patient was born in 41 + 1 week of pregnancy with bodyweight of 3270 gram in a district hospital. Following pathological pulse-oxymetric screening echocardiography was performed. After initial diagnosis of isthmus-stenosis and an aortopulmonary window, the 2-day-old neonate was referred to our ICU, presenting with tachypnoea of 70/min without other signs of congestive heart failure or hereditary malformations. Another echocardiography revealed the interrupted aortic arch, a proximal aorto-pulmonary window type 1 and under prostaglandin-therapy still patent ductus. Hence the single-stage-repair was performed. After harvesting the pericardial patch, the ductus was ligated and the aortic stenosis dissected. Following the preparation and attachment of the descending aorta to the aortic arch, the patch was sutured to the anterior half of the proximal descending aorta. Then the suture line descended to the posterior inner wall of the ascending aorta, leaving the abnormally positioned pulmonary artery on the left side of the patch. The remaining part of the aortic wall was now attached to the patch and the pulmonary artery on the other side as well. Postoperative care was uneventful.
Discussion: This rare and complex malformation requires fast and sufficient diagnosis and therapy. Due to critical condition of the mostly just days old patients, vast and invasive diagnostics are irrelevant. Echocardiography is, if performed by experienced physicians, the diagnostic method of choice. Because of low impact on the therapeutical approach angiography is mostly obsolete. A fast and complete surgical repair is essential to prevent pulmonary damage and to restore perfusion in the lower body.

P1352 - GIANT PSEUDOANEURYSM OF THE RIGHT VENTRICULAR OUTFLOW TRACT AFTER SURGICAL COMISUROTOMY OF PULMONARY VALVE SURGICAL APPROACH

Luis Zerpa[1], Alejandro Alaña[1], José Iribarren[1], Ivan Machado[2], María Arape[2], Ana Palmar[2], Cielo Rojas[2], Claudia Scanzoni[2]
Hospital De Especialidades Pediátricas/Fundación De Todo Corazón Richard Gibson, Pediatric Cardiac Surgery, Maracaibo-Venezuela[1]; Hospital De Especialidades Pediátricas/fundación De Todo Corazón Richard Gibson, Pediatric Cardiology, Caracas-Venezuela[2]

Background: Ventricular pseudoaneurysm result from rupture of myocardium with resultant localized hemopericardium. Right ventricular pseudoaneurysms are exceptionally rare, and can be a complication of cardiac surgical procedures done for congenital heart disease1 2. This can have catastrophic consequences3; so, early repair is of vital importance. We describe a case in a boy who developed a giant pseudoaneurysm three years after surgical comisurotomy of pulmonary valve for severe stenosis and RVOT ampliation with bovine pericardial parch and the surgical repair.
Case Report: A 15-years-old boy with Noonan syndrome, and diagnosed (at the age of 12 years) with Severe Pulmonary valve stenosis, was attended prior surgery at age 12 years: Through right ventriculotomy, Pulmonary Valve comisurotomy and right ventricular outflow tract ampliation with bovine pericardiac patch was achieved. Presented immediate bleeding, needing reoperation, without findings of specific point of bleeding, he was stayed in ICU during 2 days, total In-hospital stay of 10 days. At 3 years postoperative follow up the patient was consulting having dyspnea and precordial pain during ordinary physical activity. During examination he was found to have a pseudoaneurysm of right ventricular outflow tract (RVOT) by transthoracic echocardiogram (TTE). The patient underwent elective surgery, arterial and venous femoral cannulation, establish cardiopulmonary bypass, careful sternotomy was carried out, pseudoaneurysm was dissected, and under the beating heart on full cardiopulmonary bypass, the pseudoaneurysm was opened and the communication with the RVOT was confirmed and closed with a bovine pericardial patch using a continuous suture technique, reinforced with the pseudoaneurysm wall in a layer over layer manner, without postoperative complications.
Conclusions: Opportune repair of ventricular pseudoaneurysm is of vital importance4. Echocardiography is an excellent diagnostic method for this entite3 5. Althought midline sternotomy could be safe in most patients; peripheral cannulation should be considered when the pseudoaneurism adheres to the sternum.

P1353 - IMPROVING REALISM DURING PEDIATRIC ECMO SIMULATION

Bruno Claro[1], Timothy Jackson[1], Ioanna Giannakopoulou[2], Ajay Desai[3], Nigel Cross[1], Naoise O[1], Diane Frall[3], Rebecca Akehurst[3], Macrae Duncan[3]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Royal Brompton Hospital, Perfusion, London-United Kingdom[1]; Royal Brompton Hospital, Pediatric Cardiology, London-United Kingdom[2]; Royal Brompton Hospital, Picu, London-United Kingdom[3]

Background: According to the Extracorporeal Life Support Organization (ELSO) guidelines, "low volume" Extracorporeal Membrane Oxygenation (ECMO) programs (<20 cases/year) may need additional continuing education for all team members. Simulation based training is increasingly recognised as a powerful educational tool to improve safety, attitudes and teamworking surrounding emergencies with pediatric ECMO.
Methods: In order to increase the fidelity of our paediatric ECMO emergency scenarios, we established the ability to simulate the different colours of oxygenated and deoxygenated blood of the ECMO circuit, allowing us to reproduce gas supply failure and oxygenator failure scenarios. Porcine blood was used to prime our modified paediatric ECMO circuit. Our standard circuit consists of a centrifugal pump and a pediatric heparin coated hollow fiber oxygenator. We modified it to include a "de"-oxygenator and a reservoir bag inserted in series and hidden from view. This spare oxygenator is used to deoxygenate the blood by running a sweep gas of 100% carbon dioxide. The system is also used to simulate air entrainment into the circuit. The presence of blood demonstrates how easily it foams, making the scenario more realistic and difficult to deal with.
Results: This technique has been used 8 times, training 160 team members since 2013. An easily discernible difference in line colour has occurred each time. Participants strongly noted the ease of differentiating oxygenated and deoxygenated blood. Feedback supports the realism of the technique compared to clear prime simulation. Detailed analysis of the feedback will be presented.
Conclusions: Use of porcine blood in the ECMO circuit with a "de" oxygenator is feasible and improves the fidelity of the simulation training experience. Allowing oxygenated and deoxygenated blood to be recognised permits realistic troubleshooting and problem solving in ECMO emergencies such as gas supply failure, oxygenator failure and air entrainment.

P1367 - IMPROVED PROGNOSIS IN A TWO STAGE APPROACH FOR SURGICAL CORRECTION OF VENTRICULAR SEPTAL DEFECT IN PATIENTS WITH TRISOMY 18

Takamichi Uchiyama[1], *Shintarou Nemoto[2], Kanta Kishi[3], Ken Yoshimura[4]*
Takatsuki General Hospital, Pediatrics, Osaka-Japan[1] Osaka Medical College, Thoracic and Cardiovascular Surgery, Osaka-Japan[2] Osaka Medical College, Pediatrics, Osaka-Japan[3] Kansai Medical University, Pediatrics, Osaka-Japan[4]

Background: A congenital heart defect, particularly ventricular septal defect (VSD), is common in patients with trisomy 18 (T18). The indication for cardiac surgery in T18 patients is still controversial and requires discussion from the perspectives of postoperative outcomes and prognosis, in addition to bioethics.
Patients and Methods: The prognosis of surgical correction of VSD with T18 was determined in a retrospective review of medical records of 30 patients with T18 who were followed in North Osaka territorial hospitals in Japan from April 2008 to May 2016.
Results: Of the 30 patients, 16 (53%) underwent surgical treatment after careful informed consent was obtained from their parents (n = 15, VSD; n = 1, coarctation of aorta with VSD). One (6%) of these 16 patients underwent primary correction at 303 days after birth (BW: 3.5 kg) and 15 (93%) underwent first-stage palliative surgery (n = 14, pulmonary artery banding (PAB); n = 1, bilateral PAB, all with PDA ligation) from 12 to 126 days after birth (median: 127 days) (BW: 1.0 to 2.8 kg, median: 2.2 kg). In these 15 patients, there were three deaths (20%) due to pneumonia (n = 2) and sudden death (n = 1). Eleven (73%) of the 15 patients underwent second-stage correction (VSD closure and PAB debanding) 1.5 to 14.8 months (median: 8.8 months) after PAB (BW: 2.1 to 6.8 kg, median: 4.8 kg) and one is waiting for second-stage correction. Survival ranged from 15 to 85 months (median: 36.5) after second-stage correction and patients were discharged with improved symptoms. Nine (75%) of 12 patients underwent tracheostomy before correction. These 12 patients did not have severe gastrointestinal anomalies such as esophageal atresia.
Conclusion: A two-stage approach for surgical correction of VSD was practical and effective in carefully selected patients with T18. Long-term follow up is necessary to confirm the efficacy.

P1370 - THE FATE OF THE TRANSLOCATED AORTIC ROOT AFTER THE MODIFIED NIKAIDOH OPERATION

Matej Nosal, *Andrea Kantorova, Michal Sagat, Aref Nagi, Valentik Pavel*
Children's Heart Centre Slovakia, Cardiac Surgery, Bratislava-Slovakia

Background: The modified Nikaidoh operation in transposed great aretries, ventricular septal defect and pulmonary stenosis allows translocation of the whole aortic root along with both coronary arteries.
Aim: We retrospectively analyzed our results with emphasis on the translocated aortic root dimensions.
Methods: Inbetween july 2012 and july 2016 7 patients underwent the modified Nikaidoh procedure.Four patients had DTGA/VSD/PS and 3 had DORV/VSD/PS anatomy. In all patients the aortic root was excised and translocated with attached both coronaries. The VSD was closed by a dacron patch in 5 and directly in 2 patients.The pulmonary artery was directly connected to the RVOT after a LeCompte manuever.
Results: Median age at operation was 1 year(30 days-3 years), median weight 9.4 kg (3.2-11 kg) and median follow up 3.6 years (2.7- 4 years).Median duration of extracorporeal circulation and aortic crossclamp were 190 min (150-347 min) and 90 min (43-108 min) respectively. One patient died 47 days postoperatively due to multiorgan failure following cardiac transplantation after unsuccsessfull attempts of closure of multiple muscular VSD´s. At the follow up there was no gradient on the LVOT in any patient and mild aortic regurgitation in one patient. The aortic annulus Z score decreased sligtly from 3.4 (2-4.3) preoperatively to 2.7 (1.7–4) at the follow up (p = 0.08).The aortic root Z score increased insignificantly from 1.2 (0.4-4) preoperatively to 2.1 (0.1-4.4) at the follow up (p = 0.66).The ascending aorta Z score

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

remained stable from 0.9(0.4-4)preoperatively to 0.5 (0-3.5)at the follow up (p = 0.35).
Conclusions: The modified Nikaidoh operation offers unobstructive pathway from the left ventricle and preservs the aortic valve function. The Z scores of aortic dimensions indicate, that the aortic annulus, root and ascending aorta remain stable in the midterm.Further follow up is necessary to asess the longterm function of the translocated aortic valve and the root.

P1375 - RESPIRATORY VIRUSES STILL A MAJOR PROBLEM IN PEDIATRIC CARDIAC SURGERY PATIENTS

Eloisa Carvalho[1], Maria Francilene Souza[1], Ana Maria Thomaz[1], Clarisse Machado[2], Antonio Augusto Lopes[1]
Heart Institute (Incor), University of São Paulo School of Medicine, Dept. of Pediatric Cardiology and Cardiac Surgery, São Paulo-Brazil[1]; University of São Paulo School of Medicine, Tropical Medicine Institute, São Paulo-Brazil[2]

Background/Objective: Respiratory viral infections (RVIs) are critical events in infants and children with congenital heart diseases, particularly when they occur during hospital stay for cardiac surgery. However, they are relatively rare events. We therefore used sophisticated statistical armamentarium (generalized linear models – GzLMs) to analyse risk factors and consequences of RVIs in this population.
Patients/Methods: Of 1797 patients admitted from January 2012 to December 2014, 209 pediatric cardiac surgery subjects (age 1-14 months, median 7 mos.) had clinical suspicion of RVIs during hospitalization, with nasopharyngeal aspirates available for analysis. Immunofluorescence assays were performed for detection of influenza and parainfluenza viruses, adenovirus and respiratory syncytial virus (RSV). The periods of observation were registered for construction of GzLMs.
Results: Viruses were detected in 22% of instances; RSV was the most prevalent one (10%) followed by parainfluenza (9%). We used Poisson regression to demonstrate a higher rate of infections in 2013 relative to 2012 and 2014 (p = 0.040). Weight quartiles 2 and 3 (lowest to highest) were associated with risk (p = 0.051 and p = 0.039 respectively) compared to quartile 1 (relative protection). We used ordinal regression to analyse the impact of age, weight, Down syndrome, type of cardiac anomaly and RVIs on the length of hospital stay and occurrence of fatal events. Weight appeared as a protective factor (for quartiles, HR, 0.79; 95% CI, 0.71-0.88); AV canal defects/left isomerism and cyanotic defects with right heart obstruction were "high risk" compared to simple shunts (respective HR with 95% CI, 3.16[1.27-7.84] and 2.21 [1.11-4.39]). RVIs were associated with prolonged hospitalization (HR, 2.11; 95% CI, 1.16-3.83), with an 18-day increase in hospital stay (p = 0.002).
Conclusions: In addition to the known seasonal variations, there are year-to-year changes in the risk of RVIs in hospitalized patients. Low weight, complex and right-heart obstructive anomalies, and RVIs are important determinants of prolonged hospital stay.

P1379 - AUTOIMMUNE VASCULITIS IN A CHILD FOLLOWING TETRALOGY OF FALLOT REPAIR IN UGANDA

Judith Namuyonga[1], Twalib Aliku[2], Emmanuel Tenywa[3], Richard Idro[4], Hume Heather[5], Sulaiman Lubega[2], Peter Lwabi[2]
Uganda Heart Institute/ College of Health Sciences, Makerere University, Paediatric Cardiology, Kampala-Uganda[1]; Uganda Heart Institute, Paediatric Cardiology, Kampala-Uganda[2]; Uganda Heart Institute, Paediatric Caardiolgy, Kampala-Uganda[3]; College of Health Sciences, Makerere University, Paediatrics and Child Health, Kampala-Uganda[4]; College of Health Sciences, Makerere University/University of Montreal, Canada, Paediatrics And Child Health, Kampala-Uganda[5]

Background: Tetralogy of Fallot is one of the conotruncal abnormalities associated with 22.q.11 deletion syndrome which presents with thymic hypoplasia, hypocalcaemia and have an increased risk of autoimmune disorders. We report about a child post TOF repair who presented to the Uganda Heart Institute diagnosed to have autoimmune vasculitis.
Clinical Case: An 11 year girl who had undergone TOF repair 8 years prior to the illness presented with persistent high grade fevers for 2 weeks, abdominal pain, petichae with no arthralgia. Clinical examination revealed a sick child febrile 39 °C, with petichae on palms and sole of the feet. Oral thrush and bleeds in the mouth and no dysmorphism. She also had blisters on the lower limbs with secondary infection. She was hypoxic with oxygen saturation of 86% on room air. Blood pressure 88/56 mmHg with grade 3/6 ejection systolic murmur in the left upper sternal edge. Baseline laboratory results upon admission showed leukocytosis, WBC 17.9 × 103, with a neutrophilia, 16 × 103(89%), Haemoglobin 12.3 g/dl, thrombocytopenia 93 × 103 /µl and elevated C- reactive protein of 80 mg/l(NR <6 mg/l). The peripheral film revealed macro platelets, left shift and no schistocytes. The electrolytes were deranged; hypocalcaemia 1.6 (2.1-2.5), hypokalemia 2.6 mmol/L and hypomagnesaemia 0.6 mEq/L. Thyroid function tests and PT/APTT were normal. No organisms were grown on blood culture. urine analysis revealed yeast cells and cultured >105 candida albicans. Despite antibiotics, she worsened with headache, seizures and loss of consciousness. Cardiac echo showed intact VSD patch, moderate PA conduit stenosis and no vegetations. Brain CT was normal. Autoimmune panel C-ANCA was elevated (18U/ml). Intravenous methyl prednisolone was initiated and the child regained consciousness in 24 hours.
Conclusion: Tetralogy of Fallot patients may manifest with hypocalcaemia, severe infections and have a tendency of autoimmune disorders. A multidisciplinary model is necessary in the management of these patients.

P1384 - CARDIAC ECMO IN A MEDIUM-SIZED CONGENITAL HEART UNIT: THE CASE FOR INCREASING AVAILABILITY WORLDWIDE

Bennett Samuel[1], Neal Hillman[1], Giedrius Baliulis[1], Brian Boville[2], Marcus Haw[1]
Helen DeVos Children's Hospital Congenital Heart Center Grand Rapids-United States[1]; Helen DeVos Children's Hospital Pediatric Intensive Care Unit Grand Rapids-United States[2]

Background/Hypothesis: Survival free of major complications is uncertain in children on VA-ECMO for cardiac failure. Current literature maintains volume is the key quality indicator for cardiac programs.
Materials and Methods: We reviewed outcomes of all children on VA-ECMO in a medium-sized congenital heart unit over a 4-year period (June 2012-December 2016). Primary outcomes were survival to de-cannulation and discharge, and current survival status. Secondary outcomes included bleeding events, cannulation site infection, blood/blood product utilization, degree of cardiac recovery, return to catheterization lab or operation room (OR), days on VA-ECMO and current functional status.
Results: 29 children were supported on VA-ECMO: 24 post cardiac surgery; 1 cardiac failure; 2 septic shock; and 2 intractable

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

arrhythmias. 12 were placed on VA-ECMO post single-ventricle repair; 10 from cardiac arrest; and 5 from weaning failure from CPB. Median length of ECMO was 5 days (6 hours-18 days). 11 required re-exploration for bleeding and 7 required return to the OR and/or catheterization lab. 27 (93%) were de-cannulated successfully; and 23 (79%) were discharged home. There have been no late deaths. 2 remain with tracheostomy; 1 required femoral artery reconstruction; 1 required stent placement in the SVC secondary to cannulation for 18 days; and 1 patient had loss of digits secondary to DIC and small vessel thrombosis. Post-operative ECMO represented 2.2% of major cardiac cases during this period.
Conclusions: Excellent outcomes can be achieved in very high-risk VA-ECMO candidates in medium-sized cardiac units. A professional circuit team, intensive cardiac functional monitoring and daily multidisciplinary rounds are critical for optimal outcomes.

P1388 - OUTCOMES OF TRIFECTA VALVE IN THE PULMONARY POSITION: A SINGLE-CENTER EXPERIENCE

Christopher DeBano[1], Harikrishnan Kurup[2], Mario Zambito[3], Bennett Samuel[1], Samuel Lacina[1], Joseph Kuruvilla[1], Neal Hillman[1], Giedrius Baliulis[1], Joseph Vettukattil[1], Marcus Haw[1]
Helen DeVos Children Congenital Heart Center Grand Rapids-United States[1]; Sree Chitra Tirunal Institute for Medical Sciences and Technology Cardiology Trivandrum-India[2]; Inova Fairfax Hospital General Surgery Falls Church-United States[3];

Objective: Evaluate early and midterm outcome of pulmonary valve (PV) replacement using Trifecta (St. Jude Medical, Inc.) bioprosthetic valve.
Methods: 28 patients underwent PV replacement with Trifecta valve (October 2012-December 2014). Median age was 12.0 years (3.2-62.6 years). Primary diagnosis was Tetralogy of Fallot (n = 13, 46.4%). Preoperative diagnosis was PV insufficiency (n = 23, 82.1%). Redo sternotomy was performed in 25 patients (89.3%). Median implanted valve size was 25 mm (19mm-29mm). Median length of stay was 5 days (3-53 days). Median follow-up was 14.0 months (6.6-26.3 months). Echocardiograms were evaluated by 3 cardiologists and scored for pulmonary insufficiency, right ventricular (RV) size, and PV gradient. Echocardiograms were designated early post-operative (median 22.3 days), intermediate post-operative (median 119 days), and late post-operative (median 425.9 days). Numerical values were assigned: normal = 1, mild = 2, moderate = 3, and severe = 4 for pulmonary insufficiency and RV size. Mean scores were obtained to determine final classification.
Results: There were no early or intermediate valve-related deaths. In-hospital mortality was nil (n = 0). No patients required replacement of PV prosthesis within the study period. No post-operative valve thrombosis was noted. Early echocardiography results showed a decrease in pulmonary insufficiency and RV size with mean scores of 2.3 and 1.4 respectively. At last follow-up, 3 patients (14.2%) were found to have moderate to severe PV insufficiency (score ≥3). Peak PV gradient was 12.5 + /-5.6 at last follow-up. RV size was normal or mildly dilated in 24 (85.7%) patients at last follow-up compared to 24 (85.7%) patients with severely dilated ventricles preoperatively.
Conclusions: Trifecta valve can be placed in the pulmonary position with good early results; care must be given to the position of the valve to ensure leaflets are not impinged upon by surrounding native pulmonary artery tissue.

P1412 - CUSTODIOL VERSUS CONVENTIONAL CARDIOPLEGIA IN TETRALOGY OF FALLOT SURGERY

Pirapat Makarapong[1], Jule Namchaisiri[2], Kanyalak Vithessonthi[3]
Rajavithi Hospital, Cardiovascularthoracic, Bangkok-Thailand[1]; King Chulalongkorn Memorial Hospital, Cardiovascularthoracic, Bangkok-Thailand[2]; Pediatric Cardiac Surgery Foundation, Pediatric Cardiology, Bangkok-Thailand[3]

Background: We examine whether Custodiol and conventional cardioplegia have differential effects on patients' perioperative and postoperative conditions.
Materials and Methods: The initial sample consists of 90 pediatric patients with Tetralogy of Fallot (TOF) who underwent a total correction surgery from March 2014 to November 2016. The patients were randomly allocated to receive Custodiol or conventional cardioplegia. Both groups of patients' perioperative and postoperative conditions were collected. We employed ordinary least square (OLS) regressions and probit models to test our hypotheses. Perioperative conditions include cardiopulmonary bypass (CPB) and aortic cross-clamping (ACC) time. Post-operative conditions consist of right and left ventricular ejection fraction (RVEF and LVEF), mechanical ventilation time, ICU stays, overall stays, arrhythmia, complications and Vasoactive Inotropic Score (VIS).
Results: Based on the final sample of 78 patients, we find that Custodiol and conventional cardioplegia have the differential effects on CPB time, ACC time and post-operative outcome for patients undergoing TOF surgery. The results indicate that patients who received conventional cardioplegia tend to have shorter CPB time than those receiving Custodiol. In addition, patients who received conventional cardioplegia tend to have shorter ACC time than those receiving Custodiol. These results remain evident after controlling for operation procedure (i.e. transannular patch vs. nontransannular patch), other lesions (e.g., PDA, ASD), and the presence of previous shunt. In addition, there is evidence to suggest that CPB time had a positive effect on VIS during the first 24 hours after surgery and had a negative effect on RVEF. Overall, there is no evidence to support the notion that CPB time had any effect on postoperative mechanical ventilation time, ICU stays, overall stays, arrhythmia, and complications.
Conclusions: Relative to the use of conventional cardioplegia, the use of Custodiol results in longer CPB time, longer ACC time and higher VIS during the first 24 hours after surgery.

P1413 - 39 YEARS OF EXPERIENCE OF TREATING TRANSPOSITION OF THE GREAT ARTERIES IN A SINGLE LOW VOLUME CENTER

Karolis Jonas[1], Virginijus Jakutis[2], Rita Sudikiene[1], Virgilijus Lebetkevicius[1], Virgilijus Tarutis[1]
Vilnius University, Department of Cardiovascular Medicine, Center of Heart Surgery, Vilnius-Lithuania[1]; Vilnius University, Clinic of Anesthesiology and Intensive Care, Centre of Anesthesiology, Intensive Therapy and Pain Treatment, Vilnius-Lithuania[2]

Introduction: The success rate of arterial switch operation (ASO) depends on the experience of the congenital heart surgery team, which in turn depends on the case volume of the surgical center.
Objective: We report our 39 year experience in ASO's and follow-up results.
Methodology/Statistical Analysis: Between January 1977 and December 2016, 115 patients underwent ASO at our center. The patients were divided into three groups according to the time period in which they were operated. Group-1 (n = 18) was

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

operated from 1977 to 1998. Group-2 (n = 24) was operated during the international knowledge transfer program between Wessex Cardiothoracic Center, Southampton General Hospital and our center from 1999 to 2002. Group-3 (n = 73) was operated in post-program years (2003-2016). Patients were followed for early and late mortality, postoperative morbidity and reintervention or reoperation.
Results: Median follow-up time was 5.1 years (Interquartile range (IQR) 2.76-9.1 years). A median number of 2 (IQR 0-6) procedures/year is performed at our center. Early mortality in groups was 77.8% vs 41.6% vs 4.1% accordingly ($p < 0.001$). The Kaplan-Meier estimated 15-year-survival-rate in groups is 6.3%, 44.5%, 91.4% respectively ($p < 0.001$). In total 6 (5.2%) patients died during the late postoperative period and 7 (6.1%) were lost to follow-up. 25 (21.7%) of the followed patients have mild to moderate aortic valve insufficiency. 4 (3.5%) patients underwent a balloon angioplasty for re-coarctation of the aorta, and 4 (3.5%) for pulmonary artery stenosis. 1 (0.86%) patient underwent right ventricle infundibulectomy and bidirectional Glenn shunt. 2 (1.7%) patients have severe development impairment.
Conclusions: Knowledge transfer programs between high expertise pediatric cardiac surgery centers and low-volume centers can be beneficial in lowering early post-operative mortality rates. It is possible to perform arterial switch operations safely and with good outcome in a low-volume center.

P1422 - AORTIC VALVE REPAIR WITH PARTIAL LEAFLET SPARING METHOD IS THERE ANY POTENTIAL TO GROW

Noritaka Ota, Toshihide Aso, Yuko Takeda, Mariko Kobayashi, Hiroshi Okada, Yayuko Onakatomi, Hidekatsu Asai
Kanagawa Children, Department of Cardiovascular Surgerypartment of Cardiovascular Surgery, Yokohama-Japan

Objective: Aortic valve repair has encouraging midterm results in selected patients. However, in terms of the growth of aortic valve, there has not been reported. We introduced aortic valve plasty (AVP) with partial leaflet sparing method. We try to preserve leaflet tissue as much as possible.
Methods: Between September 2004 and July 2016, eleven pediatric patients with aortic valve regurgitation (AR) underwent primary aortic valve repair with partial leaflet sparing electively. A variety of techniques were used in performing partial leaflet sparing AVP, depending on the specific cause of regurgitation in each patient.
Results: The age (median) and body weight at the operation were 5.4 years (1.7–16) and 14.0 kg (9.1–44.6). There was no mortality. The follow up was 100%. The follow up period (median) was 5.6 (0.4–11.2) years. The previous operations prior to AVP were performed in 6 patients (VSD closure (n = 2), AVSD repair (n = 1), Norwood (n = 1), arterial switch operation (n = 1), PDA division (n = 1)). And concomitant procedures are following: VSD closure (n = 4), mitral valve repair (n = 2), mitral valve replacement (n = 1), RVOTR (n = 1) and TCPC (n = 1). There were bicuspid aortic valve in 1 patient and tricuspid aortic valve in 10. The one leaflet extension was performed in 6 patients, one cusp replacement with using pericardium in 1, patch augmentation in 2, and leaflet plication in 2. Leaflet slicing was performed, if needed. All pericardium was treated with glutaraldehyde. The recent echo showed that AR ($p = 0.0011$) and LVDd ($p = 0.019$) were improved significantly, compared with pre-OP and the aortic valve size was growing within normal range (Table). Freedom from reoperation was 100% at 10 years.
Conclusions: The present method with partial sparing of aortic leaflet can yield the growth potential of aortic annulus to pediatric patients with AR as well as effective reduction of the degree of AR..

Table 1. Results form recent Echocardiogram

	Pre-valve repair	Recent echo	P value
AR	3.1 ± 0.4	1.8 ± 0.7	0.0011
LVDd (% of normal)	126.2 ± 13.9	102.9 ± 24.6	0.019
Aortic valve diameter (% of normal)	125 ± 40	142 ± 37	0.41

AR: aortic regurgitation, Scoring of AR grade (1 in trivial, 2 in mild, 3 in moderate, 4 in severe); LVDd: left ventricular diastolic dimension

P1425 - INCREASED PRESSURE IN A PULMONARY ARTERY IS IT A CONTRAINDICATION TO BIDIRECTIONAL CAVOPULMONARY CONNECTION

Nadezhda Ershova, Elena Kavardakova, Olga Yanulevich, Evgeniy Krivoshchekov
Cardiology Research Institute, Cardiovascular Surgery Department, Tomsk-Russia

Background: Bidirectional cavopulmonary connection (BCPC) is optimal intermediate stage for hemodynamic correction of congenital heart diseases with single ventricle. There is no identical opinion upon optimal criteria for BCPC performance.
Materials and Methods: Over the 2012 to 2014 period 89 patients with SV at the age from 2 months to 13 years old (Me = 0,64; IQR:0,5-1,18) were involved into the study. They were performed catheterization of heart cavities with pulmonary resistance calculation at different stages of hemodynamic correction. The patients were divided into two groups: the first group (n = 64) – children with initial pulmonary artery (PA) pressure under 15 mm Hg, the second group (n = 25) – patients with PA pressure above 15 mm Hg.
Results: The average PA pressure was 11 mm Hg (IQR:10,00–13,75), indexed pulmonary blood flow volume (iQp) - 3,57 (mL/Min)/M2 (IQR; 2,69-4,87), indexed pulmonary resistance (iRp) - 1,41 Ед.Wood/м2 (IQR;0,90-1,98) in the first group. In the second group the average PA pressure was 20 mm Hg (IQR:17,00-26,00), iQp 4,56 (mL/Min)/M2 (IQR: 3,17-6,04), iRp 2,36 Ед.Wood/м2 (IQR:1,85-3,10). Taking into consideration increased PA pressure, oxygen test was performed. A slight decrease of average PA pressure up to 19 mm Hg (IQR:17,00-30,00),), $p = 0,02$, iQp increase up to 11,2 (mL/Min)/M2 (IQR:5,85-15,6), $p = 0.003$) and iRp decrease up to 1,37 un. Wood/м2 (IQR:0,72-1,95), $p = 0,002$ were marked after the test. All the patients were performed BCPC. Before the total cavopulmonary connection the average PA pressure was 8 mm Hg (IQR:7,00–9,13), iQp 2,69 (mL/Min)/M2 (IQR;2,14-3,15), iRp was 1,04 un.Wood/м2 (IQR;0,81-1,57), $p = 0,1$ in the first group. In the second group it was 8 mm Hg (IQR:6,38–11,25), iQp 2,46 (mL/Min)/M2 (IQR;2,22-3,30), iRp was 1,23 un. Wood/м2 (IQR:0,86-2,3). Significant difference between two groups was not disclosed, $p > 0,05$.
Conclusion: Thus, the pressure in a pulmonary artery higher than 15 mm Hg is not a contraindication to BCPC.

P1426 - HAND SEWN VALVED BOVINE PERICARDIAL CONDUITS FOR RIGHT VENTRICULAR OUTFLOW TRACT RECONSTRUCTION A SINGLE CENTER EXPERIENCE

Ravi Agarwal, Roy Varghese, Swaminathan Vaidyanathan, Mubeena S.
Madras Medical Mission, Cardiac Surgery, Chennai-India

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Right ventricle to pulmonary artery conduit is an essential part of treatment in some forms of congenital heart disease. Ideal conduit should be easily available, cost effective and should have longevity. There are various conduits available but they do not demonstrate growth potential, which creates patient prosthesis mismatch as the child grows. There are some reports that decellularised bovine pericardium may have growth potential due to repopulation by the host cells. This study reviews our experience with implantation of hand sewn valved bovine pericardial conduits for right ventricular outflow tract reconstruction.
Materials and Methods: 18 patients underwent right ventricle to pulmonary artery reconstruction using hand sewn decellularized bovine pericardial conduits; material used for constructing the valve being either decellularized bovine pericardium or 0.1 mm polytetrafluoroethelene. We analyzed the preoperative characteristics, intra-operative details and short term results including mortality.
Results: Mean age of the patients was 45.9 ± 74.6 (Range: 1-312) months. Mean weight was 11.6 ± 11.2 (Range: 3.7-51.2) kilograms and height 80.3 ± 27.6 (Range: 54-167) centimeters. Mean body surface area was 0.49 ± 0.31 (Range: 0.23-1.54) M2. Mean expected pulmonary artery size with respect to body surface area preoperatively was 11.4 ± 2.3 mm (Range: 8.4-17.6). Mean implanted conduit size was 14.1 ± 2.0 mm (Range: 12-18). Mean CPB time was 235 ± 62 (Range: 88-360) minutes and aortic cross clamp time was 125 ± 45 (Range: 44-229) minutes. There was no mortality in the immediate postoperative period or follow up. Four out of eighteen (22%) patients had mild valvar regurgitation in the follow up echo. One patient out of eighteen (5.5%) required pulmonary artery stenting in the post operative period.
Conclusion: Hand sewn bovine pericardial conduits used for right ventricular outflow tract reconstruction provide effective palliation with excellent short term conduit function. Continued long term follow up studies are necessary to determine the perceived growth potential of the decellularized tissue.

P1427 - SERIES OF DIRECT CLOSURE OF TYPE 1 AORTOPULMONARY WINDOW WITH GOOD SHORT AND MID TERM RESULTS; SAFE AND COST EFFECTVIE TECHNIQUE

Jamal Abdul Nasir, Syed Muhammad Ali Bukhari, Faiz Rasool, Abid Rafique Chaudry, Muhammad Asim Khan, Salman Ahmed Shah
Institute of Children Health, Pediatric Cardiac Surgery, Lahore-Pakistan[1]

Background: We are reporting here case series of sixteen cases of APW during the last five years out of which ten patients were done through direct surgical closure. Direct closure has advantage of avoiding cardio pulmonary bypass (CPB) and post op sequelae of CPB.
Materials and Methods: From January 2010 to December 2015, sixteen infants with Aortopulmonary window were operated in the department of Paed.cardiac surgery, Institute of children health Lahore, Pakistan. Out of Sixteen, ten were type 1 APW, in whom Operative technique included direct closure of the defect without using CPB. Operative technique included careful dissection, going around and getting control of APW, observing the ECG changes and confirming the absence of distortion of right pulmonary artery (RPA) and residual flow through echo. Immediate concern of direct ligation of APW is distortion of aortic valve, pulmonary valve, left coronary ischemia and obstruction of origin of right pulmonary artery. These ten patients were further analyzed for operative technique and clinical outcome. Age at operation ranged from 1.5 to 10 months (median 5 months). Weight at operation ranged from 3 to 6 kg (median 5 kg).
Results: Follow up ranged from 2 months to 48 months. There were no early or late deaths postoperatively. There were no residual defects or distortion of RPA in our series. ICU stay ranged from 1 to 2 days postoperatively.
Conclusion: Direct closure of type 1 APW is safe and has excellent short and mid term results in terms of cost and health of patient especially in those countries where limited resources are main factors affecting management of patients.

P1439 - AGGRESSIVE RECONSTRUCTION OF PULMONARY ARTERIES AT THE TIME OF SYSTEMIC TO PULMONARY SHUNT PLACEMENT IN NEONATES REDUCES THE RISK OF REINTERVENTIONS

Objectives: the purpose of present study was to evaluate whether pulmonary artery patch repair at the time of shunt placement is beneficial in terms of reintervention rate.
Methods: 27 neonates with pulmonary atresia and confluent pulmonary arteries were included in the study. Following methods were used to create shunts: modified Blalock-Taussig shunt (n = 14, 52%), side-to-side aorto-Gore-Tex central shunt (n = 13, 48%). In 9 cases (group 1) where ductal insertion distally from the ostium of either left or right pulmonary artery was noted, relevant pulmonary artery was repaired with autopericardial or pulmonary homograft patch. In other 18 cases (group 2) only shunt placement was performed. Decision to perform pulmonary artery repair was based on surgeon's judgment. Surgical mortality and pulmonary arteries obstruction, required re-intervention prior to next stage or repair were recorded. Chi-square Pearson's test and Fisher's exact test were utilized to compare outcomes between groups.
Results: In group 1 there we no pulmonary artery obstructions, requred reintervention. In group 2 there were 8 cases (44%) of pulmonary artery obstruction, required reintervention. p = 0.015.
Conclusions: Pulmonary artery reconstruction at the time of systemic-to-pulmonary shunt placement in neonates with pulmonary atresia reduces the risk of re-interventions for pulmonary artery obstructions. Aggressive patch repair may be beneficial even in cases of usual ductal incertion.

P1440 - SHORTER CROSS CLAMP TIME AND SELECTIVE CORONARY PERFUSION IMPROVE SURVIVAL AFTER STAGE I PROCEDURE

Anton Avramenko[1], *Sergey Shorokhov*[1], *Mikhail Khokhlunov*[1], *Irina Kozeva*[2], *Irina Baeva*[2], *Evgeniia Suslina*[3], *Sergey Khokhlunov*[4]
Samara Regional Clinical Cardiac Hospital, Pediatric Cardiac Surgery, Samara-Russia[1]; *Samara Regional Clinical Cardiac Hospital, Pediatric ICU, Samara-Russia*[2]; *Samara Regional Clinical Cardiac Surgery, Cardiology, Samara-Russia*[3]; *Samara Regional Clinical Cardiac Hospital, Cardiac Surgery, Samara-Russia*[4]

Objectives: The purpose of present study was to assess different myocardial protection strategies and their impact on stage-I outcomes.
Methods: 59 newborns underwent Stage-I procedure during 2005-2015 were include in the study. 28 patients (group 1) were operated on moderate hypothermia (26 C) and two-regional perfusion

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(selective antegrade cerebral and coronary) during distal arch reconstruction, followed by cordioplegic cardiac arrest and selective cerebral perfusion during proximal arch and accending aorta reconstruction. 31 patients (group 2) were operated on deep hypothermic circulatory arrest (18 C) with and without selective antegrade cerebral perfusion during all stages of aortic reconstruction. There were no significant difference between groups by BSA, urine output and serum lactate level prior to surgery (p is 0,311; 0,409 and 0,206 respectively). Mortality rate was compared between groups.
Results: Cross-clamp time (mean): group 1 - 63,1 ± 5,8 min., group 2 - 87,2 ± 3,1 min. (p = 0.001). 30-days mortality: group 1 - 25%, group 2 - 53% (p = 0.028).
Conclusions: Shorter aortic cross-clamp time achieved by utilizing two-regional perfusion improves myocardial function and reduces 30-days mortality rate after Stage-I procedures.

P1441 - EFFECTS OF POSTURAL CHANGE ON OXYGEN SATURATION IN PATIENTS AFTER THE FONTAN OPERATION COMPARISON OF FENESTRATED AND NON FENESTRATED PATIENTS

Seiichi Sato, Kiyotaka Takefuta, Takefuta Sakurai, Taisuke Nabeshima, Atsuya Shimabukuro, Mami Nakayashiro
Okinawa Prefectural Nanbu Medical Center & Children's Medical Center, Pediatric Cardiology, Okinawa-Japan

Purpose: The aim of this study was to compare oxygen saturation alteration between fenestrated and non-fenestrated Fontan patients.
Method: We divided 26 patients into 2 groups: 7 patients who had fenestrated Fontan (group F) and 19 patients who had non-fenestrated Fontan (group NF). SpO2 were measured by pulse oximeter in the supine and sitting positions. In F (3male, 2-9year-old: median 5), all 7 patients were performed Extracardiac TCPC. In NF (9male, 3-31year-old: median 7), 3 were APC, 13 were Extracardiac TCPC, and 3 were Extracardiac TCPC with naturally closed fenestration.
Results: In NF, SpO2 changed from 92-98(mean; 95)% to 91-97 (mean; 94)% (p < 0.01), which was the same result of previously published report. Contrary, in F, SpO2 changed from 81-91 (mean; 89)% to 84-94 (mean; 91)% (p < 0.01).
Considerations: The blood flow via fenestration is much more due to IVC's flow. In sitting, the fenestration flow might reduce than that in the supine. First, in sitting position, to keep adequate brain blood flow, SVC flow should increase. Second, IVC flow will decrease because resistance of lower limbs:LL will become bigger, or because much more blood will be kept in LL during sitting.
Conclusion: There are some study limitations. First the number of patients was still small. Second, changes of blood flow through fenestration were'nt checked. But we demonstrated in Fontan patients with fenestration SpO2 was a little bit increase during sitting than supine position. We think SpO2 itself should increase when fenestration naturally closed, but the patterns of SpO2 alteration with postural change will suggest an occlusion of the fenestration.

P1442 - NATIVE AORTIC COARCTATION IN NEONATES AND INFANTS COMPARISON OF OUTCOMES WITH BALLOON COARCTOPLASTY AND SURGERY

Supratim Sen, Sandeep Garg, Snehal Kulkarni, Smrutiranjan Mohanty, Suresh Rao
Kokilaben Hospital, Children's Heart Centre, Mumbai-India

In neonates and infants with severe native aortic coarctation, surgical repair is the standard therapy while balloon angioplasty remains controversial. At our institution, balloon coarctoplasty was initially restricted to critically ill patients as a salvage treatment. However, with good immediate results in these patients, we sought to compare our midterm outcomes of balloon and surgical coarctoplasty in infants.
Methods: Retrospective records review: we analyzed all patients with coarctation who underwent balloon or surgical coarctoplasty at our center with age <1 year at presentation and >6-months post-procedure follow up. Patients with significant aortic arch hypoplasia, long segment coarctation and associated intracardiac lesions were excluded. Clinical, echocardiographic and procedural details were recorded at initial presentation and follow-up. Need for reintervention was noted.
Results: 75 total patients: 28 balloon coarctoplasty (group A), 47 surgical coarctoplasty (group B). Table 1. There were two deaths (immediate mortality 4.2%) in group B, and none in group A. For neonatal presentation, group A patients had a significantly higher reintervention rate than group B (p = 0.006). On logistic regression analysis, balloon coarctoplasty and residual coarctation post-procedure were significant predictors of reintervention. On Kaplan-Meier analysis with neonatal presentation, freedom from reintervention in group B was significantly higher than group A (P = 0.0036). Freedom from reintervention was also greater for group B as a whole, and conversely greater for group A than group B for presentation between 1-12 months (not statistically significant).
Conclusion: Our results demonstrate balloon coarctoplasty is a viable alternative to surgery for native coarctation in infants outside the neonatal age, with low mortality, shorter hospital stay and comparable reintervention rates. In contrast, in neonates, surgery yields better results with low mortality and significantly lower reintervention rates, and should be the preferred treatment modality.

Table 1. Native aortic coarctation in neonates and infants: Comparison of outcomes with balloon coarctoplasty and surgery

Therapeutic Modality	Balloon Coarctoplasty (Group A) N = 28	Surgical Coarctation Repair (Group B) N = 47
Age (months): Median [range]	1 [0-10]	1 [0-12]
Weight (kg) (mean +/- S.D.)	3.87+/- 1.70	3.80 +/- 1.77
Sex- Male: Female	20:8	35:12
Presentation		
Shock	4	1
Tachypnea, no shock	24	46
LV dysfunction		
None	12	29
Mild	2	8
Moderate	5	5
Severe	9	5
Isthmus z-score (mean +/- S.D.)	-2.43+/- 1.47	-3.87+/- 1.63
Associated mild transverse arch hypoplasia	13 (46.4%)	22 (46.8%)
Residual coarctation at discharge	8 (28.6%)	3 (6.4%)
Hospital Stay (days): Median [range]	2 [1-20]	15 [10-44]
Follow up duration (months): Median [range]	6 [6-68]	6 [6-42]
Reintervention (neonates)	9 (60%)	4 (16%)
Reintervention (1-12 months)	3 (23.1%)	10 (45.5%)
Surgical Technique: Total (Reintervention)

P1452 - INTERNATIONAL QUALITY IMPROVEMENT COLLABORATIVE PROGRAM IN CONGENITAL HEART SURGERY AT HOSPITAL DE NIÑOS CÓRDOBA ARGENTINA 2012 2015 EXPERIENCE

Ernesto Juaneda[1], Ignacio Juaneda[2], Irma Azar[3], Julieta Perez Ferrero[3], Emilia Benedetto[3], Rosa Rodriguez[3], Hector Diaz[2], Edgardo Banille[3], Alejandro Peirone[4], Marcos Loconte[2]
Hospital De Niños, Pediatric Cardiology, Córdoba-Argentina[1]; Hospital De Niños, Congenital Heart Surgery, Córdoba-Argentina[2]; Hospital De Niños, Cardiac Intensive Care Unit, Córdoba-Argentina[3]; Hospital De Niños, Interventional Cardiology, Córdoba-Argentina[4]

Background: Health system experiments an increasing interest in crossing the quality care chasm between actual and expected results. Congenital Heart Surgery (CHS) has improved outcomes and quality of life in congenital heart disease; nevertheless, CHS may have infection and mortality rate that need to be sequentially quantified in order to improve results. International Quality Improvement Collaborative (IQIC) for CHS in developing countries may help to achieve these goals.
Methods: Prospective interventional study, in a tertiary public Hospital from January 2012 to December 2015. All patients with a history of CHS at Hospital de Niños de Córdoba, Argentina (HNCA) were sequentially introduced to IQIC database in order to assess: age and weight at surgery, Risk Adjust Congenital Heart Surgery (RACHS) and Infection - Mortality unadjusted rate. Key drivers were sequentially introduced as interventions: Safe Perioperative Practice, Infection Control and Team Work implementation.
Results: 373 consecutive patients were enrolled (203 males, 170 females). Annual percentage of RACHS, age and weight are shown on tables 1, 2 and 3 respectively. 2012-2015 semestral Unadjusted Infection Rate were 20%, 21.9%, 24.6%, 13.3%, 12.8%, 26%, 9.1% and 17.1% respectively being IQIC standard 4.3% -6.9% ; Semestral Unadjusted mortality rate were 6.7%, 3.1%, 6.3% ,8.9%, 11%, 0%, 0%, 4.9% respectively being IQIC standard 4,5%-6,2%. Annual Standardized Infection Rate were 1.89, 1.87, 2.0, 1.22 and Annual Standardized Mortality Rate were 0.85, 1.82, 1.07, 0.36 for years 2012, 2013, 2014 and 2015 respectively. Safe Perioperative Practice, Infection Control and Team Work implementation were sequentially introduced.
Conclusion: IQIC program implementation in CHS at HNCA contributed to quantify results and to introduce Key drivers in order to improve outcomes. Reduction in Mortality rate was successfully achieved compared to IQIC standards values and Infection rate is decreasing but still above IQIC standards.

P1455 - CONGENITAL HEART SURGERY IN LOW BIRTH WEIGHT INFANTS <2KG IN AN UNDERPRIVILIGED COUNTRY EXPERIENCE IN ARGENTINA

Ignacio Juaneda[1], Christian Kreutzer[2], Benjamin Chiostri[3], Daniel Klinger[3], Mariana Lopez Daneri[4], Augusto Gutierrez[5], Silvio Torres[4], Alejandro Peirone[6], Juan Diaz[7]
Hospital Privado Universitario De Córdoba, Congenital Heart Surgery, Córdoba-Argentina[1]; Hospital Universitario Austral. Hospital Posadas. Hospital Universitario Privado De Córdoba, Congenital Heart Surgery, Buenos Aires-Argentina[2]; Hospital Universitario Austral. Hospital Posadas, Congenital Heart Surgery, Buenos Aires-Argentina[3]; Hospital Universitario Austral, Critical Intensive Care Unit, Buenos Aires-Argentina[4]; Hospital Universitario Austral, Pediatric Cardiology, Buenos Aires-Argentina[5]; Hospital Privado Universitario De Córdoba, Pediatric Cardiology, Córdoba-Argentina[6]; Hospital Privado Universitario De Córdoba, Critical Intensive Care Unit, Córdoba-Argentina[7]

Background: Low birth weight (LBW) is a risk factor for mortality in infants undergoing surgery for congenital heart disease. Typical management relies on supportive therapy or palliative surgery and delayed definitive repair. Nonetheless, the morbidity and mortality of this approach has been shown to be high. We report our experience in LBW patients (P) who underwent repair of complex cardiac defects at three institutions (Hospital Universitario Austral, Hospital Universitario Privado de Cordoba and Hospital Posadas) in Argentina.
Material and Methods: The outcomes we analyzed were hospital mortality, early reintervention, postoperative length of stay (postopLOS) and mortality (at last follow-up) in 6 P <2 kg at time of surgery who underwent open cardiac repairs from August 2008 to August 2016 at our institutions. Diagnosis were transposition of great arteries (2 P), hypoplastic left heart syndrome (2 P), aortic valve endocarditis and total anomalous pulmonary venous drainage.
Results: Average age and weight at surgery were 18.6 days (5-34) and 1.66 Kg (1.2-1.9) respectively. Surgical procedures consisted of arterial switch operation (2), Norwood (2), Ross (1) and sutureless repair of TAPVD (1). Cardiopulmonary bypass and aortic cross clamp time were 114.16 minutes (55-150) and 54 minutes (20-111) respectively. Four P had deep hypothermic circulatory arrest for 17,5 minutes (5-40). Delayed sternal closure was used in 4 P during 3.75 days (2-7). There were no unplanned early reintervention. Hospital mortality was 13%. Excluding one patient who died 20hs post surgery, postop LOS was 59.8 days (41-95). Survival was 83.3% at a mean follow up of 3.72 + /- 3.08 years.
Conclusion: Although there is risk for death in infants < 2 kg undergoing congenital heart surgery, procedures can be performed with low mortality. Our initial experience suggests that repair of complex defects is possible in LBW infants and a dedicated neonatal cardiac program yields encouraging outcomes.

P1461 - DEVELOPMENT OF AN ORTHOPEDIC APPLIANCE TO CORRECT PIGEON CHEST AFTER MIDLINE STERNOTOMY IN INFANTS

Hayato Konishi[1], Ryo Shimada[1], Hideki Ozawa[1], Kenta Fujihara[2], Toru Nagano[3], Shintaro Nemoto[1]
Osaka Medical College Hospital, Pediatric Cardiovascular Surgery, Takatsuki-Japan[1]; Osaka Medical College Hospital, Orthopedic Surgery, Takatsuki-Japan[2]; Nagano Prosthetic&Orthotics Company Limited, Moriguchi-Japan[3]

Background/Hypothesis: ostoperative keel-type pigeon chest occasionally occurs after median sternotomy in infancy. There is no effective prophylactic method, and correction by worn appliances is required. However, current orthodontic appliances compress the entire thorax, rather than the deformity alone, and there are concerns about children wearing these appliances at important times for growth of the thorax and development of lung function. The aim of this study is to develop a new orthopedic appliance to prevent deformation and exacerbation through application of moderate compression force only to the sternal protrusion, and not to the entire thorax.
Materials and Methods: We designed a structure that has an outer shell that fits the shape of the rib cage, except for the protruding region, and a pad that generates pressure only on the protrusion. Pressure adjustment is achieved with elastic Velcro material and compression of low repulsion material. The efficacy and safety of use of this device were investigated in 18 patients, including 6 with 21-trisomy and 7 after redo sternotomy. Ages at surgery were newborn (n = 1), 1-6 months (n = 9), 7-12 months (n = 4), and 1-3 years (n = 4).
Results: The infants started wearing the appliance at 1 to 32 months (median: 11 months) after surgery and the period of use was 1 to 33 months (median: 16 months). Sagittal protrusion measured

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

using a 3D scanner improved from 138 ± 8.5° before use to 151 ± 7.4° after use. Subjective evaluation of the degree of improvement by parents indicated 3 cases of improvement and 15 of prevention of progression. There were no complications such as cutaneous pressure ulcers.
Conclusions: Our orthopedic appliance improved or prevented development of pigeon chest. The most appropriate pressure setting for compression of an affected region requires data from case accumulation. Further improvements will also be made after long term follow-up.

P1462 - A NEW NON WOVEN FABRIC SHEET BASED ON SILK FIBROIN FOR USE IN CONGENITAL CARDIOVASCULAR SURGERY

Ryo Shimada[1], Hayato Konishi[1], Yoshikazu Motohashi[1], Hideki Ozawa[1], Shintaro Nemoto[1], Yasumoto Nakazawa[2], Ryou Tanaka[3]
Osaka Medical College Hospital, Thoracic and Cardiovascular Surgery, Osaka-Japan[1] Tokyo University of Agriculture And Technology, Biotechnology and Life Sciense, Tokyo-Japan[2] Tokyo University of Agriculture and Technology, Animal Medicine Center, Tokyo-Japan[3]

Background/Hypothesis: Expanded polytetrafluoroethylene (ePTFE) products are used in surgical correction for congenital cardiovascular anomalies, but have several drawbacks, including major bleeding from needle holes, calcification, and intra-luminal peeling resulting in stenosis. To resolve these issues, we developed a new non-woven fabric sheet with physical properties that improve surgical safety and biocompatibility. This sheet contains silk fibroin, a natural protein used in biomedicine. The aim of this study was to investigate whether the sheet is suitable for surgical use.
Materials & Methods: A solution of silk fibroin purified from silkworm cocoon and thermoplastic polyurethane (Pellethane®) was used to create a non-woven silk fibroin/polyurethane (SFP) sheet by laminated injection molding with nanofibers using the electrospinning method. The in vitro mechanical properties of the SFP sheet were compared with those of an ePTFE product. For in vivo evaluation, parts of the vascular wall of the rat abdominal aorta and the canine descending aorta were replaced with a SFP sheet or ePTFE. The sheet was explanted after 1 and 3 months for histological examination.
Results: Flexibility, water permeability, and suture retention strength of the SFP sheet were excellent and equivalent to those of ePTFE. Notably, the amount of bleeding from needle holes was negligible. The SFP patch had excellent handling properties and fitted well to the native vascular wall. The intraluminal surface of the explanted SFP sheet was covered with smooth intimal tissue without stenosis or aneurysmal changes. Histologically, there was no calcium deposition, which was detected in the excised ePTFE product, and minimal inflammatory reaction. Mild infiltration of mononuclear cells was found between the electrospun layers, but there were no signs of sheet degradation.
Conclusion: The SFP sheet had better mechanical properties and tissue compatibility than ePTFE. These favorable features and biodegradability of the SFP sheet warrant long-term follow-up.

P1472 - SYSTEMATIC REVIEW COMPARISON BETWEEN FIGURE OF EIGHT AND SIMPLE WIRE TECHNIQUE FOR STERNAL CLOSURE IN PREVENTING STERNAL DEHISCENCE AFTER OPEN HEART SURGERIES

Talha Khawaja[1], Aleezay Asghar[1], Muneer Amanullah[2]
The Aga Khan University, Medical College, Karachi-Pakistan[1]; The Aga Khan University, Surgery, Karachi-Pakistan[2]

Introduction: Multiple techniques have been employed for sternal closure following cardiothoracic surgery. These include the figure of eight method and the simple wire technique. This study aims to investigate the advantages of employing the figure of eight technique over the simple wire method.
Objective: To assess whether the figure of eight technique is superior to the traditional technique of sternal closure in reducing the chance of sternal dehiscence in patients undergoing open heart surgeries.
Methods: In this systematic review we searched through Pubmed, Cochrane Library (Wiley) and Scopus for articles relevant to our study. We narrowed down our search to Randomized Control Trials, Clinical Trials, Retrospective Cohort Studies, Journal Analyses, Systematic Reviews and Meta-analyses published since 2000. We excluded any animal studies and articles published in any other language but English.
Results: A total of 394 articles were retrieved. Upon excluding duplications, protocols only papers, case reports, case series and reviews, 121 papers were finally selected and reviewed independently by two critics. Of the 7 articles that were finally included in the study, 4 articles stated that the figure of eight method reduced the chances of sternal dehiscence in patients undergoing open heart surgeries. 3 articles, however, showed that there was no significant difference between the incidences of sternal dehiscence with each technique of sternal closure. None of the articles showed an increase in the risk of sternal dehiscence with the figure of eight technique.
Conclusion: Majority of articles showed a decreased risk of developing sternal dehiscence with the figure of eight technique. Hence, we can conclude that the figure of eight technique is superior to the traditional wire technique since it lessens the risk of sternal dehiscence in patients undergoing open heart surgeries.

P1489 - INFERIOR CAVOPULMONARY ANASTOMOSIS IS A SAFE PALLIATION IN HIGH RISK CHILDREN ADULT FONTAN PATIENTS

Samphant Ponvilawan[1], Preecha Laohakunakorn[2], Thamabovorn Neti[3], Boonchob Pongpanich[2]
Bumrungrad International, Cardiac Surgery, Bangkok-Thailand[1]; Bumrungrad International, Pediatric Cardiology, Bangkok-Thailand[2]; Bumrungrad International, Anesthesiology, Bangkok-Thailand[3]

Background/Hypothesis: Superior Glenn is a standard shunt in small children with single ventricle that provides adequate pulmonary blood flow. In older children/adult with high risk Fontan, inferior cavopulmonary anastomosis (ICPA) may provide better results in term of oxygenation and bridging to Fontan.
Materials and Methods: Six patients (UVH3,CAVC2,PA-IVS1) with systemic-to-pulmonary shunt and/or pulmonary artery branches stenosis or interruption underwent ICPA using standard CPB at 33 C with extra-cardiac PTFE graft during 2005-2009. Pre and post-operative parameters were evaluated with intermediate term follow-up.
Results: Six patients (4 F,2 M) median age of 13.5 year (4.8-23.9) and weight 32 kg (13-56.6) were included. Pre-operative diagnosis were UVH + PS/PA (3cases), unbalanced CAVC (2cases) and PA-IVS (1). All except one had one or more systemic-to-pulmonary shunt. Pre-operative mean PA pressure was 20.4 mmHg (17-22), mean SpO2 was 84%(80-90). Three patients (50%) had pulmonary artery branch stenosis and one had non-confluence PA. Two patients had severe CAVC regurgitation. ICPA using PTFE graft diameter 18mm (2), 20mm (1) and 22mm (3). Standard CPB was established at 33 C (32-34) with mean bypass time of 108 minutes (90-156), mean aortic cross-clamped

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

time 15 minutes (0-30). Immediate post repair mean PA pressure was 14.5 mmHg(12-17) with mean SpO2 of 90% (84-95%). There was one early death due to sudden pulmonary hypertensive crisis. Mean hospital stay was 15 days (10-24). Mean follow-up time was 3.68 year (0.55-8.06). Five patients were in normal sinus rhythm with one patient showed atrial arrhythmia. There was one late death at 14 months post ICPA. Four patients were in NYHA I with one patient was in class III. Post-operative heart size were reduced with good PA pressure in four patients (80%). Two patients had Fontan completion at 0.87 and 1.98 year after ICPA with post-Fontan follow-up of 4.28 and 5.12 year with good SpO2 (96%), both were in NYHA I with sinus rhythm.
Conclusion: ICPA is a safe palliation for children/adult with high risk Fontan. The patients can tolerate ICPA without intra-abdominal complication.

P1495 - LE COMPTE MANEUVER IN SURGICAL CORRECTION OF ABSENT PULMONARY VALVE. DOES IT IMPROVE SEVERE BRONCHIAL COMPRESSION

Bulent Saritas[1], Emre Ozker[1], Ozlem Sarisoy[2], Canan Ayabakan[2], Ismail Caymaz[3], Burcak Gumus[3], Sait Aslamaci[1]
Baskent University, Cardiovascular Surgery, Istanbul-Turkey[1]; Baskent University, Pediatric Cardiology, Istanbul-Turkey[2]; Baskent University, Interventional Radiology, Istanbul-Turkey[3]

Background: Here, a case of absent pulmonary valve syndrome with severe respiratory symptoms is presented. The treatment options to alleviate the airway obstruction are discussed.
Materials and Methods: A 2,5 month-old boy diagnosed of TOF and APVS was intubated because of respiratuary failure and was referred to our clinic for treatment. Pulmonary artery and the aorta were transected. Dilated pulmonary artery and branches were excised and the plicated. The maneuver of Le-Compte was then performed, translocating the pulmonary artery anterior to the aorta. End-to-end anastamosis of the aorta was completed. A size 12 valved conduit was interposed between right ventricle and main pulmonary artery.
Results: The patient was extubated shortly after readmission to the ICU. However this was short-lived because of the imminent respiratory acidosis. The chest x-ray showed total atelectasis of the left lung Thoracic CT was repeated to evaluate the bronchial tree postoperatively, which demonstrated the persisting left bronchial obstruction The details of the site and extent of the obstruction were delineated with bronchography performed by the interventional radiologist and the obstruction was dilated by deploying a 19mm (length) - 5 mm (width) balloon expandable endovascular stent.
Conclusions: Absent pulmonary valve syndrome is not only a congenital heart defect, but also a disease of the tracheobronchial system that has a high propensity to persist after the surgical correction of the heart defect. Regardless of the surgical technique used, the persisting respiratory disorder may complicate the postoperative course and may result in adverse outcomes. Although its main disadvantage is the lack of progressive grow in children, endobronchial stent appication may be an effective option in such cases.

P1505 - ESTABLISHMENT OF A COMPREHENSIVE BLOOD CONSERVATION PROGRAM REDUCES BLOOD UTILIZATION ESPECIALLY FOR JEHOVAH'S WITNESS PATIENTS

Alistair Phillips[1], Nicole Berndsen[1], Pooja Nawathe[2], Vincent Olshove[1]
Cedars-Sinai Medical Center, Surgery, Los Angeles-United States[1]; Cedars-Sinai Medical Center, Pediatrics, Los Angeles-United States[2]

Background: Cardiac surgery on Jehovah's Witnesses (JW) can be challenging given the desire to avoid blood products. Establishment of a blood conservation program involving the pre-, intra-, and post-operative stages for all patients may lead to minimized need for blood transfusion in all patients.
Methods: Pre-operatively all JW patients were treated with high dose erythropoietin 500 U/kg twice a week. JW patients were compared to like non-JW patients from the congenital cardiac database, two per JW to serve as control. Blood use, ventilation time, bypass time, hematocrit pre-operative, first in intensive care unit (ICU), and at discharge, and 24-hour chest drainage were compared. Preoperative huddle, operating room huddle and postoperative bedside handoff were done with the congenital cardiac surgeon, perfusionist, anesthesiologist, intensive care team in all patients for goal alignment.
Results: Five JW patients (mean weight 24.4 24.9 Kg, range 6.3–60 Kg) were compared to 10 non-JW patients (weight 22.9 22.2 Kg, range 6.9–67.8 Kg). There was no difference in bypass, cross clamp, time to extubation (0.8 versus 1.7 hours), peak inotrope score (1.8 versus 2.0), or chest drainage. No JW patient received blood product compared to 30% of the non-JW. Pre-operative Hct was statistically greater for the JW patients (46.1 3.3% versus 36.7 4.6%, $p < 0.001$), and ICU and discharge Hct were also higher for the JW (37 1.8% vs 33.8 7.4%, and 41 8.1% versus 32.8 7.4%). All patients had similar blood draws during the hospitalization (JW x 5 mL/admission vs. non-JW 6 mL/admission).
Conclusion: Developing a comprehensive blood conservation program for congenital heart patients requires teamwork that includes goal alignment, by using erythropoietin and supplemental vitamins we could perform all JW surgeries without any blood products. Our overall program has minimized blood product administration.

P1508 - HYPERCARBIC CEREBRAL BLOOD FLOW RESERVE IN SINGLE VENTRICLES PRIOR TO AND AFTER BIDIRECTIONAL GLENN PROCEDURE

Mark Fogel[1], Susan Nicolson[2], Thomas Spray[3], Matthew Harris[1], Kevin Whitehead[1], Arastoo Vossough[4], Daniel Licht[5]
CHOP, Pediatrics/radiology, Philadelphia-United States[1]; CHOP, Anesthesia, Philadelphia-United States[2]; CHOP, Surgery, Philadelphia-United States[3]; CHOP, Radiology, Philadelphia-United States[4]; CHOP, Neurology, Philadelphia[5]

Background/Hypothesis: The cerebral and systemic vascular beds vasodilate while the pulmonary vasculature vasoconstricts in response to hypercarbia; this is a sign of cerebrovascular health and intactness. We hypothesized that in large group of single ventricle (SV) patients, the increase in cerebral blood flow (CBF) under hypercarbic conditions of patients prior to bidirectional Glenn (pre-BDG) will be less than those of BDG (cerebral and pulmonary vascular beds in series) because the higher systemic runoff of pre-BDG physiology will limit the increase.
Materials/Methods: SV patients were studied with cardiac magnetic resonance phase contrast mapping in the jugular veins immediately pre-BDG and after BDG in both room air and in hypercarbic conditions (3-7 torr of carbon dioxide administered over 20 minutes).
Results: 170 consecutive subjects were studied: 58 pre-BDG (4.8 + /-1.7 months) and 112 BDG (2.9 + /-1.4 years). From room air to hypercarbia, significant increases in CBF were demonstrated at both the pre-BDG and BDG stages (both with $P < 0.05$) of 35-40% – see graph. CBF in BDG were significantly higher than pre-BDG in both room air and hypercarbia ($P < 0.05$), however, the amount of CBF increase during hypercarbia

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

from room air within each group was not statistically significant (P = 0.18). Using a mixed effects linear regression model, CBF increased by 0.596 liters/minute/meter2 after adjusting for stage.
Conclusions: Robust increases in CBF in SV during hypercarbia both prior to and after BDG occurs. The incremental CBF increase in response to hypercarbia within each group is not different, indicating the systemic runoff of pre-BDG does not limit the increase. Hypercarbic CBF reserve is therefore similar in both groups, however, it should be noted that CBF of BDG is higher than pre-BDG in both room air and during hypercarbia. As CBF has been implicated in neurodevelopment, this finding may have implications for neurodevelopmental outcomes.

P1511 - REDUCING THE INCIDENCE OF ACUTE KIDNEY INJURY (AKI) MULTIDISCIPLINARY TEAM APPROACH AND GOAL ALIGNMENT IN A CONGENITAL HEART PROGRAM

Vincent Olshove[1], Nicole Berndsen[1], Pooja Nawathe[2], Stephen Robert[2], Alistair Phillips[1]
Cedars-Sinai Medical Center, Surgery, Los Angeles-United States[1]; Cedars-Sinai Medical Center, Pediatrics, Los Angeles-[2]

Background: Acute Kidney Injury (AKI) has been shown to be associated with increased morbidity and mortality in pediatric congenital cardiac surgery. AKI has been shown to occur in adult and pediatric post-operative cardiac surgical patients between 18 and 60%. The purpose of this study was to evaluate the incidence of AKI comparing the pediatric risk, injury, failure, loss, end (pRIFLE) and the acute kidney injury network (AKIN) scoring systems in a new congenital heart program.
Methods: Perfusion and anesthesia guidelines were established to minimize fluid administration and hemodilution, and included pre-operative goal alignment. Retrospective analysis of all congenital heart surgeries requiring cardiopulmonary bypass between 2014 and 2016. Values for serum creatinine measured pre-operative (baseline), first on arrival to the intensive care unit (ICU), twenty-four, and forty-eight hours, urine output for the first 24 hours, bypass time, ventilation time, re-intubation, and length of stay were pulled from the quality database.
Results: Eighty cardiopulmonary bypass cases were performed, but 4 cases were excluded for pre-operative renal failure leaving seventy-six bypass cases. 28% (n = 11) had an AKI by the pRIFLE and 14.5% (n = 11) by the AKIN. The primary difference between the two scores was the requirement of a 0.3 mg/dL increase in serum creatinine with the AKIN plus a 1.5x increase over baseline. None of the patients met the oliguria guideline and none of the patients required renal replacement therapy. By the AKIN score 2.6% were stage 1, 9.2% stage 2, and 2.6% stage 3. Average Inotrope score on arrival to the ICU, peak 48 hours, length of stay, and ventilator time all increased with each increase in score.
Conculsion: Low AKI scores are achievable in a new congenital cardiac surgery program and when AKI occurs is associated with an increasing inotrope score may help guide clinical care.

P1515 - UNBIASED PROFILING OF THE GENE EXPRESSION CHANGES THAT OCCUR IN NEONATES EARLY DURING CARDIOPULMONARY BYPASS

Peter Pastuszko[1], Douglas Bittel[2], Nataliya Kibiryeva[2], Diana Connelly[2], Jennifer Marshall[2], James O[1], Christopher Benner[3], Vishal Nigam[4]
Children, Cardiothoracic Surgery, Kansas City-United States[1]; Children, Pediatric Cardiology, Kansas City-United States[2]; University of California San Diego, Medicine, San Diego-United States[3]; University of California San Diego, Pediatrics (Cardiology), San Diego-United States[4]

Rationale: The systemic inflammatory response seen during the first 24 hours after patients undergo cardiopulmonary bypass (CPB) represents a significant clinical problem, especially in neonatal patients. Unfortunately, the molecular pathogenesis of this process is poorly understood. Understanding the gene changes that occur during CPB would advance efforts to limit the post-CPB inflammatory response, thereby improving outcomes for these patients.
Methods: RNA was isolated from the nucleated blood cells before CPB and 1 hour after the initiation of CPB from neonatal patients who underwent cardiac surgery. The five patients (3 males, 2 females) were between 6 and 19 days of age at the time of surgery. 3 of the patients had total anomalous pulmonary venous return. One had a diagnosis of transposition of the great arteries. The other patient had double inlet left ventricle. mRNA sequencing was performed on these samples. Bioinformatic analyses were performed with a multiple testing corrected p-value of $p < 0.05$ being considered significant.
Results: 1230 genes were altered 1 h after the initiation of CPB (496 genes were upregulated). There was significant enrichment of genes associated with cytokine response ($p = 8.32 \times 10\text{-}12$) with 8.1% of the genes changed being associated with this gene ontology group. 7.6% of the genes changed were associated with gene ontology group for innate immunity ($p = 2.0 \times 10\text{-}9$). There was significant enrichment for the transcription factors NFAT ($p = 1.06 \times 10\text{-}9$), EGR (early growth response factor) ($5.46 \times 0\text{-}8$), and NF-kB ($p = 6.84 \times 10\text{-}4$) within 5 kilobases of the start sites for the genes at were changed 1 hour after the initiation of CPB.
Conclusions: To our knowledge, this abstract is the first report of unbiased profiling of the gene changes that occur during first hour of CPB in neonatal patients. Our bioinformatic analyses suggests that modulation of NFAT, EGR, and/or NF-kB signaling may result in amelioration of the post-CPB inflammatory response.

P1520 - LONG TERM SURVIVAL AFTER EXTRACORPOREAL LIFE SUPPORT FOLLOWING PEDIATRIC CARDIAC SURGERY A STUDY FROM THE PEDIATRIC CARDIAC CARE CONSORTIUM

Lazaros Kochilas[1], Courtney Mccracken[2], Amanda Thomas[2], Subhadra Shashidharan[3], Bahaaldin Alsoufi[3]
Emory University and Healthcare of Atlanta, Pediatrics, Atlanta-United States[1]; Emory University, Pediatrics, Atlanta-United States[2]; Emory University and Healthcare of Atlanta, Surgery, Atlanta-United States[3]

Background: Extracorporeal Life Support (ECLS) is increasingly used during recovery after surgery for congenital heart diseases (CHD).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Although successful to salvage critically ill patients in the immediate postoperative course, the long-term outcomes of ECLS survivors after operations for CHD are not well studied. We used a multicenter US-based registry, the Pediatric Cardiac Care Consortium, to examine the long-term survival and risk of transplant of patients with history of ECLS after pediatric cardiac surgery.
Methods: We identified 348 children needing ECLS after surgery for CHD between 1982 and 2003. Patients that survived to discharge were linked with the National Death Index (NDI) and the United Network for Organ Sharing (UNOS) using direct identifiers to determine their long term vital and transplant status until 12/31/2014.
Results: A total of 117 patients (34%) were discharged alive, 87 with two-ventricle and 30 with single-ventricle physiology. Follow up data through NDI and UNOS were provided for a median of 13.8 years (max 24.9 years) after discharge. The 15-year transplant-free survival was significantly higher in patients with two-ventricle physiology compared to those with single-ventricle (76% vs. 43%, $p < 0.001$)(see Kaplan-Meier plot). The median time of death or transplant after discharge from the ECLS-associated operation is 15.8 years for the two-ventricle and 8.4 years for the one-ventricle group respectively. Single-ventricle patients included 22 with stage I physiology (9 Norwood and 13 aorto-pulmonary shunts); of them 14 (63.6%) underwent Glenn procedure with 10 (45.5%) reaching Fontan completion, while 8 (36.3%) needed transplant or died without additional CHD surgery.
Conclusions: ECLS survivors after CHD surgery for two-ventricle lesions have an acceptable long term transplant-free survival. For single-ventricle patients, history of ECLS support is associated with short survival after discharge even though 2/3 of them will be able to progress to at least one of the subsequent.

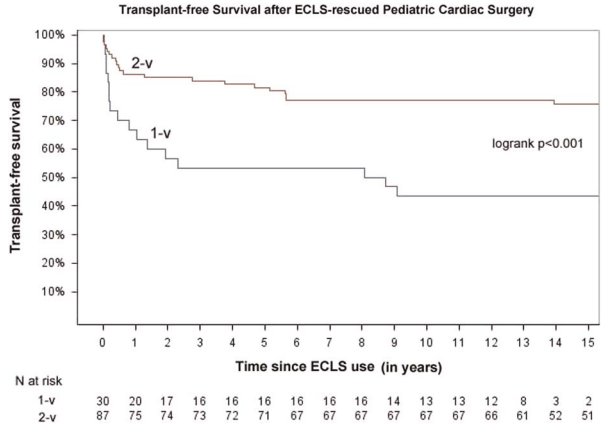

Figure.

P1521 - EARLY AND RAPID STENOSIS OF AORTIC POSITION MITROFLOW®LXA BOVINE PERICARDIAL TISSUE VALVE – A FOLLOW UP STUDY

Susan Saleeb[1], Kimberlee Gauvreau[1], John Mayer[1], Jane Newburger[1]
Boston Children's Hospital, Cardiology, Boston-United States[1]

Background/Hypothesis: We previously reported that young patients who underwent aortic valve replacement (AVR) with the Mitroflow® LXA, compared with Magna®/Magna Ease®, bovine pericardial valve were at high risk for early failure and rapid progression to severe prosthetic aortic stenosis. We here present the longer-term follow-up of an expanded group of patients.
Materials and Methods: All patients with Mitroflow® LXA and Magna®/Magna Ease® AVR were followed for prosthetic valve function by serial echocardiograms.
Results: AVR with the Mitroflow® LXA was performed in 18 patients (44% male) at median age 18.9 years (range 7.6-40.0), and with the Magna®/Magna Ease® in 63 patients (56% male) at median age 20.0 years (range 3.8-66.7). Freedom from failure with the Mitroflow® LXA valve vs. Magna®/Magna Ease® valve, respectively at 1, 2, 3, and 5 years was 100% vs. 100%, 77% (95% confidence interval [CI] 50-91%) vs. 100%, 48% (CI 23-68%) vs 100%, and 26% (CI 8-50%) vs. 94% (CI 63-99%) (logrank $p < 0.001$). Failed Mitroflow® LXA valves experienced a period of hyper-accelerated stenosis with progression from ≤ mild to severe stenosis over a 3-12 month period despite absence of symptoms. In contrast, Magna®/Magna Ease® valves were explanted for severe stenosis and endocarditis in one patient each, 6.1 and 3.1 years post implant, respectively. Five Mitroflow® LXA valves remain in situ ≥ 3 years in patients 20-40 years old at implant; 2 have severe structural valve deterioration.
Conclusions: With longer-term follow-up, the Mitroflow® LXA valve continues to demonstrate premature failure in young patients, particularly those under 30 years of age at implant. Rapid progression from mild to life-threatening aortic stenosis occurred over months. Young patients should not undergo AVR with the Mitroflow® LXA valve, and those with the valve in situ require heightened echocardiographic surveillance due to rapid development of stenosis.

P1524 - SURGICAL OUTCOME OF BILATERAL PULMONARY ARTERY BANDING FOR BIVENTRICULAR REPAIR

Yusuke Iwata[1], Satoshi Okugi[1], Yuki Nakayama[1], Takamasa Takeuchi[1], Atsushi Terazawa[2], Tetsuya Yamamoto[2], Kentaroh Omoya[2], Hiroko Gotoh[2], Naoki Kuwabara[2], Takashi Kuwahara[2]
Gifu Prefectural General Medical Center, Pediatric Cardiac Suregry, Gifu-Japan[1]; Gifu Prefectural General Medical Center, Pediatric Cardiology, Gifu-Japan[2]

Objective: Recently bilateral pulmonary artery banding (BPAB) is performed for avoiding preoperative risks of the congenital heart defects depending on patent ductus arteriosus even if it was originally performed for TAC. We select BPAB if patient had a risk such as shock status, low body weight (<2.5 kg) or severe extra cardiac anomalies. The purpose of this study was to investigate the outcome of BPAB for biventricular repair (BVR).
Patients and Methods: 10 patients underwent BPAB between 2003 and 2015. There were IAA/CoA in 7 and TAC in 3. BPAB was performed by lasso technique.
Results: Median age and body weight at the surgery were 7.2days (1-27 days), 2.6 kg (1.6-3.2 kg), respectively. The reasons of BPAB were shock in 6, low body weight in 5, LVOT size in 2, ventricular size in 1 and extra cardiac anomaly in 1. The circumference of BPAB was 12.5mm (9.0-13.5 mm). The duration to 2nd surgery was 62 days (28-313 days). Re-PAB (adjustment) was required in 2. Completion of BVR was in 7 (Yasui in 3, Rastelli in 2, ICR in 2), Waiting of BVR in 2, HD in 1 (preoperative brain hemorrhage due to shock). One patient died at 5 years after Rastelli operation. 2 patients with low body weight (1.6 kg, 1.8 kg) required PTA before 2nd operation because of decreased pulmonary blood flow. 6 patients required PA angioplasty or PTA at BVR or later.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Summary: The reason of BPAB was simply avoiding risk rather than morphological reason. BVR for low body weight patients could be performed after several PTAs. Although PA angioplasty was required at BVR or conduit replacement, there was no re-operation for just branch PS because PTA was effective.

P1527 - LONG TERM OUTCOMES AFTER SURGERY FOR ANOMALOUS LEFT CORONARY ARTERY FROM THE PULMONARY ARTERY A STUDY FROM THE PEDIATRIC CARDIAC CARE CONSORTIUM

Amanda Thomas[1], Alice Chan[2], Bahaaldin Alsoufi[3], Lazaros Kochilas[2]
Emory University, Pediatrics, Atlanta-United States[1]; Emory University and Children, Pediatrics, Atlanta-United States[2]; Emory University and Children, Surgery, Atlanta-United States[3]

Background: Anomalous left coronary artery from the pulmonary artery (ALCAPA) is a rare congenital cardiovascular anomaly with limited information regarding its long-term outcomes after surgical intervention.
Methods: This is a cohort study from the Pediatric Cardiac Care Consortium, a multi-institutional US-based registry of interventions for congenital heart diseases. We identified 186 patients with the diagnosis of ALCAPA having adequate identifiers for linkage studies. Long term outcome data are provided by linkage to the National Death Index (NDI) and the United Network for Organ Sharing (UNOS) up to the latest update of 12/31/2014.
Results: The median age at time of repair was 6 months (range: 9 days-17.2 years). Of the 186 patients, 141 underwent coronary re-implantation (76%), 28 Takeuchi procedure (15%), 7 coronary artery bypass grafting (4%), and 10 ligation of the anomalous coronary artery (5%). A total of 162 patients survived to discharge (87%). Concomitant procedures at time of repair for these individuals included mitral valve surgery (n = 14), interatrial communication closure (n = 11), and patent ductus arteriosus ligation (n = 3). Twenty-four patients (14.8%) needed subsequent procedures including mitral valve surgery (n = 9), coronary artery intervention (n = 7), pulmonary angioplasty (n = 10), heart transplant (n = 4) and other procedures (n = 5). There were 8 deaths (two after heart transplant) over 32 years of follow up as provided by linkage to the NDI and UNOS. The 20-year transplant-free survival rate was 94.3% for ALCAPA patients discharged alive (see Kaplan-Meier survival plot), with a median follow-up of 17.9 years (IQR = 14.3-23.4).
Conclusions: 20-year transplant-free survival after surgery for ALCAPA reaches 94.3%, but there is significant remaining morbidity requiring additional interventions. The most common long-term complications after surgical intervention are mitral regurgitation, Takeuchi tunnel leak or stenosis, pulmonary artery stenosis and heart failure.

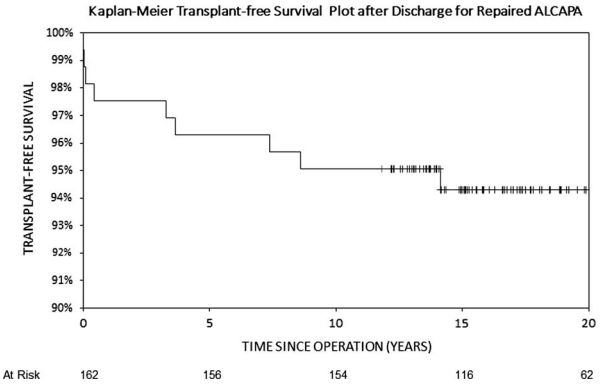

Figure.

P1528 - CLINICAL SIGNIFICANCE OF LEFT VENTRICULAR HYPERTROPHY IN INFANTS AFTER VENTRICULAR SEPTAL DEFECT REPAIR

Wan-ling Chih[1], Shuenn-Nan Chiu[2], Mei-Hwan Wu[2], Jou-Kou Wang[2], Chun-Wei Lu[2], Ming-Tai Lin[2], Chun-An Chen[2], Shu-Chien Huang[3], Yih-Sharng Chen[3]
Taipei Municipal Wanfang Hospital, Department of Pediatrics, Taipei-Taiwan[1]; National Taiwan University Hospital, Department of Pediatrics, Taipei-Taiwan[2]; National Taiwan University Hospital, Department of Surgery, Taipei-Taiwan[3]

Background: Left ventricular hypertrophy (LVH) is a not uncommon post-operative change after ventricular septal defect (VSD) repair in infants. The mechanism and clinical effect of this post-operative LVH are still unclear.
Methods: From 2013 to 2015, all consecutive patients received surgical repair of isolated VSD within 12 months of age were enrolled. We analyzed the pre- and post-operative echocardiographic data (within 14 days after surgery) and correlate with clinical parameters.
Results: Totally 37 infants (24 male and 13 female) were enrolled. The mean age of operation was 3.49 months, with mean duration of ICU stay and hospitalization 6.16 ± 4.69 and 15.4 ± 7.74 days respectively. Increase in LV mass was observed in 13 (35.1%) patients (LV thickening group). Their mean LV mass Z-score was +0.40 (-3.38 to +2.99) before surgery and +1.69 (-1.38 to +4.88) after surgery. We compare demographic data, pre-operative parameters, bypass time, cooling temperature, and post-operative clinical course between two groups. LV thickening group had smaller LVEDD Z-score (+1.18 vs +4.60, $p = 0.005$) and LV mass index (70.2 vs 127.5 g/m2, $p < 0.001$) pre-operatively. Cooling temperature during operation tends to be lower in LV thickening group (28.5°C vs 30.5°C, $p = 0.062$), but not bypass time and aortic cross clamp time. As for post-operative clinical course, there's no significant difference in duration of intubation, inotropic agent use, ICU and hospital stay between two groups, but chest tube drainage duration tends to be longer in LV thickening group (6.23 vs 4.50 days, $p = 0.058$). The LVH regressed at later follow-up and normalized within 3 months.
Conclusions: LVH after VSD repair occurs in a significant portion of infants with isolated VSD. It implicates with smaller pre-operative LV size, LV mass index, and lower operative cooling temperature. However, the clinical course is benign and will not prolong hospitalization.

P1535 - INFERIOR CAVOPULMONARY ANASTOMOSIS WITH SIMPLE TRICUSPID ANNULOPLASTY IS EFFECTIVE TREATMENT FOR SEVERE FORM EBSTEIN'S ANOMALY

Samphant Ponvilawan[1], Preecha Laohakunakorn[2], Thamabovorn Neti[3], Boonchob Pongpanich[2]
Bumrungrad International, Cardiac Surgery, Bangkok-Thailand[1]; Bumrungrad International, Pediatric Cardiology, Bangkok-Thailand[2]; Bumrungrad International, Anesthesiology, Bangkok-Thailand[3]

Background/Hypothesis: Repairing of severe forn Ebstein is technically demanding and provided unpredictable results in unexperience hands. Young surgeon may need long learning curve due to its rare incident. Inferior cavopulmonary anastomosis (ICPA) with simple tricuspid valvuloplasty (STV) might be a simple and reproducible technique to manage these rare problems.
Materials and Methods: Fourteen patients with severe Ebstein underwent ICPA with STV using standard CPB at 32 C during 2005-2014. ICPA performed by using extracardiac PTFE graft.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Tricuspid valve repair by simple annuloplasty, suturing clefts or closure of TV. Associated lesions included ASD (11),PS/PA + PDA(2),WPW(3) were also corrected. Pre and post-operative clinical parameters were evaluated. Statistical data represented in mean with range.
Results: 14 patients (F = 9, M = 5) with severe Ebstein (type C = 12, type B = 2), mean age 16y (5.4-48y), mean weight 38.4 kg (14.2-83 kg) were included. All were symptomatic (cyanosis = 11, dyspnea = 7, palpitation = 3, CHF = 2, fainting = 1). Standard CPB was established at 32 C. ICPA using extracardiac PTFE graft diameter 16mm (1), 18mm (5), 20mm (5) and 22mm (3). Tricuspid valvuloplasty by simple annuloplasty (5), suture cleft (8), closure (1). Intra-operative alasion of WPW was done in 1 patient. Mean bypass time was 103 minutes (87-155), mean aortic cross-clamped time was 33 minutes (0-64). All patients were in NYHA I post-operatively vs pre-op NYHA II (4), III (7), IV (3). Post-op CT ratio reduced from 0.57 (0.44-0.78) to 0.52 (0.42-0.68). Post repair echo showed no TR (6), mild TR (6), moderate TR (1) vs pre-op mild TR (2), moderate TR (4), severe TR (8). Post-op SpO2 improved to 96.9% (89-100%) vs pre-op 88% (73-96). Post ICPA + STV CVP was 9.2 mmHg, mean PAP was 14.8 mmHg (12-22) vs pre-op 14 mmHg (13-15). CCU stay was 3.5 days (1-9). ICD drainage was 2.4days (1-4). Hospital stay was 10.6 days (4-20). There was one early death on day2 due to low cardiac output. Follow-up the patients (n = 13) to 27.99 patient year (0.2-11.3y). No late death. No reoperation. The first case still alive 11.3y post surgery in NYHA I without reoperation/medication.
Conclusion: ICPA + STV is safe and reproducible technique to treat severe Ebstein. Improvement of functional class, degree of TR, oxygenation and reduce cardiac size were demonstrated.

P1545 - ASSESSMENT OF CHILDREN WITH COMPLETE VASCULAR RING

Münevver Dereli, Mehmet Fatih Ayik, Emrah Sisli, Osman Nuri Tuncer, Yüksel Atay
Ege University, Cardiovascular Surgery Department, Izmir-Turkey

Backgraound: A complete vascular ring is a rare congenital cardiovascular anomaly which encircles the trachea and oesophagus compressing them. This study assessed the presentation symptoms, diagnostic methods and treatment results after surgery in children with complete vascular ring.
Methods: Symptomatic complete vascular ring patients undergoing surgery between January 2010 and August 2016 at Ege University, Faculty of Medicine Hospital,İzmir, were retrospectively assessed. The presentation symptoms, demographic characteristics, and diagnostic tests were evaluated. Operative data and postoperative follow up, complications and problems were also examined in detail.
Result: Nine patients underwent surgery, 6 (66%) of whom were male. Median age was 10 months (range, 28 day- 4 years). Among these patients, 44,4% (n = 4) had ligamentum arteriosum, 55,5% (n = 5) had double aortic arch. Three patient had right-sided aortic arch + ligamentum arteriosum, One patient had left-sided aortic arch + aberrant right subclavian artery, and Kommerell's diverticulum was identified in three patient. Preoperative tracheomalacia was identified via bronchoscopy in two patient. Concomitant tracheal reconstruction was not performed in any patient. Computed tomography (CT) angiography was performed in 5/9 patients. All the patients were successfully operated on. None patient died in the early period.
Conclusions: Outcomes of division of a complete vascular ring are excellent. Preoperative bronchoscopy, oesafography and CT angiography is effective for the differential diagnosis and visualization of vascular ring abnormality. Complete vasculer ring couse of ligamentum arteriosum treat with transected both of the ligamentum arteriosum and fibrous cord. In such cases, full recovery can be assured with early diagnosis and surgery.

P1549 - MINIMALLY INVASIVE TECHNIQUE OF PLACING A DUAL CHAMBER PERMANENT PACEMAKER IN CHILDREN

Somia Razzak[1], Fazal Khan[2], Muneer Amanullah[2]
Sindh Medical University, Medical College, Karachi-Pakistan[1]; Aga Khan University, Cardiothoracic Surgery, Karachi-Pakistan[2]

Background: Permanent pacing in pediatric population is challenging with consideration of body growth, patient's size, presence of coexisting congenital heart disease and intra-cardiac shunts. There are different approaches for permanent pacemaker implantation which includes thoracotomy, sternotomy or Video Assisted Thoracotomy. We present a technique for dual chamber permanent pacemaker implantation via the xiphisternal approach.
Materials and Methods: This is a retrospective review of all cases of dual chamber pacemaker implantation using the xiphisternal approach performed at the Aga Kahn University from January 2011 to December 2016.
Operative Procedure: The patient is placed in a supine position. A 4-6 cms vertical midline incision over the xiphoid process is made to gain entry into the pericardial cavity. A pericardial well is created. The atrium is held with soft clamps. Atrial pacing leads are attached to the body of the right atrium using two 5/0 polypropylene. Ventricular pacing leads are implanted on the diaphragmatic surface of the right ventricle using two interrupted 5/0 polypropylene sutures each. The pacemaker generator box pocket is created beneath the rectus abdominis muscle via a transverse incision in the left lumber region. The pacing leads are connected to the generator via a subcutaneous tunnel. After maintenance of a satisfactory pacing threshold by an electro-physiologist the anterior rectus sheath, subcutaneous tissue and skin are closed. The pericardium is left open and the xiphoid incision is closed in layers.
Results: This technique was successful in 15 patients, (3 months - 10 years), in both primary and post-cardiotomy patients with no morbidity. Successful atrio-ventricular synchrony was established along with excellent pacing and sensing thresholds. This technique is associated with minimal surgical trauma, pain and results in early discharge.
Conclusion: This minimally invasive Xiphisternal technique of implanting a dual chamber pacemaker in children is easily reproducible and associated with minimal morbidity.

P1565 - THE ROLE OF SURGICAL VALVULOPLASTY IN PEDIATRIC PATIENTS WITH CONGENITAL AORTIC STENOSIS

Roman Gebauer, Tomas Tlaskal, Oleg Reich, Rudolf Poruban, Viktor Tomek, Jan Janousek
2nd Faculty of Medicine and Motol University Hospital, Children's Heart Centre, Prague-Czech Republic

Objectives: Balloon valvuloplasty is firmly established as effective treatment of congenital aortic stenosis (AS) in children. Surgical techniques of aortic valve repair have improved and there is controversy on the best approach to treat congenital AS. Direct surgical valvotomy with exact splitting of fused commissures, shaving off of obstructing nodules and enlarging of aortic sinuses may produce a better functioning valve in comparison to blind ballooning.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Methods: Retrospective review of data from 31 consecutive patients (boys = 26, girls = 5, newborns = 8) undergoing surgical valvuloplasty for isolated congenital valvular AS as the initial interventional procedure between 2012-2015. Median (IQR) age at surgery was 8.6 months (34 days–5.1 years). Median (IQR) clinical and echocardiograhic follow-up was 1.6 (0.8-2.9) years. Aortic regurgitation was graded as 0 = none, 1 = mild, 2 = moderate and 3 = severe.
Results: Prior to surgery the median diameter (z-score) of the aortic annulus was 11.2 mm (-1.24 z). Operation included aortic valvotomy in all patients and additional procedures in 29/31: cusp shaving = 15, enlargement of aortic sinus using autologous pericardium = 15, pericardial cusp extension = 5 and left ventricular outflow tract myectomy = 2. No patient has died. One patient had to be re-operated. Peak aortic systolic gradient was efficiently reduced by surgery. Aortic regurgitation was well tolerated and remained to be less than moderate in the majority (Table).
Parameter Before surgery After surgery Last follow-up p.
Peak systolic aortic gradient [mmHg].
median (IQR) 100 (90-108) 34 (28-45) 44 (31-57) <0.001.
Aortic regurgitation [grade].
median (IQR) 0 (0–0.5) 1.0 (0–1.5) 1.0 (0.5–2.0) <0.001.
Conclusions: Surgical valvuloplasty remains our strategy to treat patients with congenital AS if we can offer more than simple valvotomy. The procedure is safe. Short- to mid-term reoperation free survival and functional results are favorable (Supported by MH CZ - DRO, University Hospital Motol, Prague, Czech Republic 00064203).

P1567 - USE OF DUAL AORTIC CANNULATION TECHNIQUE FOR AORTIC ARCH REPLACEMENT IN CHILDREN WITH AGGRESSIVE GENETIC AORTOPATHIES

Anji Yetman[1], James Hammel[2]
CHMC, Cardiology, Omaha-United States[1]; CHMC, CT Surgery, Omaha-United States[2]

Background: Children with genetic aortopathies are at risk of developing aneurysmal dilation of the aortic arch following ascending aortic replacement. The value of aortic arch replacement at the time of initial surgery has been debated with opponents citing increased complexity and risk of adverse outcome due to prolonged deep hypothermic circulatory arrest (DHCA). At our institution, total aortic arch replacement is performed with the use of a dual cannulation technique (innominate artery and descending aorta) with continuous mildly hypothermic full-flow cardiopulmonary bypass (CPB) to the entire body. We sought to compare surgical outcomes in children with genetic aortopathies undergoing either the traditional valve-sparing aortic root replacement (VSRR) or VSRR with total arch replacement with use of DAC (AAR-DAC).
Methods: Record review of all children (age <21) with a genetically confirmed diagnosis of aortopathy undergoing aortic surgery in the past 5 years was performed. Patients undergoing concomitant valve surgery or Ravitch procedure were excluded.
Results: VSRR was performed in 7 patients and VSRR plus total arch with DAC in 3. There was no difference in age (14.4 + /-5.8 vs 8.5 + /5.8, p = 0.17), weight (57.7 + /-28.9 vs 50.7 + /-49.6, p = 0.79), CPB time (166.3 + /-49.0 vs 205.0 + /-59.9; p = 0.31) or length of stay (4.9 + /-1.9 vs 4.3 + /-1.5, p = 0.68). Six of the 7 patients undergoing VSRR and 2 of 3 undergoing AAR-DAC were extubated in the OR.
Conclusions: Despite a more complex operation, patients undergoing additional aortic arch replacement with use of DAC and avoidance of DHCA had no increase in complication rate with mean time to discharge of only 4 days. Consideration of aortic arch replacement at the time of initial VSRR should be considered in patients with Loeys-Dietz syndrome and other aggressive aortopathies.

P1572 - ARCH REPAIR IN UNUSUAL AORTIC CONFIGURATION OTHER THAN LEFT AORTIC ARCH AND LEFT DESCENDING AORTA

Jong Yoon Park[1], Jeong-Jun Park[1], Won Kyoun Park[1], Bo Sang Kwon[2], Chun Soo Park[1], Tae-jin Yun[1], Jae Suk Baek[2], Jeong Jin Yu[2], Young-hwue Kim[2], Jae-Kon Ko[2]
Asan Medical Center, Pediatric Cardiac Surgery, Seoul-Korea, South[1]; Asan Medical Center, Pediatric Cardiology, Seoul-Korea, South[2]

Background: One of major concerns during arch repair is to prevent airway compression. Majority of arch obstruction patients have a configuration of left arch and left descending aorta. However, some patients have unusual configuration which may cause more challenging surgical technique and a postoperative airway compression. We reviewed our experiences of arch repair in these patients retrospectively since December 2010.
Methods: Among the total 198 arch repaired patients, nine patients with unusual aortic configuration other than left arch and left descending aorta underwent arch repair after CT evaluation. Body weight was 3.1 ± 0.5 kgs. Aortic arch obstruction was coarctation of aorta in 8 (including 2 HLHS variant) and type B interrupted aortic arch in 1. Aortic configuration were circumflex retroesophageal left aortic arch in 2, left aortic arch and right descending aorta crossing vertebrae in 5, right aortic arch and left descending aorta in 1, and right aortic arch and right descending aorta with retroaortic innominate vein in 1. In eight patients, aortic arch was repaired under selective cerebral perfusion after extensive mobilization of descending aorta. One patient who had no intracardiac defect underwent arch repair via left thoracotomy.Five patients needed patch material for arch reconstruction including two Norwood operations. Intraoperative bronchoscopy was done routinely.
Results: There was no mortality. There were no additional operations for arch stenosis or airway compression. All patients achieved the aortic configuration at the same side of arch and descending aorta.Two patients on the single ventricle repair tract finished Fontan operation following neonatal Norwood operation.
Conclusion: Individualized arch repair even in unusual aortic configuration provides a good midterm result and preoperative CT scan is very helpful for the surgical planning. Also, extensive mobilization of descending aorta is mandatory and using patch material is helpful.

P1577 - COR TRIATRIATUM WITH TRANSPOSITION OF GREAT ARTERIES VSD UNROOFED LSVC IN A YOUNG ADULT – A RARE COMBINATION RESULTING IN PHYSIOLOGIC ATRIAL SWITCH CASE REPORT AND SURGICAL SIGNIFICANCE

Ganapathy Krishnan[1], Balakrishnan K.[1], Arul Narayanan[2], Venkataswamy K.[2]
Fortis Malar, Cardiac Surgery, Chennai-India[1]; Fortis Malar, Cardiology, Chennai-India[2]

Cor triatriatum represents 0.1% of all congenital cardiac malformations and may be associated with other cardiac defects in as

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

many as 50% of cases. The association of Cor with transposition of great arteries has not been reported before. We report, how a rare combination of anomalies lead to physiologic atrial switch leading to his late presentation and how with altered simple surgical approach, significant palliation could be obtained, in this rare combination of anomalies. 22 yr old presented to us with gradually worsening dyspnea on exertion over the last 5-6 yrs, when he presented to medical attention 5 yrs back he was informed that he has inoperable complex congenital cardiac problem. He came to us with worsening dyspnea over the last 1 month, he was saturating 80% in room air with significant clubbing. He had a hemoglobin of 20 g%. The RA incision was like superior septal approach for the mitral valve. The right atrial appendage was sutured to the apex of the incision at the roof of left atrium. This resulted in a wide opening so that the pulmonary veins could drain unimpeded into the right atrium At one year follow up he is saturating 90% and is class NYHA class I. This case is reported for (1)Rare association of Cor triatriatum with TGA and VSD (2) How the Cor membrane functions the first layer of Senning's procedure and how in this patient, the presence of unroofed LSVC and occluded RSVC by aneurysmal PA and atrial septal defect resulted in physiologic Sennings procedure.

P1584 - CLINICAL AND FINANCIAL IMPACT OF ON TABLE EXTUBATION AFTER OPEN HEART SURGERY IN CHILDREN – A RETROSPECTIVE COHORT STUDY

Aleezay Asghar[1], Talha Khawaja[1], Muneer Amanullah[2]
Aga Khan University, Medical College, Karachi-Pakistan[1]; Aga Khan University, Cardiothoracic Surgery, Karachi-[2]

Background: On-table extubation after open heart surgery in children is beneficial in a developing country. It is cost effective, reduces hospital stay, increases patient satisfaction with a low complication rate.
Objective: To determine the impact of on-table extubation on morbidity, mortality and cost benefit in pediatric patients undergoing open heart surgery.
Study Design: This is a descriptive retrospective cohort study. The study population includes all open heart surgeries performed at Aga Khan University in children (6 months -18 years) from January 2012 – June 2014.
Methods: All patients with Risk Adjustment for Congenital Heart Surgery category 1-3 were included while those in 4-6 were excluded. Criteria for extubation; patients fully concious, hemodynamically stable and with normal post-operative arterial blood gases and echocardiogram. Complications included re-intubation, cardiopulmonary arrest, high chest tube output, respiratory acidosis and low cardiac output syndrome. The patients were anesthetized using a standard technique and the patients were assessed for OTE using standard extubation criteria.
Results: Out of 630 surgeries, 108 patients (15.4%) underwent OTE. Surgical correction included Ventricular Septal Defect, Tetralogy of Fallot, Atrial Septal Defect, Glenn shunts and Fontan surgery. There were 7 complications. One patient needed re-intubation due to respiratory failure, one patient had atrial arrhythmia, another patient had respiratory acidosis, two required tube thoracotomy for pleural effusions and two had superficial sternal wound infections. There was no mortality. The estimated cost of an intubated and ventilated patient is PKRs: 60,000/= while a non-intubated patients cost is 30,000/=. The length of stay of an extubated patient in CICU is less than 24 hours and hospital stay lesser by 48 hours as compared to an intubated patient.
Conclusion: OTE is an attractive practice with positive impact on cost and has low complication rates in a selected group of pediatric patients undergoing open heart surgery.

P1600 - TECHNICAL PERFORMANCE SCORE AS A PREDICTOR OF PERIOPERATIVE OUTCOMES IN COMPLEX CONGENITAL HEART SURGERY PERFORMED IN A LOW VOLUME SURGICAL PROGRAM

Entela B. Lushaj[1], Heather Bartlet[2], Luke Lamers[2], John Carter Ralphe[2], Petros V. Anagnostopoulos[1]
University of Wisconsin-Madison, Surgery/Cardiothoracic, Madison-United States[1]; University of Wisconsin-Madison, Pediatrics/Cardiology, Madison-United States[2]

Objective: Technical Performance score (TPS) has been associated with postoperative outcomes in large volume surgical programs. We assessed the ability of TPS to predict perioperative outcomes in complex congenital heart surgeries performed in a low volume program.
Methods: Eighty-eight consecutive patients undergoing cardiac surgery over 4 years at our institution were retrospectively reviewed. A TPS was assigned to each patient based on discharge echocardiographic findings and need for re-interventions in anatomic areas of interest.
Results: There were 76 STAT 4 and 12 STAT 5 category patients. Fifty-five patients were neonates (62%), 19 (22%) infants, 10 (11%) children and 4 (5%) adults. Sixty percent of the patients were males and 16% were premature. An optimal TPS score (class 1) was assigned to 56 (64%) patients. An adequate TPS score (class 2) was assigned to 13 (15%) patients and an inadequate TPS score (class of 3) was assigned to 11 (13%) patients. Eight patients were not scored as their operation was not included in the original TPS scoring system. Median length of stay (LOS) was 16 (IQR: 9, 29) days. 30-day and in-hospital mortality rate was 6% ($n = 5$). Early post-op complications (within 30-days post discharge) included: delayed sternal closure (26%), reintubation (17%), arrhythmias (17%), chylothorax (10%), pneumothorax (4%), infection (3%), cardiac re-operation (1%), and stroke (1%). No patient required dialysis post-discharge. Unplanned readmission rate was 14% ($n = 12$). TPS score was associated with reintubation, ICU LOS and post-op LOS ($p < 0.05$). Other outcomes such as unplanned 30-day readmissions, reoperation, inotropic score and mortality were not shown to be effected by TPS score ($p > 0.05$).
Conclusions: Technical performance score is a useful tool in predicting postoperative outcomes after high complexity cardiac surgery in a low volume program and should be part of program review and quality improvement initiatives in congenital heart programs of all sizes.

P1602 - INCIDENCE ETIOLOGY AND RISK FACTORS OF UNPLANNED READMISSIONS AFTER CONGENITAL HEART SURGERIES

Entela B. Lushaj, Kari Nelson, Kate Amond, Eugene Kenny, Petros V. Anagnostopoulos
University of Wisconsin-Madison, Surgery/Cardiothoracic, Madison-United States

Objective: The first year after congenital heart surgery (CHS) is a period of increased health care utilization. We analyzed the rate, etiology, risk factors and patient mortality associated with unplanned readmissions within one year following CHS.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Methods: We retrospectively reviewed 262 patients undergoing CHS at our institution from 08/2011-06/2015. Scheduled readmissions including second stage palliation for single-ventricle patients were excluded.
Results: Seventy patients (27-infants, 21-children, 22-neonates) were readmitted 119 times (1.7times/patient). On multivariate analysis, age, STAT-category, surgery and intubation time, ICU and hospital length-of-stay (HLOS) were risk factors associated with unplanned readmissions. Leading causes of unplanned readmissions within 12-months post-CHS included viral illness (34%), respiratory distress (16%), gastrointestinal (14%) and cardiac causes (8%; Table-1). Forty-six (39%) of these readmissions were within 30-days post-discharge. Leading causes of 30-day readmissions included viral illness (33%), wound infections (15%) and cardiac causes (13%; Table 1). Median time-to-first readmission was 21 (IQR: 12-58) days. Median HLOS at readmission was 2 (IQR:1-8) days. The 1-, 3-, 6- and 12-month freedom from first readmission was 83%, 73%, 71% and 69% respectively. There was no significant difference in survival between readmitted and non-readmitted patients ($p = 0.68$). Time-to-readmission and readmission frequency didn't impact patient survival ($p > 0.05$).
Conclusions: Unplanned readmissions are common during the first year after CHS especially in high risk patients. Viral infections were the leading cause of unplanned readmissions. Readmissions didn't impact long-term survival of patients after CHS.

Table 1. Major primory etiologies of readmission after congenital heart surgery.

Readmission Etiology	No. of Readmissions	No. of Patients	No. of Readmission/ patient	No. of 30-day readmissions
Viral illness	40	26	1.5	15
Respiratory distress	19	16	1.2	4
Gastrointenstinal	17	14	1.2	4
Cardiac	10	10	1.0	6
Neurological	9	8	1.1	1
Superficial wound infections	8	8	1.0	7
Other	8	7	1.1	4
Infection other	5	5	1.0	2
Pericardial/ pleural effusions	3	3	1.0	3
Total	**119**	**70**		**46**

Other = chylothorax, failure to thrive, anemia, weight loss.
Infection other = otitis media, urinary tract infections, infectious cellulities.

P1626 - RESULTS OF VALVE SPARING AORTIC ROOT REPLACEMENT SURGERY IN ASIAN POPULATION A SINGLE CENTER STUDY

Kim Chai Chua, Kok Hooi Yap, Yi Chuan Tham, Tar Toong Chao, Yee Jim Loh
National Heart Centre Singapore, Cardiothoracic Surgery, Singapore-Singapore

Objective: We aimed to investigate the outcomes of valve sparing aortic root replacement surgery (David procedure) in patients with connective tissue disease in Asian population.
Method(s): All patients underwent David procedure were retrospectively reviewed. Patient's presentation, severity of aortic root dilatation and post operative outcomes were examined.
Results(s): Between January 2013 and December 2016, 8 David procedure was performed in National Heart Centre Singapore. 7 patients have been diagnosed of Marfan syndrome and 1 with Loeys-Dietz syndrome (4 Male, 4 Female, age 11-51). 5 patients had elective operation performed for dilated aortic root during follow up; 3 patients presented with Type A dissection and had emergency David procedure performed, 2 of emergency cases also had concurrent ascending aorta and aortic arch replacement with elephant trunk. Mean pre-operative sinus of valsalva size was 5.14 cm (3.9 cm – 6 cm, 3.9 cm with Z score of +9.8 belonged to the 11 years old Loeys-Dietz syndrome patient). There were 2 in-hospital mortalities, both patients had cardiovascular collapse post emergency David procedure and concurrent surgeries. All other patients had smooth recovery and still on follow up. All patients, including the 2 demised patients, had post operative echocardiogram showed no more than mild degree of aortic regurgitation with acceptable gradient. Mean follow up was 512 days; cumulative follow up was 8.4 patient-year.
Conclusion: Valve sparing aortic root surgery is an effective treatment for aortic root dilatation with connective tissue disease, sparing patients from disadvantages of prosthetic valve. In our experience, patients with just David procedure do much better than those who had more complex surgeries (David procedure + surgery on other part of aorta) done. Longer duration of follow up is needed to assess aortic valve competency in long term.

P1634 - NORWOOD OPERATION WITH PRIMARY CAVOPULMONARY SHUNT IN UNIVENTRICULAR HEARTS WITH HIGH FLOW UNRESTRICTED PULMONARY BLOOD FLOW

Osman Al-radi
King Abdulaziz University, Surgery, Jeddah-Saudi Arabia

Objective: Children with univentricular heart lesion with coarctation and arch hypoplasia are treated with a Norwood operation with a systemic to pulmonary shunt as the first stage of palliation. Delayed presentation to specialised centers is a challenge in developing countries. A subgroup of patients who present late and have high pulmonary blood flow and low resistance may be treated by a primary cavopulmonary shunt (CPS) as a source of pulmonary blood flow at the time of the Norwood operation.
Methods: Patients with univentricular heart lesions including hypoplastic heart syndrome (HLHS) who presented beyond the neonatal period without previous interventions and with evidence of low pulmonary resistance were treated with a Norwood type operation combined with a primary bidirectional CPS. Patients received postoperative pulmonary vasodilators and were followed through hospital discharge and as outpatients.
Results: Seven patients received the Nrowood-CPS operation. Four patients had HLHS, one with mitral atresia and aortic stenosis, and two with mitral stenosis and artic stenosis. One of the latter patients also had an interrupted inferior vena cava. Two patients had tricuspid atresia with transposed great arteries and coarctation of the aorta. One patient had double inlet left ventricle with coarctation and arch hypoplasia. All patients had unrestricted pulmonary blood flow with systemic pressure in pulmonary arteries. Six patients underwent preoperative heart catheterisation showing reactive pulmonary vasculature with left to right shunt. The age at operation ranged from 6 weeks to 1 year. Six patients survived the operation and were discharge, operative mortality was 14%. One patient, who was 1 year of age at the Norwood-CPS operation, died of pulmonary hypertension and failed cavo-pulmonary circulation.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: In late presenters requiring a Norwood type operation, primary CPS is a viable option if there is evidence of low pulmonary vascular resistance.

P1639 - IN HOSPITAL INTERSTAGE CAN DECREASE MORTALITY AFTER NORWOOD STAGE ONE OPERATION THE BROMPTON'S EXPERIENCE

Guido Michielon[1], Olivier Ghez[1], Julene Carvalho[2], Alain Fraisse[2], Zdenek Slavik[2], Anke Furck[2], Michael Rigby[2], Giselle Rowlinson[2], Andrea Kelleher[3], Aw Tc[3], Ajay Desai[4], Margarita Burmester[4], Duncan Macrae[4]
Royal Brompton, Paediatric Cardiac Surgery, London-United Kingdom[1]
Royal Brompton, Paediatric Cardiology, London-United Kingdom[2]
Royal Brompton, Paediatric Anaesthesia, London-United Kingdom[3]
Royal Brompton, Paediatric Intensive Care, London-United Kingdom[4]

Objective: interstage mortality after Norwood stage-one remains between 12 and 20% in current series. We present our preliminary experience with in-hospital interstage program, aimed at facilitating escalation of care, possibly improving survival until stage-two.
Methods: a prospective study was designed for patients with diagnosis of HLHS and HLHS-variants, offering in-hospital stay after Norwood operation until stage-two completion. Daily and weekly investigational plans were tailored to the individual patient. Primary end-point was overall survival until stage-two.
Results: between May 2015 and August 2016, 15 consecutive patients with prenatal diagnosis of HLHS (9) or HLHS-variants (6), underwent Norwood stage-one (13) or comprehensive-Norwood operation (2). Preliminary bilateral pulmonary artery banding was performed in 7. Stage-one Norwood-Sano was preferred in 11 (73.3%). In-hospital interstage was achieved in 14 patients (93.3%). Norwood operative and interstage survival were 93.3% and 100% at 20 months (mean follow-up 9.8 ± 2.2 months). During in-hospital interstage, 5 patients (33.3%) required urgent and efficacious escalation of care, due to haemodynamically compromising atrial arrhythmias affecting tricuspid valve function (2), or Sano shunt stenosis (3). These potentially fatal events occurred 2.4 months after primary Norwood-Sano. Additional interstage interventions included: residual aortic arch obstruction repair (1) neo-aortic valve repair (1), redo Sano (1) and Sano-conduit dilatation (1) or stenting (1) by catheter intervention. Bidirectional Glenn (10) or comprehensive-Norwood stage 1&2 (2) were successfully completed in 12 patients at 5.1 months with 100% survival. Two patients are currently awaiting stage-two within the in-hospital interstage plan.
Conclusions: in-hospital interstage program facilitates escalation of care, which is possibly efficacious in reducing interstage mortality after Norwood stage-one.

P1640 - RISK FACTORS FOR PERSISTENT PLEURAL EFFUSIONS FOLLOWING TOTAL CAVOPULMONARY CONNECTIONS

Sachin Talwar[1], Anupam Das[1], Rajesh Khadgawat[2], Manoj Sahu[1], Shiv K. Choudhary[1], Balram Airan[1]
All India Institute of Medical Sciences, New Delhi, CTVS, New Delhi-India[1]; All India Institute of Medical Sciences, New Delhi, Endocrinology, New Delhi-India[2]

Background: Total cavopulmonary connection (TCPC) is followed by significant fluid retention manifesting commonly as pleural effusions. We aimed to study various pre, intra and postoperative factors including serum cortisol in producing persistent pleural effusion defined as lasting for more than two weeks or more than 20 mL/kg/day.
Materials and Methods: We conducted a prospective cohort study of 38 patients undergoing TCPC between September 2015 and November 2016. All patients underwent trans thoracic echocardiography and cardiac catheterization. Factors studied included age, weight, height, symptomatology, echocardiography findings of normal or diseased atrio- ventricular valves, aortic and pulmonary valves, ventricular function, pulmonary artery pressures, oxygen saturation in the femoral artery, presence of aorto pulmonary collaterals, type of TCPC procedure, cardiopulmonary bypass duration, inotropic requirement, mechanical ventilation, conduit size and fenestration size, if any.
Results: The mean age at operation was 13.1 ± 5.6 years. The mean duration of chest tube drainage was 15.76 ± 13.2 days and the mean drainage was 9.15 ± 4.6 mL/kg/day. The statistically significant risk factors for pleural effusions were history of syncope ($p = 0.04$), pulmonary artery (PA) pressures ($r = 0.328$, $p = 0.003$, odds ratio 1.30), higher hemoglobin levels ($p = 0.04$), Wernowsky inotropic score ($r = 0.4$, $p = 0.01$), rise in the serum cortisol ($p = 0.03$) and central venous pressure at 6 hours ($r = 0.44$, $p = 0.005$) and 12 hours ($r = 0.4$, $p = 0.01$) in the post operative period. The duration of mechanical ventilation showed a statistically significant positive correlation with the amount of pleural drainage ($r = 0.45$, $p = 0.005$). Although the study showed a positive correlation of Fontan pressure with pleural drainage but a statistical significance could not be obtained ($r = 0.25$, $p = 0.13$). There was 1 in- hospital mortality following Fontan failure and takedown.
Conclusions: Higher PA pressures (>15 mmHg), higher Wernowsky inotropic score, higher hemoglobin levels, higher CVP and lower serum cortisol levels post operatively were associated with persistent pleural effusions after the TCPC.

P1651 - RIGHT VENTRICULAR OUTFLOW TRACT RECONSTRUCTION USING A HAND SEWN TRILEAFLET VALVE CONDUIT

Salman Shah, Asim Khan
Children Hospital Lahore, Cardiac Surgery, Lahore-Pakistan

Background: Prohibitive cost and subsequent unavailability of valved homograft or CONTEGRA conduits lead us to construct our own hand-sewn conduits for right ventricular outflow tract (RVOT) reconstruction. We have implanted hand-sewn conduits made of a bovine pericardial tube with 1mm PTFE (PRECLUDE/ GORE TEX) trileaflet cusps. This report assesses the short-term outcome of these prostheses.
Material and Methods: From 2012 to 2016, self-sewn tri-leaflet conduits were implanted in 46 patients. During surgery on a back-table a piece of bovine pericardium is taken and cut to size as per a pre-calculated nomogram. A 1mm PTFE membrane is similarly cut and shaped to pre -determined size and is then sewn onto the bovine pericardium as three semilunar leaflet cusps. This is then sewn into the shape of a tube, thus making a valved conduit.
Results: The mean age at operation was 9.6 years (range: 0.1 to 38 years). The most common procedure performed was a Rastelli operation in 28 patients followed by Ross procedure in 10 patients. 4 patients had previously placed conduits replaced and 2 patients had primary Truncus arteriosus repair, while 2 had primary repair of Tetralogy of Fallot (TOF). The most common size conduits were 20mm (24 patients) and 22mm (19 patients). Follow-up was complete. There were 2 in-hospital deaths. Both were unrelated to the conduit. None of the 46 PTFE tri-leaflet

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

conduits developed significant obstruction. Mean gradient across the valve conduit was 19 mmHg 10-38 mmHg). No patient has required re-operation for graft failure till last follow up There was one late death in a patient who developed infective endocarditis in the implanted conduit. Overall functional status of patients was excellent at last follow-up.
Conclusions: Short term results show that hand-sewn tri-leaflet conduits have provided a reliable conduit for RVOT reconstruction. Longer follow-up is needed to determine durability and longevity.

P1665 - ENDOPHENOTYPIC PATHWAYS DETERMINE THE ANATOMIC VARIANTS OF ATRIOVENTRICULAR SEPTAL DEFECTS

Rachel Magnan[1], Rebecca Zhang[1], Lillian Kang[1], Suk Regmi[1], James Cheverud[2], Patrick Jay[1]
Washington University in St. Louis School of Medicine, Pediatrics, Monte Sereno-United States[1]; University of Wisconsin-Madison, Biology, Madison-United States[2]

Background: An atrioventricular septal defect (AVSD) is characterized by a common AV junction. Its anatomic variants are defined by the associated defects of AV septal components. Genetic mutations are known that cause AVSD in general, but the pathways that lead to an anatomic variant are undefined.
Methods: We quantified the incidence of AVSD caused by Nkx2-5 haploinsufficiency in four crosses involving five inbred mouse strains (1293 to 8406 hearts/cross; 14,723 total). Anatomic endophenotypes of the atrial and ventricular septae were examined. The incidences of AVSD, anatomic variants and endophenotypes were compared between crosses to detect the effect of genetic modifiers. Correlations between endophenotypes were assessed to infer the hierarchy of developmental pathways that lead to the anatomic variants of AVSD.
Results: AVSD incidence in Nkx2-5 + /- hearts varied from 0.4-7.6% between the crosses. No AVSD was found in the wildtype. All anatomic variants were observed, even unbalanced AV canal defects and ones with an intact atrial and ventricular septum. The incidences of certain variants varied significantly between crosses. An absent vestibular spine is a hallmark of an AVSD, yet one was present in 20-40%, depending upon the cross. Hypoplastic vestibular spines were common and appeared related in part to insufficient growth of the dorsal mesenchymal protrusion in either the anterior-posterior or apical-basal axes. Deficiencies of the inlet ventricular septum could be classified as either anterior or posterior. The former is correlated with a "divot" on the right ventricular side of the left ventricular outflow tract septum. The latter is correlated with an absent vestibular spine.
Conclusions: Our results support a model in which an AVSD mutation causes a common AV junction, while polymorphic modifier genes in endophenotypic pathways determine the susceptibility to AVSD in general and the anatomic variant. Correlated defects of certain AV septal components suggest novel pathway relationships.

P1666 - MID TERM OUTCOMES OF TRANSVENTRICULAR VALVOTOMY APPROACH FOR INITIAL TREATMENT OF PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM

Gang Chen, Lin Wu, Fang Liu, Ming Ye, Yaping Mi, Bing Jia
Children's Hospital of Fudan University, Cardiovascular Center, Shanghai-China

Objective: To review the medium term surgical outcomes of transventricular pulmonary valvotomy(TPV) in patients with PA/IVS and non-right ventricular dependant coronary circulation.
Methods: Data were reviewed retrospectively for 21 patients with PA/IVS treated with TPV from 2010-2013 in our center. The mean body-weight of the 21 patients was(3.2 ± 0.7)kg and mean age was(16 ± 8)d. The Z-score of tricuspid valve ranged from -2.5~2.2(-0.9 ± 0.4). All the patients were followed up for over 12months. All the patients were divided into two groups: Bi-ventricle repair(BVR) and non-BVR group and the percutaneous saturation, Z-score of tricuspid valve, reintervetion data were collected at 3,6,12,24,36,48 months after the procedure.
Results: There was one early death after the TPV procedure for severe hyoxemia and parents refused to reoperation. 12 patients finally underwent BVR and 5 underwent one and half ventricle repair. 3 patients were on follow-up after TPV. The mean follow-up time was (32.3 ± 10.3)months without late death. Early reintervention were needed in 4 patient(20%). One was in BVR group and accepted the percutaneous pulmonary valve balloon dilation for residual obstruction. 3 were in one-BVR group and got hyoxemia need modified B-T shunts in 2 and PDA stent in 1 patient (8.3% vs 37.5%, $p < 0.01$). Z-score in BVR group was significantly larger than non-BVR group, with mean Z-score of (-0.5 ± 0.3) and (-1.5 ± 0.6), respectively($p = 0.01$). The freedom from reoperation was 80, 70, 35% at 6 months, 1 and 3 years, respectively. In BVR group, 9 of 12 received the ASD closure. In non-BVR group, 5 received bidirectional Glenn shunt and close the ASD; 1 received reconstruction of right ventricle outflow for muscular obstruction. The mean Z-score ranged from -2~2.2 (-0.5 ± 0.4),-2.1~2.2(-0.5 ± 0.3), -2.3~2.0(-0.2 ± 0.3), -0.4~2.2 (0.5 ± 0.8)~-0.5~2.2(0.6 ± 0.8), -0.2~2.2(0.7 ± 0.3) at 3months, 6months,1year,2,3 and 4years after TPV.
Conclusions: The results of a hybrid approach to treating patients with PA/IVS are excellent and proved to be safe and effective to improve the function of right ventricle. TPV can be used as an alternative method to transcatheter approach.

P1669 - ATRIOVENTRICULAR VALVE RECONSTRUCTIONS USING LEAFLET EXPANSION AND A SUB PARTIAL ANNULOPLASTY

Per Wierup[1], Jens Ramgren[1], Thomas Higgins[2], Nina Hakacova[2], Torsten Malm[1], Katarina Hanseus[2]
Lund University Hospital, Pediatric Cardiac Surgery, Lund-Sweden[1]; Lund University Hospital, Pediatric Cardiology, Lund-Sweden[2]

Background: Atrioventricular valve reconstruction in the pediatric population is a challenge due to the frequent combination of type I and IIIb dysfunction, i.e. annular dilatation and leaflet restriction. The need for growth potential further challenges the available repair techniques. We have elected a strategy using leaflet expansion and sub-partial annuloplasty with PTFE reinforcement.
Materials and Methods: From August 2014 through October 2016, six children aged five months – three years (median 19 months) underwent elective atrioventricular valve repair due to severe regurgitation (MR/TR) at Lund University Hospital, in Sweden. Their primary diagnoses were idiopathic congenital mitral regurgitation (three patients), progressive mitral regurgitation after previous AV canal repair (one patient), severe mitral regurgitation after treatment for endocarditis (one patient), and hypoplastic left heart syndrome with depressed right ventricular function and severe secondary tricuspid regurgitation. Their surgery consisted of leaflet expansion with autologous, untreated pericardium and sub-partial annuloplasty with PTFE reinforcement. Two patients had one additional procedure performed each: VSD closure and ductus ligation.
Results: All children survived the surgeries with uneventful post-operative courses, except for one patient who needed an early

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

reoperation for functional stenosis due to a "spinnaker phenomenon", which was corrected by creating neo-chordae with PTFE. The sub-partial annuloplasty was not performed in this patient, being the first in this serie. All patients were alive and asymptomatic after a median follow-up of eight months (range one – 22 months). Their echocardiographic data at that time showed no greater than 1 MR/TR and a median gradient of 4 mmHg (range 3-9 mm Hg).
Conclusions: Leaflet expansion with autologous pericardium and sub-partial annuloplasty with PTFE reinforcement for atrioventricular regurgitation in the pediatric population gives satisfactory results both early and at intermediate follow-up. However, the long-term results and growth potential needs to be studied further.

P1672 - CAROTID ARTERY RECONSTRUCTION WITH CRYOPRESERVED CAROTID HOMOGRAFT

Per Wierup[1], Jens Ramgren[1], Linus Blohmé, Katarina Hanseus[3], Torsten Malm[1]
Lund University Hospital, Pediatric Cardiac Surgery, Lund-Sweden[1]; Karolinska University Hospital, Vascular Surgery, Stockholm-Sweden[2]; Lund University Hospital, Pediatric Cardiology, Lund-Sweden[3]

Background: Carotid artery reconstruction is rare in the pediatric population. Moreover, the need for growth potential further limits the surgical options. We describe two cases were we have used cryopreserved homografts for carotid artery reconstructions.
Materials and Methods: The two patients were operated on in November, 2015 and July, 2016, respectively. The first patient was 10 years old and had progressive bilateral carotid artery and aortic arch stenosis as components of a supravalular aortic stenosis syndrome. He underwent carotid artery bifurcation plasty with an aortic homograft patch at the origin of the right common carotid and subclavian arteries with support of a innominate artery -carotid artery shunt and subsequent patch enlargement of his entire aortic arch including the first two centimeters of the left carotid artery using a branched aortic arch homograft. The latter surgery was performed with extracorporeal circulation, deep hypothermia, and circulatory arrest. The second patient was a 10 year old boy with a tracheostomy due to nemalin myopathy. He had a severe bleeding from a tracheo-innominate artery fistula that was initially treated with endovascular stenting. When the bleeding recurred, the patient underwent excision of the innominate artery and the proximal two centimeters of the right common carotid artery and the subclavian artery, respectively, excising all the infected stent material and replacement by an adult-sized homograft consisting of innominate-carotid-subclavian arteries. The operation was performed with extracorporeal circulation and moderate hypothermia.
Results: Both patients had an uneventful postoperative course with no signs of perioperative cerebral injury. Echocardiographic evaluation revealed unobstructed laminar flow. Both patients were asymptomatic at follow-up after 5 and 14 months, respectively.
Conclusions: Cryopreserved homografts are a valuable vascular graft for carotid reconstruction. However, we have only used it in two patients and the the long-term results and growth potential needs to be studied further.

P1673 - POSTOPERATIVE FOLLOW UP OF PATIENTS WITH ATRIOVENTRICULAR SEPTAL DEFECT AT BASKENT UNIVERSITY BETWEEN 1996 2016

Ozlem Sarisoy[1], Canan Ayabakan[1], Kursad Tokel[1], Murat Ozkan[2], Ilkay Erdogan[1], Birgul Varan[1], Sait Aslamaci[2], Bulent Saritas[2], Emre Ozker[2], Riza Turkoz[3]
Baskent University, Pediatric Cardiology, Istanbul-Turkey[1]; Baskent University, Cardiac Surgery, Ankara-Turkey[2]; Acibadem University, Cardiac Surgery, Istanbul-Turkey[3]

Purpose: Follow-up results of patients with atrioventricular septal defect (AVSD) operated in 1996-2016 at Başkent University are presented.
Method: Data obtained from hospital records consists of echocardiographic and angiographic details before surgery, age and weight at surgery, operative details, presence of Down's syndrome, details of postoperative care (durations of mechanical ventilation, inotropic agent infusion, stay in intensive care unit-ICU, inotropic score, postoperative arrhythmias, infections, time to discaharge), early postoperative and latest echocardiographic findings and hospitalization for reintervention.
Results: 498 patient-files were reviewed including 335patients (67.4%) with complete and162patients (32.6%) with partial AVSD (48.6% Down syndrome). AV valve morphology was Rastelli A in 90% (299), B in 9% (29), C in 1% (4) of patients. All patients underwent biventricular repair. Operative technique was single-patch in 21.7% (108), double-patch in 26% (129) and modified single-patch technique (Wilcox) in 52.3% (260). Left AV valve cleft was unsutured in 27 patients. Follow up time was 37.82 ± 46.77 (range 0.5-96) months. 68patients (12%) had arrhythmias in ICU, pacemaker was implanted in 6patients. 78patients (17%) were treated for pulmonary hypertensive crisis. Early-mortality-rate was 9.7 (47patients). In late follow-up, 11patients underwent left AV valvuloplasty, 16patients had MVR. Left ventricular outflow tract obstruction (LVOTO) was seen in 19patients. Late mortality was due to postoperative death after MVR in 2patients. Late reintervention was more frequent in modified single-patch technique ($p = 0.04$). Patients with Down syndrome were younger and weighed less at surgery; duration of mechanical ventilation, frequency of infection and hypertensive crisis were more; late LVOTO and AV-valve reintervention were less. Severe left AV valve regurgitation was more in patients without Down syndrome.
Conclusion: Morbidity and mortality rates are still high early after surgery in AVSD. Although Down syndrome patients are disadvantaged in early postoperative period, late morbidity and mortality are less.

P1674 - A NOVEL TECHNIQUE FOR PATIENTS WITH SCIMITAR SYNDROME WITHOUT ASD AND A SMALL LEFT ATRIUM – THE "TRENCH TECHNIQUE"

Per Wierup[1], Jens Ramgren[1], Katarina Hanseus[2], Torsten Malm[1]
Lund University Hospital, Pediatric Cardiac Surgery, Lund-Sweden[1]; Lund University Hospital, Pediatric Cardiology, Lund-Sweden[2]

Background: The partial anomalous pulmonary venous connection seen in Scimitar syndrome is a challenge to reconstruct, especially in the setting of an intact atrial septum and a small left atrium. The surgical correction carries a relatively high risk for the development of a subsequent tunnel obstruction. We describe a novel technique that we have used in two patients with Scimitar syndrome.
Materials and Methods: From July, 2015 through September, 2016 two children, aged five months and three months, underwent elective surgical correction of their partial anomalous pulmonary venous connection. Both children had a complete venous drainage from their right lung via a single vertical scimitar vein that descended to enter the inferior vena cava posteriorly. Neither of them had an atrial septal defect and both left atria were small. One

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

of the patients was highly symptomatic with heart failure, severe pulmonary hypertension and failure to thrive. The other patient had only mild pulmonary hypertension and was asymptomatic. The technique consisted, apart from the traditional intracaval tunnel formation and atrial septectomy, of creating a posterior widening of the tunnel by a full thickness posterior incision and expansion by autologous pericardium (one patient) and cryopreserved pulmonary homograft patch (one patient). This "trench"widened the tunnel and expanded the left atrium, thereby reducing the angle of venous return from the right lung to the left atrium.
Results: Both patients had an uneventful postoperative course. There were no signs of obstructions of the pulmonary venous return at follow-up(two and 16 months, respectively) and the children were asymptomatic.
Conclusion: The "trench technique" for anomalous pulmonary venous connection seen in Scimitar syndrome seems to be a promising strategy. However, we have only used it in two patients and the long-term results and growth potential needs to be studied further.

P1685 - REGIONAL DIFFERENCES IN COST AND LENGTH OF STAY AMONG NEONATES WITH HYPOPLASTIC LEFT HEART SYNDROME

Luma Essaid[1], Paula Strassle[2], Eric Jernigan[3], Jennifer Nelson[3]
UNC School of Medicine, UNC School of Medicine, Cary-United States[1]; UNC School of Medicine, Unc Gillings School of Global Public Health, Department of Surgery, Department of Epidemiology, Chapel Hill-United States[2]; UNC School of Medicine, Department of Surgery, Chapel Hill-United States[3]

Background: Hypoplastic left heart syndrome (HLHS) is one of the most resource-intensive congenital heart diseases. Understanding geographic variation in mortality, hospital charges and length of stay (LOS) can inform policy decisions and aid quality improvement efforts.
Methods: Infants ≤28 days old and born with HLHS between 2000-2012 were identified using the Kids' Inpatient Database. Hospitalizations were stratified into two groups: 1) birth hospitalization and 2) secondary/transfer hospitalizations. United States regional differences in hospital charges and LOS were compared using adjusted linear regression.
Results: 2,431 primary birth hospitalizations were identified. There were 449 (18.5%) inpatient deaths, with significant differences across regions ($p = 0.02$). Infants in the Northeast had the shortest LOS and lowest hospital charges. Compared to the Northeast, LOS in the South was, on average, 7.8 days longer (95% CI 2.8, 12.9,$p = 0.002$), but no significant differences in LOS in the Midwest and West were seen. The South also charged, on average, $93,483 more (95% CI $29,145, $157,820), compared to the Northeast, the Midwest charged $77,983 more (95% CI $4,682, $151,284) and the West $171,275 more (95% CI $99,492, $243,059). 1,895 secondary hospitalizations were identified, with 472 (24.9%) inpatient deaths. Significant differences in mortality were observed across regions ($p = 0.02$). Compared to the Northeast, the South stayed, on average, 10.4 days longer (95% CI 4.9, 15.9,), the Midwest 7.0 days longer (95% CI 1.6, 12.4), and no significant differences were seen in the West. Additionally, the South charged, on average, $212,398 more (95% CI $141,228, $283,567), the Midwest $139,617 more (95% CI $70,098, $209,136), and the West $103,302 more (95% CI $35,565, $171,039).
Conclusions: Significant geographic variations in mortality, LOS, and hospital charges exist in care of HLHS newborns in the US. A better understanding of these differences could improve quality of care and reduce costs..

Table 1. Standardized average length of stay (LOS) and hospital charges (in thousands of dollars), stratified by region, among neonates during primary hospitalizations, n = 2,431, and secondary hospitalizations, n = 1,895.

	Average LOS (95% CI)	Average Hospital Charges[a] (95% CI)
Primary hospitalizations[b]		
Northeast	24.9 (20.8, 29.0)	272.4 (220.4, 324.4)
Midwest	28.5 (24.4, 32.5)	350.4 (298.7, 402.0)
South	32.7 (29.9, 35.5)	365.9 (330.0, 401.8)
West	28.5 (24.8, 32.2)	443.7 (395.1, 492.3)
Secondary hospitalizations[b]		
Northeast	29.0 (24.9, 33.1)	274.0 (220.5, 327.5)
Midwest	36.0 (32.8, 39.2)	413.6 (372.1, 455.0)
South	39.4 (35.8, 43.1)	486.4 (438.8, 533.9)
West	27.2 (24.1, 30.3)	377.3 (337.7, 416.9)

P1698 - OUTCOMES FOLLOWING MECHANICAL ATRIOVENTRICULAR VALVE REPLACEMENT IN PATIENTS UNDERGOING SINGLE VENTRICLE PALLIATION

Conall Morgan, Deane Yim, Christoph Haller, Luc Mertens, Osami Honjo
The Hospital For Sick Children, The Labatt Family Heart Centre, Toronto-Canada

Background: Outcomes following mechanical atrioventricular valve (AVV) replacements in patients with single ventricles are uncertain.
Methods: From 1997-2016, 14 consecutive patients with functionally single ventricles underwent mechanical AV valve replacement for valve dysfunction at our institution. Operative mortality was defined as death within 30 days of surgery or prior to hospital discharge.
Results: Seven patients (50%) had hypoplastic left heart syndrome, 4 (29%) had an unbalanced atrioventricular septal defect, 2 (14%) had tricuspid atresia and 1 patient (7%) had pulmonary atresia with intact ventricular septum. Prior to AVV replacement, 12 patients (85%) had qualitatively normal or mildly reduced ventricular function and 2 (14%) had severely decreased function. 13/14 (91%) had severe AVV regurgitation. Median age of replacement was 2 years old (range 0.36- 6.75 years). St. Jude's valve was used in all patients (range 19 to 31mm). Following AVV replacement, 6 (43%) patients had normal or mildly reduced ventricular function, 3 (21%) had moderately decreased function and 2 (14%) patients had severely reduced ventricular function. Operative mortality was 43% (6/14). There were 2 late deaths. Kaplan-Meier survival estimates of the cohort are shown in Figure 1. Follow up was 100% complete with a median follow up period of 5.4 years (range, 0.08-8.8 years). 4 (21%) patients had complete heart block postoperatively that did not recover. 6 (43%) patients reached Fontan completion, 2 of whom died. Significant bleeding occurred in 57% (8/14) with 3 patients suffering major cerebrovascular accidents. There were 5 events of valve thrombosis in 4 patients. At last follow up, 2 patients had moderate or severe ventricular dysfunction, 1 had severe valve stenosis and none had significant valve regurgitation. No independent risk factors for mortality were identified.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Mechanical valve replacement carries significant mortality and morbidity. Careful consideration should be made before embarking replacement.

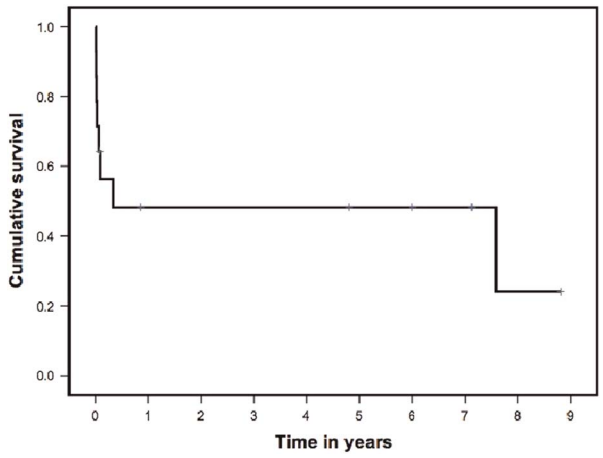

Figure.

P1702 - MID TERM FOLLOW UP OF TRICUSPID VALVE ANATOMICAL RECONSTRUCTION (CONE REPAIR) IN EBSTEIN'S ANOMALY

Valentyna Khanenova[1], Iuliia Kuzmenko[2], Tetiana Yalynska[3], Maryna Meshkova[4], Nadiia Rudenko[5], Iliia Yemets[6]
Ukrainian Childrens Cardiac Center, Reconstructive Surgery, Kiev-Ukraine[1]; Ukrainian Children's Cardiac Center, Cath Department, Kiev-Ukraine[2]; Ukrainian Children's Cardiac Center, Radiology Department, Kiev-Ukraine[3]; Ukrainian Children's Cardiac Center, Electrophysiology Department, Kiev-Ukraine[4]; National Medical Academy of Postgraduate Education Named After P.l Shupyk National Medical Academy of Postgraduate Education Named After P.Shupik, Head of A Chair, Kiev-Ukraine[5]; Ukrainian Children's Cardiac Center, Director, Kiev-Ukraine[6]

Ebstein's anomaly (EA) is a congenital heart defect (CHD) in which the septal leaflet of the tricuspid valve (TV) is displaced into the cavity of the right ventricle toward its apex. Its prevalence is 0.5-1% of all congenital heart defects. In some cases the defect is diagnosed late because primarily patients are asymptomatic, but the final stage of this disease is a heart failure. Usually, a first symptoms are serious arrhythmias or sudden death.
Objective: To analyze a mid-term follow up of successful cone reconstruction of TV in Ebstein's anomaly.
Methods: From 2012 to 2016 in Ukrainian Children's Cardiac Center 26 patients with Ebstein's anomaly were operated by performing the cone reconstruction of TV. The mean age of patients was 7.8 + 3.2 years. Preoperative diagnosis was made by the anatomy of the tricuspid valve: type "A" in 5 patients, type "B" in 10 patients, type "C" in 8 patients, type "D" in 3 patients. All patients were conducted electrophysiological study (if necessary, conducted high-frequency catheter ablation) and a cardiac catheterization before surgery. 7 patients had cone reconstruction combined with the Glenn shunt because of right ventricle failure.
Results: Early postoperative mortality was 7.7% (2 patients). Mid-term follow-up was 26.5 + 14.8 months. During the follow-up visit the clinical condition of the patients was examined, tests of physical tolerance, ECG, echocardiography, chest X-Ray and magnetic - resonance imaging of the heart were performed. By Echo there were from mild to moderate insufficiency on the TV, contractile function of the left ventricle is good and mild decreased right ventricle's contractility, indicating good result of correction. In late postoperative period reoperation was performed in 3 patients through a severe tricuspid insufficiency.
Conclusions: Cone reconstruction of TV is a very effective technique of surgical anatomical treatment of Ebstein's anomaly with good follow up results.

P1711 - AIR EMBOLISM TEAM TRAINING; NEEDS ASSESSMENT USING SIMULTION FOR PEDIATRIC CARDIAC SURGERY

Jennine Paugh[1], Deborah Rooney[2], Theron Paugh[1], Gregory Kline[1], Jennifer Ramano[3]
Univ of Michigan, or Nursing, Ann Arbor-United States[1]; Univ of Michigan, Medical School, Ann Arbor-United States[2]; Univ of Michigan, Cardiac, Ann Arbor-United States[3]

Introduction: Massive air embolism (MAE) is a rare but potentially catastrophic event. A recent root-cause analysis of a MAE event identified communication as a contributing factor. Recognizing patient safety is a collective function of individual clinicians, multidisciplinary teams and organizational systems we report on utilization of high fidelity simulation team training for MAE response.
Method: 44 clinicians were divided into 7 teams, each containing a pediatric cardiac surgeon, anesthesiologist, nurse/scrub technician and perfusionist. The MAE scenario was performed twice; bi-caval and single atrial cannulation techniques, as well as pre and post aortic cross clamp periods to ensured typical evaluation. Team performance was assessed by expert raters for gaps in procedural skills and team communication. Each scenario was debriefed with intention to address identified performance gaps. Learners' perceived value of simulation-based training was also solicited.
Results: Observations indicated poor team communication was primary barrier to successful execution of MAE protocol. Post-evaluation participant responses were positive. All participants felt the training program should be made mandatory, and 95% of respondents suggested at least annual training. Sample responses included, "This training was great. It gives you the opportunity to know what to expect should this occur," suggesting nurses and scrub technicians felt they had a better understanding of the protocol.
Conclusion: Comprehensive team training using high fidelity simulation for MAE has potential to improve understanding of procedure and protocol. Evaluation of the program's impact on cardiac team communication should be assessed prior to full implementation.

P1725 - PULMONARY VALVE REPLACEMENT IN PATIENTS WITH RIGHT VENTRICLE OUTFLOW RECONSTRUCTION

Bulent Saritas[1], Emre Ozker[1], Murat Ozkan[1], Ozlem Sarisoy[2], Canan Ayabakan[2]
Baskent University, Cardiovascular Surgery, Istanbul-Turkey[1]; Baskent University, Pediatric Cardiology, Istanbul-Turkey[2]

Background: The most frequent reoperation is the pulmonary valve replacement in patients having performed right ventricle outflow reconstruction. In this article, the early surgical outcome of the patients who had undergone PVR was discussed.
Materials and Methods: Seventy-six patients had PVR surgery for pulmonary insufficiency that developed after right ventricle outflow reconstruction between 2009 and 2016. Symptoms like

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

exercise intolerance or arrhythmias that are attributed to right ventricular volume overload or dysfunction with or without branch pulmonary artery stenosis were considered as surgical indications for PVR. Surgical indication was made according to MRI measurement in asymptomatic patients.
Results: There was no early mortality and late mortality after 60 ± 19 months of follow up. The mean right ventricular ejection fraction (RVEF) value in symptomatic patients is increased in the postoperative term, although this result is statistically insignificant. There is decrease in right ventricular area index (RVAI), right ventricular volume index (RVHI) and tricuspid annulus measurements compared to preoperative results.
Conclusions: PVR can be performed with low morbidity and mortality rates. It shall be performed before the irreversible changes in the right ventricular volumes and functions begin.

P1727 - SHOULD EXTUBATION IN OPERATING ROOM BE THE STANDARD OF CARE IN TETRALOGY OF FALLOT REAPIR EVIDENCE FROM A PROSPECTIVE OBSERVATIONAL STUDY

Debasis Das[1], Manish Kumar Sharma[2], Amitabha Chattopadhyay[3], Rangan Koley[2], Pradeep Narayan[4]
Narayana Superspeciality Hospital, Cardiac Surgery, Kolkata-India[1]; Narayana Superspeciality Hospital, Cardiac Anaesthesia, Kolkata-India[2]; Narayana Superspeciality Hospital, Pediatric Cardiology, Kolkata-India[3]; Rabindranath Tagore International Institute of Cardiac Sciences, Cardiac Surgery, Kolkata-India[4]

Background: Despite known benefits early extubation is not widely practiced in tetralogy of Fallot (TOF) repair. Aim of study was to assess feasibility of extubation in operating room in TOF repair and identify factors hindering early extubation strategy.
Methods: This was a prospective observational study between January 2015 and September 2016 which included 132 consecutive patients undergoing total correction for TOF. Extubation in the operating room was aimed for in all cases. Data was collected for baseline characteristics and operative variables to assess outcome measures. Risk factors were analyzed to identify independent correlation with failure to extubate in operating room.
Results: 132 (69 males, 63 females) patients underwent total correction for TOF. 77(58.3%) were extubated in the operating room. Of the remaining 55(41.7%) the median ventilation time was 105 minutes (inter quartile range: 71-135 mins.). 25/132 (18.9%) patients were less than 10 kg in body weight and 13/132 (9.8%) patients were less than one year in age. Transannular patch was created in 87/132(65.9%) while pulmonary valve was preserved in 45/132(34.1%) patients. Mean cardiopulmonary bypass time was 86.5 ± 20.3 mins and mean aortic cross clamp time was 57.5 ± 14.7 mins. Mean ICU stay was 23.1 ± 4.4 hrs and average post operative length of stay was 4.8 ± 0.6days. There was one death (1/132, 0.7%) due to low cardiac output. None of the risk factors analyzed appeared to be related to a failure to extubate on-table- age <1 year(Odds ratio 0.81, 95% CI 0.25-2.57); weight <10 kgs (OR 0.72; 95% CI 0.3-1.74); post repair Right Ventricle/ Left Ventricle (pRV/LV) ratio > 0.7 (OR 1.01; 95% CI 0.43-2.34); cross clamp time (OR 0.72; 95% CI 0.35-1.42); CPB time (OR 0.68; 95% CI 0.31-1.5).
Conclusions: Most children undergoing total correction for repair of tetralogy of Fallot can be extubated safely in the operating room. None of the perceived risk factors are real impediments for extubation in operating room.

P1730 - SURGICAL MANAGEMENT FOR PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM: A SINGLE CENTER 17 YEARS EXPERIENCE AND MEDIUM TERM FOLLOW UP

Jinghao Zheng
Shanghai Children's Medical Center, Shanghai Jiao Tong University School of Medicine, Department of Pediatric Cardiothoracic Surgery, Shanghai-China

Objective: The optimal surgical strategies for pulmonary atresia with intact ventricular septum (PAIVS) are still not well established. This study reviewed our 17 years' experience for the management of PAIVS.
Methods: Between July 1999 and June 2016, 194 patients were treated for PAIVS in our heart center. Based on the morphology of right ventricle (RV), age and surgical approaches, the patients were divided in to two groups: one-stage surgery group (n = 39) and staged surgery group (n = 155), in which received definitive repairs, including biventricular repair, 1.5 ventricular repair and univentricular palliation without or with initial intervention. Median follow-up time was 6.9 years (range, 1 to 17 years), and survival, risk factors for death, and clinical status after operation were assessed.
Results: In the one-stage surgery group, there were 4 deaths postoperation, and estimated 1, 5, and 15-year survival rates were 96.8%, 93.5%, and 88.4%, respectively. In the staged surgery group, 26 patients died, including 17 cases in the awaiting period after initial intervention. Estimated 1, 5, and 15-year survival rates of staged group were 89.7%, 88.5%, and 69.3%, without significant difference as comparing to one-stage surgery group ($P > 0.05$). Independent predictors of mortality were severe RV hypoplasia ($p < 0.05$) and lower tricuspid valve Z-score ($p < 0.01$). At latest follow-up, most of patients have well clinical status after definitive repairs in the both groups, while re-operation rate was 18.5% (5/27) in the one-stage surgery group and 17.8% (8/45) in the staged surgery group.
Conclusions: Both of one-stage and staged surgical procedure had acceptable surgical outcomes in this retrospective study. Initial intervention is suitable for neonates or younger patients to promote the growth of the RV, and one-stage definitive repair is a beneficial choice for older patients with PAIVS, in whom the growth potential of the RV is limited.

P1733 - THE RASTELLI PROCEDURE LONG TERM OUTCOME IN 25 YEARS OF EXPERIENCE

Claudia Natalia Villalba[1], Mariela Mouratian[1], Maria Victoria Lafuente[1], Mauricio Dilascio[1], Tassat Laila[1], Garcia Delucis Pablo[2], Barretta Jorge[2], Sciegata Alberto[3], Alonso Jose[3], Capelli Horacio[1]
Children´s Hospital J P Garrahan, Cardiology Department, Buenos Aires-Argentina[1]; Children´s Hospital J P Garrahan, Cardiovascular Surgery Department, Buenos Aires-Argentina[2]; Children´s Hospital J P Garrahan, Cardiac Catheter Laboratory, Buenos Aires-Argentina[3]

Background: The Rastelli operation is the conventional treatment for patients (p) with transposition of the great arteries (TGA) with ventricular septal defect(VSD) and pulmonary stenosis(PS). Its results, however, are suboptimal.
Objective: To analyze the medium and long-term outcome of the Rastelli surgery at our hospital.
Material and Methods: This study analyzed 63p operated on with the Rastelli procedure at our institution between 1991 and 2016. Median age at surgery was 3.8 years (IQR = 2.7-4.9). The median time of follow-up was 12.5years (IQR = 6.9-16). Two anatomical

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

variants were identified: TGA with VSD and PS(31p) and double outlet right ventricle with PS(32p). The VSD was unrelated to the aorta in 20 (32%) and restrictive in 9p (14%).
Results: The survival rate at 5 and 10 years was 97% and it was 94% at 15 years. The 98% of the survivors are in CF I-II with good ventricular function. The right ventricular to pulmonary artery (RV-PA) conduit developed a moderate or severe obstruction in 30p (57,7%) and severe regurgitation in 6p. Fourteen patients (26.9%) acquired left ventricular outflow tract obstruction (LVOTO). Seven of them had a non-committed VSD ($p = 0.01$). Ten patients required reoperation to relieve the LVOTO. In the long-term follow-up, the incidence of arrhythmias was 17% (8p) and the mortality was 3,8%(2p). Freedom from interventional catheterization at 5, 10, 15 and 20 years was 74%, 55%, 35% and 28%, respectively. Freedom from reoperations at 5, 10, 15 and 20 years was 83%, 46%, 26% and 19%, respectively. The main indication of reintervention (interventional catheterization = 84% and reoperation = 76%) was RV-PA conduit obstruction and/or incompetence.
Conclusions: - The Rastelli procedure has shown a good long-term survival.

- The most frequent adverse event was RV –PA dysfunction.
- Reinterventions were required in 61% of patients.
- The LVOTO was more frequent in patients with non-committed VSD.

P1741 - AORTIC ARCH RECONSTRUCTION USING AUTOLOGOUS PULMONARY ARTERY TISSUE IN INTERRUPTED AORTIC ARCH REPAIR AS A NEW SURGICAL APPROACH

Uygar Yörüker[1], Klaus Valeske[1], Matthias Müller[2], Dietmar Schranz[3], Hakan Akintürk[1]
Justus Liebig University, Pediatric Cardiac Surgery, Gießen-Germany[1]; Justus Liebig University, Pediatric Cardiac Anesthesiology, Gießen-Germany[2]; Justus Liebig University, Pediatric Cardiology, Gießen-Germany[3]

Background: This retrospective analysis aims to evaluate our experience using autologous pulmonary artery tissue in patients with interrupted aortic arch (IAA) as a new surgical approach.
Methods: Between 2005-2016 ten patients with the diagnosis of IAA (Type A: 3, Type B:7) and ventricular septal defect (VSD) were operated using autologous pulmonary artery tissue for aortic reconstruction. Six patients were treated initially with hybrid stage 1 approach due to the borderline left-sided heart structures. As a further operation they underwent to a total correction including IAA repair and VSD closure with a combination of bilateral pulmonary artery reconstruction and removal of the ductal stent. The remaining four patients underwent to a primary complete repair. In all patients arch reconstruction was performed under moderate hypotermic (28-30 °C) cardiopulmonary by-pass combined with selective cerebral perfusion. While reconstructing the aortic arch, a quadrangular shaped autologous pulmonary artery tissue was harvested from the anterior wall of the pulmonary artery. The harvested pulmonary autograft was then used to reconstruct the posterior wall of the aortic arch between the aorta ascendes and the aorta descendes (Video Presentation). Anterior wall of the aortic arch was reconstructed with autologous pericardium. The created defect in the main pulmonary artery was replaced with xenopericardium or with autologous pericardium. Nine out of ten patients could be biventricular treated.
Results: Median follow-up time was 70 months. In-hospital mortality occurred in one patient. Freedom from re-intervention and reoperation for aortic arch was %100. There were no hypertension and no bronchial compression observed.
Conclusion: In some cases, especially in IAA type B, applying the direct anastomosis is sometimes not possible or could be dangerous for restenosis. In this condition posterior wall reconstruction with autologous pulmonary artery tissue can be a good alternative to other techniques due to the growth potential of the pulmonary artery and anatomical correction of the arch.

P1757 - INNOVATIVE MIRROR IMAGE TRANSATRIAL TECHNIQUES FOR BIVENTRICULAR REPAIRS IN SITUS INVERSUS AND DEXTROCARDIA

Gananjay Salve[1], Shreepal Jain[1], Manglesh Nimbalkar[1], Kshitij Sheth[1], Bharat Dalvi[1], Krishna Kumar[2], Sandip Katkade[1], Jeril Kurien[1], Jigar Surti[3], Shivaprakash Krishnanaik[1]
Sir H.N. Reliance Foundation Hospital, Paediatric Cardiac Sciences, Mumbai-India[1]; Amrita Institute of Medical Sciences, Dept. of Paediatric Cardiology, Cochin-India[2]; U.N. Mehta Hospital, Dept. of Paediatric Cardiac Surgery, Ahmedabad-India[3]

Background: Correction of congenital heart defects with situs inversus and dextrocardia represent technical challenges due to possible injury to the conduction system. Published approach is trans-ventricular for accomplishing biventricular repair (BVR), with chief surgeon operating from right side of the patient. We present our experience of BVR in these subsets from left side of the patient using innovative pre-operative mirror image techniques.
Materials and Methods: 15 patients with these subsets underwent BVR through innovative trans-atrial approach from left side of the patient. Orientation of intra-cardiac anatomy was obtained pre-operatively by rendering standard illustrations in a reversed and inverted way using standard software. Male: female ratio was 7:8. Mean age and weight were 4 years (4.5 months-31 years) and 10.16 kg (3.4-59 kg) respectively. The surgical spectrum included closure of ventricular septal defects (VSD) (n = 6), complex intra-ventricular tunneling for double outlet right ventricle (n = 3), tetralogy of Fallot (TOF) repair (n = 6), with trans-annular patch (n = 2), with conduit (n = 2), and with double barrel technique (n = 1). One patient underwent Double switch operation (DSO) with Hemi-Mustard procedure for corrected transposition, VSD and pulmonary stenosis. Septal and anterior leaflet detachment was performed whenever necessary (n = 5).
Results: Mean bypass and clamp time was 153 mins and 101 mins respectively. None developed complete heart block. Mean hospital stay was 12.4 days with no hospital mortality. On follow-up, all patients remain in NYHA class I. One adult awaits device closure for a small residual VSD. One required right pulmonary artery plasty (Balloon) after total correction. Patient with DSO got readmitted for supra-ventricular tachycardia and is on beta-blockers. She remains symptom-free till date.
Conclusion: Trans-atrial BVR of these complex subsets is feasible and reproducible. The innovative illustrations facilitated in accomplishing successful repairs while avoiding heart blocks and ventriculotomy. Short-term results are satisfactory.

P1760 - MODIFICATION OF NORWOOD TYPE PROCEDURE AFTER BILATERAL PULMONARY ARTERY BANDING AND DUCTAL STENTING FOR HYPOPLASTIC LEFT HEART SYNDROME

Bilateral pulmonary banding and ductal stenting can be used as a hybrid alternative to Norwood-type procedure for palliation of neonates. We reported modification of arch reconstruction using stented ductal tissue for hypoplastic left heart syndrome. A two-month-old boy with hypoplastic left heart syndrome underwent bilateral pulmonary artery banding on Day 5 and subsequent ductal stenting. Cardiopulomnary bypass was established through a aortic cannula was inserted in graft which anastomosed with the innominate artery and right atrium was cannulated. The aortic arch between the innominate artery and the left common carotid artery was clamped and the left common carotid artery and the left subclavian artery were snugged with small tourniquets. The main pulmonary artery was transected just proximal to the bifurcation. The origin of the branch pulmonary arteries was resected as a single large button that meant the anterior wall of the main pulmonary artery was completely preserved for the aortic reconstruction. The continuity of the branch pulmonary arteries was restored by folding the pulmonary button. The clamp on the proximal aortic arch was moved to the origin of the innominate artery. The ascending aorta was transected at the level of the proximal pulmonary stump, and then blood cardioplegia was delivered. The area of apposition between the small ascending aorta with the lesser curvature of the aortic arch and the stented ductus was divided towards the orifice of the aortic isthmus. The stented ductal tissue was used as a patch. The aortic arch was reconstructed by sewing the free edges of the divided duct to the opened native aortic arch. Continuity was then restored with the main pulmonary artery and proximal aorta.The branch pulmonary artery bands were removed, and the branches were dilated. The artificial connection between right ventricle and pulmonary artery was created with a 5.0mm EPTFE tube graft.

P1774 - FACTORS ASSOCIATED WITH INTERSTAGE MORTALITY FOLLOWING FIRST STAGE SINGLE VENTRICLE PALLIATION

Bahaaldin Alsoufi, Courtney Mccracken, Kirk Kanter, Subhadra Shashidharan, E. Dean Mckenzie
Emory University, Cardiac Surgery, Atlanta-United States

Background: Several advances have led to improved hospital survival following first-stage single ventricle palliation. Nonetheless, a number of patients continue to suffer from interstage mortality prior to subsequent second-stage palliation. We aim to study patients' characteristics, anatomic and surgical details associated with interstage mortality in the current era.
Methods: 453 neonates survived to hospital discharge following first-stage palliation. Competing-risks analysis modeled events after first-stage surgery (Glenn, transplantation or death) and examined variables associated with interstage mortality.
Results: Competing-risks analysis showed that 1 year following first-stage palliation, 10% of patients had died, 86% had progressed to second-stage palliation, 1% had received heart transplantation and 3% were alive without subsequent surgery. On multivariable analysis, factors associated with interstage mortality risk were: weight ≤2.5 kg (HR = 2.4(1.2-4.6), p = 0.013), premature birth ≤36 weeks gestation (HR = 2.0(1.0-4.0), p = 0.05), genetic syndromes (HR = 3.2(1.7-6.1), p < 0.001), unplanned cardiac reoperation (HR = 2.1(1.0-4.4), p = 0.05) and prolonged intensive care unit stay >30 days following first-stage palliation (HR = 2.5 (1.4-4.5), p < 0.001). First-stage palliation surgery type (shunt vs. Norwood vs. band) was not associated with interstage mortality except for Norwood with shunt as opposed to RVPA conduit (HR = 5.4(1.5-19.2) p = 0.01). Of interest, while underlying cardiac anatomy was associated with hospital mortality, that was not associated with interstage mortality among hospital survivors (HR = 1.1(0.6-2.2), p = 0.749). Additionally, ECMO use at first stage palliation was not associated with interstage mortality among hospital survivors (HR = 1.1(0.4-3.8) p = 0.800).
Conclusion: In the current era, interstage mortality following first-stage palliation occurs in 10% of hospital survivors. Contrary to hospital death, underlying single ventricle anomaly was not associated with interstage death. Conversely, several patient factors (such as prematurity, low weight and genetic syndromes), clinical factors (the need for unplanned reoperation and prolonged intensive care unit stay following first-stage palliation) are risk factors for interstage mortality. Vigilant post-discharge home monitoring might be warranted to improve survival in those high-risk patients.

P1775 - SIMPLE TECHNIQUE TO PREVENT SUPRAVALVAR PULMONARY ARTERY STENOSIS IN ARTERIAL SWITCH OPERATION

Oleg Kornoukhov, Vladimir Ilyin
Filatov Children's Hospital, Cardiac Surgery, Moscow-Russia

Objectives: A number of techniques aimed to avoid stenosis after pulmonary artery (PA) reconstruction in arterial switch operation (ASO) have been described. However, this complication is still observed in 4-6% cases. We present our follow-up results of PA reconstruction using single non-bifurcating pericardial patch.
Methods: 87 consecutive patients who underwent ASO for transposition of the great arteries (TGA) between December 2008 and December 2014 were included in this prospective cohort study. Median age and weight at the time of surgery were 12 (3–486) days and 3.6 (2.5–10.3) kg, respectively. Median follow-up duration was 3.2 (0.2–7.3) years. Proximal main PA was routinely reconstructed during aortic cross-clamp period with a single trapezium-shaped, non-bifurcating fresh autologous pericardium patch. Posterior commissure of the neo-pulmonary valve was attached to the pericardium patch using a single stitch. The anastomosis was fashioned during rewarming using continuous 7/0 polypropylene suture.
Results: Freedom from supravalvar pulmonary stenosis defined as Doppler-derived peak systolic pressure gradient (PG) more than 20 mm Hg, and neo-pulmonary regurgitation graded higher than mild, at 7,3 years follow-up was 100%. No patient developed subvalvar right ventricular outflow tract obstruction. Main PA z-score was 0.261,25, neo-pulmonary valve z-score was 0.251,12, left and right PA z-scores were -0.251.03 and -0.551.14,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

respectively. Median peak systolic pressure gradient on the left branch PA was 9 mm Hg (3-28) and on the right 11 mm Hg (4-50). One patient (1.1%) who required two-staged repair for TGA with multiple VSDs had developed clinically significant right branch PA stenosis (PG 50 mm Hg).
Conclusions: Medium-term results of the ASO with application of a single non-bifurcating fresh autologous pericardium patch during reconstruction of main PA demonstrated almost complete freedom from supravalvar main PA stenosis and re-intervention for any right-sided obstructive lesions in all patients.

P1782 - INTRA AND POSTOPERATIVE PREDICTORS OF EXTRACORPOREAL CIRCULATORY SUPPORT REQUIREMENT IN HIGHER RISK CONGENITAL CARDIAC SURGERY

Christoph Haller[1], Edward Hickey[1], Arezou Saedi[1], Rachel Parker[1], Jessica Magerman[1], Kasey Moss[1], Ben Sivarajan[2], Anne-marie Guerguerian[2], Glen Van Arsdell[1], Osami Honjo[1]
The Hospital for Sick Children, University of Toronto, Cardiovascular Surgery, Toronto-Canada[1]; The Hospital for Sick Children, University of Toronto, Critical Care Medicine, Toronto-Canada[2]

Background/Hypothesis: Prediction of postoperative low cardiac output and requirement of extracorporeal membrane oxygenation (ECMO) allows for preemptive measures.
Materials/Methods: 510 patients (weight 6.44 ± 3.87 kg;age 300.7 ± 402.6days) undergoing cardiopulmonary bypass (CPB) between 2012-2014 (aged ≤3years, RACHS-1 score ≥3) were included and analyzed. Blood gas, inotropic doses and transfusion were collected at 3 time points (termination of CPB [T1], end of procedure [T2], 2-4 h post ICU admission [T3]). Procedure related ECMO was considered any ECMO within 48 h of surgery. Multivariate logistic regression was used to identify predictors.
Results: A total of 21(4.1%) patients were supported by ECMO. Among those with ECMO initiation on ICU, 6(66.7%) underwent ECPR. Total mortality was 6.3%(n = 32). 4(33.3%) of intraoperative ECMO patients, and 3(50.0%) of ECPR patients died. All patients who underwent semi-elective ECMO in ICU survived. Mortality of non-supported patients was 5.1%(n = 25). Predictors of any ECMO included lower milrinone dose at T1 (r = -2.65;p = .0859), higher epinephrine dose at T2 (r = 8.77; p = .0068), worse grade of residual left atrioventricular valve regurgitation (r = 0.48;p = .0150), residual coronary artery lesion (r = 1.50;p = .0063), aortopulmonary shunt placement (r = 1.55; p = .0003), and longer CPB (r = 0.017;p < .0001)(c = .936). Predictors of ECMO in the operating room included longer CPB (r = .0228;p = .0002), aortopulmonary shunt placement (r = -1.71; p = .0029), higher norepinephrine dose at T1 (r = 4.93;p = .0341), and worse grade of ventricular dysfunction (r = 1.08;p = .0064) (c = .99). Predictors of postoperative ECMO included lower milrinone dose at T1 (r = -4.26;p = .0083), higher norepinephrine at T1 (r = 23.9;p = .0002), residual coronary artery lesion (r = 2.66; p = .0009), procedure involving repair of aortic arch/coarctation (r = 2.32;p = .0037), atrial septectomy (r = 2.27,p = .0038), and longer crossclamp time (r = .0249;p = .0001)(c = .96).
Conclusions: Patients needing ECMO postoperatively had high mortality, especially after ECPR. Patients with high inotropic support, long CPB, and residual anatomic or physiologic lesions are at higher risk to need ECMO. Given high mortality associated with ECPR, a low threshold to place patients with those risk factors on ECMO prior to cardiac arrest may improve survival. Development of a predictive model would be helpful in decision-making.

P1796 - RACIAL ETHNIC AND HEALTHCARE DISPARITIES ASSOCIATED WITH PEDIATRIC CARDIAC SURGERY OUTCOMES IN THE UNITED STATES

Jennifer Peterson[1], Yanjun Chen[2], Danh Nguyen[3], Shaun Setty[1]
Miller Children, Heart & Vascular Institute, Long Beach-United States[1] University Of California, Irvine, Biostatistics, Epidemiology, and Research Design Unit, Irvine-United States[2]; University of California, Irvine, Medicine, Irvine-United States[3];

Background/Hypothesis: Despite overall improvements in congenital heart disease outcomes, racial and ethnic disparities continue in the United States. The effect of age on these health disparities is unclear.
Materials and Methods: From the 2012 Healthcare Cost and Utilization Project Kids Inpatient Database (KID), we identified 13,130 records with Risk Adjustment in Congenital Heart Surgery complexity score-eligible procedures. We assessed the effect of race and ethnicity, as well as other risk factors on in-hospital mortality and length of stay (LOS) through multivariate logistic and linear regression modeling with survey weights, stratification and clustering.
Results: No significant mortality differences were found among all race and ethnicity groups across each age group. Black neonates had a longer LOS (Estimate = 8.73 days, p = .0034), as did black infants (Estimate = 1.10 days, p = 0.0253), relative to whites. Income quartile was not associated with mortality or increased LOS in any age group, except for neonatal LOS in the first quartile (Estimate = 4.58 days, p = 0.0325), compared to fourth quartile. Medicare/Medicaid insurance was associated with increased odds of neonatal mortality (odds ratio [OR] = 1.51, p = .0055), and with increased LOS in neonates (Estimate = 4.26 days, p = .0009) and infants (Estimate = 1.52 days, p = .0181) relative to private insurance. Chronic conditions and hospital-acquired injuries/complications were strongly associated with mortality and LOS in all age groups.
Conclusions: Racial/ethnic disparities in congenital heart surgical outcomes continue in the United States. The number of chronic conditions and incidence of medical injuries/complications are significant contributors to mortality and LOS.

P1805 - A RARE CONGESTIVE HEART FAILURE REASON IN AN INFANT AORTICO LEFT VENTRICULAR TUNNEL

Zulal Ulger[1], Munevver Dereli[2], Fatih Ayik[2], Yuksel Atay[2]
Ege University Hospital,Pediatric Cardiology, Izmir-Turkey[1]; University Hospital,Cardiovascular Surgery, Izmir-Turkey[2]

The aortico-left ventricular tunnel is a very rare congenital malformation, characterized by an abnormal communication between the ascending aorta and the left ventricle. Generally the tunnel is situated above the right coronary sinus. The pathogenic mechanism of this congenital anomaly is not completely understood yet. In most cases the first symptoms appear in early infancy. Clinical presentation and the hemodynamics are similar to those of aortic valve insufficiency. Definitive diagnosis is established by echocardiography and angiocardiography. Early operation is recommended before the aortic annulus becomes excessively dilated. The method of choice for surgical correction is a patch closure of the aortic orifice of the tunnel. we report a case of aortico-left ventricular tunnel that was associated with right ventricular outflow tract obstruction due to the aneurysmal tunnel. The aortico-left ventricular tunnel was closed so as to treat the gradually increasing left ventricular systolic dysfunction.

P1809 - EARLY RESULTS 2 YEARS OF CARDIOCEL® PATCH IMPLANTATION IN CHILDREN

Carine Pavy[1], Olivier Ghez[1], Guido Michielon[1], Robertus Jan Lukas[2], Lacour Gayet François[1]
Royal Brompton Hospital, Pediatric Heart Surgery, London-United Kingdom[1] Royal Brompton Hospital, Pathology, London-United Kingdom[2]

Hypothesis: Early results after 2 years of CARDIOCEL® patch (Admedus Regen Pty Ltd, Perth, WA, Australia) in paediatrics for congenital heart disease repair shows an unexpected early re-stenosis when sutured in aortic position.
Materials and Methods: Single centre retrospective study of all patients aged 18 year-old and under, operated for congenital heart diseases. Standard follow-up was performed, clinically and with echocardiograms. In case of re-operation for graft failure, the patch was removed and sent to pathology.
Results: Between March 2014 and April 2016, 101 patients with a congenital heart disease had a surgical repair using the CARDIOCEL® patch. The mean age was 7 months old (range: 3 days – 18 years) and the mean weight was 6,7 kg (range: 1,83-96 kg). The mean bypass time was 156 min (+74 min) and the mean aortic cross clamp time was 103 min (+49 min). No infections, no intraoperative implantation difficulties were related to the patch. The mean follow up was 175 days (range: 4-726 days). The 30-day overall post-operative mortality was n = 4 (3,8%), none were related to graft failure. 5 infants were re-operated because of graft failure, all in aortic position. The indication for the patch in aortic position was truncus arteriosus, coarctation and aortic arch hypoplasia repair. The mean time between the first and the second operation for graft failure was 189 days (range: 16-480 days).
Conclusions: Our experience shows a good tolerance of the patch in septal, valvar and pulmonary artery position. However, we experienced graft failures in infants in aortic position.

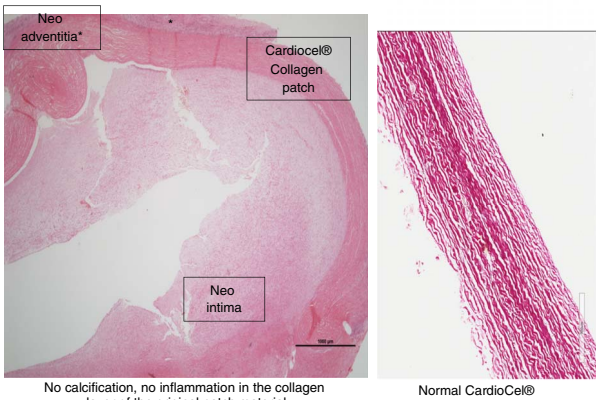

Figure.

P1811 - RAMP UP AN ITERATIVE TOOL TO ENSURE PEDIATRIC HEART PROGRAM PERFORMANCE

Camille Hancock Friesen[1], Stacy O[1], John Finley[2], Andrew Warren[2]
IWK/Dalhousie, Surgery, Halifax-Canada[1]; IWK/Dalhousie, Pediatrics, Halifax-Canada[2]

Background: Clinical care of patients with complex congenital heart disease is a multidisciplinary undertaking. Critical human resource changes in a heart program can threaten its ability to deliver consistent outcomes. We describe a "Ramp Up" process, employed three times in a small-volume high-performance program, to mitigate risk delivering pediatric cardiac care.
Methods/Materials: The IWK Heart Program is comprised of pediatric cardiologists (n = 5), cardiac surgeons (n = 2), cardiac anesthetists (n = 1) and intensivists (n = 4). The program provides care to patients of the four Atlantic provinces with all congenital cardiac pathologies and performs all surgeries except ventricular assist device and transplantation. Outcome data for each procedure is submitted to a national database (Congenital Cardiac Surgery Database, CCSDB, Hospital for Sick Children, TO) with caregiver consent. Three times over the past 12 years (2003, 2006, 2015) there have been sufficient disruptions to the staffing complement (retirement or relocation) that we have employed a Ramp Up strategy to ensure program performance (Fig. 1a).
Results: Overall 12y program mortality rates remain low (3.3%)and comparable to national standards (4.3%, Fig. 1b). Mortality in benchmark cases (VSD, ASD secundum, complete AVSD, Fontan, tetralogy of Fallot, coarctation, arterial switch and Stage 1) was likewise comparable to national data (IWK 2.8% v CCSDB 2.8%). We also instituted complication monitoring which shows that we have similar outcomes to STS data.
Conclusions: "Ramp Up" requires buy-in from all local team members. External validation of outcomes is critical to provide an arms-length opinion as to the preparedness of the team to move on to cases of greater complexity based on qualitative and/or quantitative observations. "Ramp Up" has proven invaluable as a concept and practice to ensure delivery of the best possible outcomes in pediatric cardiac surgery.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

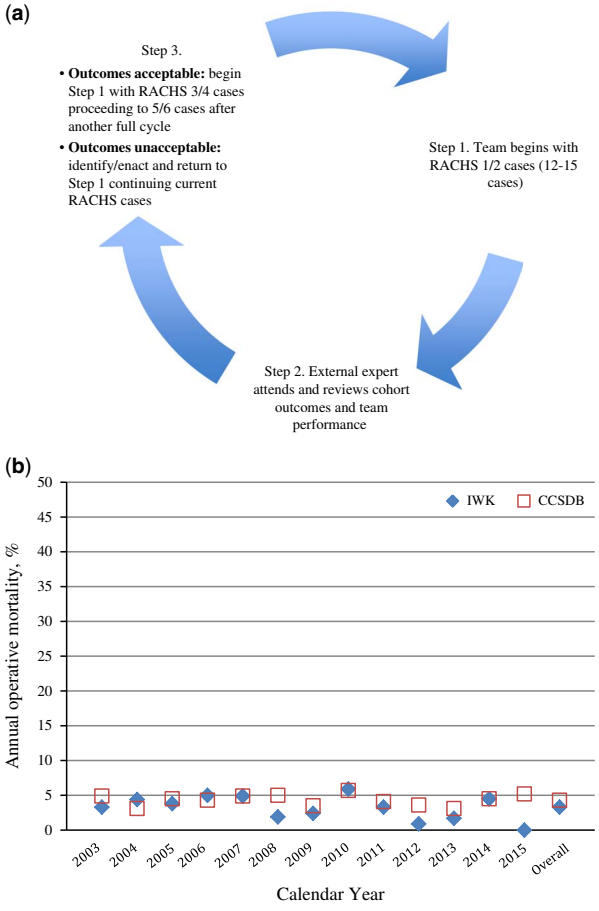

Figure.
(a) Ramp Up process. (b) Annual mortality rates (IWK v CCSDB aggregate 2003-2015) illustrate the maintenance of stable outcomes despite change in surgical staff members (2003, 2006) and anesthesia staff members (2015). (Note annual operative scale is truncated at 50%)

P1812 - QUALITY IMPROVEMENT INITIATIVES TO REDUCE THE WAITING TIME AND MORTALITY FOR PATIENTS UNDERGOING SURGICAL CORRECTION TETRALOGY OF FALLOT IN INSTITUTE JANTUNG NEGARA

Norliza Yusoff[1], Nurul Fakhri Mohamaed[2], Rozainah Said[1], Hasri Samion[1], Sivakumar Sivalingam[1]
Intitute Jantung Negara, Paediatric and Congenital Heart Centre, Kuala Lumpur-Malaysia[1]; Intitute Jantung Negara, Research Deparment, Kuala Lumpur-Malaysia[2]

Introduction: The incidence of Congenital Heart Diseases (CHD) among Malaysian children is about 8 to 10 per 1,000 live births which half will require some form of intervention. In IJN the total number of patients undergoing intervention for congenital heart lesions is around 1400 per year.
Objectives: The objective of this study was to reduce the mortality for TOF correction to below 1% as a part of the initiative of Quality Improvement and Patient Safety standards from Join Commission International and to bring down the waiting list for patients with TOF awaiting surgical correction.
Methods: Between January 2015 and December 2016, 230 patients underwent surgical correction of Tetralogy of Fallot. This was the period during which the quality and patient safety initiative was conducted in the institute. The data was obtained from the IQIC redcap database. The patients were screened according to the age, weight complexity of the lesion and distributed accordingly to the surgical teams. Based on the individual surgeons numbers and performance we limited the credentialing the number of surgeons who performed the surgical correction.
Results: The total number of patients on the waiting list reduced from 216 to 22. The median age for patients undergoing total correction reduced from 4.8 years to 2 years. The average slotting of cases per week for TOF correction increased to 10 cases per month. The average mortality of patients who underwent total correction reduced to 0.97%. Based on the performance the number of surgeons who were credentialed to perform the surgery were reduced from 6 to 3 surgeons.
Conclusion: Centralized waiting list and patient selection based on complexity and age and referral to individual surgeons and limiting the credentialing to perform the surgery based on volumes and outcomes has helped to reduce the mortality and waiting times following surgical correction.

P1813 - SUCCESSFUL RE IMPLANTATION OF THE ABNORMAL LEFT CORONARY ARTERY ARISING FROM THE RIGHT VALSALVA SINUS AND COURSING BETWEEN THE ASCENDING AORTA AND THE PULMONARY TRUNK

Yutaka Imoto, Tomoyuki Matsuba, Hiroyuki Yamamoto, Kazuhisa Matsumoto, Kenichi Arata, Kousuke Mukaihara, Itsumi Imagama, Yoshikazu Kawazu
Kagoshima University, Cardiovascular Surgery, Kagoshima-Japan

Background: Congenital abnormality of the coronary arteries is one of the major causes of sudden death among healthy young people. Although early diagnosis and safe and sure treatment are inevitable to avoid disastrous clinical course, they are sometimes difficult. We present our experience of successful re-implantation of the abnormal left coronary artery (LCA).
Case: A 14-year-old boy without any symptom with non-specific ECG-change was referred to us with a diagnosis of an abnormal LCA originating from the right Valsalva sinus (RVS) and coursing between the ascending aorta and the pulmonary trunk (Fig 1). The origins of the RCA and LCA formed a short common trunk. Cardiac scintigraphy showed no myocardial ischemia. According to the ACC/AHA guideline, surgical operation is indicated with Recommendation Class-1 in this type of coronary abnormality. Some surgical options were considered, such as fenestration, unroofing, CABG, pulmonary translocation and LCA re-implantation. The first two methods were rejected because the LCA had no intramural course. CABG was not suitable because the LCA flow was not reduced and early graft obstruction due to flow competition was concerned. Pulmonary translocation, in our opinion, has little effect to relieve the LCA obstruction. LCA re-implantation is easily indicated when the LCA had a separate ostium, but our case had single ostium. After all, we chose LCA re-implantation. The LCA was divided just distal to the LCA-RCA bifurcation. The LCA was dissected free as distal as possible, over the LCA-LAD bifurcation. The proximal end of the LCA was incised to form a good shape of "Cobra head", which was anastomosed to the left Valsalva sinus. Postoperative course was uneventful and postoperative CT showed non-obstructive LCA (Fig2). In conclusion, re-implantation of the LCA originating from the RVS can be achieved safely even when the LCA and RCA had common trunk.

P1814 - THE INFLUENCE OF ISOLATED BIDIRECTIONAL CAVOPULMONARY CONNECTION ON PULMONARY ARTERY

Nadezhda Ershova, Elena Kavardakova, Natalya Shmakova, Olga Yanulevich, Evgeniy Krivoshchekov
Cardiology Reserach Institute, Tomsk Nrmc, Cardiovascular Surgery Department, Tomsk-Russia

Background: Bidirectional cavopulmonary connection (BCPC) is the best interim stage for hemodynamic correction of congenital heart diseases with single ventricle (SV). Still the problem of additional source of pulmonary blood flow at BCPC for adequate flow is unsolved.
Materials and Methods: 89 patients at the age from 2 months to 13 years (Me = 0,64; IQR:0,5-1,18) with SV were included into the study. They were not performed heart catheterization at the stages of hemodynamic correction with pulmonary angiography to assess achitoctonics of pulmonary blood flow and index of pulmonary artery (PA): Nakata index, McGoon ratio and Reddy index from 2012 to 2014 years.
Results: Initially, Nakata index was Me = 326,0 мм2/м2 (IQR:241,5-410,0), Reddy index - Me = 215,0 мм2/м2 (IQR:151,5-283,5) and McGoon ratio Me = 1,8 (IQR:1,7-2,2). In 30 months after BCPC increase of the following PA indices was marked: Nakata index до Me = 336,5 мм2/м2 (IQR:240,0-415,5), p = 0,717, Reddy index till Me = 222,0 мм2/м2 (IQR:140,5-288,8), p = 0,147 and McGoon correlation increased up to Me = 2,0 (IQR:1,7-2,2), p = 0,288. All PA indices and McGoon correlation after BCPC corresponded to normal values. The comparative analysis of right and left PA diameters showed significant difference, p = 0,005: right PA - Me = 12,05 mm (IQR:10,57-14,4), left PA - ЛА - Me = 11,5 (IQR:9,57-12,6). Diameters of distal PA branches also showed significant difference: right distal PA - Me = 11 mm (IQR:8,35-11,5), left distal PA - Me = 9,5 mm (IQR:8,4-10,8).
Conclusion: BCPC without additional source of pulmonary blood flow provides sufficient pulmonary flow. However, asymmetric growth of PA branches is marked.

P1825 - THE CLINICAL ANALYSIS OF 99 CASES WITH CONGENITAL VASCULARRING

Xiaoyun Wu, Xin Zhang, Tiewei Lv, Min Zheng, Xiaojuan Ji, Chuan Feng
Children's Hospital of Chongqing Medical University, Cardiology, Chongqing-China

Bacground and Objevtive: Congenital vascular rings (CVR) are rare. This study is to evaluate the clinical characteristics,diagnosis and prognosis of CVR in children.
Methods: 99 cases of CVR in our hospital from January 2006 and December 2015 were retrospective riviewed.According to the prognosis of divided into survival group and death or give up the treatment group, the risk factors of poor prognosis analysis.
Results: 99 cases with congenital vascular rings included 55 males and 44 females,age median 7.2 months.The diagnosis including pulmonary artery sling in 51 cases,double aorta arch in 32 cases, right aortic arch with left ductus arteriosus in 15 cases,left aoaic arch with vagus right subclavian artery in 1 case.Merge heart malformations in 64 cases (64.6%), of which the merger pure ASD in 31 cases, VSD in 2 cases, 9 cases with ASD + VSDand 22 cases of complex cardiac anomalies. Tracheobronchial stenosis in 69 cases, esophageal stenosis in 14 cases, 10 cases of laryngeal cartilage dysplasia, 9 cases of congenital bronchial pulmonary hypoplasia. The diagnosis accuracy of echocardiographic was 57.4% and that of computed tomography angiography was 91.6%,26 cases checks on the fiber bronchoscope were found airway stenosis; 14/17 (82.3%) line barium esophageal imaging examination in esophageal pressure distortion and narrow. 57 cases of congenital vascular ring completed the operation,including 4 cases died, postoperative offline difficult to give up treatment of 6 cases.Non-surgical treatment of 42 cases,among which 1 case death and 10 cases of offline difficult to give up treatment. Dead or abandoned children, age, and proportion of the pulmonary artery sling with pulmonary dysplasia group is significantly higher than survival.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Eehocardiography combined with CTA is the best way to diagnose vascular ring.Type of vascular ring,age and the combining pulmonary hypoplasia were risk factors worsening the patients'prognosis.

P1833 - A RETROSPECTIVE STUDY OF VARIOUS TECHNIQUES OF SURGICAL CLOSURE OF ATRIAL SEPTAL DEFECT

Gopi Nallaiyan
Devadoss Multispeciality Hospital, Paediatric Cardiac Surgery, Madurai-India

Hypothesis: A Retrospective study of Various surgical techniques used for ASD closure by a single surgeon form June 2013 TO December 2016 and its merits and demerits.
Material and Methods: All cases of surgical closure of ASD was evalvauated restrospectively from June 2013 to December 2016 by a single surgeon. There was 193 cases of Surgical closure of ASD of various age form 3 years to 48 years. All cases were not suitable for ASD Device closure and reffered for surgery by Paediatric cardiologist. Out of 193 cases, 136 cases were done by standard Sternotomy,44 cases by Lower partial sternotomy and 13 cases by Right Anterolateral Thorocotomy.
Results: All cases do have similar CPB and Cross clamp time, irrespective of Technique uses. Only 11 of the 193 cases were ventilated for more than 4 hours post operatively in the ICU. All the 44 Lower partial sternotomy cases were less than 10 years of age and they were dischared on the 3rd Post operative day. No difference in Hospital stay between the Standard sternotomy and Anterolateral thorocotomy cases.
Conclusion: Lower partial sternotmy is an effective and surgically safe alternative to ASD device closure in children less than 10 years and less than 25 kg weight, compared to standard Sternotomy or Anterolaterlal thorocotomy surgical ASD closure techniques.

P1835 - HYBRID APPROACH IN PULMONARY ATRESIA WITH VENTRICULAR SEPTAL DEFECT AND COLLATERALS COIL OCCLUSION AND RIGHT VENTRICLE PULMONARY ARTERIES CONDUIT IMPLANTATION WITH POST REPAIR ANGIOGRAPHY IN A HYBRID OPERATING ROOM. INITIAL EXPERIENCE

Incor HC FMUSP and HCOR, Pediatric Cardiovascular Surgery, São Paulo-Brazil[1]; Incor HC FMUSP, Pediatric Cardiovascular Surgery, São Paulo-Brazil[2]; Hcor, Pediatric Cardiovascular Surgery, São Paulo-Brazil[3]; Hcor, Pediatric Cardiology, São Paulo-Brazil[4]; Incor Hc Fmusp And Hcor, Cardiac Surgery, São Paulo-Brazil[5]

Introduction: Pulmonary Atresia with Ventricular Septal Defect and major aortopulmonary collateral arteries surgical timing and approach is a challenging situation. MAPCAS surgical intervention is difficult and time consuming. Sometimes various surgical approaches are necessary. Hybrid procedures bring the best of two interventions in a lot of congenital cardiac diseases.
Objective: We sought to evaluate an initial experience with an hybrid (interventional + surgical) approach in patients with Pulmonary Atresia with Ventricular Septal Defect and major aortopulmonary collateral arteries. Methods: Retrospective study. Between November 2014 and November 2016, 18 consecutive patients with median age of 10.5 months and median weight of 7.5 kg.
Results: Thirteen out of 18 patients (72.2%) were submitted to sucessfull coil collateral embolization pre-bypass. Four unifocalizations and three PA enlargements were performed. VSD closure were perfomed in 14 patients (77,7%), in the other 4 patients, RV-PA conduits were implanted and VSD were left open due to poor pulmonary vascular bed. Bypass and cross-clamp median time was 156.5 and 83 minutes, respectively. Ten patients (55.5%) were submitted to post-repair angiography through RV cannulation. In five (50%) pulmonary angioplasty and stent implantation were performed in the same operative time. Intubation and ICU median time was 4.5 and 9 days, respectively. The 30-day mortality was 11.1% (2 patients) and there was one late death.
Conclusion: Hybrid OR allows a combined and integrated approach to Pulmonary Atresia with Ventricular Septal Defect and major aortopulmonary collateral arteries patients enabling a thorough procedure in one surgical time.

P1845 - MITRAL VALVE REPLACEMENT USING STENTED BOVINE JUGULAR VEIN GRAFT (MELODY VALVE) IN INFANTS AND SMALL CHILDREN

Atsuko Kato[1], Kyong-Jin Lee[1], Rajiv Chaturvedi[1], Luc Mertens[1], Glen Vanarsdell[2], Osami Honjo[3]
The Hospital for Sick Children, Department of Pediatrics, Division of Cardiology, The Labatt Family Heart Centre, Toronto-Canada[1]; The Hospital For Sick Children, Department of Surgery, Division of Cardiovascular Surgery, The Labatt Family Heart Centre, Toronto-Canada[2]; The Hospital For Sick Children, Department of Surgery, Division of Cardiovascular Surgery, Toronto-Canada[3]

Background: Melody® valve (Medtronic, MN) implantation in the mitral position is an emerging alternative to a mechanical valve especially in younger children. It is implantable in a small mitral valve (MV) annulus and does not require long-term anticoagulation. The aim of the current study was to evaluate our initial experience with mitral valve replacement (MVR) with Melody® in small children.
Method: The clinical records of patients who underwent MVR using Melody® from 2014 to 2016 were retrospectively reviewed. The Melody® (22 mm) valve was prepared by sewing a 3.5 mm Gore-Tex tube graft at the middle of the stent as a cuff and resecting one or three zigs to avoid left ventricular outflow tract (LVOT) obstruction. All values are represented as median with range.
Results: Five patients (age, 11 months, 5-16 months; weight, 6.8 kg, 4.6-8.6 kg) were included. All patient had a dysplastic MV with severe stenosis (n = 3) and/or regurgitation (n = 3). Three patients underwent Melody® valve MVR as a salvage procedure after mechanical valve thrombosis (n = 2) or tissue valve dysfunction (n = 1). Cardiopulmonary bypass time was 160 minutes (60–199 minutes) and cross-clamp tim e was 106 minutes (40-134 minutes). The valve was dilated to 18 mm (n = 2) or 20 mm (n = 3). Intraoperative echocardiography revealed no or trivial regurgitation in all patients with a mean pressure Doppler gradient of 2 mmHg (1–4 mmHg), and peak LVOT gradient of 5 mmHg (0–12 mmHg). A patient required intraoperative revision for LVOT obstruction due to the stent. All the patients but one were discharged home. There was one patient who had sudden death at 3 months after surgery.
Conclusions: Melody® valve MVR is a viable alternative to mechanical MVR in small children not only as a primary strategy but as a salvage strategy for dysfunctional valves. The long-term outcome remains to be investigated.

P1853 - PULMONARY ARTERY BANDING AS A PALLIATION; EARLY AND MID TERM RESULTS

Aybala Tongut[1], Tuncer Eylem[2], Ali Can Hatemi[2], Fusun Guzelmeric[3], Hande Gurun[4], Hakan Ceyran[2]
Mehmet Akif Inan Educational and Research Hospital, Pediatric Cardiac Surgery, Sanliurfa-Turkey[1] Kartal Koşuyolu Educational and Research Hospital, Pediatric Cardiac Surgery, Istanbul-Turkey[2] Kartal Koşuyolu Educational and Research Hospital, Clinic of Anesthesiology, Istanbul-Turkey[3] Marmara University, Marmara Faculty of Medicine, Department of Public Health, Istanbul-Turkey[4]

Pulmonary Artery Banding (PAB) is the first palliative procedure of a staged approach to complex congenital cardiac anomalies in patients with unrestricted pulmonary blood flow (PBF).
Materials and Methods: The medical records and follow-ups of 81 patients who underwent PAB between January 2011 and June 2016 were reviewed. The study subjects were grouped into 2 categories based on their cardiac diagnoses. Group 1 (n = 26, 10 female, 16 male) included single-ventricle variants with unrestricted PBF and no evidence of systemic outflow tract obstruction. Group 2 (n = 55, 32 female, 23 male) involved candidates for terminal biventricular repair and critical medical conditions with unrestricted PBF. The endpoints were assigned as: early death after PAB, death following stages, total correction for biventricular physiology or definitive operation for single-ventricle variants, awaiting definitive operation and declined follow-up.
Results: A total of 81 patients (39 men, 42 women; median age 4 months, IQR:6) were identified. PAB mortality at the first stage was 12.3%, and was markedly elevated in Group 2 ($p < 0.01$) but not related to the gender, age, hospitalization or duration of PAB. The band was inadequate in 3 patients at the follow-up. Median duration of PAB (7 months in Group 1, IQR:10, 27.5 months in Group 2, IQR:5) was not related to the age, diagnostic categories and overall results. The overall mortality during the period studied was 18.4% and significantly higher in Group 2 than Group 1 ($p < 0.01$). Thirty-five patients (44.4%) have had a final definitive repair, and 24 (29.7%) patients are awaiting their final definitive repair. 6 patients (7.4%) were declined follow-up.
Conclusions: PAB is indicated in both patients with excessive PBF and single ventricle variants and patients with two balanced ventricles that are not amenable to early primary repair. However the role of palliative PAB in biventricular repair remains controversial with high early mortality rate.

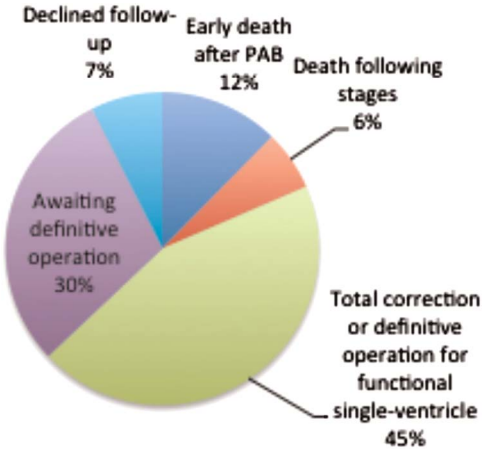

Figure 1.
Outcome of patients after PAB at follow-up.

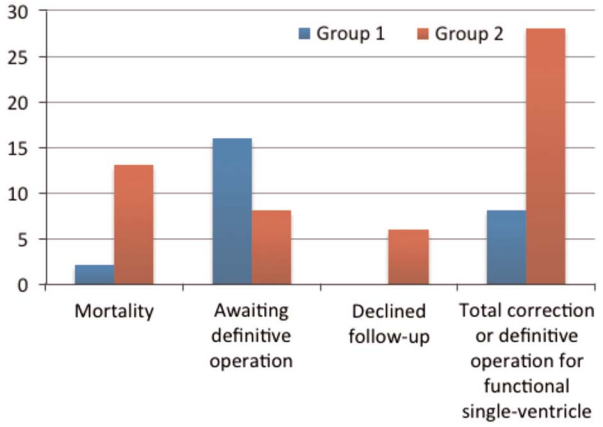

Figure 2.
The distribution of endpoints after PAB procedure based on their cardiac diagnoses. Group 1 includes candidates for single-ventricle variants with unrestricted PBF and no evidence of systemic outflow tract obstruction. Group 2 includes candidates for terminal biventricular repair and critical medical conditions with unrestricted PBF.

P1856 - MID TERM OUTCOMES OF ARTERIAL SWITCH OPERATION A SINGLE CENTRE EXPERIENCE

Ejaz Ahmed Sheriff
Madras Medical Mission, Cardiac Surgery, Chennai-India

Background: The arterial switch operation (ASO) is the surgical approach of choice for d-transposition of the great arteries (d-TGA). Our study evaluates the midterm outcomes in this population.
Materials and Methods: In this retrospective study 78 such patients between January 2011 and July 2016 were included. The mean age was 21 ± 143 days.68%(53) were male and 32%(25) were female. 64%(49) had an intact septum, 46%(29) had a ventricular septal defect, and 12%(10) had Taussig Bing anomaly. The usual coronary pattern (Yacoub type A) was found in 76% (60) abnormal coronary pattern was found in (types B, C, D, E) 24% (18). Palliation prior to arterial switch was performed in the form of balloon atrial septostomy in 8% (7) and maintenance of ductal patency by stenting 10% (8) and prostaglandin infusion 15% (12) of the patients. The follow-up period was 260 patient-years.
Results: The all-cause mortality rate was 7.5% in the early postoperative period. The 10-year rates of freedom from significant neo aortic regurgitation, arrhythmias, pulmonary stenosis were 94.6 ± 4.6%, 97.8 ± 2.3%, 95 ± 3.4% respectively. Most of the patients (98%) were functionally at New York Heart Association (NYHA) class 1 activity. By multiple logistic regression, the following variables were significant risk factors for early mortality: dynamic left ventricular outflow tract obstruction (LVOTO) resection at time of ASO ($p < 0.001$; odds ratio [OR] 19.0; 95% confidence interval [CI] 3.3 to 111.1), a weight <2.5 kg at time of ASO ($p < 0.001$; OR 22.5; 95% CI 5.5 to 91.4), presence of a severe pulmonary artery hypertension ($p < 0.001$).
Conclusion: ASO remains the primary procedure of choice for simple TGA and acceptable choice for complex TGA in terms of overall survival and freedom from re intervention. Long term follow up is essential for further results.

P1874 - PREOPERATIVE ADMINISTRATION OF SILDENAFIL TO PEDIATRIC PATIENTS WITH CONGENITAL CARDIAC SHUNTS AND MODERATELY ELEVATED PULMONARY VASCULAR RESISTANCE

Ana Maria Thomaz[1], Leina Zorzanelli[1], Mariana Meira Clavé, Nair Yukie Maeda[2], Luiz Junya Kajita[3], Antonio Augusto Lopes[1]
Heart Institute, University of São Paulo School of Medicine, Dept. Pediatric Cardiology and Adult Congenital Heart Disease, São Paulo-Brazil[1]; Pró-sangue Foundation, Dept. of Research, São Paulo-Brazil[2]; Heart Institute, University of São Paulo School of Medicine, Dept. of Hemodynamic, São Paulo-Brazil[3]

Background and Objective: Preoperative administration of pulmonary vasodilators has been considered in congenital heart disease with pulmonary hypertension. One could use this strategy to analyse characteristics of pulmonary circulation rather than to define operability, which involves several other factors. We therefore decided to test for pulmonary vasoreactivity by administering sildenafil preoperatively to pediatric patients. We also measured serum levels of inflammatory mediators.
Patients and Methods: Patients (n = 29) were aged 11.8 [7.5–20.8] months (median and interquartile range), all of them with unrestrictive cardiac communications. At cardiac catheterization, pulmonary vascular resistance (PVR) was 4.7 [3.7–7.9] units x m2. Oral sildenafil (1.0–5.0 mg/Kg/day) was administered for 8 – 70 days until development of pulmonary congestion (desired effect) or confirmation of "no effect" (minimum, 60 days). Sildenafil effect was further tested by measuring pulmonary-to-systemic blood flow ratio (Qp/Qs, echocardiography). Interleukin 6 (IL-6) and intercellular adhesion molecule 1 (ICAM-1) were measured by chemiluminescence before and during sildenafil administration.
Results: At cardiac catheterization, a 33% decrease in PVR was observed during nitric oxide inhalation ($p < 0.001$). Subsequently, sildenafil administration was followed by a 10% increase in Qp/Qs ratio (2.0 [1.4–2.2] to 2.2 [1.7–2.5], $p = 0.017$) associated with a 2% increase in peripheral oxygen saturation (93% [90–96%] to 95% [93–97%], ($p = 0.022$). Thus, 71% of patients responded to inhaled nitric oxide, while 65% of cases responded to sildenafil. However, there was no correlation between responses ($r = 0.12$, $p = 0.564$). Sildenafil administration resulted in a 46% decrease in circulating IL-6 ($p = 0.027$); in responders, there was a 21% decrease in ICAM-1 ($p = 0.011$). Twenty-six patients were subsequently considered as suitable for surgery.
Conclusions: Patients responded differently to acute inhalation of nitric oxide and sustained use of oral sildenafil. Both responses may be clinically relevant. Changes in mediators of inflammation suggest effects of sildenafil administration beyond simple pulmonary vasodilation.

P1883 - PEDIATRIC VENTRICULAR ASSIST DEVICE EXPLANTATION PREDICTORS OF SUCCESSFUL WEANING

Srujan Ganta[1], Scott Bradley[1], Andrew Savage[2], Minoo Kavarana[1]
Medical University of South Carolina, Surgery, Charleston-United States[1]; Medical University of South Carolina, Pediatrics, Charleston-United States[2]

Background/Hypothesis: Long term pediatric mechanical support as a bridge to heart transplantation is associated with significant risks of pump thrombosis and stroke. Ventricular assist device (VAD) weaning protocols for children are not standardized. We evaluated three children that were successfully separated from VAD support following life threatening thromboembolic complications in order to identify predictors of successful weaning.
Materials and Methods: A single center retrospective review was performed of all VADs (22 devices, 21 patients) implanted from April 2008 to December 2016. Of 4 explants performed, 3 were in children that were analyzed for hemodynamic, biochemical and echocardiographic parameters to gain insight into why explantation was successful. The fourth explant was excluded as it was a temporary RVAD post heart transplant. Echocardiographic data pre-VAD implantation was compared to data obtained either following explant (emergency explantation, N = 2), or with the device turned off in the setting of a pump change (N = 1). Data was analyzed using paired student t-tests.
Results: Demographic data and devices are listed in Table 1. The 3 patients with LVADs were explanted due to thromboembolic complications. Mean duration of VAD support for the 3 patients was 37 days. Children explanted demonstrated significantly reduced LV end diastolic volume (LVEDV), LV end diastolic dimension (LVIDd) and increased LV ejection fraction (EF; Table 2). Brain natriuretic peptide (BNP) levels were reduced peri-VAD explantation. All three patients are alive and well at 3 years follow-up with one patient undergoing heart transplant.
Conclusions: Children undergoing VAD implantation have a very high risk of thromboembolic complications. Significant LV functional recovery was observed in patients explanted. We recommend that pediatric VAD recipients should have a predetermined, structured weaning protocol and those with significant reduction in LV size, improvement in LVEF, and decreased BNP should be considered for explantation..

P1893 - USE OF BIOPULMONIC® CONDUIT FOR RVOT RECONSTRUCTION SINGLE CENTRE MID TERM OUTCOMES

Amandine Martin[1], Antonio Ravaglioli[2], Markku Kaarne[2], Nicola Viola[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

University Hospital of Rennes, Thoracic and Cardiovascular Surgery Department, Rennes-France[1] Southampton University Hospital, Wessex Cardiac Center, Southampton-United Kingdom[2]

Introduction: We present mid-term outcomes of the Biopulmonic® (BioIntegral Surgical Ldt.) conduit for RVOT reconstruction.
Methods: All patients undergoing RVOT reconstruction between January 2013 and August 2016 at Southampton University Hospital were retrospectively reviewed.
Results: Thirty-seven conduits were used in 35 patients. Median age at implant was 3.7 years (2 months - 29.9 years). Diagnoses included Tetralogy of Fallot spectrum (52,%), aortic valve disease (10,8%), transposition of great arteries (10,8%), pulmonary atresia with intact ventricular septum (5,4%), double outlet right ventricle (5,4%), interrupted aortic arch (5,4%), truncus arteriosus (5,4%), congenital corrected transposition of great arteries (2,7%). Surgical indications included pulmonary valve anomalies (48.6%), completion of repair after shunts (16%), pulmonary arteries stenosis (13,5%), Ross procedure (5,4%), conduit compression (5,4%), endocarditis (5,4%), coronary stenosis (2,7%) and tricuspid atresia (2,7%). Preoperative transpulmonary gradient was 49 mmHg (3.1–110 mmHg). Median bypass time was 194 min (89–364 min) and median aortic cross-clamp time of 112 min (0–224 min). Thirty patients (92%) underwent redo surgeries, and a previous RV to PA conduit was replaced in 28 procedures (76%). Additional procedures were performed in 31 patients (83,7%). At discharge, median peak gradient across the pulmonary valve was 11.29 mmHg (1,70–29.4) and pulmonary regurgitation was absent or trivial in 65%. At latest follow-up (mean 269 days) gradient rose to 32.5 mmHg (8.76–112) in 22 patients (59%), and two-thirds patients had no or trivial pulmonary regurgitation. There were no conduit-related deaths, but two patients required early BioPulmonic® conduit replacement and one underwent early pulmonary artery angioplasty.
Conclusion: The BioPulmonic® conduit is safe and provides very good hemodynamic parameters at mid-term. Further data is needed to evaluate its long-term performance.

P1895 - A NOVEL BIOABSORBABLE PULMONARY VALVED CONDUIT – SURGICAL TECHNIQUE AND INITIAL CLINICAL RESULTS

Zsolt Prodan[1], Tomasz Mroczek[2], Mohd Azhari[3], Zsolt Nagy[1], Janusz Skalski[2], Sivakumar Sivalingam[3], Thierry Carrel[4], Martijn Cox[5], Oleg Svanidze[6]
Children Heart Center, Pediatric Cardiac Surgery, Budapest-Hungary[1]; Jagiellonian University, Pediatric Cardiac Surgery, Krakow-Poland[2]; National Heart Institute, Pediatric Cardiac Surgery, Kuala Lumpur-Malaysia[3]; University Hospital, Pediatric Cardiac Surgery, Bern-Switzerland[4]; Xeltis Bv, Research And Development, Eindhoven-The Netherlands[5]; Xeltis Ag, Medical Affairs, Zurich-Switzerland[6]

Background/Hypothesis: The bioabsorbable pulmonary valved (PV) conduit is designed to allow patient's own cells to infiltrate and replace the polymeric device material by a process called Endogenous Tissue Restoration, leading to natural tissue growth. After implantation the conduit while remaining fully functional is gradually being replaced by the components of native tissue. This prospective feasibility study evaluated safety and performance of a novel bioabsorbable PV conduit in pediatric patients requiring right ventricular outflow tract (RVOT) reconstruction.
Materials and Methods: Twelve patients aged 2–12 years (50% males) requiring RVOT reconstruction have been enrolled in the study from July to December 2016. In 6 patients various conduits were previously implanted (3 Contegras, 2 Hancocks and 1 homograft), in 3 patients transannular patch RVOT repair (including 1 with monocusp valve) was previously performed. In 3 patients RVOT has been intact. The bioabsorbable PV conduits (16mm -5, 18mm – 7) have been implanted using monofilament continuous sutures (6-0 for distal, 5-0 for proximal anastomoses). The device performance evaluation has been performed by transthoracic ultrasound.
Results: All 12 patients have been successfully recovered from the procedure and completed 6 weeks to 6 months follow-up. In all cases successful implantation has been achieved. No device related complications were reported to date. Ultrasound studies have demonstrated anatomical (conduit diameter, leaflet and wall thickness) and functional (hemodynamics, leaflet motion, absence of thrombosis) stability of the valved conduits in all patients at up to 6 months postoperatively.
Conclusions: The bioabsorbable PV conduit demonstrated ability to be successfully implanted in various anatomical conditions using standard surgical techniques. The early clinical outcomes are looking promising for this technology with the potential to improve results of RVOT reconstruction. Long term follow-up studies to confirm these observations are warranted. ((Figure 363)).

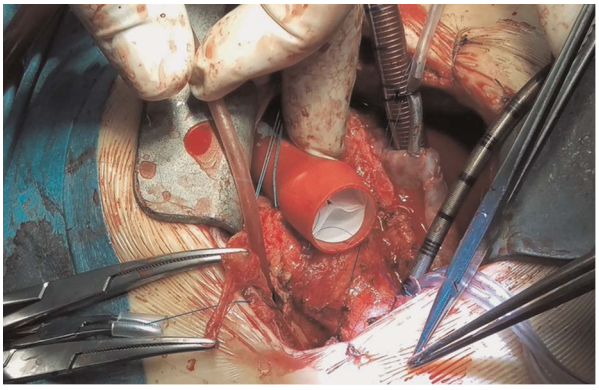

Figure.

P1898 - ANOMALOUS LEFT CORONARY ARTERY FROM "RIGHT" PULMONARY ARTERY; RARE BUT DISTINCTIVE ANOMALY OF DIAGNOSTIC AND SURGICAL IMPORTANCE

Masaaki Kawada[1], Ko Yoshizumi[1], Koichi Kataoka[2], Kensuke Oka[2], Daisuke Matsubara[2], Yu Suzuki[2]
Jichi Children's Medical Center, Pediatric and Congenital Cardiovascular Surgery, Tochigi-Japan[1] Jichi Children's Medical Center, Pediatric Cardiology, Tochigi-Japan[2]

Anomalous left coronary artery (LCA) from "Right" pulmonary artery (RPA) is rare, but clinically distinct anomaly compared to usual ALCAPA syndrome with LCA of main pulmonary artery origin. Two cases, aged 5 months, 1 year and 6 months respectively, with this anomaly were encountered, the former with free-standing LCA after origin from RPA and the other with intra-mural course of proximal LCA in the posterior wall of ascending aorta before appearing in the usual retro-pulmonary space. Associated anomalies included mitral regurgitation with significant left ventricular dysfunction in the first and Chromosome 4p- syndrome with ventricular septal defect in the other. First case required LCA extension with tubed RPA segment for anastomosis to left common carotid artery and the second case repaired with unroofing technique of intra-mural portion with closure of LCA origin from RPA. Both cases showed satisfactory

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

post-operative courses and post-operative studies disclosed well patent LCA in both. Mitral regurgitation disappeared and LV function normalized within 6 months without surgical intervention in the first. The second case had undergone preparatory pulmonary artery banding for associated VSD and extreme low birth weight (1506 g) without recognition of the coronary anomaly. Banding tape positioned at the bifurcation had risk of catastrophic coronary artery injury at the time of procedure or risk of ischemia after banding. LCA anatomy and configuration in these cases were NOT suitable for direct reimplantation or intrapulmonary tunneling procedure for surgical repair. This rare variant of coronary anomaly has significant diagnostic and surgical importance of recognition for successful repair.

P1901 - A RETROSPECTIVE ANALYSIS OF THE SURGICAL INDICATIONS FOR VALVE SPARING AORTIC ROOT REPLACEMENT IN PATIENTS WITH CONNECTIVE TISSUE DISORDERS ACCORDING TO THE AHA SURGICAL GUIDELINES

Pilar Brinez
Lincoln Medical and Mental Hostipal, Pediatric Cardiology-Palliative Care and Pain Management, Nyc-United States

Objective: We aim to evaluate how closely our institution follows the current recommended guidelines in regards to the timing of valve sparing aortic root replacement (VSRR).
Background: Based on the AAC/AHA guidelines for the diagnosis and management of patients with genetic syndromes with thoracic Aortic disease 2010, patients are classified in two main classes. Class I include indications for medical approach of these patient since (from the time) the diagnosis is confirmed. Class II is divided in two categories where Class IIa indicates considerations for surgical intervention in all patients with Loeys-Dietz syndrome or a confirmed TGFBR1 or TGBR2 mutation and an aortic diameter of 4.2 cm or greater by TTE or 4.4 to 4.6 cm or greater by CT and/or MRI. For women with Marfan Syndrome contemplating pregnancy, to consider prophylactic replace the aortic root and ascending aorta if diameter exceeds 4 cm. If maximal cross-sectional area in square centimeters of the ascending aorta or root divided by the patient's height in meters exceeds a ratio of 10, surgical repair is reasonable because shorter patients have dissection at a smaller size and 15% of patients with Marfan syndrome have dissection at size smaller than 5 cm.
Methods: We reviewed the charts for the last 30 patients who underwent valve sparing aortic root replacement at The Johns Hopkins Hospital and who also had a preoperative echo with aortic dimensions annotated. Patients who were followed and referred by other institution different to Johns Hopkins without a preoperative echocardiogram and patients without a conformed connective tissue disorder were excluded.
Hypothesis: Our hypothesis was that as an institution we were following the current recommendations greater than 90% of the time.
Significance: The results of this retrospective chart review will give our Pediatric Cardiology and Pediatric Cardiothoracic surgery departments insight into our current.

P1903 - SMALL DOUBLY COMMITTED VENTRICULAR SEPTAL DEFECT AND AORTIC REGURGITATION THE ERA OF EARLY SURGICAL REPAIR

Zek Sen Lim[1], Zhia Ning Lim[2], Zhen Yue Lim[3], Siew Cheng Tan[4]
UMMC, Paediatric Cardiology, Kuala Lumpur-Malaysia[1]; University of Leicester, Faculty of Medicine, Leicester-United Kingdom[2]; Cardiff Six Form College, Six Form College, Cardiff-United Kingdom[3]; UMMC, Paediatric Intensive Care, Kuala Lumpur-Malaysia[4]

Background: Aortic regurgitation is a well-known complication associated with doubly committed VSD. Lack of support at the valve and Venturi effect of the jet was believed to cause aortic valve prolapse. Early operation are normally recommended especially when the size is significant. However for small doubly committed VSDs no definitive consensus in treatment was established. Furthermore there can be difficulty in differentiating doubly committed VSDs and outlet muscular VSDs.
Methods: This is a retrospective study looking at all VSD seen in the past 3 years in University Malaya Medical Centre, a regional unit. All patients with doubly committed and outlet muscular VSDs are recruited in the study. Their images were reviewed by a pediatric cardiologist to confirm the diagnosis. Diagnosis error between doubly committed and outlet muscular were noted. The characteristics of the VSDs and evidence of prolapse were reviewed. The time interval when aortic regurgitation occurs is documented.
Results: There are a total of 318 patients with VSDs in the registry. 5 have incomplete data and has to be excluded. There were 8 patients (2.5%) with doubly committed VSDs and 10 (3.1%) with outlet muscular VSDs. There are no significant differences in the baseline characteristics for both group of patients. Kaplan Meier analysis suggest that small doubly committed VSDs is likely to progress to aortic regurgitation although this may take many years, unlike outlet muscular VSDs. There was also a significant proportion (60%) of outlet muscular VSDs misdiagnosed as doubly committed.
Conclusion: Small doubly committed VSDs should be closed surgically as there are risks of aortic valve prolapse and regurgitation. This effect is not seen with outlet muscular defect. Differentiating the two diagnosis is important.

P1923 - ANTI INFLAMMATORY AND CARDIOPROTECTIVE EFFECT OF NITRIC OXIDE DURING PEDIATRIC CARDIOPULMONARY BY PASS – CLINICAL RANDOMISED STUDY

Jacek Kolcz[1], Elzbieta Karnas[2], Wojciech Stycula[1], Magdalena Borowka[1], Zbigniew Madeja[2], Ewa Zuba-Surma[2], Janusz Skalski[1]
Jagiellonian University, Pediatric Cardiac Surgery, Kraków-Poland[1]; Jagiellonian University, Cell Biology, Kraków-Poland[2]

Objective: Cardio-plulmonary bypass (CPB) used for open heart surgery, induces systemic inflammatory response (SIRS) and contributes to ischemia-reperfusion injury of the cardioplegia-arrested heart. Multiple strategies have been elaborated to mitigate effects of CPB on perioperative stress response. We carried out a randomised clinical study to investigate an effect of nitric oxide (NO) inhalation into the oxygenator during CPB, in children.
Methods: Blood samples were taken from 24 patients (aged 8 days-13 years) during open heart surgery. CPB was managed according to previously reported, standard approach. Repeated measures were carried out before surgery, during the procedure, and 4, 8 12 and 24 hours after the operation. During the procedure nitric oxide (NO) was inhaled into the oxygenator according to the separate protocol in 12 patients. Relevant panel of cytokins and angiogenic factors was profiled by human proteome profiler Array Kits and quantitively analyzed by milliplex map kit assay. Based on screening, following analytes were selected for high-sensitivity quantative analysis: IL-10, IL-1b, TNF-a, GM-CSF, IL-6, IL-8, SDF-1, VEGF, IL-1ra, MMP-8, pentraxin-3, NT-proBNP, CK-MB, troponin I, TIMP-4, angiopoietin-2, insulin, lectin.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Glucose and lactates were additionally measured. Repeated measures Friedman ANOVA was used for statistic evaluation of data. *Results:* Inhalation of NO decreased concentration of TnI and CK-MB and reduced level of IL-6, IL-8 and Pentraxin-3. Anti-inflammatory IL1-ra and TIMP 4 was significantly increased in NO group. SDF 1 and GM-CSF were also significantly increased in particular time points. NO-patients had lower post-bypass concentration of lactates and glucose and higher levels of Insulin, leptin and angiopoetin 1 in postoperative period. All above mentioned effects were significant at $p < 0.05$ in post hoc tests. *Conclusions:* Intraoperative NO inhalation into the oxygenator during pediatric cardiopulmonary by-pass can have anti-inflammatory, cardioprotective and reliving-metabolic-stress effects.

P1930 - THE EFFECT OF MODIFIED BLALOCK TAUSSIG SHUNT ANASTOMOSIS ANGLE AND PULMONARY ARTERY DIAMETER ON PULMONARY FLOW

Ahmet Arnaz[1], Senol Piskin[2], Yusuf Yalçinbaş, Kerem Pekkan[2], Tayyar Sarioglu[1]

Acibadem University, Department of Cardiovascular Surgery, Istanbul-Turkey[1] Koc University, Department of Mechanical Engineering, Istanbul-Turkey[2] Acibadem Bakirkoy Hospital, Department of Cardiovascular Surgery, Istanbul-Turkey[3]

Background: Modified Blalock-Taussig shunt (MBTS) is a palliative procedure for patients with severe cyanotic congenital heart disease associated with reduced or absent pulmonary blood flow. In this case, it was aimed to find out the best graft to pulmonary artery (Pa) anastomosis angle measuring the pulmonary blood flow, wall shear stress and shunt flow which are invariable in shunt diameter (Figure 1).
Material and Methods: Computational model of Tetralogy of Fallot with pulmonary atresia was studied using three-dimensional geometries of cardiovascular system. Three different MBTS anastomosis angle configurations connecting the right subclavian artery to the right Pa were parameterized (60 o lean to the left Pa, 90 o and 60 o lean to the right Pa) on three different Pa diameter configurations. Velocity and wall shear stress were analysed in the PTFE shunts. Flow rates at the right and the left Pa's were calculated for all configurations for comparison.
Results: In case of equal 4 mm diameter arteries, vertical shunt configuration produces the least flow rate in both pulmonary arteries. This can be explained by stagnation point at the anastomosis region of shunt and right pulmonary artery. When the left Pa diameter is doubled in size, flow going into right Pa is almost the same with same Pa diameter configuration while left Pa flow increases for all shunt angle configurations. For the third diameter configuration of 8 mm of right Pa and 4 mm of left Pa, flow going into right Pa increases slightly in case of vertical or leaned left shunt configurations (Table 1).

Table 1. Percent of total puknonary flow spirt ratios for all cases sttxied. All values are normalized by dividing by the mawmum total flow (vertical shunt, diameter of 4 mm - 8 mm).

RPA-LPA diameters	4 mm - 4 mm	4 mm - 8 mm	8 mm - 4 mm
Vertical (90*)	88	100	97
Lean right (60*)	88	88	93
Lean left (60*)	91	95	90

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: Anastomosis angle between conduit and pulmonary arteries have crucial effect on flow splits directed to pulmonary arteries. Vertical anastomosis configurations increase the total Pa flow and thus those configurations are preferable compared to leaned anastomosis conduit configurations..

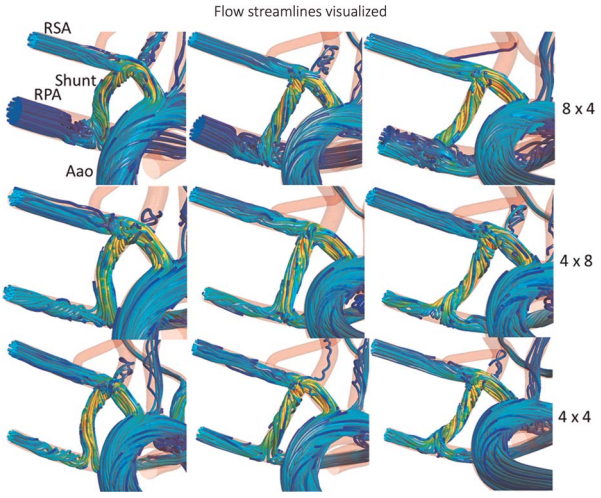

Figure 1.

P1938 - GROWTH OF LEFT VENTRICULAR OUTFLOW TRACT AND PREDICTORS OF FUTURE REINTERVENTION AFTER REPAIR OF VENTRICULAR SEPTAL DEFECT AND AORTIC ARCH OBSTRUCTION

Abdulraouf Jijeh[1], Muna Ismail[2], Fahad Alhabshan[2]
Kacc, Pediatric Cardiac ICU, Riyadh-Saudi Arabia[1]; Kacc, Pediatric Cardiology, Riyadh-Saudi Arabia[2]

Ventricular septal defect and aortic arch obstruction is usually associated with a narrow left ventricular outflow tract. The aim of the study was to analyze the growth and predictors of future obstruction of left ventricular outflow tract after surgical repair of these cases.
Methods: Retrospective review of patients who underwent repair of ventricular septal defect and aortic arch obstruction (coarctation or interrupted aortic arch) between July 2002 and June 2013. Echocardiographic data was reviewed and the need for reintervention was evaluated.
Results: A total of 89 patients were included. A significant left ventricular outflow tract growth was noticed after surgical repair. Preoperatively mean left ventricular outflow tract Z-score was -1.46 + /-1 (range -5.5 to 1.1) and raised to a mean Z-score of -0.7 + /-1.3 (range -2.7 to 3.2) at last follow-up ($p = 0.0001$); demonstrating relevant growth of left ventricular outflow tract after repair of ventricular septal defect and aortic arch obstruction. After primary repair 11 patients (12.3%) required reintervention with surgical repair for left ventricular outflow tract obstruction after a mean period of 36 + /-21 months. There were no significant differences in age, weight and indexed aortic valve and left ventricular outflow tract measurements between those who developed obstruction and those who did not.
Conclusion: Significant left ventricular outflow tract growth is expected after repair of ventricular septal defect and aortic arch obstruction. Small aortic valve and left ventricular outflow tract at diagnosis are not risk factors to predict the need of surgical reintervention for left ventricular outflow tract obstruction in future.

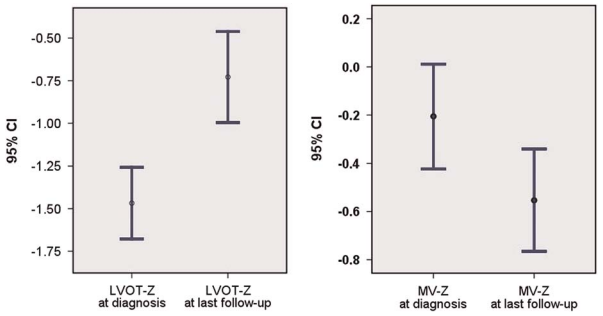

Figure.

P1946 - LONG TERM TRANSPLANT FREE SURVIVAL FOLLOWING REPAIR OF TOTAL ANOMALOUS PULMONARY VENOUS CONNECTION (TAPVC) A STUDY FROM THE PEDIATRIC CARDIAC CARE CONSORTIUM (PCCC)

James St.louis[1], Courtney Mccracken[2], Jeffrey Vinocur[3], Logan Spector[4], Lazaros Kochilas[2]
Children, Surgery, Kansas City-United States[1]; Emory University, Pediatrics, Atlanta-United States[2]; Unversity of Rochester, Pedaitrics, Rochester-United States[3]; University of Minnesota, Pediatrics, Minneapolis-United States[4]

Long-term survival, risk of transplantation, and causes of death for infants undergoing early repair of TAPVC remain ill defined. We attempted to link an international congenital cardiac surgical database of patients undergoing correction of TAPVC to two national registries, the National (USA) Death Index (NDI) and the United Network for Organ Sharing (UNOS), to understand long-term outcomes in children surviving TAPVC repair. We identified 811 survivors within the PCCC that had undergone TAPVC repair before one year of life and had sufficient personnel identifiers for linkage with the NDI and UNOS. Overall late mortality or need for transplantation was 9.3% with median follow-up of 18.6 yrs. The risk of mortality/transplant following TAPVC repair was highest in the first 18 months following hospital discharge. Comparison between patients with complex or simple TAPVC is provided in Table I. Parametric model of transplant-free survival for TAPVC conditioned to hospital discharge is presented in Figure I. Cardiac causes account for 47% of deaths for patients with simple TAPVC and 65% for those with complex TAPVC. The

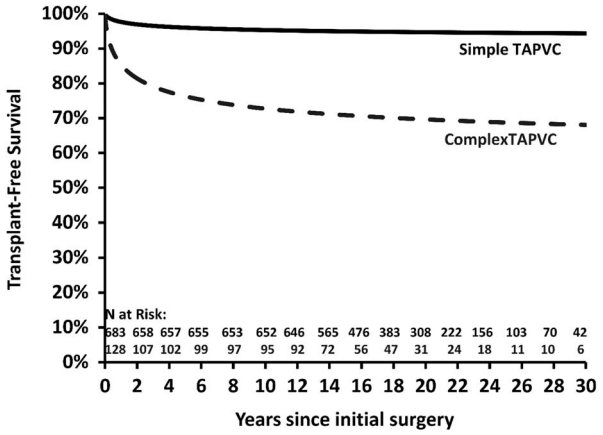

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

multivariable parametric regression models for transplant-free survival demonstrated that complex TAPVC (HR:5.07, 95% CI: 3.04-8.45), mixed TAPVC (HR:2.81, 95% CI: 1.56-5.03) and postoperative length of stay were associated with increased risk of death or transplant. Surprisingly, birth and surgical weight, age at repair, preoperative obstruction, and need for emergent surgery did not affect long-term transplant-free survival. Transplant-free survival after TAPVC repair is excellent with most deaths or transplant events occurring during the first postoperative year. Factors associated with worst long-term outcomes include: complex TAPVC, mixed TAPVC and prolonged postoperative LOS. Risk factors important during the immediate post-operative period had no significant effect on long-term outcomes.

Table 1. PCCC Variables, Post-Discharge Mortality and Transplantation

PCCC Variables	Overall (N = 811)	Simple[1] (N = 683)	Complex[2] (N = 128)	P-value[3] (95%)
Male	507(62 5%)	436 (63 8%)	71 (55.5%)

Post-operative length of stay[5] (days), (n = 749) median (IQR)	11 (7 –18)	10 (7–16)	17 (9–29)	<0.001
Duration of Follow-up[6] (years), median (IQR)	-18 6 (14.5–23.0)	19.2 (15.1 –23.4)	15.3 (12.6–20 3)	<0.001
Post Discharge Mortality	66 (8.3%)	34 (5.0%)	32 (25.0%)	<0.001
Post Discharge Cardiac Tx	9 (1.1%)	1 (0.1%)	8 (6.3%)	<0.001

[1]Simple TAPVC (including PDA and ASD only),
[2]Complex TAPVC (including Associated Cardiac Anomalies)
[3]P-value refers to comparison between simple and complex TAPVC
[4]Obstruction as defined by the individual centers
[5]Post-operative length of stay was defined as date from surgery to discharge from PCCC
[6]Follow-up was defined as date of surgery until date of death or 12/31/2014.

P1953 - MID TERM OUTCOMES OF REPEAT RIGHT VENTRICULAR OUTFLOW TRACT RECONSTRUCTION USING A STENTLESS PORCINE AORTIC ROOT BIOPROSTHESIS

James Kuo[1], Tyler Hamby[2], Maham Munawar[3], Eldad Erez[4], Vincent Tam[5]
Cook Children, Cardiology, Fort Worth-United States[1]; Cook Children, Research, Fort Worth-United States[2]; University of North Texas Health Sciences Center, School of Medicine, Fort Worth-United States[3]; Hadassah Medical Center, Cardiothoracic Surgery, Jerusalem-Israel[4]; Cook Children, Cardiothoracic Surgery, Fort Worth-United States[5]

Background/Hypothesis: A stentless porcine aortic root bioprosthesis has been primarily used in our institution for right ventricular outflow tract (RVOT) reconstruction in congenital heart disease. We hypothesize its longevity is similar to other conduits for this indication.
Materials and Methods: We performed a retrospective review of all RVOT reconstructions using a porcine aortic root in our institution. Ross procedure, loss of follow-up within a year of surgery, and non-cardiac related deaths were excluded. Survival and re-intervention, either by surgery, transcatheter valve implantation, balloon valvuloplasty, or bare metal stent placement were recorded. Factors associated with reintervention were assessed using Cox regression.
Results: Between January 2002 and December 2015, there were 163 patients meeting inclusion criteria. The median age was 12.2 years (range 0.7 to 36.9), median weight was 39.1 kg (range 6.9 to 176), and median body surface area 1.23 m2 (range 0.4 to 2.7). Ninety-three (57%) patients had tetralogy of Fallot. The median follow up was 5.3 years (range 1.04 to 13.7). There were no operative or cardiac related deaths. Thirty eight patients (23%) required reintervention. The rate of freedom from reintervention was 93.2% (95% CI 86.7-96.6%) at 5 years and 48.4% (95% CI 34.9-60.6%) at 10 years. Age <10 years, weight <39 kg, and body surface area <1.2 m2 at the time of valve placement, as well as valve size ≤25 mm were significantly associated with need for earlier reintervention. Sex, orthotopic versus heterotopic position, diagnosis, or concomitant pulmonary artery augmentation were not associated with earlier reintervention.
Conclusions: The porcine aortic root in the RVOT is associated with excellent survival and low mid-term need for reintervention. It longevity is comparable to published data on homografts and other bioprosthetic valves..

Table.

		5-Year Freedom from Reintervention		10-Year Freedom from Reintervention	
		Rate	95% CI	Rate	95% CI
BSA	<1.2	**95.22%**	85.82-98.44%	**24.05%**	10.06-41.29%
	≥1.2	**92.22%**	80.13-97.08%	**74.05%**	54.00-86.37%
Age	<10 years	**92.47%**	81.07-97.12%	**18.01%**	6.51%-34.12
	≥10 years	**93.57%**	83.41-97.60%	**82.59%**	66.99-91.27%
Weight	<39 kg	**93.84%**	84.32-97.66%	**25.65%**	11.76-42.11%
	≥39 kg	**92.36%**	80.49-97.13%	**79.16%**	61.18-89.48%
Valve Size	≤25 mm	**92.42%**	82.66-96.79%	**33.20%**	18.43-48.74%
	27, 29 mm	**93.88%**	81.36-98.09%	**76.31%**	54.65-88.61%

P1956 - IS BICUSPID PULMONARY VALVE USING POLYTETRAFLUOROETHYLENE MEMBRANE SUPERIOR THAN BIOPROSTHETIC VALVE NOT SUPERIOR BUT NOT INFERIOR COMPARISON STUDY OF DURABILITY AND FUNCTION

Soick Jang[1], Sang Yun Lee[1], Chul Lee[2], Jae Gun Kwak[3], Su Jin Park[1], Sun Hwa Hong[4], Chang-ha Lee[5], Seong Ho Kim[1]
Sejong General Hospital, Pediatrics, Bucheon-Korea, South[1]; St. Mary's Hospital, Thoracic and Cardiovascular Surgery, Seoul-Korea, South[2]; Seoul National University Children's Hospital, Thoracic and Cardiovascular Surgery, Seoul-Korea, South[3]; Sejong Genral Hospital, Radiology, Bucheon-Korea, South[4]; Sejong General Hospital, Thoracic and Cardiovascular Surgery, Bucheon-Korea, South[5]

Background: The hand-sewn polytetrafluoroethylene (PTFE) bicuspid valve is good alternatives in pulmonary position. The aim

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

of this study is to evaluate midterm outcome of PTFE bicuspid valve with comparison with bioprosthetic valve.
Methods: We retrospectively reviewed 149 patients who underwent pulmonary valve replacement (PVR) for chronic pulmonary regurgitation from Jan 1999 to Dec 2015. Patients were divided two groups; Hancock II porcine valve group (group 1, N = 80) and PTFE valve group (group 2, N = 69). We evaluated durability and function of valves.
Results: The mean ages at PVR were 19.4 ± 10.5 years old in group 1 and 19.6 ± 7.8 years old in group 2 (p = 0.909). The median valve sizes were 25mm (range; 19 ~ 27mm) in group 1 and 28mm in group 2 (range; 20 ~ 30mm) (p = 0.000). There were 1 early hospital death in group 2 due to cardiac dysfunction and 1 late death in group 1 due to heart failure. The median follow up durations were 8.6 years (range; 0 ~ 15 years) in group 1 and 2.9 years (range; 0 ~ 6.3 years). The 15 years survival rate in group 1 was 98.8% and 6 years survival rate in group 2 was 98.6% (p = 0.916). The event free rate for reoperation or catheter intervention were 83.2% at 10 years and 72.1% at 15 years in group 1, and 82.8% at 6 years in group 2 (p = 0.07). For MRI analysis, the right ventricular volumes of both groups significantly decreased. However, right ventricular ejection fractions (RVEF) of both group were not improved.
Conclusion: The overall durability and survival rate of PTFE membrane in pulmonary position were satisfactory and there was no significant difference in comparison with Hancock II porcine valve. And, there was no significant difference in the effect of volume reduction and RV function.

P1957 - A CASE OF COMBINATION THERAPY WITH RENAL REPLACEMENT THERAPY AND SURGICAL REPAIR FOR IDIOPATHIC MITRAL VALVE CHORDAE RUPTURE IN AN INFANT

Tomoyuki Matsuba, Yutaka Imoto, Yoshikazu Kawazu, Hideaki Kanda, Kosuke Mukaihara, Itsumi Imagama, Kazuhisa Matsumoto, Kenichi Arata, Hiroyuki Yamamoto
Kagoshima University Graduate School of Medical and Dental Sciences, Cardiovascular and Gastroenterological Surgery, Kagoshima-Japan

Background: Idiopathic mitral valve chordae rupture is a sudden onset and life threatening disease due to severe cardiac failure. The disease was thought to be rare in young children, but several cases in infants without congenital malformations of mitral valve have been reported in Japan. Recently, the disease has gained significant attention as a cause of sudden death in infants. We encountered a case with severe cardiac failure, acute kidney injury and hepatic congestion due to idiopathic mitral valve chordae rupture, and a combination therapy with surgical repair and renal replacement therapy was effective.
Cases: A 7-month-old boy had fever and diarrhea that lasted for five days. Ten days later, he presented to a family doctor with sudden onset of paleness and tachypnea. Heart murmur and tracheal stenosis sound were heard, and the patient developed metabolic acidosis and cardiogenic shock. Severe mitral regurgitation and anterior leaflet prolapse was detected with echocardiography, and he was diagnosed with idiopathic mitral valve chordae rupture. He was intubated and air-transferred to our hospital for operative management. On arrival at our hospital, metabolic acidosis and cardiogenic shock had improved. However, the patient was in a state of acute kidney injury and severe hepatic congestion. After renal replacement therapy, the patient was operated next day. Operative findings confirmed ruptured chordae of the anterior mitral leaflet and posterior commissure. There were no structural abnormalities or signs of vegetation. Surgical procedure included mitral valve repair with artificial chordae and commissural plasty. Postoperative course was good with no recurrence of regurgitation.
Conclusion: Combination therapy with surgical repair and renal replacement therapy led to a good outcome in a patient with idiopathic mitral valve chordae rupture. Early and adequate treatment prior surgery coupled with decision on appropriate timing for surgery might be a crucial factor for the better outcome.

P1961 - CONE RECONSTRUCTION FOR EBSTEIN'S ANOMALY WHAT DEFINES THE NEED FOR ADDITIONAL BIDIRECTIONAL CAVOPULMONARY ANASTOMOSIS

Stanislav Ovroutski[1], Anastasia Schleiger[1], Oliver Miera[1], Mi Young Cho[2], Murin Peter[2], Joachim Photiadis[2], Felix Berger[1]
Deutsches Herzzentrum Berlin, Department of Pediatric Cardiology and Congenital Heart Disease, Berlin-Germany[1]; Deutsches Herzzentrum Berlin, Department of Congenital Heart Surgery and Pediatric Heart Surgery, Berlin-Germany[2]

Objectives: We aimed to investigate whether the tricuspid valve (TV) diameter after "cone reconstruction" (CR) as primary biventricular, "anatomical" correction of Ebstein's anomaly decisively influences the need for additional bidirectional cavopulmonary anastomosis (BCPA, "one-and-a-half" repair).
Methods: Retrospective echocardiographic analysis of the postsurgical TV annulus was performed in patients who underwent CR between 06/2013 and 1/2017. The Z scores were calculated and correlation with the bi or "one-and-a-half" result was checked. Further, the influence of the Carpentier classification for the outcome was analysed.
Results: Thirty three CR were performed without mortality in 31 patients (median age 4 years, weight 18.6 kg), in 15 (48%) of them with and in 16 (52%) without BCPA. The postsurgical course was uneventful (mechanical ventilation in median 19 h, hospital stay 8 d) except for temporary ECMO support in one patient. Small atrial septal defect was left in 16 patients. Central venous pressure at the end of the operation was in median 12 mmHg and showed no correlation with BCPA necessity. According to the Carpentier classification (class B: 12 (23%), C: 19 (53%)) we found no correlation with regard to BCPA. Postsurgical TV regurgitation was absent in 13 (43%), low in 13 (43%) and mild in 4 (14%) patients. The mean diameter of the TV annulus and equivalent Z score were significantly lower (p = 0.002 and p = 0.01, respectively) in patients who needed an additional BCPA.
Conclusion: The resultant diameter of the TV created using CR seems to be co-decisive: in the case of Z score > - 2 the additional BCPA may be avoided even with severe dysplasia of the TV; however, it seems to be necessary with smaller TV diameter/Z score. Intraoperative TV-Z score determination after CR may be helpful in the decision-making with regard to "biventricular" or "one-and-a-half" correction of the Ebstein anomaly.

P1963 - LONG TERM FOLLOW UP AFTER ANOMALOUS ORIGIN OF THE LEFT CORONARY ARTERY REPAIR

Esther Aurensanz Clemente[1], Alex Pérez Casares[1], Jose María Caffarena Calvar[2], Javier Mayol Gómez[2], Joan Sánchez De Toledo Sancho[1]
Sant Joan De Deu Barcelona Children's Hospital, Pediatric Cardiology, Barcelona-Spain[1]; Sant Joan De Deu Barcelona Children's Hospital, Cardiac Surgery, Barcelona-Spain[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Anomalous origin of the Left coronary artery from the pulmonary artery (ALCAPA syndrome) is an uncommon congenital malformation that affects 0.008% of population.
Materials and Methods: Retrospective review of all children diagnosed with ALCAPA at our institution over the last 15 years. Surgical techniques, as well as clinical, ecocardiographic and electrocardiographic variables associated with outcomes were evaluated.
Results: 15 consecutive children were included. Initial presentation was: 8 (53.3%) incidental finding, 6 (40%) heart failure and 10 (6.6%) cardiogenic shock. Fourteen (93.3%) children had ECG abnormalities. Different surgical techniques were used: coronary reimplantation in numero (60%), Takeuchi technique in 10 (6.6%) and ligation in numero (26.6%). Mitral repair was necessary in 2 (13.3%). One patient died before surgery and there was one case of early postoperative death. Average follow-up was 5.50 ± 2.71 years. At follow-up, number (86,66%) were asymptomatic. Two major complications were identified: prosthetic mitral valve dysfunction and aortopulmonary fistula (patient treated with Takeuchi tecnique). All ecocardiographic values improved, with significant differences in EF ($p = 0.02$). Mitral regurgitation improved in most of the cases (67% of patients with moderate to severe MR at diagnosis vs 20% after one year, $p = 0{,}016$). In n (60%) of cases, normalization of ECG changes was observed.
Conclusions: Translocation of the left coronay to the aorta has proved to have good overall results, with significant clinical improvement and a progressive normalization of the LV systolic function. Correction of ECG changes and a decrease in mitral regurgitation was also observed in most of the patients.

Table 1. Ecocardiographic variables at diagnosis and one year after surgical treatment.

	At diagnosis (mean ± SD)	After one year (mean ± SD)	P
LVEDd (mm)	41.3 ± 7.3	39 ± 10,23	0.10
LVEDd (Z)	3.3 ±2.3	2.4 ± 2.1	0.08
EF (%)	46.8 ± 15.5	60.1 ± 9.0	0.02*
FS(%)	26.8 ± 8.0	33.5 ± 0.8	0.18
Degree of mitral regurgitation	n(%)	n(%)	
- Mild (%)	2 (13.3)	6 (40)	0.12
- Moderate (%)	7 (46.6)	1 (6.6)	0.03
- Severe (%)	3 (20)	2 (13.3)	1.00

LVEDd: left ventricular end diastolic. EF: Ejection fraction. FS: Fractional Shortening.

P1969 - GROSS AND HISTOLOGICAL CHARACTERISTICS OF VENOUS HOMOGRAFTS USED IN HEART SURGERY

Annachiara Benini[1], Christopher Baird[2], Michele Borisuc[2], Sitaram Emani[2], Sophie Hofferberth[2], Robert F. Padera, Jr[3], Stephen P. Sanders[4]
University of Verona, Cardiology, Verona-Italy[1]; Boston Children, Cardiac Surgery, Boston-United States[2]; Brigham and Women, Pathology, Boston-United States[3]; Boston Children, Cardiology/ Pathology, Boston-United States[4]

Background: Saphenous/femoral vein homografts are used increasingly to establish right ventricle - pulmonary artery continuity in complex heart defects.
Methods and Materials: We examined 15 of 16 vein homografts (exclusion for internal stent placement) explanted from October 2015 to December 2016 and describe their gross and histological characteristics. Explanted grafts were examined fresh and sectioned for histological examination. Slides were scored semi-quantitatively for inflammation, remodeling, neointima formation, and calcification.
Results: The vein grafts (3 saphenous, 12 femoral) were implanted in infants 1-118 days old (median 4.5 days) as part of a composite Sano shunt (11 patients) or to establish right ventricle-pulmonary artery continuity in 2-ventricle hearts (4 patients). The duration in situ was 96-389 days (median 130 days). The vein homografts were explanted for conversion to bidirectional Glenn (11 patients), distal homograft stenosis (1 patient), pseudoaneurysm at anastomosis (1 patient), or elective upsizing at other surgical procedure (2 patients). Vascularized fibrous or granulation tissue covered the grafts externally. The vein wall appeared thickened in all cases due partly to a fibrous neo-intima. The venous valve was intact in 12 cases. Histological exam showed consistent invasion of host cells (predominantly fibroblasts) into the vein wall with few inflammatory cells (macrophage, lymphocytes). Graft collagen appeared to be undergoing remodeling with deposition of new host collagen. Host blood vessels invaded the adventitia of most grafts and a mild foreign body reaction (giant cells, histiocytes) was noted in those with an external, confining stent. Calcification, mostly at suture lines, was absent or mild in 14 cases and moderate in 1 case. Neointima formation was mild in 10 and moderate in 5 cases.
Conclusion: Vein homografts appear to remodel, provoke minimal inflammation and calcification. The valve functions at least 1 year.

P1970 - GROSS AND HISTOLOGICAL FINDINGS IN BIOPROSTHETIC MITRAL VALVES EXPLANTED FROM CHILDREN UNDER 5 YEARS OF AGE

Laura Gellis[1], Christopher W. Baird[2], Sitaram Emani[2], Michele Borisuk[2], Kimberlee Gauvreau[1], Robert F. Paders, Jr.[3], Stephen P. Sanders[4]
Boston Children, Cardiology, Boston-United States[1]; Boston Children, Cardiac Surgery, Boston-United States[2]; Brigham and Women, Pathology, Boston-United States[3]; Boston Children, Cardiology/ pathology, Boston-United States[4]

Background: Mitral valve replacement (MVR) in very young children is challenging. We investigated the mechanisms for early bioprosthetic mitral valve failure in young patients through review of the macroscopic and microscopic findings in explanted bioprosthetic valves.
Methods: Patients who underwent MVR with a bioprosthetic valve at Boston Children's Hospital between January 2010 to April 2016 at <5 years of age were identified by searching the departmental computerized database. Valve failure was defined as prosthetic mitral valve explantation with mitral valve re-replacement. Valves were examined fresh and sections of leaflets prepared for histology.
Results: Porcine (25) or bovine pericardial (6) bioprosthetic valves were used in 31 of 77 MVRs during the study period. Valve failure (predominantly stenosis) occurred in 10 patients (32%) and was due to pannus deposition (5 porcine, 2 pericardial) and intrinsic leaflet calcification (3 porcine). Pannus formation occurred predominantly on the ventricular surface of leaflets adjacent to the posterior wall but not the leaflet near the outflow tract. In 6 of these valves thrombus was identified at the leading edge of pannus formation. Microthrombi were identified on the leaflets of another normally functioning valve studied at autopsy after 1 month in situ but not on one studied after 1 week in situ. Pannus involved the atrial surface in 2 other valves (1 porcine, 1 bovine

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

pericardial) and appeared to be an extension of the fibrous tissue covering the sewing ring.
Conclusions: In addition to intrinsic calcification, excessive pannus deposition is a prominent cause of early bioprosthetic valve failure in very young patients. Pannus formation appears due to organization of thrombus deposited on leaflets and to ingrowth from host tissue contiguous to the sewing ring as part of a foreign body reaction.

P1991 - VARIATION IN PERIOPERATIVE CARE ACROSS CENTERS FOR INFANTS UNDERGOING THE STAGE II PALLIATION FOR HYPOPLASTIC LEFT HEART SYNDROME

Aaron Eckhauser[1], Sara Pasquali[2], Chitra Ravishankar[3], Linda Lambert[1], Jane Newburger[4], Andrew Atz[5], Nancy Ghanayem[6], Steven Schwartz[7], Chong Zhang[8], Jeffery Jacobs[9], Luann Minich[10]
University of Utah, Primary Children's Hospital, Surgery, Pediatric Cardiothoracic, Salt Lake City-United States[1]; University of Michigan, Pediatrics, Cardiology, Ann Arbor-United States[2]; Children's Hospital of Philadelphia and University of Pennsylvania, Pediatrics, Cardiology, Philadelphia-United States[3]; Boston Children's Hospital, Pediatrics, Cardiology, Boston-United States[4]; Medical University of South Carolina, Pediatrics, Cardiology, Charleston-United States[5]; Medical College of Wisconsin, Pediatrics, Critical Care, Milwaukee-United States[6]; University of Toronto, The Hospital For Sick Children, Pediatrics, Critical Care, Toronto-Canada[7]; University of Utah, Internal Medicine, Epidemiology, Salt Lake City-United States[8]; Johns Hopkins, All Children's Hospital, Surgery, Pediatric Cardiothoracic, St. Petersburg-United States[9]; University of Utah, Primary Children's Hospital, Pediatrics, Cardiology, Salt Lake City-United States[10]

Background: In the Single Ventricle Reconstruction (SVR) Trial, neonates with hypoplastic left heart syndrome were randomized to a modified Blalock-Taussig or right ventricle-pulmonary artery shunt. They otherwise received local standard of care. We analyzed practice variation at Stage II (S2) surgery.
Methods: Perioperative data were collected prospectively and available in the SVR public use database. Practice variations across the 14 centers are described for 397 subjects who underwent S2. All data are center-level specific and reported as median, interquartile (IQR) and full range unless otherwise specified.
Results: The median age and weight at S2 was 5.4 months (IQR 4.9-5.7; full range 4.0-6.6) and 5.7 kg (5.5-6.1; 5.1-6.7) with 30% performed urgently/emergently. Prior to S2, a majority had a catheterization (IQR 98.5-100%), digoxin was used by 11 centers in 25% of subjects (23-31%; 13-50%), and 81% were on oral feeds (68-84%; 63-95%). In 12/14 centers, 85% of subjects (58-90%; 22-100%) had a bidirectional Glenn and 5 centers used a hemi-Fontan in 55% (33-92%; 18-100%). Cardiopulmonary bypass time was 96 minutes (75-113; 40-130). In aggregate, 26% (103/397) of subjects had deep hypothermic circulatory arrest (DHCA) >10 minutes. In 13/14 centers using DHCA, a median of 12.5% of subjects had DHCA >10 minutes (8-32%; 4-100%). In 7/14 centers, 5% of subjects (2-40%; 1-70%) were extubated in the operating room. Postoperatively, ICU length of stay (LOS) was 4.8 days (4.0-5.3; 3-10) and total LOS was 7.5 days (6-10; 5-14). At 11/14 centers, 19% of subjects (12-25%; 2-83%) were discharged on oxygen with a median saturation of 83% (80-84%; 79-85%).
Conclusions: In the SVR trial, practice varied widely among centers for nearly all perioperative factors surrounding S2. These findings are consistent with variation previously reported for the Norwood procedure. Further analysis may facilitate establishing best practices by identifying the impact of practice variation.

P1994 - LONG TERM OUTCOMES OF FONTAN PROCEDURE IN PATIENTS WITH ATRIOVENTRICULAR VALVE DISFUNCTION

Guilherme Viotto Rodrigues Da Silva[1], Luiz Fernando Canêo[1], Aida Luiza Turquetto[1], Leonardo Miana[1], Carla Tanamati[1], Juliano Penha[1], Fabio Biscegli Jatene[2], Marcelo Biscegli Jatene[1]
Heart Institute, University of São Paulo, Pediatric Cardiac Surgery, São Paulo-Brazil[1]; Heart Institute, University of São Paulo, Cardiac Surgery, São Paulo-Brazil[2]

Background: Atrioventricular valve (AVV) regurgitation management still a challenge in patients with single ventricle physiology and is one of the predictors of adverse outcomes after the Fontan procedure (FP).
Methods: We studied patients who underwent FP and concomitant valve surgery between 1984 and 2015. Factors associated with patient outcome were investigated retrospectively.
Results: A total of 420 patients underwent FP. Sixty-four (15.2%) patients had AAV regurgitation, and 36 (8,6%) underwent concomitant valve surgery (valve repair = 31; valve replacement = 5). Previous AAV regurgitation (hazard ratio [HR], 3.499; 95% confidence interval [CI], 1.566 to 7.817; $p = 0.002$), concomitant valve repair (HR, 3.334; 95% CI, 1.352 to 8.224; $p = 0.009$) and valve replacement (HR, 9.358; 95% CI, 2.205 to 39.720; $p = 0.002$) were risk factors for mortality.
Conclusion: In our series, a greater number of patients with AAV regurgitation were treated simultaneously with the FP. Performing concomitant valve repair/replacement was a risk factor, so whenever possible these procedures should be done during the bidirectional Glenn shunt to improve the selection of the candidates to complete the FT operation.

P2000 - REPAIR OF LATE PRESENTING INTERRUPTED AORTIC ARCH WITH SEVERE PULMONARY HYPERTENSION USING A PULMONARY AUTOGRAFT TUBE

Cheul Lee[1], Jae Young Lee[2], Eun-jung Lee[2]
Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Department of Thoracic and Cardiovascular Surgery, Seoul-Korea, South[1]; Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Department of Pediatrics, Seoul-Korea, South[2]

Background: The optimal surgical technique for repair of interrupted aortic arch (IAA) remains controversial. We present a case of late-presenting IAA with severe pulmonary hypertension which was repaired using a pulmonary autograft tube.
Materials and Methods: A 34-month-old boy from a foreign country was admitted to our hospital for management of his congenital heart disease. Echocardiography revealed type A IAA with a large perimembranous ventricular septal defect (VSD) and severely dilated main pulmonary artery. Cardiac catheterization was performed and pulmonary vascular resistance was calculated as 8.9 units at room air. It fell to 5.8 units with 100% inspired oxygen. The VSD was closed using a bovine pericardial patch with a 5.6 mm fenestration. An autograft tube of diameter 12 mm was made of anterior wall of the main pulmonary artery. The arch was repaired by interposing the pulmonary autograft tube between the descending thoracic aorta and the ascending aorta under selective cerebral perfusion.
Results: The patient could not be weaned from cardiopulmonary bypass because of pulmonary hypertension and right ventricular dysfunction. He underwent extracorporeal membrane oxygenation support for 3 days. Postoperative course was complicated by

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

mediastinal bleeding and small amount of subdural hematoma. There was no neurologic deficit persisting at discharge. Echocardiography at discharge revealed left-to-right shunt through a VSD fenestration and normal biventricular systolic function. Postoperative computed tomography showed wide patent aortic arch with natural geometry (Figure).

Conclusions: Repair of IAA using a pulmonary autograft tube can be a good option in selected patients because of its ability of maintaining natural arch geometry, growth potential, and possible beneficial effect in preventing left main bronchus compression.

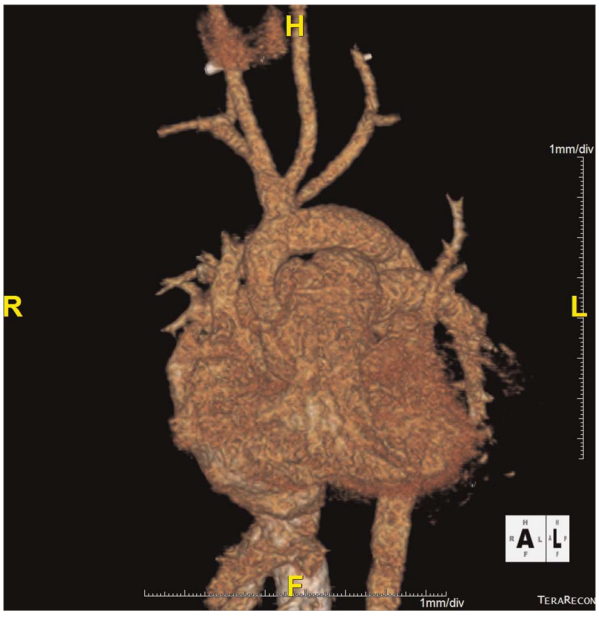

Figure.

P2004 - UNUSUAL CONGENITAL GERBODE DEFECT ASSOCIATED WITH DOWN SYNDROME; RARE CASE WITH SUCCESSFUL COMPLEX HEART SURGERY REPAIR IN THIRD WORLD HOSPITAL

Yopie Afriandi Habibie[1], Herlina Dimiati[2]
The Zainoel Abidin General Hospital, Thoracic Cardiac & Vascular Surgery, Banda Aceh-Indonesia[1]; The Zainoel Abidin General Hospital, Pediatric Cardiology, Banda Aceh-Indonesia[2]

Gerbode defects are left ventricular (LV) to right atrial (RA) communications, a rare case (0.08%) which could be congenital or acquired. Can result from either direct communication between LV and RA, or indirect connection from a membranous ventricular septal defect (VSD) and a defect in the tricuspid valve leaflet. 76% of all congenital heart disease in neonates correlates with Down syndrom. We hereby, report one rare case of indirect type III Gerbode defect from a 1 years old baby boy with down syndrome presented with dyspnoe, difficulty of breast feeding and failure to thrive. History of ANC regularly in obstetrician, already known for heart abnormalities during 7 months of pregnancy. Normal baby labour, aterm with birth weight 3300 grams. Clinical examination revealed a pansystolic murmur and grade 2 parasternal heave. Echocardiogram showed 3,4 mm and 7,8 mm of perimembranous VSD with left-to-right shunt (2 jet) and small ASD with left-to-right shunt measuring 5 mm in diameter. Came to our hospital for surgery repair after been diagnosed in abroad. Under cardiopulmonary bypass, bicaval cannulation and right atriotomy, showed there were a perimembranous VSD measuring 10 mm in diameter, defect from LV to RA measuring 5 mm in diameter known as Gerbode defect lies beneath the septal leaflet of tricuspid valve. Underwent successful closure defect with 0,4 mm goretex pacth of his VSD and Gerbode defect using 5–0 prolene with pledgets and followed by primary ASD closure by leaving residual ASD 2 mm. Septal tricuspid leaflet was free with no perforation. Tricuspid valve was tested using saline injection into the RV and found to be competent. Hospitalized for one week and became healthy. He was doing well at 18-months of follow up.

P2006 - SHORT TERM OUTCOME OF THE OF ASD CLOSURE BY RIGHT VERTICAL AXILLARY THORACOTOMY A SINGLE CENTRE EXPERIENCE

Dr.Mohammad Rokonujjaman
Ibrahim Cardiac Hospital, Cardiac Surgery, Dhaka-Bangladesh

Background: This prospective observational study aims to evaluate the outcome of Atrial Septal Defect closure by right vertical axillary thoracotomy in terms of safety, reliability, reproducibility and cosmetic result.

Methods: The study was conducted in the department of Cardiac Surgery at Ibrahim Cardiac Hospital and Research Institute Dhaka during the period of May 2016 to January 2017. Within this 9 months period total 20 cases of ASD closure done by right vertical axillary thoracotomy. 12 were female and 8 were male. Age ranged from 4 yrs to 30 yrs (Mean 12.35 yrs). Body weight ranged from 12 kg to 58 kg. (Mean 25 kg). Outcome was assessed in terms of Total duration of CPB, Aortic occlusion time, Total operating time, volume of drainage, ICU stay, Duration of ventilation, Total hospital stay, Length of incision.

Result: Mean duration of CPB and aortic occlusion time was 50 min and 35 min respectively. Mean total operating time was 200 min. Mean duration of ventilation, ICU stay and hospital stay were 3 hrs and 18 hours and 7 days respectively. Drainage were minimal and Chest drains removed on 1st POD in all the cases. No blood transfusion required in any case. Mean length of incision was 5.5 cm. No mortality or morbidity or wound related complications observed. No narcotic analgesic required after operating day. Psychological and cosmetic results were excellent. There was no residual shunt in the follow up. echocardiogram.

Conclusion: ASD closure by right vertical axillary thoracotomy is equally safe and reproducible maneuver with superior cosmetic and psychological outcome than all other surgical technique and can be practiced in selected cases where device closure is not suitable and in patients who are not agreed to accept Device closure.

P2008 - REPAIR OF TETRALOGY OF FALLOT WITH VALVE AND ANNULUS PRESERVATION BASED ON MORPHOLOGY OF LEAFLETS – EARLY FOLLOW UP

Anil Dharmapuram, Sudeep Verma, Nagarajan Ramadoss, Goutami Vejendla, Rao Ivatury
Kims Hospitals, Paediatric Cardiac Services, Secunderabad-India

Background: Conventional repair of TOF is based on size of the pulmonary annulus. We addressed the repair purely based on the morphology of the leaflets of pulmonary valve. If the leaflets are supple and pliable, we preserved the annulus aggressively irrespective of the Z-score to avoid pulmonary regurgitation.
Methods: From March 2013 to December 2016, 138 patients underwent repair of TOF with annulus preservation using the valve sparing technique. The age ranged from 4 months to 6 years (median 18 months) and the weight from 4.2 to 17 kg (median 8.4 kg). 60 patients had a pre operative Z score $\leq$ -3. The infundibular resection was done from the trans-atrial side and then the pulmonary artery was opened to inspect the valve. If the valve was salvageable, the commissural fusion was carefully split with sharp blade and the subvalvular tissue was aggressively resected with sharp scissors all around the RVOT. The main pulmonary artery was augmented with a pericardial patch.
Results: There were one death due to complications associated with infection. The median follow up was 20 months. Three patients who had a pre operative Z score of < -3 developed significant obstruction requiring re-operation. Two patients required a trans-annular incision and RVOT reconstruction with PTFE valve. One patient required further resection of the infundibular muscle. Twelve patients developed moderate gradient (30–40 mmHg) at the infundibular level and are on close follow up. The remaining 122 patients have gradients $\leq$ 25 mmHg at the infundibular level.
Conclusions: Preservation of the annulus during repair of TOF prevents pulmonary regurgitation and protects the right ventricular function. Morphology of the pulmonary valve leaflets determines the decision to preserve the annulus and valve function in TOF repair irrespective of the Z-score.

P2012 - OPTIMAL PEDIATRIC MYOCARDIAL PROTECTION SAME GOAL DIFFERENT WAYS

Ventsislav Boshnakov, Ivaylo Mitev, George Konstantinov, Stojan D. Lazarov
National Heart Hospital, Congenital Heart Surgery, Sofia-Bulgaria

Background: Myocardial protection in pediatric population during heart surgery is still a matter of considerable debate. Looking for the best cardioplegic strategy, we surveyed congenital heart surgeons about their practice.
Methods: A questionnaire was e-mailed to 88 institutions and we recieved 33 responses, which were analyzed. The survey adressed the type of cardioplegia, dosage, administration, pressure and difference in cyanotic/acyanotic patients. The respondents had to choose among several predefined response options. All percentages are based on the number of the entire reporting cohort (n = 33).
Results: Almost half of surgeons (45%) use more than one type of cardioplegia. A wide variety of cardioplegic solutions were described. More than a half (52%) use both crystalloid or blood-based cardioplegia in different situations. Induction and maintance dosage depend on the type of cardioplegia. There is also difference in calculation of the dosage with 12% of the surgeons using BSA, and another 12% measuring exposure time. When using more than one type, CUSTODIOL (®) is generally associated with long and complex operations. The majority (n = 18) of surgeons prefer delivery pressure between 30-50 mmHg, measured in the aortic root. None of the respondents use different cardioplegia in cyanotic/acyanotic patients.
Conclusions: This survey demonstrates that myocardial protection strategies differ greatly in type of solution, pressure and even in measuring methods from one surgeon to another. More studies associated with postoperative markers of the different strategies should be considered.

P2014 - RIGHT VENTRICULAR OUTFLOW RECONSTRUCTION WITH HANDMADE VALVE CONDUIT – A SHORT EXPERIENCE

Syed Shahabuddin, Muneer Amanullah
Aga Khan University Hospital, Surgey, Karachi-Pakistan

Background: Right ventricular outflow tract continuity abnormalities are one of the most commonly encountered entities in the field of congenital cardiac surgery. Various strategies including homograft, valve conduit, Contegra, and patch enlargement with valve replacement or reconstruction are used to restore anatomical and functional continuity between right ventricle and pulmonary artery. In countries like Pakistan these may not be easily available and affordable. We report the experience of our short observational study of using a handmade trileaflet valve conduit to reconstruct the right ventricular outflow tract.
Materials and Methods: From September 2015 to December 2016, a total of 15 patients with different congenital heart disease diagnoses in the pediatric age group (up to 16 years) at the Aga Khan University Hospital underwent open-heart surgery including restoration of RV to PA continuity by using handmade valve conduit. The size of the conduit was determined by using an available nomogram. The bovine pericardium and thin sheet PTFE sheets (0.5mm) were used to construct conduit and valve respectively.
Results: Patients ranged from 1 year to 16 years. Seven patients have had previous palliation including 4 BT Shunts and 3 PA banding. One patient underwent 3rd time redo procedure for RV to PA homograft stenosis. Postoperative complications were observed in 4 patient including 2 in hospital deaths and 2 required interventions. One patient developed aneurysm at RV- conduit junction requiring surgical repair and the other underwent conduit dilatation for moderate to severe stenosis (gradient 60mmg). No significant regurgitation was observed in this series. Overall postoperative gradients were stable with mean gradient 25.3 mmhg (8mmhg – 60mmhg).
Conclusions: This short report highlights that the handmade valve conduits are a cost effective alternative in this part of the world where well-established conduits have cost implications and questionable availability.

P2017 - STAGED HYBRID CLOSURE OF PATENT DUCTUS ARTERIOSUS IN PATIENTS WITH PATENT DUCTUS ARTERIOSUS AND SEVERE PULMONARY ARTERIAL HYPERTENSION

Eun Seok Choi[1], Chang-Ha Lee[1], Sungkyu Cho[1], Su-Jin Park[2], Sang-Yun Lee[2], Seong Ho Kim[2]
Sejong General Hopistal, Department of Thoracic and Cardiovascular Surgery, Bucheon-Korea, South[1]; Sejong General Hopistal, Department of Pediatric Cardiology, Bucheon-Korea, South[2]

Background: The purpose of the study is to evaluate outcomes of staged hybrid closure of patent ductus arteriosus (PDA) in patients with PDA and severe pulmonary arterial hypertension (PAH).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: From January 2007 to December 2016, 12 patients with PDA with severe PAH underwent surgical partial closure of PDA. Medical records of them were reviewed retrospectively.
Results: The mean age of patients was 11.0 ± 10.2 years old (range: 0.9 ~ 36.6, median: 7.5 years old). The mean preoperative right ventricular (RV) to left ventricular (LV) pressure ratio was 0.87 ± 0.11 (range: 0.67 ~ 0.97, median: 0.93). The mean preoperative pulmonary vascular resistance index was 8.9 ± 3.7 Wood units (WU) (range: 3.8 ~ 14.4, median: 8.6 WU). During the follow-up, there was no mortality and no symptoms associated with right heart failure. Eight patients underwent staged complete closure of PDA percutaneously after a mean follow-up of 17.8 ± 8.4 months (range: 10.1 ~ 33.7, median: 14.1 months). The RV to LV pressure ratio was significantly reduced to a mean 0.56 ± 0.08 (range: 0.44 ~ 0.67, median: 0.52) and pulmonary vascular resistance index was also significantly reduced to a mean 6.0 ± 2.0 WU (range: 2.5 ~ 8.3, median: 6.2 WU). Two patients wait for complete closure and 2 patients were lost to follow-up.
Conclusions: Staged hybrid closure of PDA is a safe treatment option in patients with PDA and severe PAH.

P2034 - MODIFIED BLALOCK TAUSSIG SHUNT COMPARISON BETWEEN STERNOTOMY AND THORACTOMY IN A SINGLE CENTER

Francisco Vera[1], Juan Ignacio Zabala[2], Esteban Sarria[1], Lourdes Conejo[2], Victorio Cuenca[2], Beatriz Picazo[2], Antonio Morales[3], Patricia García[3], José Camacho[3], Enrique Ruiz[1]
Hospital Materno Infantil, Congenital Cardiovascular Surgery, Málaga-Spain[1]; Hospital Materno Infantil, Pediatric Cardiology, Málaga-Spain[2]; Hospital Materno Infantil, Pediatric Intensive Care Unit, Málaga-Spain[3]

Background/Hypothesis: To compare the results in terms of morbidity and mortality between patients who received a modified Blalock-Taussig Shunt (BTS) performed by thoracotomy or by sternotomy under cardiopulmonary bypass (CPB).
Material and Methods: Retrospective review. We analyzed all the patients younger than 3 months who needed a BTS to assure pulmonary flow between 2005 and 2016. We excluded patients following a Norwood operation. In this period, 33 BTS were performed in our centre: 13 (39,4%) were performed by sternotomy under CPB (Group A) and 20 (59,6%), by thoracotmy (Group B).
Results: Pre-operative characteristics are shown in Table 1. In-hospital mortality was 6% (7,1% in group A and 5,3% in group B). 6 patients (18%) developed acute thrombosis of the BTS (7,8% in group A and 26% in group B). Average time of ICU, mechanical ventilation and hospitalization are shown in Table 2. 70% of patients required inotropes (85% in group A and 60% in group B). No significant differences were observed between the two groups regarding the postoperative outcomes. Median follow-up was 38 months (Range 7-80 months). Survival after follow-up was 84% (91,7% in group A and 78,9% in group B). Next-step surgery was achieved in 57,6% of patients (38,5% in group A and 75% in group B). 27,3% of patients needed stenting of pulmonary artery (7,7% in group A and 40% in group B, p value <0,05) 15,1% of patients needed ductus stenting due to BTS failure (0% in group A and 25% in group B, p value = 0,01).
Conclusion: We consider that midline approach under CPB is safer than thoracotomy, due to a lower risk of acute thrombosis and inferior rate of ductus stenting or pulmonary artery intervention during the follow-up..

P2040 - AN APPRAISAL OF MATERIALS AND VALUE FOR PATCH RECONSTRUCTION OF THE PULMONARY ARTERIES

William Hollabaugh[1], Michael Mcginnis[2], William K Johnson[3], Michael E Mitchell[4], James S Tweddell[5], Ronald K Woods[4]
Medical College Wisconsin, Medical Student 3, Milwaukee-United States[1] Wayne State University, Medical Student 2, Detroit-United States[2] Medical College Wisconsin, Children, Surgery, Milwaukee-United States[3] Medical College Wisconsin, Chidlren, Surgery, Milwaukee-United States[4] Univ of Cincinnati College of Medicine, Surgery, Cincinnati-United States[5]

Background/Hypothesis: We sought to evaluate quality (re-intervention) and cost of various patch materials used for main and branch pulmonary artery (PA) patch reconstruction.
Patients/Methods: We conducted a retrospective chart review of all patients undergoing patch reconstruction of the main or branch PAs (w/wo other cardiac surgery) at our institution over the interval of 1990-2015. We analyzed 5 patch materials: CM – porcine submucosal matrix; BovP – bovine pericardium; BPH – branch patch pulmonary homograft; G – goretex; and AutP – autologous pericardium. Primary outcome was re-intervention on the reconstructed PA site (not number of patients). Median follow-up was 5.3 years (IQR 2.5-9.5).
Results: The cohort included 341 patients and 442 patch reconstruction sites. Median age (IQR) and weight were 0.53 yrs (0.3-1.4) and 6.9 kg (5.1-8.9). TOF/PS and other biventricular repair constituted 54.3% of the cohort. Patch sites included main PA (w/wo) extension to branch for 143 patches (32.4%); L PA and hilar for 90 (20.4%); R PA and hilar for 105 (23.8%); and both branches for 65 (14.7%). Discharge and late mortality occurred in 4 (0.8%) and 12 (2.6%) of patients. Surgical or catheter-based re-intervention occurred as primary indication for 66 patches (14.9%); another 68 patches received re-intervention which may not have occurred had another major procedure not been indicated. Intervention and cost per material data are shown in Table 1 – notably for AutP re-intervention occurred in 11.5% of patches versus 30.6% of BPH patches, p = 0.0003.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: For PA reconstruction, there is considerable variability in types of patches, unit cost per patch, and material-related re-intervention. Autologous pericardium is free and provided the lowest rate of patch re-intervention.

Table 1. Re-intervention and Costs for PA Reconstruction Patches

Type of patch used at index procedure	Patch Unit Cost	Total number of patches used	Number of patches needing re-intervention	Re-intervention (%)	Total Cost
Porcine submucosal matrix (CM)	$795	65	11	16.9	$51,675
Bovine pericardium (BovP)	$500	63	23	36.5	$31,500
Branch patch pulmonary homograft (BPH)	$6397	212	84	39.6	$1,356,164
Goretex (G)	$581	34	10	29.4	$19,754
Autologous pericardium (AutP)	$0	61	7	11.5	$0

P2051 - INTERMEDIATE TERM FOLLOW UP AFTER TRANSCATHETER FENESTRATION CLOSURE IN PATIENTS WITH FENESTRATED FONTAN PROCEDURE; SINGLE CENTER EXPERIENCE

Soo In Jeong[1], Ji Hee Kwak[2], Heirim Lee[3], I-Seok Kang[3], Jinyoung Song[3], Ji Hyuk Yang[4], Tae Gook Jun[4], June Huh[3] Ajou University Hospital, Pediatrics, Suwon-Korea, South[1] Myongji Hospital, Pediatrics, Goyang-Korea, South[2]
Samsung Medical Center, Sungkyunkwan University School of Medicine, Pediatrics, Seoul-Korea, South[3] Samsung Medical Center, Sungkyunkwan University School of Medicine, Thoracic And Cardiovascular Surgery, Seoul-Korea, South[4]

Objective: To review and compare the clinical and catheterization data before and after device closure of fenestration on patients treated with fenestrated Fontan procedure.
Methods: The clinical records were reviewed for demographic, laboratory and hemodynamic data of patients who underwent follow up cardiac catheterization after fenestration closure.
Results: Thirty two patients underwent fenestration closure from 1998 to 2009 at Samsung medical center. Twenty four asymptomatic patients underwent follow up cardiac catheterization at median 8.8 years after closure (range: 4.4-12.5). Median age at follow up catheterization was 13.2 years (range: 10.7-21.8). In theses 24 patients, various devices including detachable coils($n=8$), Amplatzer duct occluder ($n=2$) and Amplatzer vascular plug I ($n=14$) were used for fenestration closure at median interval of 19 months after Fontan operation (range: 8-107). Twenty two patients had aspirin medication. Systemic ventricular morphology was left ventricle in 11 patients, right ventricle in 10 patients and undetermined morphology was in 3 patients. On follow up angiography, fenestration leakage was noticed in 4 patients who underwent fenestration closure with coil. Mean pulmonary artery pressure(PAP) was 10.9 ± 2.3 mmHg at fenestration closure and 13.7 ± 4.5 mmHg at follow up ($p=0.003$). Pulmonary vascular resistance was 1.97 ± 0.93 wood units at closure and 1.63 ± 0.7 wood units at follow up (p-value $=0.08$). Mean ventricular end-diastolic pressure(VEDP) was 7.0 ± 3.2 mmHg at closure and 11.3 ± 3.4 mmHg at follow up ($p<0.01$) Mean VEDP at follow up was correlated with duration of Fontan circulation ($r=0.35$, $p=0.023$), interval between closure and follow up ($r=0.333$, $p=0.029$), and mean PAP at follow up ($r=0.477$, $p=0.006$).
Conclusions: There was statistically significant change in mean PAP and mean VEDP at median 8.8 years follow up after fenestration closure. It is unclear whether these changes are due to natural course of Fontan surgery or is due to the result of fenestration closure.

P2062 - STAGED SURGICAL REPAIR FOR CHILDREN WITH INTERRUPTED AORTIC ARCH

Shye-Jao Wu[1], Min-Ren Chen[2]
Mackay Memorial Hospital, Cardiovascular Surgery, Taipei-Taiwan[1]; Mackay Memorial Hospital, Pediatric Cardiology, Taipei-Taiwan[2]

Background: Interrupted aortic arch is a rare congenital cardiac anomaly. Without treatment, mortality rate is approaching 90% within the first year of life.
Purpose: There are several surgical strategies for corrective repair of interrupted aortic arch. Here, we reported our surgical result of staged policy of corrective repair for the patients with interrupted aortic arch.
Method: From November 2003 to July 2015, there were 14 infants (8 boys, 6 girls) with interrupted aortic arch treated at our hospital. We routinely used intravenous infusion of prostaglandin E1 for all the infant patients to keep adequate end organ perfusion before the first surgical intervention. Then, staged surgery is our treatment policy.
Result: At the time of the first surgery, we did the first staged surgery with anastomosis between aortic arch and descending aorta, division of patent ductus arteriosus and banding of pulmonary trunk through left thoracotomy. The surgical survival rate of the first staged surgery was 100%. At the time of the second surgery, we did the corrective repair with the surgical procedures including repair of ventricular septal defect, de-banding of pulmonary trunk and enlargement of pulmonary trunk with pericardium under cardiopulmonary bypass through median sternotomy. The surgical survival rate of the corrective surgery was also 100%.
Conclusion: For the infants with interrupted aortic arch, ventricular septal defect and patent ductus arteriosus, we think the surgical result of staged repair can be approaching 100% by experienced surgeons and the good surgical result can be reproducible without significant difficulty.

P2063 - PRO BNP PROGNOSTIC VALUE IN PEDIATRIC PATIENTS WITH SINGLE VENTRICLE PHYSIOLOGY

Tatyana Ivanova-Razumova[1], Almira Baigalkanova[2], Aikerim Zhanatkyzy[2], Ludmila Mameganova[2]
National Research Cardiac Surgery Center, Pediatric Cardiology, Astana-Kazakhstan[1]; Diac Surgery Center, Pediatric Cardiology, Astana-Kazakhstan[2]

Purpose: To determine the prognostic value of pro-BNP level in patients with single ventricle physiology after hemodynamic corrections.
Methods: 70 children with physiology of single ventricle after hemodynamic corrections were included (January 2013 - December 2016). Age ranged from 6 days to 15 years. Standard clinical investigations, ECHO, 24-hours ECG-monitoring and pro-BNP levels were measured pre-operatively and 3, 6 months after. For analyze dates we have used Statisica 6.0 program.
Results: children from 0 to 3 years were predominant - 52 children (74%).Types of operation: BT-shunt– 10 patients (14.4%), Glenn procedure – 22 patients (31.4%), pulmonary artery bending – 14

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

patients (20%), Norwood I surgery – 6 patients (8.5%), Fontan surgery – 18 patients (25.7%). Patients were divided into two groups. First group - patients with complications after surgery – 41 (58%); second group - patients without any complications – 29 patients (41.4%). The most common complications in the late post-operative period were heart failure (HF), arrhythmias. Mean pro-BNP levels in two groups pre-operatively were 1587 ± 52 pg/ml and 779 ± 34 pg/ml accordingly. In early post-operative period pro-BNP level was significantly higher in first group - 4576 ± 65 pg/ml and 998 ± 23 mg/ml, respectively ($p < 0.05$). After 3 months in the first group pro-BNP level was - 2942 ± 38 pg/ml, in the second group 389 ± 19 pg/ml ($p < 0.05$). 6 month after the first group still had high levels of pro-BNP, whereas in the second group pro-BNP level was near normal. Correlation analysis between pro-BNP level and morbidity in late post-operative period was performed. The value was 0.75.
Conclusions: Pro-BNP can be used as a morbidity prognostic marker in children after hemodynamic corrections, level $\geq$ 2500 pg/ml in early post-operative period predict development of arrhythmias.

P2074 - PATIENTS WITH AORTIC COARCTATION OPERATED WITHIN THE FIRST YEAR OF LIFE DIFFERENT SURGICAL TECHNIQUES AND PROGNOSTIC FACTORS 12 YEARS OF EXPERIENCE

Francesca Pluchinotta[1], Mario Giordano[2], Alessandro Giamberti[3], Guido Oppido[4], Giuseppe Santoro[2], Maria Giovanna Russo[2], Giuseppe Pomè[3], Alessandro Frigiola[3], Mario Carminati[1], Gianfranco Butera[1]
IRCCS Policlinico San Donato, Pediatric Cardiology, Milan-Italy[1]; Campania University - Monaldi Hospital, Pediatric Cardiology, Naples-Italy[2]; IRCCS Policlinico San Donato, Pediatric Cardiac Surgery, Milan-Italy[3]; Monaldi Hospital, Pediatric Cardiac Surgery, Naples-Italy[4]

Background: The authors reviewed the clinical files of patients with coarctation of the aorta (CoAo) operated within the first year of life in two Italian centers, in order to assess the outcome of different surgical techniques and prognostic factors.
Materials and Methods: Patients operated between 2004 and 2016 were included in the study. Patients with complex heart defects (CHD) which underwent univentricular heart palliation were excluded. Several parameters were analyzed: sex, age at surgery, associated anomalies, associated surgical procedures, re-operation, mortality and need for re-intervention.
Results: 247 patients were operated during the study period; 61% were male. Surgery was performed at a median age of 13 days of life (range 0-346). 59% of the patients had isolated CoAo, 33% had CoAo associated to ventricular septal defect (VSD), and 7% had CoAo associated to other CHD. 85% of the patients were treated with end-to-end anastomosis, 12% with patch enlargement of the aorta, and 3% with a subclavian flap according to the presenting anatomy. During surgery 21% of the patients had an associated surgical procedure: banding of the pulmonary artery was performed in 70% of the cases, VSD closure in 15%, and arterial switch in 7.5%. One patient died after surgery due to sepsis; 17 patients were lost at follow-up. Among the remaining 229 patients, recoarctation occurred during follow-up in 24%. All but three underwent cardiac catheterization that was successful in 81% of the cases. Recurrence of coarctation was similar (22%) in patients who underwent either termino-terminal anastomosis or patch enlargement of the aorta, and it was higher in the group treated with subclavian flap (28%).
Conclusions: Mortality is very low. Risk of ricoarctation is almost 1/4 and is higher in patients who have been treated with subclavian flap. In case of recoarctation, cardiac catheterization is the first choice with good results.

P2075 - SURGICAL EXCLUSION OF DYSPLASTIC RIGHT VENTRICLE IN A CASE OF UHL'S ANOMALY

Musthafa Janeel Moosa[1], Neville Solomon[1], Ponduru Trilok[1], Muthukumaran Sivaprakasam[2], Anuradha Sridhar[2]
Apollo Children's Hospital, Paediatric Cardiac Surgery, Chennai-India[1]; Apollo Children's Hospital, Paediatric Cardiology, Chennai-India[2]

We report a case a 2 year old boy with Uhl's anomaly presented with history of progressive respiratory distress, syncopal attacks and failure to thrive since birth. He underwent Surgical exclusion of right ventricle which included Bidirectional Glenn shunt anastomosis, atrial septectomy, interruption of main pulmonary artery, and fenestrated patch closure of tricuspid valve.Post-operative recovery was uneventful and anticoagulation was done. Biopsy report of right ventricle free wall showed only fibrous tissue with few blood vessels and nerve bundles. No myocardium was seen. There are very few successful surgical repairs in the literature and hence presenting our approach.

P2079 - UNIQUE CASE OF AORTICO LEFT VENTRICULAR TUNNEL (ALVT) ARISING FROM LEFT CORONARY NON CORONORY COMMISURE

Musthafa Janeel Moosa[1], Neville Solomon[1], Anuradha Sridhar[2], Muthukumaran Sivaprakasam[2]
Apollo Children, Paediatric Cardiac Surgery, Chennai-India[1] Apollo Children, Paediatric Cardiology, Chennai-India[2]

Aortico-left ventricular tunnel (ALVT) is a a paravalvular, extracardiac communication between aorta to left ventricle with a incidence of 0.001%.Most case reports shows it arising from right coronory sinus with very few reports shows arising from left coronory sinus. We report a unique case where it was arising from the commissure rather than sinus. Intraoperatively The aortic end of the tunnel was found to be around 15 mm X 15 mm was from the commissure with opening into both sinuses. The leftward end was close to the left coronary orifice with just enough margin for the sutures.The LV end was small, oval 8mm X 6mm below the base of non coronary cusp at aorto-mitral continuity..

P2080 - HIGH ALTITUDE MAY PROTECT AGAINST THE DEVELOPMENT OF EISENMENGER SYNDROME IN CHD PATIENTS

Alexandra Heath[1], Inge Von Alvensleben[1], Brian Graham[2], Rubin Tuder[2], Carlos Brockman[3], Erika Perez[3], Carla Arteaga[1], Claudia Scherer[1], Franz Fruedenthal[1]
Kardiozentrum, Pediatric Cardiology, La Paz-Bolivia[1]; University of Colorado, Pulmonary Medicine, Denver-United States[2]; Cmqbb, Cardiac Surgery, Cochabamba-Bolivia[3]

Background: Congenital heart disease (CHD) occurs at increased prevalence at high altitude, but there may be a later onset of the development of Eisenmenger syndrome. We hypothesized that CHD patients at high altitude are protected from the development of Eisenmenger syndrome.
Methods: Prospective observational case series study of patients who underwent surgery for CHD in La Paz, Bolivia, located at 3600 m. Patients aged 5 to 29 years (mean 12 years) with relevant post tricuspidal shunts (Qp/Qs 5,8 during hyperoxia test versus Qp/Qs :2,6 in hypoxia) underwent right heart catheterization pre-operatively and six to nine months post-operatively, and had a lung biopsy performed at the time of the surgery. Control lung tissue was obtained from patients who had pulmonary hydatid cyst resection.
Results: N = 10 CHD patients and N = 4 control patients were analyzed. Pre-operatively, the patients had significant response to hyperoxia with a fall in mPAP from 59,6 (DS 7,74) to 46,3 (DS11,1); (P = 0,05). Post-operatively, the patients had an excellent response to surgery, with a mPAP of 26,4 (DS6,42) (P < 0,05 versus pre-operative pulmonary pressures). Analysis of the lung histology did not show evidence of pulmonary vascular remodeling in the CHD patients compared to the control patients.
Conclusions: Chronic hypobaric hypoxia may protect CHD patients from early changes in the pulmonary vasculature and for instance from irreversible pulmonary hypertension at young ages.

P2094 - YOUNGER AGE AT FONTAN IS ASSOCIATED WITH BETTER 4.5 YEAR NEUROCOGNITIVE OUTCOMES

Billie-jean Martin[1], Gwen Bond[2], Joseph Atallah[2], Bryan Acton[3], Ari Joffe[4], M. Florencia Ricci[2], Gonzalo Garcia Guerra[4], Mohammed Al Aklabi[1], David Ross[1], Ivan Rebeyka[1], Charlene Robertson[2]
University of Alberta, Surgery, Edmonton-Canada[1]; University of Alberta, Pediatrics, Edmonton-Canada[2]; University of Saskatchewan, Pediatrics, Saskatoon-Canada[3]; University of Alberta, Critical Care, Edmonton-Canada[4]

Background: Optimal age for performing the Fontan operation is unclear, with recent suggestions that this step in single ventricle palliation should be delayed as long as possible to avoid accruing Fontan related complications. However, the association between age at Fontan and neurocognitive outcomes has not been previously assessed.
Methods: All subjects enrolled in the prospective Western Canadian Complex Pediatric Therapies Follow-up Program who underwent a Fontan operation between 1999 and 2015 were included. Follow-up clinical and neurocognitive data were obtained from the database. Psychologists completed neurocognitive testing on all surviving children at a median of 54 months of age using The Wechsler Preschool & Primary Scale of Intelligence. Generalized linear models were constructed to determine the association between pre-, intra- and post-operative variables, neuromotor or neurosensory disability, as well as characteristics over the course of palliation and neurocognitive outcomes.
Results: A total of 170 subjects (61 female, 97 with hypoplastic left heart syndrome) underwent a Fontan, with 163 surviving to undergo neurocognitive assessment. Median age at Fontan was 3.2 years (IQR 2.8, 3.7), and subjects most commonly had an extracardiac type Fontan (95, 56%). Twenty-two subjects had a neuromotor and/or neurosensory deficit diagnosed prior to undergoing a Fontan. Median Full-scale IQ (FSIQ) was 91 (IQR 77, 102), Performance IQ (PIQ) was 90 (78, 101), Verbal IQ (VIQ) 93 (81, 102) and Visual-Motor Integration (VMI) score 90 (IQR 78, 98). Older age at Fontan was associated with lower scores for each endpoint (Figure). In multivariable models including adjustment for any disability, age in years was a negative predictor for all neurocognitive endpoints (FSIQ -6.43; PIQ -6.60; VIQ -4.94; VMI -5.55; each p < 0.0001).
Conclusion: Younger age at Fontan is associated with better neurocognitive outcome at 4.5-years. The present trends towards delaying Fontan palliation needs to be considered in light of these findings..

P2097 - LEAVING A RIGHT VENTRICULAR PULMONARY ARTERY CONDUIT OPEN AT THE TIME OF BIDIRECTIONAL CAVOPULMONARY ANASTOMOSIS POST NORWOOD SANO OFFERS NO BENEFIT

Billie-Jean Martin[1], Cameron Seaman[2], Nee Khoo[2], Mohammed Al Aklabi[1], David Ross[1], Ivan Rebeyka[1]
University of Alberta, Surgery, Edmonton-Canada[1]; University of Alberta, Pediatrics, Edmonton-Canada[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Introduction: It is unclear whether the Right Ventricular-Pulmonary Artery (RVPA) conduit should be left open at the time of bidirectional cavopulmonary anastomosis (BCPA) in Norwood-Sano patients, as the role of additional pulmonary blood flow in these patients post-BCPA has not been evaluated. We therefore aimed to evaluate the impact of additional pulmonary blood flow in this cohort.
Methods: All subjects that underwent a BCPA post-Norwood-Sano from 2002-2016 were included. Subjects were categorized according to the status of their RVPA post Norwood (OS – open Sano/PC- partially closed/CL – closed). Characteristics at the time of Norwood, BCPA and Fontan were compared across RVPA Status. The association between RVPA status and freedom from death and pulmonary artery intervention were assessed using cox proportional hazards models.
Results: 146 infants underwent a BCPA post-Norwood-Sano (53 female, 103 HLHS); 22 had their RVPA left OS, 56 PC, 68 CL. Subjects who had OS were more likely to have thrombosed head and neck veins pre-BCPA (45.4% vs 10.9% in PC vs 7.5% CL) and had significantly higher BCPA pressures (18.1 vs 16.9 PO vs 15.1 CL) and oxygen saturations post-BCPA (86% vs 84.2 PO vs 79.6% OS) (all $p < 0.05$). Patients with an open RVPA were younger at Fontan (3.2 OS vs 3.6 years CL, $p = 0.012$) and were more likely to suffer from post-Fontan stroke (OS 33.3%, PC 11.1%, CL 5.8%, $p = 0.042$). Furthermore, an open RVPA conduit was associated with increased mortality (OR 4.27 (1.29, 14.1)) but no reduction in need for pulmonary artery re-intervention (OR 0.57 (0.13, 2.51)).
Conclusions: Leaving the RVPA conduit open at the time of BCPA post-Norwood-Sano appears to offer no benefit but significant risk. This association may be due to the frequency of pre-BCPA venous thrombosis seen in the OS group, suggesting strategies to reduce thrombotic risk may also reduce myriad complications in this cohort.

P2108 - TAKEUCHI TECHNIQUE FOR TREE CASES OF ANOMALOUS LEFT CORONARY ARTERY FROM THE PULMONARY ARTERY

Juan Miguel Mantilla[1], Jose Leonardo Cely-andrade[2], Jose Leonidas Olaya[3], Monica Marcela Moreno[3], Alfonso Velandia[4]
Hospital Cardiovascular Del Niño De Cundinamarca, Pediatric Cardiovascular Surgery, Soacha-Colombia[1]; Hospital Cardiovascular Del Niño De Cundinamarca - Universidad Del Bosque - Universidad Manuela Beltran, Research Department, Soacha - Bogotá-Colombia[2]; Hospital Cardiovascular Del Niño De Cundinamarca, Cardiovascular Surgery Departement, Soacha-Colombia[3]; Hospital Cardiovascular Del Niño De Cundinamarca, Cardiovascular Anhestesiology Departement, Soacha-[4]

Anomalous left coronary artery from the pulmonary artery (ALCAPA), also known as Bland-White-Garland syndrome (1) is a rare congenital cardiac disease that can cause myocardial infarction, heart failure and even death in paediatric patients (2), is present in 1 of 300 000 live births and accounts for 0.05% of congenital cardiac malformations (3). Surgical treatment is ever the treatment election and success overlive is most than 90%; coronary reimplatation is now the elective treatment when it is not possible, takeuchi technique is the elective treatment; this technique repairs intrapulmonary tunnel and is a unique procedure for repairing anomalous origin of the left coronary artery with left and posterior possition from the pulmonary artery (3) Four female clinical cases are presented: a 4 years old, 5,8 y10-months all patients with dilated cardiomyopathy with severe ventricular dysfunction, LVEF 15%, 20% 20% and and 40%, respectively, with moderate mitral insufficiency secondary to anomalous origin of the left coronary artery Of the Pulmonary Artery Trunk (ALCAPA), Takeuchi surgery was performed in all cases, with excellent results given by recovery of ventricular function as a whole. Follow-up time of 6 to 3 years.

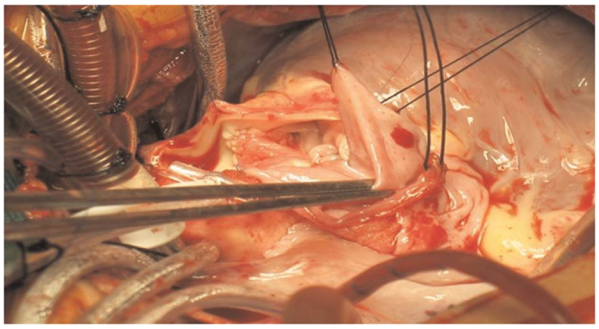

Figure 1.

P2113 - WHICH IS THE EXACT SIZE OF THE TRANSANNULAR PATCH NEEDED TO ACHIEVE A NORMAL DIAMETER OF THE PULMONARY ANNULUS DURING SURGICAL CORRECTION OF TETRALOGY OF FALLOT

Ignacio Lugones[1], Sivakumar Sivalingam[2], Leong Ming Chern[3], Hanif Othman[3], Martínez Inés Ana[4], Biancolini María Fernanda[4], De Dios Ana María[4]
Children´s Hospital Buenos Aires "Pedro De Elizalde", Cardiac Surgery Unit, Buenos Aires-Argentina[1] National Heart Institute, Cardiac Surgery Unit, Kuala Lumpur-Malaysia[2] National Heart Institute, Cardiology Department, Kuala Lumpur-Malaysia[3] Children´s Hospital Buenos Aires "pedro De Elizalde", Cardiology Department, Buenos Aires-Argentina[4]

Introduction: The main concern about using a transanular patch (TAP) during surgical correction of tetralogy of Fallot is that insufficient enlargement of the annulus leaves residual stenosis and excessive enlargement aggravates pulmonary regurgitation (PR). PR impairs right ventricular function and increases postoperative mortality. Thus, achieving a normal postoperative pulmonary annulus diameter (PAD) becomes highly desirable.
Materials and Methods: From March to December 2016, 20 patients with hypoplastic pulmonary annulus (defined as PAD < -2 z-value) were operated on in the two involved institutions. Patients: 9 males and 11 females; median age: 13 months; mean weight: 9.4 kg (6.3–16). Transthoracic echocardiography was performed to determine the preoperative PAD (mean: 6.85 mm; range: 6–10). Exact width of the TAP for each possible situation was obtained by subtracting the perimeter of the preoperative pulmonary annulus from the normal one. Values are depicted in Table 1.
During surgery, the right ventricular outflow tract, the pulmonary annulus and the main pulmonary artery were enlarged using a glutaraldehyde-treated autologous pericardial patch cut to size according to this geometrical rule.
Results: There were no postoperative deaths. PAD measured by transthoracic echocardiography in the early postoperative period ranged from 0.9 mm smaller to 1 mm larger than respective normal value. Mean postoperative PAD was 11 mm for a mean normal annulus of 11.1 mm. Mean percentage of deviation of the post-operative PADs from respective normal values was 0.6%. Average transpulmonary gradient was 26 mmHg, meaning mild residual pulmonary stenosis. PR was moderate in 50% of the cases and mild or less in the remaining patients.
Conclusion: This geometrical rule accurately defines the exact width of the TAP needed to achieve a normal postoperative PAD, avoiding residual gradients and severe PR in order to prevent right ventricular dilation in the follow-up of these patients.

P2119 - COMPARISON OF MINIMALLY INVASIVE TRANSTHORACIC DEFECT CLOSURE AND CARDIOPULMONARY BYPASS FOR THE TREATMENT OF SUBARTERIAL VENTRICULAR SEPTAL DEFECT IN PEDIATRIC PATIENTS

Weize Xu[1], Qiang Shu[2], Jingjing Ye[2], Jianhua Li[2], Jiangen Yu[2]
The Children, The Heart Center, Hangzhou-China[1]; The Children's Hospital of Zhejiang University School of Medcine, The Heart Center, Hangzhou-China[2]

Objective: To investigate the feasibility, safety and effectiveness of MITDC for the treatment of subarterial VSD.
Methods: Analyzed clinical data of pediatric patients diagnosed of subarterial VSD by echocardiography from October 2011 to September 2016. There were a total of 54 cases underwent MITDC and 91 cases received surgery under CPB. Patient's clinical data before and after surgery were collected, and efficacies of the two methods were compared.
Results: There was no significant difference in age, gender and body weight between the two group of patients ($P > 0.05$);defect diameter of the MITDC group was significantly smaller than that of the CPB group ($P < 0.01$), and the percentage of right aortic sinus prolapse in the MITDC group was lower than that in the CPB group ($P < 0.01$). Postoperative ICU intubation time and duration of hospital stay of the MITDC group were both shorter than that of the CPB group ($P < 0.01$), and the percentage of patients requiring blood transfusion was significantly lower in the MITDC group than in the CPB group ($P < 0.01$). Compared with the preoperative level, rate of mild postoperative tricuspid regurgitation among patients in the MITDC group was significantly reduced ($P < 0.01$). The MITDC group had a significantly lower postoperative pulmonary peak flow velocity than the CBP group ($P < 0.01$). The percentage of postoperative incomplete right bundle branch block was higher than that the preoperative rate in both groups ($P < 0.01$), the rate of postoperative arrhythmia remained the same as compared to the preoperative level in both groups ($P > 0.05$). There was no statistically significant difference in the rate of pericardial effusion between the MITDC and the CPB groups ($P > 0.05$). There was no other complication observed in the two groups except the above mentioned complications.
Conclusion: MITDC is an effective procedure for the treatment of subarterial VSD, MITDC had the advantages of less trauma, shorter ICU intubation time, shorter hospital stay, less need for blood transfusion.

P2121 - NEW VALVE SPARING TECHNIQUE FOR TETRALOGY OF FALLOT REPAIR

Praveen Reddy Bayya[1], Brijesh P Kottayil[1], Luis Baquero[1], Rakhi Balachandran[2], Amitabh Sen[2], Jessin P Jayasankar[2], Soumya Kasturi[3], Krishnakumar Raman[3]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Research Centre, Cardiac Anesthesia, Kochi-India[2]; Amrita Institute of Medical Sciences and Research Centre, Pediatric Cardiology, Kochi-India[3]

Background: We present a modified technique of valve sparing surgery to preserve the pulmonary annulus and prevent pulmonary regurgitation (PR) following intracardiac repair (ICR) for Tetralogy of Fallot (TOF).
Methods and Results: The data of 86 consecutive patients (median age 11 (3-161) months) undergoing TOF repair (March 2015-December 2016) was reviewed. Transannular patch (TAP) was avoided in 55 (64%); 25 (29%) required only infundibular resection and pulmonary valvotomy (trans-atrial ICR) while 30 (35%) patients underwent modified valve sparing surgery (mVS-ICR) to preserve the pulmonary valve (PV) and pulmonary artery (PA) annulus using following techniques: commissurotomy, commissural release, sinus incisions in the PA, T-incision of right ventricular out flow tract (RVOT) and balloon dilatation of PA annulus, leaflet delamination to increase leaflet height and achieve coaptation in the setting of the new larger PA annulus and, augmentation of individual sinuses and RVOT with autologous treated pericardium. There was no difference in the age, weight, surgical support times, intensive care and ventilation duration and mortality between the three groups. Key results are summarized in the table.
Conclusion: The modified valve sparing correction of TOF can be used to preserve the valve in selected patients with small PA annulus. Short-term results appear promising. Long-term follow-up is required to determine growth of PA annulus and progression of PR..

P2122 - SURGICAL EXCISION OF CARDIAC TUMORS 20 YEAR EXPERIENCE AT A SINGLE INSTITUTION

Giuseppe Pelella, *Rafael Guerrero, Ramana Dhannapuneni, Attilio Lotto*
Alder Hey Children Hospital, Cardiac Surgery, Liverpool-United Kingdom

Background: Cardiac tumors are rare with heterogeneous histology and location. Indication for surgical resection is dictated by symptoms and position. The aim of the present study is to review our institution's results in patients who underwent resection of cardiac tumors since 1997.
Materials and Methods: Retrospective review from January 1997 to January 2017 was accomplished. We followed up all patients including echocardiography assessing regression or progression.
Results: 13 patients with a diagnosis of cardiac tumor were operated at our Institution in the study period. The demographic of the population and the histology subtype are described in the Table. -Rhabdomyomas: Four of the six patients were operated in neonatal age, the remaining two at 2 and 3 months of age. In 4 of the 6 patients, the tumor was in the LVOT causing significant obstruction, while in two patient2 there was RVOT obstruction. -Myxomas: Patients with this subtype were older. All the myxomas were excised from the left atrial septum repaired with a patch. One patient had associated mitral valve repair. -Pericardial Teratoma: One patient was operated in neonatal age, while the second was 10 months old. One patient with extension of the tumor into the aortic root died 23 days postoperatively for massive haemorrhage following aortic root repair. -Fibroma: one patient had a fibroma excised from the RV free wall at 8 months of age -Haemangioma: one patient with right atrial haemangioma encasing the RCA was successfully operated and the coronary repaired. We had one (1/13 7.6%) in hospital death and no late death. At a mean follow up time of 77 + /- 67 months no patient required reoperation and echocardiogram excluded regrowth of the tumour.
Conclusions: Surgical excision can be performed with low mortality even when patients are operated in neonatal age. We showed good long term follow up with no regrowth of tumor.

P2130 - LIMITED EXTREME LATERAL CAVOATRIOTOMY FOR SURGICAL CORRECTION OF ANOMALOUS PULMONARY VENOUS CONNECTION FACILITATED BY LIMITED POSTERIOR THORACOTOMY APPROACH

Luis Baquero[1], *Brijesh Kottayil[1], Praveen Reddy[1], Amitabh Sen[2], Sumangala Sunil[1], Krishna Kumar[3]*
Amrita Institute of Medical Sciences, CVTS, Kochi-India[1]; Amrita Institute of Medical Sciences, Cardiac Anesthesia, Koch-India[2]; Amrita Institute of Medical Sciences, Pediatric Cardiology, Kochi-India[3]

Introduction: Surgical correction of partial anomalous pulmonary venous connection (PAPVC) to Superior venacava (SVC) is often associated postoperatively with Sinus node dysfunction and venous obstruction. We present a modified approach by limited right posterior thoracotomy (LPT) for surgical correction of this anomaly which has excellent cosmetic advantage and also facilitates surgical correction by our modified extreme lateral cavoatriotomy approach which avoids injury to the sinus node.
Methods: 53 patients who underwent surgical correction of PAPVC to SVC with our modified approach between January

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

2010 and December 2016 were evaluated retrospectively. All patients underwent surgical correction by LPT with median extent of the incision stopping short of posterior axillary fold. Modified extreme lateral cavoatriotomy incision is made flush with the draining pulmonary vein facilitated by thoracotomy approach which brings the draining pulmonary veins parallel to the surgical view and atrial incision stops short of cavoatrial junction avoiding injury to sinus node.
Results: Median age was 4 years (1-25 years). Median weight was15 kg (6-63 kg). At a median follow up period of 27 months (1 -60 months) there were no early or late mortality. None of the patients had any sinus node dysfunction or arrhythmia.On follow up there were no significant SVC or pulmonary venous obstruction. One patient had mild flow acceleration in SVC with mean gradient of 3 mm of hg. All patients had excellent wound healing with cosmetic advantage over standard median sternotomy approach.
Conclusion: Extreme lateral cavoatriotomy approach via LPT is a safer technique for surgical repair of PAPVC to SVC with excellent cosmetic advantage. In addition this technique potentially offers the patient the lowest risk for the development of sinus node dysfunction after surgical correction.

Figure.

P2134 - COMPREHENSIVE SURGICAL APPROACH DURING REPAIR OF MULTIPLE MUSCULAR VENTRICULAR SEPTAL DEFECTS

Anil Dharmapuram, Sudeep Verma, Nagarajan Ramadoss, Goutami Vejendla, Rao Ivatury
Kims Hospitals, Paediatric Cardiac Services, Secunderabad-India

Background: To eliminate the left to right shunt completely during intra cardiac repair of multiple VSD is a surgical challenge. We adopted a comprehensive surgical approach to minimize the residual shunt after repair.
Methods: Between March 2012 to December 2016 we did primary repair of multiple VSD in 52 patients. The age ranged from 3 months to 12 years (median 8 months). The weight ranged from 2.7 to 11 kg (median 4.6 kg). Intraoperatively, we closed the major VSD's with separate pericardial patches (70 VSD's). The moderate and smaller sized anterior muscular, mid muscular and apical VSD's were addressed by endothelial suturing using continuous polypropylene suture in two layers tied on pericardial pledgets (37 patients). The apical and mid-muscular VSD's which had a single opening on the LV side and sizeable multiple holes on the RV side were addressed by double breasting using teflon patches on both sides of the septum and suturing the RV side of the patch to the endocardium by continuous suturing (8 patients).
Results: Intraoperatively, a bubblegram with TEE guidance was performed using the LV vent in addition to SVC and PA saturation step up. There was no operative mortality. Three patients required re-operation for significant residual shunt in the immediate post-operative period. Two patients died in the late post-operative period due to lung infection. All the other patients have been followed up (median follow up 22 months) and are doing well without congestive heart failure. 2D echo evaluation during follow up showed no significant residual shunts.
Conclusions: A combination of surgical techniques is required to manage multiple VSD's. Endothelial suturing is a very useful surgical strategy and preserves LV function without compromising RV cavity. Double breasting with teflon patches should be reserved for selective cases.

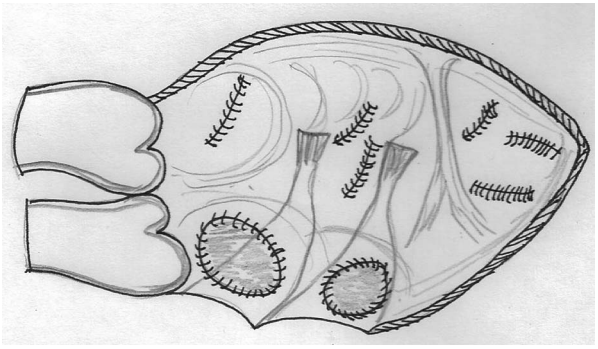

Figure.

P2136 - IMPACT OF DELAYED STERNAL CLOSURE FOLLOWING PAEDIATRIC CARDIAC SURGERY ON WOUND INFECTIONS

Maria Von Stumm[1], Daniel Biermann[1], Urda Gottschalk[2], Götz Müller[2], Hermann Reichenspurner[3], Rainer Kozlik-Feldmann[2], Arlindo Riso[1], Jörg S. Sachweh[1]
University Heart Center Hamburg, Cardiac Surgery For Congenital Heart Disease, Hamburg-Germany[1]; University Heart Center Hamburg, Department of Paediatric Cardiology, Hamburg-Germany[2]; University Heart Center Hamburg, Department of Cardiovascular Surgery, Hamburg-Germany[3]

Background: Delayed sternal closure (DSC) is a well-established procedure to reduce postoperative hemodynamic and respiratory instability following neonatal or infant cardiac surgery. Though, DSC is associated with an increased rate of sternal wound infection

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(SWI), sepsis and mortality. Currently, indication and duration of DSC vary substantially between paediatric cardiac centres worldwide. Therefore, we reviewed our experience with DSC to determine the incidence of SWI and to evaluate potential perioperative risk factors.
Materials and Methods: A retrospective study was conducted of 55 consecutive paediatric patients (33 male, 22 female; median age 14 days, range 1 day - 14 years; median body weight 3.6 kg, range 2.0–63.0 kg) who underwent DSC between January 2013 and December 2014 at our centre. DSC was routinely performed after initial palliation for single ventricle disease (29%; n = 16). In all other cases decision for DSC was made electively inside the OR.
Results: Median duration of sternal opening was 3 days (1 to 32 days). Overall mortality was 14.5% (n = 8). Eight patients experienced SWI following DSC and wound cultures were positive in six cases, detecting staphylococcus aureus (n = 3), coagulase-negative staphylococcus (n = 2), and staphylococcus epidermidis (n = 1). One patient needed surgical revision for a deep SWI four weeks after chest closure. An indipendent perioperative risk factor for SWI was former support with ECMO (OR 7.07, 95% CI 1.27-39.41, p = .03). There was no significant correlation between SWI and prolonged cardiopulmonary bypass time (>180 min), aortic clamp time (>100 min), length of ICU stay (>7 days), duration of open chest (>4 days) and usage of foreign material during operation.
Conclusion: DSC is a safe and feasible procedure to avoid postoperative hemodynamic instability. Although, sternal wound infection is an aggravating side effect of DSC, especially in patients with ECMO, surgical revision is rarely needed.

P2137 - COMPREHENSIVE SURGICAL APPROACH DURING REPAIR OF MITRAL VALVE IN CHILDREN WITH SPECIAL EMPHASIS ON POLYTETRAFLUOROETHYLENE NEO CHORDAE

Anil Dharmapuram, Sudeep Verma, Nagarajan Ramadoss, Goutami Vejendla, Rao Ivatury
Kims Hospitals, Paediatric Cardiac Services, Secunderabad-India

Background: Repair of congenital mitral valve disease is a challenge. A combination of techniques are required to and avoid valve replacement which is a very difficult option in this subset.
Methods: Between June 2013 to December 2016, 30 patients underwent repair for mitral valve disease. The age ranged from 2 months to 12 years (median 24 months). The weight ranged from 3.7 to 22 kg (median 8.5 kg). Six patients had mitral stenosis (3 sub-valvular fusion and 3 supra-valvular ring). The remaining patients had mitral regurgitation and among them, the associated lesions were VSD (12), ASD (5) and ALCAPA (1). Three patients had an associated tricuspid valve repair. In patients with stenosis, resection of the ring and splitting of the sub-valvular papillary muscles was done. 15 patients had significant prolapse of the AML requiring caudal shortening in 2 and insertion of polytetrafluoroethylene (PTFE) neo-chordae in 13. In ALCAPA, quadrangular resection of the AML was done to reduce the bulk before insertion of the neo-chordae. In 3 patients, a separate scallop was repaired. For annular dilatation, a posterior annuloplasty was done with pericardial strip in 14 and a commissuroplasty in 5.
Results: There was no operative mortality. There was one late mortality in the 2 month old infant due to respiratory infection. During median follow up of 16 months, all the remaining patients were doing well with no significant decongestive therapy. Mitral regurgitation assessed was moderate in 8 patients and mild in the remaining 15 patients.
Conclusions: A combination of techniques are required during repair of mitral valve in children. Use of PTFE neo-chordae is always helpful to reduce prolapse and regurgitation. Avoiding valve replacement is an important strategy, but however long-term follow up is required to see if moderate regurgitation progresses.

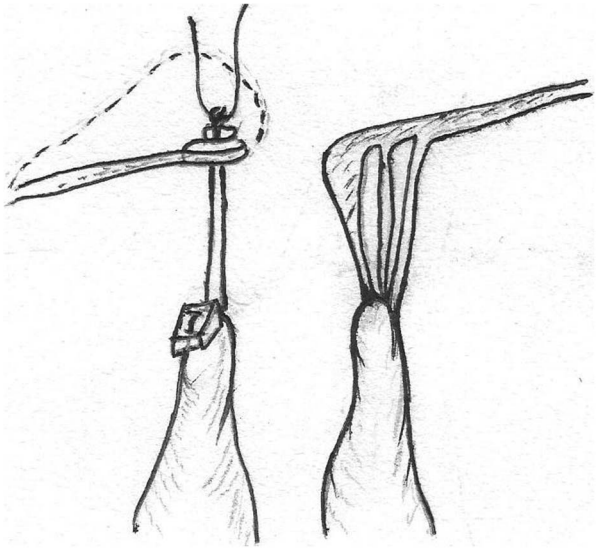

Figure 2.

P2138 - A NOVEL REPAIR TECHNIQUE OF CONGENITAL ABSENCE OF RIGHT PULMONARY ARTERY

Maria Von Stumm[1], Daniel Biermann[1], Urda Gottschalk[2], Götz Müller[2], Rainer Kozlik-feldmann[2], Gilles Greiwe[3], Matthias Göpfert[3], Hermann Reichenspurner[4], Arlindo Riso[1], Jörg S. Sachweh[1]
University Heart Center Hamburg, Department of Cardiac Surgery For Congenital Heart Disease, Hamburg-Germany[1]; University Heart Center Hamburg, Department of Paediatric Cardiology, Hamburg-Germany[2]; University Heart Center Hamburg, Department of Anaesthesiology, Hamburg-Germany[3]; University Heart Center Hamburg, Department of Cardiovascular Surgery, Hamburg-Germany[4]

Objectives: Isolated unilateral absence of a pulmonary artery (UAPA) is a rare lesion and early surgical repair of UAPA deems necessary to maintain pulmonary blood supply. Surgical approaches include creation of an aorto-pulmonary shunt or connection of a MAPCA, if present, to the main pulmonary artery (MPA) or

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

aorta. Here, we present a novel surgical technique using an autologous interposition tube graft, created from the roof of the MPA, to bridge the discontinued RPA.
Methods: An 8-days-old female (bodyweight 2,8 kg; 48 cm) with respiratory distress (SaO2 ~ 85%) was referred to our centre. Echocardiography revealed an absent RPA without other cardiac malformations. Catheterization depicted a normal-sized LPA and a ductus diverticulum at the brachiocephalic artery indicating a closed right ductus arteriosus originating from the hilar RPA (Figure1A). At surgery, a 1,5 × 3 cm piece of tissue was resected from the anterior wall of the MPA. To create a "tube", the graft was sutured around a 3mm Hegar pin. To get better access to the new RPA "bed", the ascending aorta was transected. Next, the "tube" was anastomosed to the hilar RPA and to the MPA. The MPA roof was augmented with an autologous pericardial patch (Figure1B-D).
Results: Follow-up was complicated by an anastomotic stenosis on the level of the hilar RPA. Therefore repeated balloon dilatation (Savvy 3mm/20 cm; SeQuent Please 4.0 × 17mm; BARD ultraverse 5 × 20mm) and finally stent implantation (Formula Stent 8 × 20mm; 7th postoperative month) were performed with good angiographic results (Figure1E). Today, 9 months after the inital operation, the RPA has an acceptable diameter (4mm) and the patient is thriving very well.
Conclusion: We describe a novel pulmonary graft interposition technique for UAPA repair using complete autologous material. Hence, the chance of future growth of the new RPA is increased with our approach. However, graft stenosis is of concern, mandating close follow-up and tailored treatment.

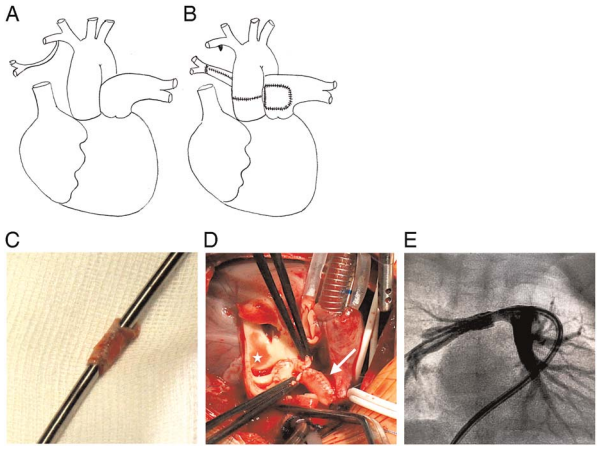

Figure 1.
Preoperative cardiac anatomy - absence of the right pulmonary artery, persistence of a right ductus arteriosus connecting the brachiocephalic artery with the hilar RPA (A). Postoperative cardiac anatomy - "tube" graft now in RPA position, MPA roof augmentation with autologous pericardial patch, transected aorta ascendens, excised right ductus arteriosus (B). Intraoperative creation of a "tube" graft using a 3mm Hegar pin 3mm and PDS 7x0 (C). Anastomosis of "tube" graft (white arrow) to the hilar RPA and MPA (white star) (D). Right heart catheterization after RPA stenting shows an acceptable RPA diameter (E).

P2140 - POST CARDIOTOMY EXTRACORPOREAL MEMBRANE OXYGENATION IN NEONATES – BENEFITS OF DELAYED SYSTEMIC HEPARINISATION

Maria Von Stumm[1], Irina Subbotina[2], Daniel Biermann[1], Urda Gottschalk[3], Götz Müller[3], Rainer Kozlik-Feldmann[3], Hermann Reichenspurner[2], Arlindo Riso[1], Jörg S. Sachweh[1]
University Heart Center Hamburg, Cardiac Surgery for Congenital Heart Disease, Hamburg-Germany[1]; University Heart Center Hamburg, Department of Cardiovascular Surgery, Hamburg-Germany[2]; University Heart Center Hamburg, Department of Pediatric Cardiology, Hamburg-Germany[3]

Background: Extracorporeal membrane oxygenation (ECMO) is a well-established treatment option for infants with postcardiotomy heart failure. However, ECMO support is associated with major complications such as excessive bleeding and thrombosis. Even though, a standardized protocol for anticoagulation on ECMO is currently missing. Thus, we seek to report our experience with a specific anticoagulation regime in neonates with postcardiotomy ECMO. The purpose of the present study was to investigate the impact of delayed systemic heparinisation on thrombosis (1), bleeding (2) and requirement of blood products (3) during ECMO treatment.
Materials and Methods: Retrospectively, we reviewed medical charts of fifteen neonates (mean age 13 ± 2.6 days; mean weight 3.1 ± 0.3 kg) who were placed on ECMO after biventricular or palliative cardiac surgery at our centre between October 2012 and May 2014. In all patients, anticoagulant effects of heparin were reversed by administration of protamine, platelets and fibrinogen (target ACT 120 ± 20 sec) with the beginning of ECMO support. Systemic heparinisation was delayed for 18 hours (range 8 – 37).
Results: Mean duration of ECMO support was 4.5 days. During that period, no thrombotic events were observed. 3 patients (20%) required re-thoracotomy for bleeding on the first postoperative day. Transfusion volumes were 24.5 ml/kg/d of packed red blood cells, 9.6 ml/kg/d of fresh frozen plasma and 7.5 ml/kg/d of platelets. Survival to hospital discharge was 87%. During follow-up (mean 15.5 month) there were no late thrombotic events observed.
Conclusion: Neonates with post-cardiotomy ECMO benefit from delayed systemic heparinisation in terms of low risk for thrombosis, reduced bleeding rates and low transfusion volumes. Though, research is clearly limited in this field. To improve neonatal and paediatric outcome on ECMO, a standardized anticoagulation protocol is urgently needed.

P2147 - SEVERE COMPLICATIONS OF INFECTIVE ENDOCARDITIS (IE) REPORT OF TWO CASES

Marilia Domingues, Salem Fraga, Raizza Costa, Alexandre Abla, Gabriela Mesquita, Viviane Sena, Andrey Monteiro, Marcelo Gomide, Walter Paiva, Cristiane Gomes
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Background: IE has nonspecific symptoms, so early diagnosis is often difficult. It presents a high morbidity and mortality. Complications such as abscesses and aneurysms are rare but potentially lethal. Both had poor dental hygiene.
Case 1: Nine-year-old boy with bicuspid aortic valve previously submitted to valve replacement. He was admitted with a history of fever for two weeks, weakness and conjunctival petechiae. Echocardiogram showed vegetation on the atrial side of the anterior leaflet of the mitral leaflet, which was also perforated and supravalvar aortic vegetation. Blood culture was positive for S. viridans and he was started on antibiotics. Computed tomography (CT) showed sings of hepatic, splenic and cerebral embolism. He was submitted to an emergency surgery, when an abscess was found in the fibrous skeleton of the heart and ascending aorta, as well as vegetations in the mitral and aortic valves. Successful Konno-Bentell surgery was performed. The histopathological

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

study demonstrated active IE. He had six weeks of venous antibiotic treatment after surgery, with good clinical outcome.
Case 2: Six-year-old boy, with previous diagnosis of ventricular septal defect (VSD), right ventricular muscle band and aortic regurgitation, with fever for four weeks and hyporexia. Echocardiogram showed a peduncular vegetation in the mitroaortic region and an aneurysm that extended from the base of the anterior mitral leaflet to the aortic root, measuring around 12 mm. He was submitted to surgery, with removal of vegetations, closure of the aneurysm ostium, aortic valve repair and ventriculoseptoplasty. Antibiotic therapy was continued for four weeks after surgery, with good clinical outcome.
Discussion: IE is a disease that should always be considered as a differential diagnosis of persistent fever, especially in children with structural disease and poor dental hygiene. The two reported cases of complicated IE had a favorable outcome, despite the severity of the lesions.

P2148 - PREDICTORS OF SURGICAL OUTCOME OF CRITICAL CONGENITAL HEART DISEASE IN THE DEVELOPING WORLD

Rekwan Sittiwangkul[1], Surin Woragidpoonpol[2], Suphachai Chuaratanaphong[2], Noppon Taksaudom[2], Suchaya Silvilairat[1], Krit Makonkaewkeyoon[1], Pawena Aneksomboonpol[3], Yupada Pongprot[1]
Chiang Mai University Hospital, Pediatric, Chiang Mai-Thailand[1] Chiang Mai University Hospital, Surgery, Chiang Mai-Thailand[2] Chiang Mai University Hospital, Pedaitric, Chiang Mai-Thailand[3]

Background: Despite a major improvement of cardiac surgery in neonates and infants with critical congenital heart disease (CCHD) currently, the mortality and morbidity of these patients remain high. Recent data of risk factors and surgical outcome of CCHD had been scanty reported among developing countries.
Objectives: To describe the patient characteristics and surgical procedures and to identify risk factors associated with in-hospital mortality in infants with CCHD at a single tertiary care center.
Method: Retrospective study of CCHD in infants who were newly diagnosed and underwent cardiac operation at Chiang Mai University Hospital, Thailand from January 2011 to December 2015.
Results: Among 183 critical congenital heart disease infants, 58% were male and the median gestational age was 38 weeks (range 27-42 weeks). The average birth weight was 2,873 ± 537 grams and 22 infants (12%) were preterm. The most common cardiac defect was TOF/PA or severe TOF (18.5%), followed by complete TGA (17%), COA or IAA (15%), single ventricle (14%), DORV (11%) and others (24.5%). Surgical procedures included modified BT shunt or central shunt (39%), simple or complexed COA or IAA repair (21%), arterial switch (15%), PA banding (9%), TAPVR repair (6%) and others (10%). The median age at palliative or corrective cardiac surgery was 29 days (interquartile range 12-89). The in-hospital mortality was 16.4% (30 of 183). Preoperative factors associated with in-hospital death were prematurity (OR 4.23, 95% CI 1.08-16.53, p = 0.038), and prenatal diagnosis (OR 6.45, 95% CI 1.59-26.18, p = 0.009), and postoperative risk factors for mortality were ECMO insertion (OR 14.23, 95% CI2.99-68.19, p = 0.001) and renal failure (OR 7.23, 95% CI 1.78-29.83, p = 0.006).
Conclusion: Surgical mortality for infants with critical congenital heart disease remains high in developing world with limited resource. Preterm infants were associated with high in-hospital mortality.

P2152 - ACUTE DYSFUNCTION OF RIGHT VENTRICULAR OUTFLOW TRACT VALVED CONDUIT IN THREE CASES IN THE FORM OF ANEURYSMAL DILATATION AND THROMBOSIS

Okan Yildiz[1], Erkut Ozturk[2], Behzat Tuzun[1], Bahadir Genc[1], Selman Gokalp[2], Alper Guzeltas[2], Sertac Haydin[1]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training And Research Center Hospital, Pediatric Cardiovascular Surgery, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[2]

Background: The Contegra® bovine jugular venous conduit is used to maintain continuity between the right ventricle and the pulmonary arteries. Younger patients and smaller grafts are risk factors for Contegra® failure and complications are possible due to variable flow in the distal pulmonary vasculature. However, early (first 30 days) aneurysmal dilatation and thrombosis are not common and have not been reported as a series. We would like to present 3 cases related to Contegra® dysfunction and replacement in early period.
Case Report: Between November 2014 and November 2016, 17 pediatric patients underwent right ventricular out flow tract reconstruction with Contegra® valved conduits. Three of these patients (<6 months) developed Contegra® (size <14 mm)

Table 1. Patients'demographics

CPB; Cardiopulmonary bypass, LCOS; Low Cardiac Output; ECLS; extracorporeal life support; E-CPR, extracorporeal cardiopulmonary resuscitation; PAs; Pulmonary Arteries

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

dysfunction in the early postoperative period (details are given in Table). ECLS support was needed in these patients because of postoperative RV failure. Conduit re-replacements were performed after diagnostic cardiac catheterization due to conduit dysfunction with high RV pressures. On inspection, the conduits were uniformly dilated and thrombosed (one completely, two partially). Degeneration, distal stenosis or dissection was not detected. After the surgery all of them were successfully weaned from ECLS. Postoperative course was unremarkable.
Conclusions: Contegra® conduit is widely applicable to RVOT reconstruction with satisfactory early and mid-term results. However, there is a significant incidence of conduit-related complications, particularly with the younger children (<1 year), smaller conduit sizes (12 and 14 mm) and high pulmonary resistance. The advantage of the Contegra® conduit over a homograft in smaller patients (<1 year) also remains uncertain. High pressure in the conduit may lead to aneurysmal dilatation and eventual valvular regurgitation. However, high pressure in the dilated conduit and valve sinuses may be associated with thrombosis. We would recommend cautious use and close follow-up of the conduits in the early postoperative period in these patients with high pulmonary artery pressures.

P2168 - LATE ARTERIAL SWITCH IN A PATIENT WITH TRANSPOSITION OF GREAT ARTERIES AND INTACT VENTRICULAR SEPTUM

Sertac Haydin[1], Erkut Öztürk[2], Okan Yildiz[1], Behzat Tuzun[1], Alper Guzeltas[2]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery Training and Research Center Hospital, Pediatric Cardiovascular Surgery, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[2]

Background: The primary arterial switch operation (ASO) has become the standard treatment of choice for transposition of the great arteries with intact ventricular septum (TGA-IVS) in the first few weeks of life. There is no any standard treatment protocol in patients more than 3 weeks of age.In this report a successful arterial switch procedure with ECMO support was presented in a patient with TGA-IVS.
Case Report: A 30 months old, Syrian male with a body weight of 12 kg was admitted to our clinic. Transthoracic echocardiography demonstrated transposition of great arteries and an atrial septal defect of 10 mm in diameter with colour Doppler. There was a banana-shaped LV involution.The measured LV/RV pressure ratio was 0.5 at the angiography. A decision was taken to proceed with an ASO. Due to insufficient LV contractions and hypotensive progress following weaning from cardiopulmonary bypass (CPB), the patient was switched to ECMO support at the postoperative second hour in the intensive care unit. Neck cannulation was performed. Inotropic support was typically administered as milrinone (0.5 microgram/kg/min) and a low dose of epinephrine (0.05 microgram/kg/min) for the first few postoperative hours. The ECMO support was reduced gradually and the patient was disconnected from the ECMO support at the end of one week.On the following days (postoperative 10th day) the general condition of the patient was good and LV returned to normal shape from the original banana shape. He was discharged without a neurologic sequela on the postoperative 20th day.
Conclusion: Late ASO operation can be performed safely in suitable patients with TGA/IVS after a detailed evaluation and with an efficient, advanced and suitable postoperative intensive cardiac unit monitorization.

P2170 - FATE OF THE LEFT VENTRICULAR OUTFLOW TRACT AFTER RASTELLI TYPE REPAIR IN 107 PATIENTS

Dawood K. Mehsood, Ramesh S. Kutty, John Stickley, Phil Botha, Natasha E. Khan, Timothy J. Jones, William J. Brawn, David J. Barron
Birmingham Children, Cardiac Surgery, Bimingham-United Kingdom

Objective: There are an increasing number of procedures for the correction of aorta arising predominantly from the Right Ventricle with a sub-arterial VSD. Rastelli repair has been subject to longest follow-up but has been criticized for a high incidence of subsequent Left Outflow Tract Obstruction (LVOTO). Resection of the infundibular septum and septomarginal muscle bundles may reduce this risk. This study addresses the risk of early and late LVOTO using Rastelli with muscle resection.
Methods: From 1988 to 2015 all 107 patients undergoing Rastelli-type procedure were studied and divided into, a. Rastelli Procedure in TGA/VSD with pulmonary atresia/stenosis (n = 44), b. Rastelli Procedure in ccTGA/VSD with pulmonary atresia/stenosis i.e. Rastelli-Senning (n = 48), c. DORV Repair in the setting of Pulmonary Stenosis/Atresia with Right Ventricle to Pulmonary Artery Conduit (n = 15).
Results: Median age at index operation was 3.2 years (IQR 1.8-6.3). VSD enlargement was performed in 28 patients. Median follow up time was 8.4 years (Range 0.2–26). 30 day mortality was 3.7% (n = 4) and late phase mortality at 27 years was 10.3%. Pacemaker was required in 7.4% (n = 8). Freedom from LVOT reintervention was 99 (CI 96-100) %, 97 (CI 92-99) % and 90 (CI 88-96) % at 1, 5 and 10 years respectively (Figure 1). There were no early deaths after reintervention for LVOTO (n = 9) and two cases required pacemaker. No patient required a second reintervention. Amongst LVOT reintervention group (n = 9), 6 had not had muscle resected at time of Rastelli.
Conclusions: The incidence of late LVOTO after Rastelli is not high, particularly with attention to muscle resection to enlarge the VSD. Reintervention is safe with no recurrence. The procedure has stood the test of time without destabilizing the aortic root or risking the coronaries. The optimal approach will only be evident when there is longer follow-up of more modern procedures.

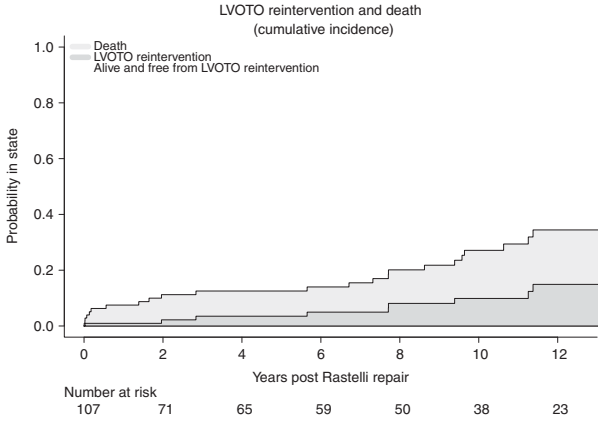

Figure.

P2179 - CONTEMPORARY OUTCOMES OF THE FONTAN OPERATION WHAT HAVE WE LEARNED IN 21 YEARS

Carlos Mery[1], Daniel Trujill-Díaz[1], Luis De León[1], Peter Ermis[2], Huirong Zhu[1], Iki Adachi[1], Lauren Kane[1], Jeffrey Heinle[1], Charles Fraser, Jr.[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Texas Children's Hospital/Baylor College of Medicine, Congenital Heart Surgery, Houston-United States[1]; Texas Children's Hospital/Baylor College of Medicine, Pediatric Cardiology, Houston-United States[2]

Background: The Fontan procedure is the accepted standard for single-ventricle palliation. Despite improvements in outcomes, ongoing assessment of risk factors for acute and chronic failure is important. We present one of the largest contemporary single-institutional cohorts.
Methods: Patients undergoing a Fontan operation between 1995 and 2016 were included. Failure was defined as death, transplantation, takedown/revision, fenestration creation or enlargement, plastic bronchitis, protein-losing enteropathy, or major perioperative reintervention. Multivariable logistic and Cox regression analyses were used. Data is reported as odds ratios (OR) or hazard ratios (HR) with 95% confidence intervals.
Results: The cohort included 610 patients. Median age at surgery and follow-up time were 4 and 6.8 years, respectively. Diagnoses were varied, with the most common being hypoplastic left heart syndrome (n = 154, 25%), tricuspid atresia (n = 103, 17%), and double-inlet left ventricle (n = 92, 15%). There were 113 patients (19%) with heterotaxy and 50 (8%) with a genetic syndrome or chromosomal abnormality. Surgical trends show increasing use of extracardiac conduits, non-fenestrated Fontan, and early extubation in the operating room. Overall, there were 15 heart transplants and 17 deaths throughout the follow-up period, with three deaths occurring in the perioperative period. Transplant-free survival at 5, 10, and 15 years was 97%, 94%, and 92%, respectively (Figure 1A); freedom-from-failure was 91%, 89%, and 87%, respectively (Figure 1B). Extubation in the operating room was associated with lower risk of acute failure (OR = 0.30, 0.11-0.87). Independent risk factors for chronic failure included genetic syndrome (HR = 2.54, 1.11-5.83), ventricular dysfunction (HR = 3.86, 1.81-8.24), cardiopulmonary bypass (CPB) time in 30-minute intervals (HR = 1.242, 1.100-1.402), and persistent pleural effusions (HR = 4.26, 2.25-8.07). Moderate/severe atrioventricular valve regurgitation (HR = 2.61, 1.13-6.02) and CPB time (HR = 1.223, 1.029-1.452) were associated with reduced long-term transplant-free survival.
Conclusion: Contemporary medium-term outcomes for Fontan patients are reassuring. Lifelong follow-up is mandatory to determine long-term outcomes and need for additional surgery as patients reach adulthood.

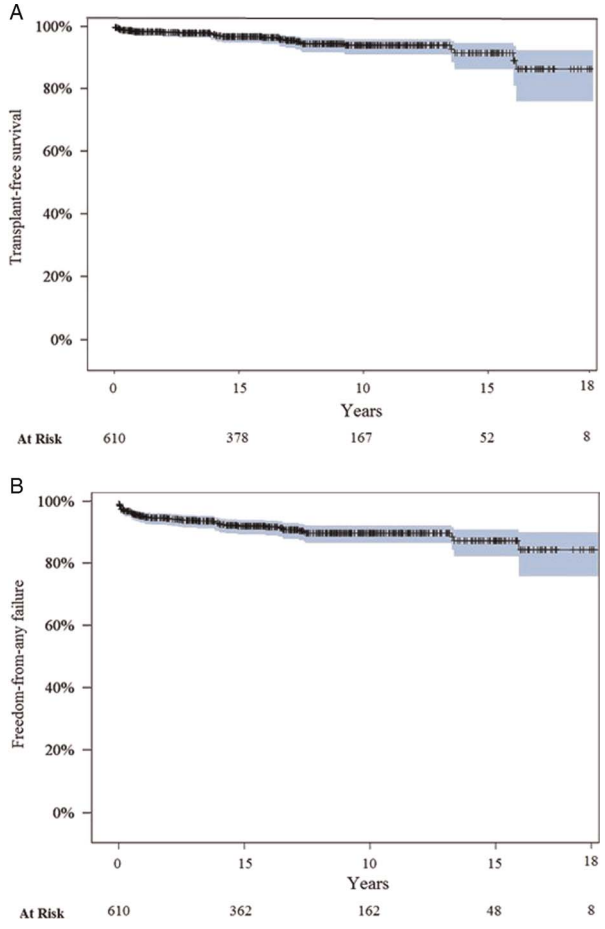

Figure.

P2184 - DURABILITY OF TISSUE ENGINEERED BOVINE PERICARDIUM (CARDIOCEL) WHEN USED FOR THE REPAIR OF CONGENITAL HEART DEFECTS AT 24 MONTHS OR LONGER FOLLOW UP

Douglas Bell[1], Sudesh Prabhu[2], Jane Armes[3], Robert Justo[4], Benjamin Anderson[4], Prem Venugopal[5], Tom Karl[6], Nelson Alphonso[5]
University of Queensland School of Medicine, Surgery, Brisbane-Australia[1]; Narayana Health, Cardiac Surgery, Bengaluru-India[2]; Mater Health Services, Pathology, Brisbane-Australia[3]; Queensland Paediatric Cardiac Services, Lady Cilento Children's Hospital, Cardiology, Brisbane-Australia[4]; Queensland Paediatric Cardiac Services, Lady Cilento Children's Hospital, Cardiac Surgery, Brisbane-Australia[5]; Johns Hopkins All Children's Hospital, Cardiac Surgery, St. Petersburg-United States[6]

Background: To investigate the indications for usage and incidence of failure of CardioCel (Admedus, Fremantle, Australia) when used for the repair of congenital heart defects in the paediatric population.
Material and Methods: Between October 2012 and November 2014, CardioCel was implanted in 130 patients (135 procedures, 194 implants) involving 16 (12%) neonates, 76 (56%) infants and 43 (32%) children >365 days with 99 (51%) simple septation procedures and 95 (49%) more complex three-dimensional reconstructions. All patients have been followed up for 24 months or longer. Implant failure was defined as embolism, infection, thrombosis, structural leak, radiologic evidence of calcification or re-intervention due to patch failure. Six explants underwent histological evaluation.
Results: CardioCel failed in 9 patients (6.7%) (neo-intima/granulation tissue formation in 8; thrombosis in 1). Only 1 implant failed within 30 days (IVC reconstruction; thrombosis). 7 of the 9 failures occurred within 12 months. 8 patients have required 12 re-interventions (6 catheter, 6 surgical). Both implants failed when used for intra-atrial baffle reconstruction in total anomalous pulmonary venous drainage and 2 of 3 implants failed when used for reconstruction of systemic veins. Cumulative freedom from implant failure was 95% (95% CI: 91–98) after 12 months, and 93% (95% CI: 89-97) after 24 months and 36 months. The incidence of failure in neonates was 18.7% (3 of 22 implants), compared to infants (6.6%; 5 of 115 implants) and older children (2.3%; 1 of 57 implants) (p = 0.14). Incidence of failure was higher when CardioCel was used for indications other than simple septation [9/95 (9.4%) versus 0/99, p = 0.001]. Histological evaluation of 6 explants demonstrated evidence of early remodeling.
Conclusion: CardioCel demonstrates good durability when used for the repair of congenital heart defects. The incidence of failure is higher when used for the reconstruction of systemic veins or anomalous pulmonary venous drainage.

P2185 - LONG TERM FOLLOW UP OF PULMONARY HOMOGRAFT PATCHES USED IN THE AORTIC POSITION IN CORRECTION OF PEDIATRIC CONGENITAL HEART DISEASE

Michael Lewis, Jens Johansson Ramgren, Torsten Malm
Skåne University Hospital, Pediatric Heart Surgery, Lund-Sweden

Background: Pulmonary homograft patches are vital components used in the reconstruction of a variety of congenital heart defects in children, particularly those requiring augmentation of the aorta. Long-term follow-up is important in the assessment of it as a reconstructive material. We present our single-institution follow-up of pulmonary homograft patches used in aortic position.
Materials and Methods: From 2001 to 2013, 70 patients (median age: 6.0 days, interquartile range: 2.0–12.8 days) underwent operative reconstruction for their heart defects which included aortic reconstruction with pulmonary homograft patches as the reconstructive material. Norwood-type aortic reconstruction was performed as the first stage of a single ventricle palliation strategy in 49 patients. Aortic arch hypoplasia (16 patients) with or without VSD and interrupted aortic arch (IAA) (five patients) accounted for the remaining patients.
Results: Complete follow-up (to be completed) was available in 58 patients (82.8%, range 2.9-13.0 years after graft implantation). Thirty-day mortality was 3.4%, and overall ten-year survival was 79%. Orthotopic heart transplantation was performed in four patients (6.9%) and ten-year transplant-free survival was 72%. Catheter-based reintervention was performed in nine patients (15.5%) of whom seven patients (12.1%) had intervention targeted to the area of prior patch reconstruction. Reoperation was performed in 35 patients (60.3%), of whom 21 patients were part of a planned staged palliation scheme. Rates of mortality (0%), reoperation (1.7%), and reintervention (12.1%) attributable to the area of patch intervention were low. No aneurysm formation of the patch areas was encountered.
Conclusions: Our diagnosis-specific survival data is similar with that of other high-volume centers. Our follow-up data shows that pulmonary homograft patches are a robust reconstructive material when used in aortic reconstruction for commonly-encountered pediatric congenital heart surgery diagnoses.

P2186 - THE ANALYSIS OF CONGENITAL HEART SURGERY RESULTS THE COMPARISON OF "RACHS 1 ARISTOTLE BASIC COMPLEXITY SCORE ARISTOTLE COMPREHENSIVE COMPLEXITY SCORE THORACIC SURGEONS AND EUROPEAN ASSOCIATION FOR CARDIOTHORACIC SURGERY MORTALITY CATEGORIES" SYSTEMS

Okan Yildiz[1], Taner Kasar[2], Erkut Ozturk[2], Behzat Tuzun[1], Husnu Firat Altin[1], Ismihan Selen Onan[1], Hasan Candas Kafali[2], Alper Guzeltas[2], Sertac Haydin[1]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiovascular Surgery, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[2]

Background: This study was about the comparison of the surgical results of our clinic according to presumption systems of RACHS-1 (Risk Adjustment in Congenital Heart Surgery), Aristotle Basic Complexity Score (ABC), Aristotle Comprehensive Complexity Score (ACC), Society of Thoracic Surgeons and European Association for Cardiothoracic Surgery mortality categories (STAT MC). Secondly our aim was to compare the affectivity of these systems to predict morbidity and mortality.
Materials and Methods: The classification and risk scoring of sequential 1950 patients who had congenital heart surgery with 4 different systems were performed between 1 October 2012- 31 December 2016. The outcome hospital mortality and morbidity (intensive care unit stay > 7days) was calculated for each category from the four models. The discriminatory ability of the models was determined by calculating the area under the ROC curve and a comparison between the curves of the four models was performed.
Results: The median weight of the cases was 7.2 kg (1.8-80 kg). Among the patients, 53% were male and 47.5% were younger than one year of age. Of 1950 operations, there were 149 (7,6%) deaths, and 541 (27,7%) morbidity (Table 1). For mortality, areas under the ROC curve were 0.803, 0.795, 0.729 and 0.712 for the STS-EACTS MC, ACC, RACHS-1, and ABC scores, respectively. For morbidty, areas under the ROC curve were 0.732, 0.731, 0.730 and 0.685 for the STS-EACTS MC, RACHS-1, ACC, and ABC scores, respectively (Table 2).
Conclusion: STAT MC and ACC systems were successful to predict morbidity and mortality of patients who would have congenital heart surgery and to evaluate the performance of the surgical centers. But STS-EACTS MC was on the fore front due to high feasibility and performance. It is easy, objective and safe for a small number of operations. ABC system had the lowest performance alone. Combinations of systems during valuation will provide the most benefit.

Table 1.

	Mortality*		Morbidity&

P2187 - THE EFFECT OF UPPER BODY CENTRAL VENOUS CATHETER INSERTION ON SUPERIOR VENA CAVA ANATOMY AND SYSTEMIC VENOUS RETURN IN INFANTS WITH SINGLE VENTRICLE

Okan Yildiz[1], Ibrahim Cansaran Tanidir[2], Behzat Tuzun[1], Emre Yasar[1], Hasan Candas Kafali[2], Erkut Ozturk[2], Alper Guzeltas[2], Sertac Haydin[1]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiovascular Surgery, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[2]

Background: The upper-body central venous (UBCV) catheter insertion is a widespread technique during pediatric cardiac surgery but might result in obstruction. This complication may especially have serious results in patients with cavopulmonary shunt (CPS). In this study our aim is to evaluate the effect of UBCVC insertion at first operation on superior vena cava (SVC) anatomy and systemic venous return during inter stage period.
Methods: The data of 103 children, who underwent palliation for single-ventricle (Norwood operation = 8, stage 1 hybrid palliation = 8, systemic to pulmonary artery shunt = 29, PA banding = 38, PDA stenting = 20) and consequently pre-CPS cardiac catheterization between 2010- 2016 were gathered retrospectively. Patients were grouped as the ones who had UBCV catheter (group 1) and ones who did not have (group 2). The SVC size was evaluated with SVC index and SVC/Nakata index ratio.
Results: UBCV obstruction occurred in 5 of 34 (14.7%) patients in group 1, and in 2 of 69 (2.9%) patients in group 2 (p = 0.038). There were 6 mortality in group 2 and 3 mortality in group 1 but there was no significant difference in mortality (p = 1.0). The mean duration of catheterization was 9 days for group 1 and this was longer in patients who had UBCV obstruction (11.4 days). The demographic data of the patients are demonstrated in Table 1.
Conclusion: This study showed significantly higher risk prevalence of obstruction in group 1. Although, there was no difference between the two groups in terms of indexes, this result might be due to high risk of venous thrombosis and stenosis associated with upper body central line placement. UBCV catheter insertion in patients with univentricular cardiac anatomy might not be proper. Future studies with larger sample sizes will help to clarify this problem.

P2189 - OUTCOMES OF THE BLALOCK TAUSSIG SHUNT IN THE CURRENT ERA A SINGLE CENTER EXPERIENCE

Navaneetha Sasikumar[1], Anthony Hermuzi[1], Jin Lee[1], Rajiv Chaturvedi[1], Edward Hickey[2], Osami Honjo[2], Glen Van Arsdell[2], Christopher Caldarone[2], Lee Benson[1]
The Hospital for Sick Children, Division of Cardiology, Toronto-Canada[1]; The Hospital for Sick Children, Division of Cardiovascular Surgery, Toronto-Canada[2]

Background: Mortality associated with the Blalock-Taussig shunt (BTS) is high in the current era despite advances in perioperative management. This study was formulated to provide data on [1] current indications, [2] outcomes, and [3] factors affecting mortality and morbidity.
Materials and Methods: A retrospective single center chart review identified 95 children operated between 2004 and 2014. Mortality and major morbidity (cardiac arrest, ECMO, re-operation (any cause), catheter intervention) were analyzed using the Kaplan-Meier method. Risk factor analysis was conducted using Cox's proportional hazard regression.
Results: The median age was 8 (0-126) days, weight 3.1(1.7-5.4) kg. 73% were neonates, another 73% had single ventricle physiology (HLHS excluded), 58% were duct dependent. Pertinent surgical data and outcomes are summarized in the table.At 1-year, survival from a BTS was 82% (95% CI [72.7%, 88.4%]), survival free of major morbidity 61.4% (95% CI [50.7%, 70.5%]). On regression analysis, duct dependency predisposed to mortality (p = 0.01, HR 6.74 [1.54, 29.53]) and composite outcome of mortality and major morbidity (p = 0.04, HR 2.15, CI [1.036, 4.466]) and higher graft index to mortality (p = 0.005, HR 1.07 [1.02, 1.12]).
Conclusions: The commonest indication for a BTS was for children with single ventricle physiology. This is different from other published large databases such as the Society of Thoracic Surgeons' series. This difference could be the result of early complete repair and interventional palliation for children with tetralogy of Fallot physiology. The morbidity and mortality associated with a BTS was considerable, partly explained by a higher risk population. The incidence of pulmonary over circulation was high compared to other published series. Change in technique e.g., sternotomy as default approach was notable, which needs further evaluation. Whether wider adaption of interventional palliation in place of BTS would improve outcomes also requires further investigation.

Table.

Sternotomy	92 (97%)	Hospital mortality	11 (12%)
BT shunt size 3 mm 3.5 mm 4 mm	24 (25%) 66 (70%) 5 (5%)	Interval mortality (from hospital discharge to planned surgery)	6 (6%)
Graft index (shunt cross sectional area (mm^2)/ BSA (m^2)	44.39 ± 8.0 4	Interval mortality (from hospital discharge to planned surgery)	6 (6%)
Shunt size (mm) to body weight (kg) ratio	1.1 ± 0.2	Shunt thrombosis (confirmed on angiogram/surgery)	12(12%)
CPB	11 (12%)	Symptomatic shunt stenosis (from insertion to takedown)	10 (11%)
Pul arterioplasty	17 (18%)	Pulmonary over circulation	28 (30%)
Outcomes		Reoperation (any cause)	12 (12%)
ICU stay (days)	8 (1-268)	Catheter interventions	8 (8%)
Hospital stay (days)	15 (1-294)	Pul arterioplasty at planned surgery	53/73 (73%)

P2193 - WHAT STIMULATES ENDOCARDIAL FIBROELASTOSIS FORMATION

Carina Vorisek, Viktoria Weixler, Shogo Shimada, Massiel Dominguez, Pedro Del Nido, Ingeborg Friehs
Boston Children's Hospital, Cardiac Surgery, Boston-United States

Background/Hypothesis: The underlying mechanism of endocardial fibroelastosis (EFE) formation is transformation of endocardial endothelial to mesenchymal cells (EndMT) as we have previously reported but the trigger is unknown. Clinical observation indicates that distension of the left ventricle is directly linked to progression of EFE. We developed an isolated whole heart combined with an endothelial cell culture model to test whether cellular strain induces EndMT.
Materials/Methods: Endothelial cells in culture (n = 3/group) were exposed to 10% uniaxial static stretch for 10 hours (stretch) with or without BMP7 (TGF-β inhibitor) on a gelatin-based drug carrier (drug delivery). Cells treated with media served as controls (control). Immature isolated perfused rat hearts (n = 3/group) were stretched to 30% of their original length for 3 hours (stretch) or treated with BMP7 localized drug delivery into the LV (drug delivery) or perfused only (control). Histological analysis by staining for VE-cadherin or CD-31 (endothelial marker) and αSMA (mesenchymal marker) was performed. Double-staining with both markers was indicative of EndMT. Statistical analysis was performed with ANOVA and Dunn's post hoc analysis. Data are expressed as mean ± SEM.
Results: In isolated endothelial cells in culture and endocardial endothelial cells in a whole heart preparation, stretch induced EndMT, reflected by significantly more double-stained endothelial cells in culture (46 ± 13% of total cell count) and endocardial cells in whole hearts (22 ± 4% of total cell count) compared to controls (cells: 7 ± 2%; heart: 6 ± 2%; $p < 0.05$ compared to stretch). In the BMP7 drug delivery group, significantly less double-stained cells were observed compared to stretch and with similar counts as in controls (cells: 7 ± 2%; heart: 3 ± 1%; $p < 0.001$).
Conclusion: In this study, we could show that mechanical strain induces EndMT. Furthermore, feasibility of localized inhibition of EndMT was demonstrated by BMP7 administration at the site of active EndMT. Successful inhibition of EndMT with BMP7 points toward a TGF-β mediated mechanism.

P2202 - MODIFIED VERSUS CONVENTIONAL ULTRAFILTRATION IN PEDIATRIC CARDIAC SURGERY BEHAVIOR OF THE IONS AND GLUCOSE TIME AND VOLUME TAKEN

Ana Maria Rocha Pinto E Silva, Valquiria Pelisser Campagnucci, Glaucio Furlanetto
Santa Casa Medical School, Department of Surgery, São Paulo-Brazil[1]

Introduction: The correction of congenital heart diseases whith cardiopulmonary bypass (CPB) always increases capillary permeability and retention of body fluid, leading to edema and dysfunction in brain, heart and lungs. The techniques to reduce the malefic effects of hemodilution are: Convecional Ultrafiltration (UF) during CPB and Modified Ultrafiltration (MUF) performed immediately after CPB.
Objective: The aim of this prospective study was to analyze the behavior of the main electolytes and Glucose in blood and fluid filtered by both techniques and to correlate the time and volume of fluid withdrawn by MUF. Method: Fifty-eight children were operated on, with UF in thirty (G1)and MUF in twenty-eight (G2). K, Na, Mg and Glucose were measured in the blood and the filtered fluid at the end of the procedure.
Results: G1: Glucose and K had similar values in serum and fluid at the end of CPB ($p = 0.887$ and $p = 0.978$). Na presented significant differences ($p < 0.001$), with a lower value of Na in fluid than serum. Mg presented lower values in the fluid($p = 0.001$). UF presented a mean time of 80.26 ± 36.26 and mean volume of 326,66 ± 126.83. G2: Glucose and K presented similar values in blood and fluid ($p = 0.222$ and $p = 0.568$). Lower values of Na and Mg were found in the fluid ($p < 0.001$ and $p = 0.038$). MUF time presented a mean of 14.39 ± 1.87 and the volume of fluid was 193.21 ± 29.07. The correlation between the time of MUF and volume was statistically significant ($p = 0.033$) and positive ($r = +0.405$), suggesting interdependent time and volume.
Conclusion: The results showed that, in UF and MUF, the filtrate has similar values of Glucose and K, and lower of Na and Mg, compared to serum values. MUF can be done choosing either time or fluid volume.

P2214 - MODIFIED IN SITU PERICARDIAL REROUTING TECHNIQUE FOR SCIMITAR SYNDROME REPAIR

Ignacio Lugones[1], Juan Alberto Kiang[1], Cesar Bodetto[1], Victoria Eugenia Pacheco Zerpa[1], Martínez Inés Ana[2], Biancolini María Fernanda[2], Damsky Barbosa Jesús María[2], De Dios Ana María[2]
Children´s Hospital Buenos Aires "Pedro De Elizalde", Cardiac Surgery Unit, Buenos Aires-Argentina[1]; Children´s Hospital Buenos Aires "Pedro De Elizalde", Cardiology Department, Buenos Aires-Argentina[2]

Introduction: Several surgical strategies have been described to redirect right pulmonary venous return to the left atrium (LA) in scimitar syndrome. A major complication of these procedures is pathway obstruction. In 2012, we described an alternative strategy to reduce the incidence of this complication. The in situ pericardium is used as an interposed pathway between the scimitar vein (SV) and the LA. We present a modification of this technique, especially useful in small children with marked malrotation of the heart and preoperative SV obstruction.
Materials and Methods: Patients: Two boys, 10 and 24 years-old, with recurrent pneumonias and pulmonary overflow were submitted to surgery after collateral embolization. The older boy had preoperative SV stenosis. Surgical technique: Through median sternotomy, the right pleural space is opened. After being transected above the diaphragm, the SV is longitudinally opened and sutured side-to-side to a similar incision in the lateral pericardium. Cardiopulmonary bypass with bicaval standard cannulation and mild hypothermia is established. As the LA cannot be reached from the right pulmonary venous pericardial recess, a large posterior right atriotomy is made after aortic crossclamping. Through it, the posterior portion of the atrial septum is detached from its insertion line and sutured to the anterior border of the atriotomy to close the right atrium, leaving below a wide left atriotomy. Finally, the in situ pericardium is sutured to the external surface of the heart around the left atriotomy, creating a pathway between the SV and the LA.
Results: Both patients had fast uneventful recovery, and were discharged 5 days after surgery. Postoperative echocardiogram showed wide unobstructed connection between the SV and the LA.
Conclusion: In situ pericardial rerouting technique combined with atrial septum repositioning can effectively restore normal connection between the pulmonary venous return and the LA in scimitar syndrome, by means of a straightforward, reproducible and low-risk procedure.

P2236 - DIFFERENT RESPONSES TO PRESSURE VOLUME LOAD IN RIGHT VENTRICLE HYPERTROPHY OF CYANOTIC CONGENITAL HEART DISEASE IN A RAT MODEL

Lei Qi, Sen Zhang, Shoujun Li, Kai Ma, Qiumin Chen, Fengpu He
Fuwai Hospital,Peking Union Medical College., Center of The Cardiac Surgery., Beijing-China

Objective: Right ventricular (RV) function plays a determinant role in the long-term morbidity and mortality in cyanotic congenital heart disease (CCHD), and it is strictly correlated to residual pulmonary artery stenosis or regurgitation postoperatively. However, the biomolecular changes of myocardial cell under abnormal loading pressure remain unclear. For left ventricular (LV) function, calcineurin-activation is a major factor for the development of pathological hypertrophy. We studied the functional changes of myocardial cell of the chronic hypoxia induced right ventricular hypertrophy in a rat model and the corresponding calcineurin-activation under cellular level.
Methods: Male Sprague-Dawley rats (4wk) were placed in a chamber maintained at 10% O2 for 4 week. The chamber was constantly flushed with room air to maintain low (<0.5%) CO2 concentrations. O2 (10% ± 0.5%) was maintained by a Real-time control system with 100% N2 imported. Then rats were subjected to pulmonary artery banding (PAB), pulmonary regurgitation (PR), and sham surgery (Control). After operations, rats were kept in normal air (21% O2). Six months later, rats were functionally evaluated with cardiac echocardiography (ECG), cardiac magnetic resonance imaging (CMR) and right ventricular pressure measurements. Right ventricular hypertrophy and calcineurin-activation were assessed after sacrifice.
Results: Rats with increased pressure load (PAB) or volume load (PR) of the RV developed similar degrees of hypertrophy, yet revealed different functional and molecular adaptation. By comparison, PAB increased the expression of Modulatory-Calcineurin-Interacting-Protein 1 (MCIP1), indicating calcineurin-activation, and the ratio of beta/alpha-Myosin Heavy Chain (MHC). In addition, PAB induced moderate RV dilatation with normal RV output at rest. In contrast, PR did not increase MCIP1 expression, but increased RV volumes and output obviously.
Conclusions: Pressure and volume load induced different functional and molecular adaptations in RV after chronic hypoxia induced ventricular hypertrophy. These results may give a new direction for the therapeutic strategies of CCHD.

P2246 - SHORT TERM OUTCOME OF SYSTEMIC TO PULMONARY ARTERY SHUNT PROCEDURES IN PAEDIATRIC PATIENTS SINGLE TERTIARY CENTRE CONTEMPORARY EXPERIENCE

Margarita Bartsota[1], Precylia Fernandes[1], Rajarshi Pal[1], Anke Furck[1], Michael Rigby[1], Olivier Ghez[2], Guido Michielon[2], Imran Saeed[2], Zdenek Slavik[1]
Royal Brompton And Harefield Nhs Trust, Paediatric Cardiology, London-United Kingdom[1]; Royal Brompton And Harefield Nhs Trust, Paediatric Cardiothoracic Surgery, London-United Kingdom[2]

Background/Hypothesis: Systemic-to-pulmonary artery shunts are initial palliative surgical procedures in a wide variety of congenital heart defects with biventricular (BV) or univentricular (UV) physiology. Morbidity and mortality associated with these procedures are not insignificant and they vary widely among institutions and databases reviewed.
Materials and Methods: Between January 2011 and December 2015, 101 patients (53 males, 53%) underwent 125 systemic-to-pulmonary artery shunt operations in a tertiary paediatric cardiac centre. We assessed early post-operative mortality and morbidity and identified risk factors that influence outcome.
Results: Fifty-seven patients (56%) had BV physiology and 44 (44%) had UV physiology. Forty-seven patients (46%) had exclusively shunt-dependent pulmonary blood flow and 54 (54%) had additional pulmonary blood supply. Median age at operation was 64 days (1-2623 days) and median weight 4.3 kg (1.6-18.7 kg). Median size of the shunt was 4mm (3-5 mm) and median post-operative length of stay in the intensive care unit (ICU) was 5 days (range: 1-164 days). There were 8 (7.9%) in-hospital deaths; 1 (1.7%) death in the BV group and 7 (15.9%) deaths in the UV group. There were 2 (3.7%) deaths in the group with additional pulmonary flow and 6 (12.8%) deaths in exclusively shunt-dependent patients. Only 2 (1.9%) patients developed necrotising enterocolitis post-operatively (both in the UV and shunt-dependent group). Spearman's correlation coefficient between age at the time of shunt insertion or weight at the time of shunt and length of stay in ICU was -0.25 and -0.27, respectively.
Conclusions: Short-term mortality following systemic-to-pulmonary artery shunt was markedly lower in patients with biventricular physiology and/or additional pulmonary flow source in our institution. Patient dependent factors other than early shunt patency impact on early postoperative mortality in our series. These findings will serve as a benchmark for currently used transcatheter ductal stenting procedures.

P2257 - THE SANO MODIFICATION OF NORWOOD PROCEDURE REDUCES MORTALITY AT STAGE I BUT INCREASES RE INTERVENTION ON PULMONARY ARTERIES AT STAGE II

Antonio Ravaglioli[1], Andrew Ho[1], Jacqueline Gillespie[1], Anna Zingale[1], Amandine Martin[2], Tara Bharucha[1], Markku Kaarne[1], Nicola Viola[1]
University Hospital Southampton, Wessex Congenital Cardiac Centre, Southampton-United Kingdom[1]; Bordeaux Heart University Hospital, Department of Cardiovascular Surgery, Bordeaux-France[2]

Background/hypothesis: Pulmonary artery (PA) distortion can compromise outcomes of surgical palliation of hypoplastic left heart syndrome (HLHS). We investigated the influence of stage I operative strategy on PA anatomy and outcomes.
Materials and methods: All patients palliated for HLHS (hybrid procedures excluded) between 2005 and 2016 at our institution were included. PA angiography was analyzed by a single reviewer. T-tests for continuous variables and Fisher's exact test for dichotomous variables were used.
Results: Twenty-five patients underwent Stage I with BT shunt (group A) and 15 with a Sano modification (group B), of which 14 to the left, one to the right of the neo-aorta. Median age at surgery was 6 days (range 1-99 days). Mortality up to stage II was 20% and 6.6% in group A and in group B, respectively. Thirty-four proceeded to bidirectional cavopulmonary shunt (BCPS – stage II), 28 having undergone a pre-procedural catheter. Median age at stage II was 114 days (range 30-510 days). Cross-clamp and bypass times were longer in group B, this did not reach statistical significance ($p = 0.2$). Twelve patients (86%) in group B required PA reconstruction compared to 3 (15%) in group A. Pre-stage II angiography revealed a 'Y' shape of the branch PAs in most patients in group B with significant origin stenosis in 9 patients, as opposed to an inverted 'T' shape in most group A with origin stenosis only in one. Mortality at 12 months following BCPS was 15% and 28.5% in group A and in group B, respectively.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: Stage I mortality tended to be lower in group B, but tended to increase at stage II, though the difference did not reach statistical significance at either stage. However, there was a significantly higher requirement for branch PA repair in group B at stage II, perhaps due to Y-shape induced stenosis.

P2258 - MITRAL VALVE REPAIR IN THE FIRST YEAR OF LIFE – OUTCOME AND REOPERATION

Julie Cleuziou[1], Keti Vitanova[1], Nora Lang[2], Jelena Pabst Von Ohain[1], Masamichi Ono[1], Elisabeth Beran[1], Janez Vodiskar[1], Rüdiger Lange[1]
Department of Cardiovascular Surgery, German Heart Center, Munich-Germany[1]; Department of Pediatric Cardiology, German Heart Center, Munich-Germany[2]

Objectives: Mitral valve repair (MVR) in neonates and infants is challenging and standardized methods of repair are not established. The aim of our study was to review our results of patients undergoing MVR at the age of one year or less.
Methods: Patients who underwent MVR between 1975 and 2016 were identified from our departmental database. Preoperative, surgical, postoperative and follow-up data were analysed with a focus on surgical method and echocardiographic data. End-points of the study were: mortality and mitral valve reoperation.
Results: During the study period, a total of 21 neonates and infants underwent MVR. Mean age was 4.9 ± 2.8 months, mean weight was 5 ± 1.5 kg. Eighteen patients (86%) presented with mitral valve regurgitation and 3 patients (14%) with mitral stenosis. In 17 patients (81%) the etiology of the mitral valve disease was congenital, 4 patients had an acquired mitral valve disease. Surgical repair techniques included closure of a commissure (n = 4, 19%), cleft closure (n = 4, 19%), splitting of papillary muscles (n = 5, 24%) and patch augmentation of a leaflet (n = 2, 9.5%). Two patients died within 30 days (9.5%), no patient died during a median follow-up of 8.3 years [20 days–29 years]. On discharge echocardiography, the size of the left ventricle ($p = 0.008$) and the mitral valve regurgitation had decreased significantly ($p = 0.001$). Seven patients (33%) required a mitral valve reoperation at a median time of 36 days [3 days – 2 years] after initial repair. Reoperation consisted of a re-repair in 3 and a mitral valve replacement in 4 patients. Freedom from mitral valve replacement at 10 years was 78.3 ± 9.8%.
Conclusion: MVR in neonates and infants can successfully reduce the size of the left ventricle and the degree of regurgitation. Overall survival is satisfactory, but reinterventions are necessary in selected patients.

P2267 - SURGICAL IMPACT OF TAILORED STRATEGIES FOR PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM ASSOCIATED WITH DEVELOPED SINUSOIDS

Sadahiro Sai, Satoshi Matsuo, Akinobu Konishi, Maoki Masaki
Miyagi Children's Hospital, Cardiovascular Surgery, Sendai-Japan

Background/Objectives: Pulmonary artery atresia (PA/IVS) with developed sinusoidal communication (SC) have a possibility of the RV dependent coronary circulation (RVDCC). Postoperative course with this entity often results in unfavorable course due to coronary ischemia. This study was set to investigate changes of SC through staged surgeries, and assess the efficacy of the tailored managements for this group.
Methods: 11 consecutive PA/IVS patients with SC were enrolled from 2008 to 2015. All patients have developed SC (RVDCC 36%) and hypoplastic right ventricle (RVEDV: 22.5 ± 12.0% of N) and aimed at single ventricle repair. Their average age and body weight at Blalock shunt (BTS) was 45.8 ±15.1 d and 3.1 ±0.3 kg. Severity of SC was graded by SC score at the angiogram before each stage. A week before BTS, lowering preoperative SpO2 (targeted 75-80%) was maintained to avoid heart failure by controlling lipoPGE1 or N2 inhalation while checking BNP level to decide timing of surgery (BNP < 500 pg/ml). At bidirectional Glenn shunt (BDG), Veno-Veno ECMO was used to prevent intraoperative myocardial ischemia derived from decompression of RV pressure. Myocardial ischemia was evaluated at each stage by I-123 BMIPP.
Results: There was no mortality. TCPC were completed in all patients. By the time of BTS, BNP level gradually decreased (max preoperative value: 1562.7 ± 1608.8 pg/ml, at op. value: 503.9 ± 670.7 pg/ml). At TCPC, 3 pts. were operated with V-V ECMO (total score >4), and 8 pts. with V-A bypass. The SC scores are shown in Table. Myocardial ischemia was detected in 5 pts before BDG, but improved in 2 at TCPC.
Conclusions: Tailored managements could contribute to the better results in this study. While regression of SC was shown in some cases, prevention from heart failure at BTS and control of RV pressure at BDG and TCPC are key to improve prognosis.

P2268 - RISK FACTORS FOR MORTALITY IN REOPERATIONS FOR PEDIATRIC AND CONGENITAL HEART SURGERY IN A DEVELOPING COUNTRY

Carlos Andres Villa Hincapie[1], Marisol Carreño Jaimes[1], Carlos Eduardo Obando Lopez[2], Jaime Camacho Mackenzie[1], Juan Pablo Umaña Mallarino[1], Néstor Fernando Sandoval Reyes[2]
Fundación Cardioinfantil - Instituto De Cardiología, Cardiac Surgery, Bogota-Colombia[1]; Fundación Cardioinfantil - Instituto De Cardiología, Congenital Heart Institute, Bogota-Colombia[2]

Background: The survival of patients with congenital heart disease has increased in the last years, because diagnosis improvement, better surgical techniques and perioperative care. Many patients will require reoperations as part of the stage procedures, grafts deterioration and residual or recurrent lesions. It has been discussed if cardiac adhesions in reoperations consequently increase surgery time, morbidity and operative mortality. The objective of the study was to describe the risk factor for mortality in pediatric patients undergoing a reintervention for congenital heart disease.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Methods: Historic cohort of patients underwent reoperations after pediatric cardiac surgery from January 2009 to December 2015. Previous surgical approach different to sternotomy were excluded from the analysis.
Results: In seven years, a total of 3.086 surgeries were performed, 481 were reoperations and 238 patients fulfilled the inclusion criteria. Mean reoperation rate was 1.4 ± 0.6 surgeries. Median age at the time of reoperation was 6.4 years. The most common surgical procedure was staged approach for univentricular heart disease (17.6%). Median cross clamp time was 66 minutes. Younger age at the moment of resternotomy, longer cross clamp time and a STAT risk category greater than 3 were risk factors for mortality. The number of re esternotomies was not associated to mortality. No intraoperative mortality was reported. In-hospital mortality was 4.6% and thirty days mortality was 0.54%.
Conclusions: Resternotomy in pediatric cardiac surgery is a safe procedure in our center with low mortality.

P2269 - OPEN CHEST IN COMPLEX CONGENITAL HEART SURGERY WHICH FACTORS AFFECT THE NEW ONSET INFECTION

Carlos Eduardo Obando López[1], Néstor Fernando Sandoval Reyes[1], Marisol Carreño Jaimes[2], Albert Franz Guerrero Becerra[1], Jaime Camacho Mackenzie[2], Sonia Emilsen Morales Echavarria[1], Juan Pablo Umaña Mallarino[2]
Fundación Cardioinfantil - Instituto De Cardiología, Congenital Heart Institute, Bogota-Colombia[1]; Fundación Cardioinfantil - Instituto De Cardiología, Cardiac Surgery, Bogota-Colombia[2]

Objetive: left the sternum open and packed after pediatric cardiac surgery optimizes systolic and diastolic ventricular function, improve ventilator mechanics and volumes as well as the state of tissue´s perfusion; however, it is associated with increased risk of septic complications. This study was designed to identify risk factors for the development of infection associated with the use of delayed sternal closure in pediatric cardiac surgery.
Methods: Case-control study nested in a cohort of patients with congenital heart disease undergone to surgery. We selected those who were managed with delayed sternal closure. Cases were infected patients while controls were free of it. The association between perioperative variables and the risk of infection was analyzed.
Results: Between January 2010 and September 2016, 3011 patients were operated of which 220 met the study criteria. Median age of 1.4 months (IQR 0.5-5.2). Under one month of age (63.9% vs 36.6%, p = 0.004), stunting (51(48.5-52) vs 54(50-63), p = 0.003) and malnutrition (75% vs 47.2%, p = 0.02) was significantly associated with the development of infection. Risk categories according to disease and type of surgery showed equal distribution between groups. The need for reintervention in the open mediastinum also was strongly associated with infection (30.6 vs 10.6, p = 0.005). Bivariate analysis confirms the association between infectious complications and neonatal age (OR 3.1; CI 95%(1.4-6.6), p = 0.004) and also with the need for preoperative inotropic and/or ventilator support (OR 2.6; CI 95%(1.1-6.3), p = 0.04). On the other hand, a good nutritional state was a protective factor (OR 0.37; CI 95%(0.16-0.86), p = 0.02).
Conclusions: Preoperative factors such neonatal age, low weight and/or height, malnutrition, use of inotropic support and mechanical ventilation along with the need of reinterventions in the open chest represent risk factors for the development of local or systemic infections in patients managed with delayed sternal closure after surgical correction of congenital heart disease.

P2276 - SYSTEMIC TO PULMONARY ARTERY SHUNTING WITH HEPARIN BONDED GRAFTS

Yuletta Ambarsari[1], Ariawan Purbojo[1], Robert Blumauer[1], Martin Glöckler[2], Okan Toka[2], Robert Cesnjevar[1], Andre Rüffer[1]
Hospital University of Erlangen, Department of Pediatric Cardiac Surgery, Erlangen-Germany[1]; Hospital University of Erlangen, Department of Pediatric Cardiology, Erlangen-Germany[2]

Objective: Systemic to pulmonary artery shunting remains an important palliative procedure for complex congenital heart defects. The use of Heparin-bonded polytetrafluorethylen shunts (HBPS) should decrease the risk of graft occlusion. This study summarizes the results of a single-center after implantation of HBPS in pediatric patients.
Methods: The records of 54 patients treated with HBPS between 2010 and 2016 were retrospectively reviewed. Median age and weight were 14.2 days (range 3-83 days) and 3.25 kg (range 1.8-5.7 kg), respectively. Selected shunt size was 3.5 mm in all except 1 patient (4.0 mm). Seventeen patients (32%) were planned for future biventricular repair and 37 patients (68%) went the univentricular pathway. Shunt modifications included central aorto-pulmonary shunts (n = 35) and modified Blalock-Taussig shunts (n = 19).
Results: Shunt patency until the next surgical treatment was 88 ± 5% after a median duration of 115.4 days (range: 0-241 days). Next surgical treatment in patients with open graft included corrective surgery (n = 9), Glenn procedure (n = 23) and new shunt (n = 5). Patients with subtotal HBPS thrombosis received RVOT-opening (n = 2) and new shunt (n = 4). HBPS take-down due to subtotal graft thrombosis was performed intraoperatively (n = 3), early postoperatively after 3 days (n = 1) and late after 41 days (n = 1). Additionally, 1 patient needed shunt exchange 7 days after Norwood due to thrombosis in the context of failed biventricular repair, and died. Six more patients died (30-day, n = 3) with HBPS in situ, all of them non-shunt related and with univentricular pathology. The 1 and 5 year survival in biventricular patients was 100%, and in univentricular patients 78 ± 8% and 67 ± 8%, respectively.
Conclusions: The use of HBPS is safe and seems to warrant systemic to pulmonary perfusion. Although shunt thrombosis cannot be excluded, patients can be transferred to further palliative treatment, indicating a very slow process of shunt occlusion using HBPS.

P2278 - EARLY RESULTS WITH A STANDARDIZED APPROACH TO RHEUMATIC MITRAL VALVE REPAIR IN PAEDIATRIC POPULATION WITH CUSTOMISED PTFE RING ANNULOPLASTY SINGLE INSTITUTION EXPERIENCE

Musthafa Janeel Moosa[1], Neville Solomon[1], Ashwene Ravindran[1], Anuradha Sridhar[2], Muthikumaran Sivaprakasam[2]
Apollo Children, Paediatric Cardiac Surgery, Chennai-India[1]; Apollo Children, Paediatric Cardiology, Chennai-India[2]

Paediatric rheumatic mitral valve disease is still a major health problem in developing countries and mitral valve replacement is associated with problems due to anticoagulation. Our approach now is to aggressively repair the mitral and have been using a fairly standardized approach. For 3 years from January 2013 to 2016 we have done 41 mitral valve repairs with a median age of 11.2 years. Mitral valve is approached through a transeptal modified Dubost approach, posterior leaflet patch is enhanced with pericardial patch (24/41), neochordae to anterior mitral leaflet (24/41) and customised PTFE patch posterior annuloplasty(41/41). There was no

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

early or operative mortality but one late mortality on follow up and seven were lost to follow up. There was no hemolysis or thromboembolic episodes in postoperative period. 26/33 is asymptomatic and 6 were in NYHA 2-3 and post op echo showed only 2/33 having more than mild MR. Using a PTFE customised partial ring gives flexibility in choosing the size and extent of the annuloplasty with good early results. Further long term follow up is needed to ascertain how it hold in long term.

P2283 - MITRAL REGURGITATION RISK FACTORS FOR UNFAVOURABLE OUTCOME OF MITRAL VALVE REPAIR TECHNIQUE IN CHILDREN

Sandra Sepúlveda[1], María Juliana Medina[1], Analía Martin[1], Gladys Salgado[1], Guillermo Moreno[2], Javier Cornelis[3], Pablo García De Lucis[3], Jorge Barretta[3], Horacio Capelli[4]
Hospital Profesor Juan P. Garrahan, Pediatric Cardiology, Buenos Aires-Argentina[1]; Hospital Profesor Juan P. Garrahan, Cardiovascular Critcal Care, Buenos Aires-Argentina[2]; Hospital Profesor Juan P. Garrahan, Cardiovascular Surgery, Buenos Aires-Argentina[3]; Hospital Profesor Juan P. Garrahan, Head Of Pediatric Cardiology, Buenos Aires-Argentina[4]

Objective: To analyze risk factors for unfavourable outcome (UO) in patients (pts) with mitral regurgitation (MR) that underwent mitral valve repair (MVR) technique.
Methods: Patients with MR who had MVR from 2004 to 2014 were retrospectively evaluated. Mitral stenosis, atrioventricular septal defect and complex cardiac lesions were excluded. UO was defined as reoperation or significant MR (moderate to severe (3+) or severe MR (4+)) during follow-up. Variables were expressed as median. A logistical regression multivariate analysis of predicting factors of UO was used.
Results: Sixty five pts with MR3 + and MR4 + underwent MVR. Etiology was: dysplasia 44.6%, infective endocarditis 13.8%, rheumatic fever 18.4%, abnormal coronary origin 7.7%, others 13.8%. Median age was 8.2 years (ys) (IQR25-75:3.1-13.3) and median weight was 25 kg (IQR:13.5-40.5).Median follow–up time was: 26.5 months (IQR:12-41.5).Ventricular dysfunction was documented in 44.6% and 46.1% had pulmonary hypertension. Surgical procedures were: Annuloplasty (59), cleft closure (19), commissuroplasty (14), leaflet perforation closure (9), leaflet resection (10), chordae replacement or shortening (4), leaflet extension (2), Alfieri (2).Fiftytwo pts (80%) were followed. Fifteen presented UO: 9 were reoperated (7 valve replacement and 2 re-repair). Univariate analysis demonstrated a significant association between UO and: Rheumatic fever (p0.005), preoperative mitral annulus $\geq +5$ SD (p0.002),left ventricle end-systolic diameter $\geq +4$ SD (p0.022), pulmonary hypertension (p0.024) and immediate postoperative residual MR $\geq$ moderate (p0.021). Multivariate analysis demonstrated as independent variables of UO: mitral annulus diameter (p0.012), rheumatic fever (p0.026) and early residual MR (p0.042). No mortality occurred. In mid-term follow-up, Seventy three% remain free of reoperation or significant MR.
Conclusions: A MVR strategy demonstrated a mid-term favourable outcome in children with severe MR, avoiding a valve replacement and its complications. Rheumatic fever, mitral annulus diameter $\geq +5$ SD and immediate postoperative residual MR $\geq 2+$ were predicting factors of UO. Neither age at surgery nor ventricular dysfunction showed statistically significant differences during follow-up.

P2286 - ANATOMICAL REPAIR OF TRANSPOSITION OF GREAT ARTERIES AT HIGH ALTITUDE. A SAFE PROCEDURE WITH LONG TERM SURVIVAL

Néstor Fernando Sandoval Reyes[1], Marisol Carreño Jaimes[2], Albert Franz Guerrero Becerra[1], Carlos Eduardo Obando López[1], Jaime Camacho Mackenzie[2], Sonia Emilsen Morales Echavarria[1], Juan Pablo Umaña Mallarino[2]
Fundación Cardioinfantil - Instituto De Cardiología, Congenital Heart Institute, Bogota-Colombia[1]; Fundación Cardioinfantil - Instituto De Cardiología, Cardiac Surgery, Bogota-Colombia[2]

Objective: The aim of this study was to present the outcomes of patients with transposition of the great arteries treated at 8,661 feet above sea level.
Methods: Cohort of consecutive patients with transposition of the great arteries treated medically and surgical intervened in a cardiac surgical center in South America located at 8.661 feet above the sea level between February 2003 and November 2016. Descriptive analysis was done by standard statistical tests. A bivariate analysis was performed between patients with or without ventricular septum intact. The center made the follow up by phone and outpatient consultations. Long-term mortality was made for surgical patients. All tests were done in STATA 14.0.
Results: In 13 years, 163 patients with transposition of the great arteries were treated. Secondary to preoperative clinical conditions 20 (12.3%) patients didn't receive surgical intervention and 143 were surgically corrected. Arterial switch was the most frequent procedure 84.6% (121/143). Age at surgery 26 (IQR 8-109 days), Weight at surgery Median 3.4 (IQR 3-4.8 kg), VSD 43.3% (62/143). Preoperative ventilation 21.4%, ICU stay 11(SD 8.2 days). After surgery low cardiac output was the most frequent complication 41%. Open Chest 75.9%, peritoneal dialysis 33.3%. In hospital mortality 8.5%, mortality before 2009, 12.3%, mortality after 2010, 5.6%. At 10 years survival for arterial switch was 93% (95% CI 85-96).
Conclusion: Anatomic repair of transposition of great arteries at high altitude don't affect the mortality and morbidity results and patients older than 3 months have no different outcomes possible due to a altitude related delay in pulmonary vascular resistant drop. Long term survival is good in this topographic conditions.

P2291 - ACUTE HEART FAILURE AND HEMOLYSIS AFTER TRANSCATHETER PULMONARY VALVE IMPLANTATION HEART TEAM APPROACH IN ADULT WITH COMPLEX CONGENITAL HEART DISEASE

Néstor Fernando Sandoval Reyes[1], Marisol Carreño Jaimes[2], Carlos Eduardo Obando López[1], Albert Franz Guerrero Becerra[1], Jaime Camacho Mackenzie[2], Juan Pablo Umaña Mallarino[2]
Fundación Cardioinfantil - Instituto De Cardiología, Congenital Heart Institute, Bogota-Colombia[1]; Fundación Cardioinfantil - Instituto De Cardiología, Cardiac Surgery, Bogota-Colombia[2]

Objective: The aim of this abstract is present the case of a female patient whit congenital valve disease who develop acute heart failure and severe hemolysis after the implant of a percutaneous pulmonary valve.
Methods: 24 years old patient with shone syndrome underwent to Ross procedure in 2001 without complications. In 2010 a percutaneous mitral valvulotomy was performed for severe mitral stenosis. In September 1th 2015 was found a severe stenosis with moderate regurgitation of pulmonary homograft with a NYHA functional class of III-IV, extra institutional transcatheter pulmonary valve implantation was performed. Since post implant period, patient progressed with congestive heart failure and referred to our institution. She also developed intravascular hemolysis, with secondary anemic and jaundiced syndrome, possible related to valve implant.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: Echo showed Ejection fraction 65%, mean pulmonary pressure 80 mm HG, mitral peak gradient 38 mm Hg, mitral mean gradient 14 mm hg, Wilkins index 11/16, aortic valve regurgitation II, membrane sub aortic peak gradient 77 mm Hg. Secondary to severe deterioration with pulmonary edema and mechanical ventilation after 3 days of the admission, a veno-arterial ECMO was implanted. Five days later with hemodynamic stability, percutaneous pulmonary valve was explanted, received a mitral valve replacement with mechanical prosthesis no. 23, right ventricle conduit replacement with by a dacron graft and a bio prosthesis no. 25, tricuspid valve repair, sub aortic membrane resection and ECMO explant, Cross clamp time 134 minutes, pump time 240 minutes. The postoperative evolution was favorable and on November 11th was discharged. On February 2016, secondary to atrial tachycardia and syncope a successful transcatheter ablation was done. Last outpatient clinic visit patient was on October 5th the main findings were NYHA functional class I-II, sinus rhythm, warfarin a beta block treatment.

P2293 - DELAYED TWO STAGE ARTERIAL SWTICH OPERATION. A RENEWED HOPE FOR LATE PRESENTERS WITH TRANSPOSITION OF GREAT ARTERIES AND INTACT VENTRICULAR SEPTUM

Sivakumar Sivalingam[1], Mofassel Uddin[1], Noritaka Ota[1], Chee Chin Hew[1], Mohd. Azhari Yakub[1], Kiew Kong Pau[1], Ali Alrabi[2], Yazmin Azudin[2], Mazeni Alwi[2]
National Heart Institute, Cardiothoracic Surgery, Kuala Lumpur-Malaysia[1]; National Heart Institute, Paediatric Cardiology, Kuala Lumpur-Malaysia[2]

Background: Ductal recanalization by stenting to train the left ventricle has been described for late presenters with Transposition of great vessels, intact ventricular septum (TGA,IVS) and regressed left ventricle. A rapid two stage approach will require a prolonged hospital stay which may drain the resources in developing countries. We report our results of delayed two stage approach in this group of patients.
Materials and Methods: Between February 2010 and April 2016, 16 patients who were late presenters with TGA, IVS underwent successful arterial switch operation through a delayed two stage approach. The median age at ductal stenting was 30 days(13-134 days). The interval between the ductal stenting and arterial switch was 131.75 ± 81.44 days. The median age at arterial switch operation was 136 days (33–671 days).
Results: The median hospital stay following ductal stenting was 5.5 (4.0-7.0) days. The left ventricular posterior wall thickness improved from 0.33 ± 0.04 to 0.41 ± 0.03 mm and the left ventricular mass from 50.44gm/m2 to 60.9gm/m2 after the stenting. There were no hospital deaths after the arterial switch operation. No patient needed post-operative mechanical support. The median hospital stay after switch was 10 (7-22) days. The mean left atrial pressure immediately after surgery was 19.44 ± 2.87 which dropped to 11.44 ± 3.05 before extubation. At a median follow-up of 23(4-76) months, there was one late death. All patients followed up after arterial switch are in NYHA class I and the LV mass increased to 132.21 gm/m2.
Conclusion: Delayed 2 stage arterial switch strategy for late presenters with TGA, IVS helps to train the left ventricle with a shorter hospital stay without need for post-operative mechanical support whereby reducing the financial burden in developing countries. However long term follow-up is needed to assess the left ventricular function.

P2321 - LONGTERM CLINICAL OUTCOMES AFTER FONTAN PALLIATION

Ramya Shri Chandrasekaran[1], Sudipta Bhattacharjya[1], Ejaz Ahmed Sheriff[2], Roy Varghese[2], Ravi Agarwal[2], Sivakumar Kothandam[1]
Madras Medical Mission, Pediatric Cardiology, Chennai-India[1]; Madras Medical Mission, Pediatric Cardiac Surgery, Chennai-India[2]

Background: Fontan procedure palliates a diverse range of univentricular hearts. Analysis of the indications, surgical outcomes and follow-up would help us for better clinical outcomes in future.
Methods: Patient demographics, echocardiographic anatomy, hemodynamics, surgical aspects and follow-up were retrospectively studied.
Results: 96 patients aged 10.02 ± 4.61 years (2.6-24 years) underwent Fontan surgery from 2005 to 2016. Common indications being tricuspid atresia (25%), C-TGA (18.75%), Heterotaxy syndromes (14.6%), Single ventricle (13.5%), DORV (12.5%) and d-TGA (10.4%). The mean weight, height and body surface area (BSA) were 26.64 ± 10.5 kg (9-57.5 kg), 132 ± 19.5 cm (75-175 cm) and 0.9 ± 0.26 m2 respectively. Staged Fontan was performed in 88 patients (91.7%) and primary Fontan in 7.3%. Pre-fontan catheterization performed in 93.75% patients revealed following hemodynamic data – mean PA pressure (12.2 ± 2.8 mmHg), LVEDP (11.4 ± 3.4 mmHg), PVRI (2.25 ± 1.04WU.m2). Mean pre-op systemic saturation was 78 ± 6%. 95.8% were extracardiac conduit fontan, 1 was lateral tunnel and two were extra-intracardiacfontan procedures. (16% off pump; 91% fenestrated).Post-operative complications were noted in 45% patients – take down of fontan in one, persistent pleural collection/chylothorax (26%), neurologicalevents (11%), low cardiac output (11%) need for reexploration (9%) sepsis (8%), arrhythmia (7%), diaphragm palsy (3%), gastrointestinal complications (3%), revision surgery for conduit thrombosis/kink (3). Recovery parameters included ICU stay (4.5 ± 3.7d), ventilator duration (17.7 ± 15.3 h), average saturation (90 ± 5%)and CVP (13.9 ± 2.1 mmHg) in first 48 hrs, total ICD duration (8.6 ± 6.7d) and total hospital stay (14.9 ± 8.9d).14% patients required prolonged diuretic therapy (>6 m), while anticoagulants are continued for 85% of followed-up patients (91% of total). Mortality rate was 11.5% with 9 hospital deaths. In mean follow up duration of 4.27 ± 3.12yrs (1m-11.9yrs), 12 required interventions (diagnostic-5, fenestration device closure-3, MAPCA embolization-2, fenestration creation/stenting (2). 83% patients are in NYHA functional class I, rest Class II; 84% continuing studies, 6% dropouts, 3% married, 7% employed.
Conclusion: Proper patient selection, good surgical technique and regular follow up is mandatory to assure good functional long-term outcome after Fontan Palliation.

P2340 - OUTCOME OF IMPROVEMENT STEPS IMPLEMENTED TO REDUCE RISK OF INFECTION DURING CARDIAC HOMOGRAFT PROCUREMENTS

S. Noraida Syed Nong[1], Ritha Chua Lc[2], S. Laura Mazalan[3], M. Nazeri Nordin[3], M. Ezani Md Taib[3]
National Heart Institute, Transplant Unit, Kuala Lumpur-Malaysia[1]; National Heart Institute, Perfusion Unit, Department of Anaesthesiology, Kuala Lumpur-Malaysia[2]; National Heart Institute, Department of Cardiothoracic Surgery, Kuala Lumpur-Malaysia[3]

Background/Hypothesis: Reducing the risk of infections during cardiac homografts procurements is essentials as donors are scarce. Aim was to embark on prospective measurable steps, taken to reduce risk of infections at every stage of cardiac homografts procurement procedure and analyze the outcomes.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials/Methods: A 10 years analysis (2007-2016) procurement of cardiac homograft from fresh cadaveric donors (within 24 hours of death). Procurement performed in the operating theater or mortuary. Donors screened negative cultures for blood and bodily and serology screening of Hepatitis A,B,C, HIV and Syphilis. Cause of death not attributable to infective state. From 2014, improvements steps implemented to reduce infective risk at each stages. Preferences for operating theater settings, strict aseptic harvesting techniques; ensuring patient repainted with povidone iodine and change of surgical drapes after other organs procurements. Utilization of a clean set of surgical instruments and stringent aseptic techniques in triple layering/sealant of organ bags. Homografts trimming in aseptic tissue banking facilities. At each stages, cultures taken from transport solutions, tissues and donors swaps. Penicillin and gentamycin antibiotic into homograft solutions.
Results: A total of 214 cardiac homografts procured (103 pulmonary, 111 aortic homografts). From 2007 to Dec 2013, 26 (12.1%), 13 pulmonary and 13 aortic had positive cultures from solutions and/or tissue. Positive cultures includes Klebsiella 7 (3.3%), Candida 5(2.3%), Acinetobacter 4(1.8%), Streptococcus 2 (0.9%) and others from pseudomonas, VDRL and hepatitis B. From 2014 till 2016, with implementation of new measurable steps, our infection rate is 0%.
Conclusions: Improvements process had successfully reduced procurement infection rates, retaining precious donor hearts, indirectly improves cost efficiency and promoting utilization of cardiac homografts without hesitations or fear of transmission of infections.

P2357 - TEN YEARS SURVIVAL AFTER FONTAN OPERATIONS EXPERIENCE FROM TERTIARY CENTER IN INDONESIA

Oktavia Lilyasari[1], Poppy S Roebiono[1], Maha Fitra[1], Anna U Rahajoe[1], Indriwanto Sakidjan[1], Radityo Prakoso[1], Yovi Kurniawati[1], Budi Rahmat[2], Dicky Fachri[2], Ganesja M Harimurti[1]
National Cardiovascular Center Harapan Kita, Jakarta, Indonesia, Department of Cardiology And Vascular Medicine, Faculty of Medicine, Universitas Indonesia, Jakarta-Indonesia[1]; National Cardiovascular Center Harapan Kita, Jakarta, Indonesia, Pediatric and Congenital Heart Disease Surgical Unit, Jakarta-Indonesia[2]

Background: Fontan operation is the common procedure performed for uni-ventricular anatomy. Late outcome after Fontan operation is a matter of concern. The aim of study is to evaluate 10 years survival and late morbidity after Fontan operations at National Cardiovascular Center Harapan Kita, Jakarta, Indonesia.
Methods: A retrospective study was conducted from April 2006 to August 2016. All patients surviving to hospital discharge after Fontan operations were included and followed-up until September 2016. Death, and late morbidity were evaluated during follow-up period.
Result: There were 148 patients who underwent Fontan operation during study period. Fourteen patients died post-operative and 23 patients were lost to follow up. Hundred eleven patients with median age 6(3-22) years old were included. Median follow-up period was 895(15-3816) days. Previous palliative operations were carried out in 98(88.3%) patients. Fontan with and without fenestration was performed in 97(87.4%) and 14(12.6%) patients respectively. A total of 8(7.2%) patients died during follow up. The 10 years survival rate was 92.8%. The leading cause of death includes heart failure (50%), infection (25%), arrhythmia (12.5%) and others (12.5%). Late morbidity occurred in 69(62.2%) patients. A total 36(32.4%) patients experienced arrhythmia and 5 (4.5%) required pacemaker implantation. Thromboembolic events occurred in 3(2.7%) patients while 7(6.3%) patients suffered from bleeding (gastrointestinal bleeding (42.9%) and intracranial bleeding (28.6%)). Six (5.4%) patients had right heart failure, 7 (6.3%) with congestive heart failure while 7(6.3%) patients suffered from protein loosing enteropathy. Conduit thrombosis was found in 2(1.8%)patients. Percutaneous ballooning of fontan conduit was performed in 1(0.9%) patient, whilst pulmonary artery stenting was inserted in 1(0.9%) patient. Re-do operation were performed in 4(3.6%) patients. Re-hospitalization rate was 25.2%, with arrhythmia as the common cause.
Conclusion: The rate of 10 years survival after Fontan procedure is satisfactory, although morbidities in the long run are still sub-optimal.

P2366 - TOTAL ANOMALUS PULMONARY VENOUS CONNECTION 25 YEAR EXPERIENCE SINGLE CENTER

Mateo Rios[1], Leone Ruben[2], Jorge Speyer[3], Beatriz Ceruti[4], Pedro Chiesa[5]
Md, Cicu, Montevideo-Uruguay[1]; Head Surgeron, Surgery, Montevideo-Uruguay[2]; Attending, Cicu, Montevideo-Uruguay[3]; Attending, Cardiac Transplant, Montevideo-Uruguay[4]; Attending, Cardiac Catheterization Laboratory, Montevideo-Uruguay[5]

Background: Total anomalous pulmonary venous connection (TAPVC) accounts for 3-4% of congenital heart disease. In the last 20 years there has been a considerable improvement in mortality rates of patients undergoing surgical repair. This study aims to review postoperative results of TAPVC repair over a 25 year period.
Materials and Methods: Retrospective chart review of all cases of TAPVC repairs undergone at a single center from Jan 1991 to Dec 2016. Patient demographics, operative variables, and postoperative course were analyze.
Results: 72 patients with TAPVC were reviewed. One patient died before surgery. Forty-seven (65%) were males. Median age and weight at operation were 2.8 months (range 1 day to 30 months) and 4 kg (range 2.1 to 10.9 kg), respectively. Forty-nine cases (69%) were supra-diaphragmatic and 22 (31%) infra-diaphragmatic. Drainage obstruction was present in 34 patients (47%), 21 (61%) being infra-diaphragmatic. Thirty-one (43%) were operated in the neonatal period, twelve died (38%). Single-ventricle and heterotaxy syndrome, was present in 7 cases (9%) and all of them died after surgery. Post-operative pulmonary venous obstruction occurred in 12 patients (17%), 7 were operated in the neonatal period, 4 had mix drainage and 5 were infra-diaphragmatic. Ten underwent re-intervention and only one survived. Average days of mechanical assisted ventilation were 6.5 and hospital length of stay was 15.6 days. Overall mortality was 31% (35% during the first 15 year period and 20% in the last 10 years).
Conclusions: There has been a significant improvement in mortality rate in the last ten years. Neonatal age, complex congenital heart disease and obstruction previous to surgery, were associated with bad outcome. Post-operative pulmonary venous obstruction had a high mortality rate, and it was associated with neonatal surgery, infra-diaphragmatic and mixed types of drainage.

P2370 - MIDTERM OUTCOMES OF ROSS AND ROSS KONNO PROCEDURES IN INFANTS

Denis Akatov[1], Vyacheslav Belov[7], Yuriy Shneider[7], Nataliya Ganukova[7], Dina Khomich[7], Denis Bolhovskoy[7], Andrey Makarov[7]
Center of High Medical Technologies, Kho3, Kaliningrad-Russia[1]

Background: Infants with severe left ventricular outflow tract obstruction or valve regurgitation may require replacement of the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

aortic root with pulmonary autograft. We present our experience ofthe Ross and Ross–Konno procedure in infants.
Methods: There were 8 infants with aortic stenosis operated in our centerbetween January 2015 and September 2016. Three of them underwent aortic commissurotomy and five infants underwent the Ross or Ross-Konno procedure. The median age at the time of Ross or Ross-Konno procedure was 121 days (rangedfrom 38 to 215 days). In the newborn period one patient had aortic commissurotomy and one patient had aortic commissurotomy with the arch reconstruction. They were repeatedlyadmittedto our hospital with aortic restenosis and we performed Ross procedure at the age of 5 and 7 months old, consecutively. One patientof 38 days oldwas operated with aortic commissurotomy. TEE showed severe aortic regurgitation at the operating room. That is why we immediately performed the Ross procedure. An indication for the Ross-Konno procedure was severeleft ventricular outflow tract obstruction in 2 patients.The patients had aortic valve replacement with pulmonary autograft and pulmonary homografts placed in the right ventricular outflow tract in both cases.
Results: Follow-up was available for all the patients (median 189 days, range from 51 to 401 days). There were no deaths during early and late median follow-up. Echocardiography demonstrated good valve function. We have no indications for reinterventions after the Ross or Ross-Konno procedure.
Conclusions: The Ross and Ross-Konno procedurescarry low early and mid-term mortality with low reintervention rate. Long-term results should be evaluated over time.

P2383 - THREE DIMENSIONAL PRINTING IMPROVES MANAGEMENT IN INFANTS WITH COMPLEX CONGENITAL HEART DEFECTS

Shafkat Anwar[1], Pamela K. Woodard[2], Monica Sharma[1], Pirooz Eghtesady[3], Gautam K. Singh[1]
Washington University in St. Louis, School of Medicine, Pediatrics, St. Louis-United States[1] Washington University in St. Louis, School of Medicine, Radiology, St. Louis-United States[2] Washington University in St. Louis, School of Medicine, Surgery, St. Louis-United States[3]

Background: Cardiac 3D printing produces highly accurate replicas of a patient's anatomy. Infants with complex congenital heart disease (CHD) represent the highest risk surgical category. We describe the use of 3D printing in infants for surgical planning and patient counseling.
Materials and Methods: Infants (less than 12 months old) underwent cardiac computed tomography (CT) or magnetic resonance imaging (CMRI) for clinical evaluation. CMRI was performed on a 1.5 Tesla scanner with a 3D respiratory navigated FLASH sequence after 0.03 mmol/kg blood-pool gadolinium contrast, gadofosveset trisodium. Contrast-enhanced cardiac CT was performed on a 128 slice dual-source CT scanner. Segmentation, post-processing and 3D printing were performed in collaboration with 3D Systems - Healthcare (Golden, CO) and printed on a ProJet 660 color jet printer. Models for surgical planning were graded for accuracy by two CT surgeons (0-5, 5 = very accurate), who also reported the utility of the models.
Results: 3D models were printed for thirteen infants (age range 1 day – 10 months) with a wide spectrum of congenital heart defects, vascular and related airway abnormalities (Table 1, Figure 1). 8/13 models were used for pre-procedure surgical planning. All pre-surgical models received a score of 5 (highly accurate) compared to OR findings. The surgeons reported the models helped understand complex anatomy, decide between surgical options, decrease cardiopulmonary bypass time, and avoid potential complications. Models for five patients with complex anatomy were used for trainee education and family counseling. All families reported the models aided in their understanding of the child's complex heart disease.
Conclusions: Highly accurate 3D models can be made in patients as early as 1 day of life. These models aid in surgical planning and are useful for family counseling.

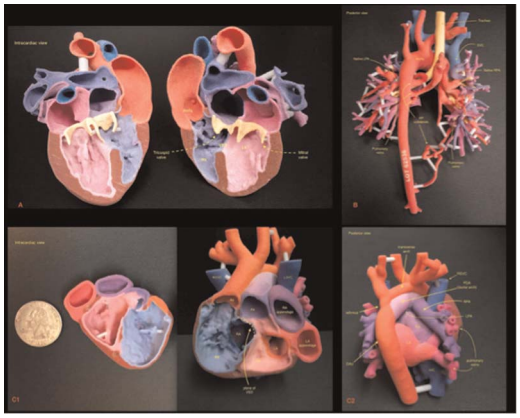

Figure 1.
3D models in infants with complex congenital heart disease. A. Four-month-old (7.7 kg) male with double outlet right ventricle (DORV), pulmonary atresia, large inlet type VSD, bilateral SVCs. The 3D model was printed for pre-surgical planning and shows the relationships between the ventricles, VSD and aorta. B. One-month-old (7.2 kg) male with Tetralogy of Fallot, pulmonary atresia, multiple aortopulmonary collaterals. The pre-surgical 3D model shows two left-sided and one right-sided AP collaterals. These were unifocalized to a RV-PA conduit with model guidance. A separate AP collateral is seen arising from the descending aorta. C. One-day-old (3.1 kg) male with dextrocardia, D-TGA, VSD, long segment arch narrowing, and coarctation of the aorta. The 3D model shows highly precise anatomic detail in a very young infant.

Table 1.

Diagnosis	Age at imaging study (days or months)	Weight at study (kg)	Reason for Printing	Imaging Modality	Accuracy via OR inspection (0-5)

P2413 - MODELLING DOUBLE OUTLET RIGHT VENTRICLE FOR SURGICAL PLANNING NEW TOOLS IN THE BOX

Giuliano Giusti[1], Claudio Capelli[2], William Regan[3], Marisa Gasparini[4], Emilie Sauvage[2], Mario Carminati[5], Silvia Schievano[2], Martin Kostolny[6], Jan Marek[6]
Great Ormond Street Hospital For Children & IRCCS Policlinico San Donato Milanese, Paediatric Cardiology, Milan-Italy[1]; University College London, Institute of Cardiovascular Science, London-United Kingdom[2]; Royal Brompton & Harefield NHS Foundation Trust, Cardiology, London-United Kingdom[3]; Kings College, School of Medical Education, London-United Kingdom[4]; IRCCS Policlinico San Donato Milanese, Paediatric Cardiology, Milan-Italy[5]; Great Ormond Street Hospital, Cardiorespiratory Unit, London-United Kingdom[6]

Background: Complex forms of DORV pose a challenge for planning optimal surgical approaches. Advances in three dimensional (3D) imaging have enabled the creation of highly realistic computational models of intra- and extra-cardiac structures. In this study, we report the early results of a single centre experience in which patient-specific models were integrated in the decision making process for improving the personalized management of patients with DORV.
Materials and Methods: A cohort of 8 DORV patients diagnosed with non-committed VSD was included in this study. Multimodality images were available for each patient including computed tomography, magnetic resonance and echocardiography. Images were post-processed to: i) recreate virtual 3D models; ii) print 3D replica of the anatomies; iii) perform in vitro surgery; iv) and simulate the virtual haemodynamic conditions following the surgical repair (Figure 1). Where possible, intraoperative surgical morphology was video recorded for post hoc correlation with the virtual model.
Results: All patients had initial palliation in the form of PAB with additional aortic arch repair in 2, PDA ligation in 1 and Blalock-Hanlon septostomy in 1. Six patients underwent a definitive biventricular repair, consisting of creation of a LV-AO tunnel and PA debanding in 4, and arterial switch operation with VSD closure towards the neo-aorta in 2. Two patients were treated along the univentricular pathway. There was no mortality; all biventricular repairs had no LVOT significant gradient at follow-up. Post-procedural peak velocity calculated by computational simulations was found to be in accordance with echocardiographic assessment.
Conclusion: Virtual models allow for good spatial orientation, planning and prediction of surgical approaches in complex DORV surgery. The promising results of this preliminary experience seem to advocate the introduction of this new tool in planning complex CHD surgeries, although further evidence on the benefits of physical models is needed on a larger series of cases.

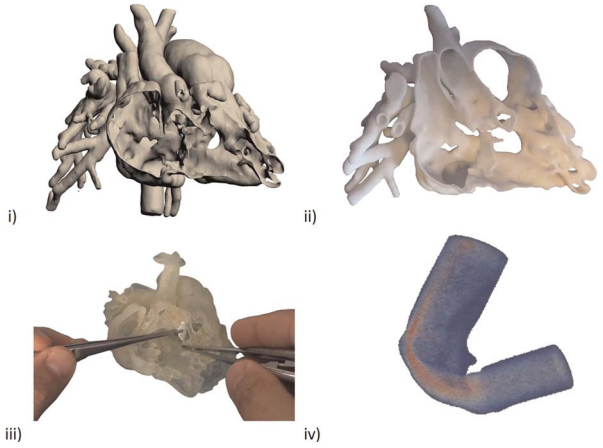

Figure.

P2416 - VIRTUAL 3D SURGICAL TREATMENT OF CONGENITAL HEART DEFECTS

Simone Speggiorin, Saravanan Durairaj, Branko Mimic, Antonio F Corno
University Hospitals of Leicester, EMCHC, Leicester-United Kingdom

Background: 3D cardiac modelling has become very popular in pediatric cardiac surgery as it allows a better understanding of complex intra-cardiac morphologies and helps to plan the surgical repair. Despite the additional information given by the 3D models, surgeons are still matching their personal experience with the intra-operative findings to accomplish the surgical repair. We introduced the virtual 3D simulation to either palliate/repair congenital heart defects and then we compared them with the intra-operative findings.
Materials and Methods: Six patients with congenital heart defects who required pre-operative CT scan were included in this study. From the available datasets, 3D segmentation was performed. The models were hollowed and the surgical palliations/repairs were simulated by creating shunts and patches, or by reassembling the intra-thoracic structures. Dimensions and shapes of the patches, and the length of the shunts were collected and used to recreate them in the surgical field.
Results: Seven procedures (in 6 patients) were 3D virtually simulated on the computer and then performed in operative room. Patches were 3D virtually simulated to repair: - common arterial trunk (1 patient) - pulmonary atresia with ventricular septal defect (1 patient) - right partial anomalous pulmonary venous connection (1 patient). Right modified Blalock-Taussig shunt for absence of right pulmonary artery (1 patient) Refashioning of the intrathoracic vessels (2 patients) In all patients who underwent surgical palliation or repair following the 3D virtual computer simulation, the patch and shunt materials, tailored based on the shape provided by the 3D virtual modelling, resulted absolutely precise and didn't require any adjustment. All surgical procedures were uneventful.
Conclusions: The initial experience of this innovative technique of 3D virtual surgical modelling proved to be easily reproducible and reliable for clinical application.

P2420 - A NOVEL ADJUSTABLE PULMONARY ARTERY BANDING DEVICE TESTED IN 3 KG RABBITS

Carlos Andres Pardo Pardo[1], Israel Valverde[2], Reza Hosseinpour[3], Antonio Ordoñez Fernandez[4]
Leeds Teaching Hospital, Congenital Cardiac Surgery, Leeds-United Kingdom[1] Virgen Del Rocio Hospital, Pediatric Cardiology, Seville-Spain[2] Virgen Del Rocio Hospital, Congenital Cardiac Surgery, Seville-Spain[3] Instituto De Investigación Biomédica De Sevilla, Cardiovascular Research Laboratory, Seville-Spain[4]

Background: Banding of the pulmonary artery is carried out in two circumstances: (i) to prevent excessive pulmonary blood flow in patients with left-to- right shunts, thus preventing pulmonary vascular disease, and (ii) in congenitally corrected transposition of the great arteries where banding is used to retrain the left ventricle and/or treat tricuspid valvar regurgitation. Banding is challenging in determining the optimal degree of constriction such that further surgical interventions may be needed for band adjustment with significant postoperative morbidity and mortality. This challenge has been addressed by the introduction of various banding devices that are adjustable without the need for further sternotomies. These are associated with reduced early morbidity and mortality compared to conventional banding. However, none of these adjustable devices have gained widespread clinical use.
Objectives: To test a novel adjustable device in rabbits.
Materials and Methods: We developed a bidirectionally adjustable pulmonary artery band, using a ball chain that is exteriorised through the ribs and is fixed in a small box placed under the pectoral muscle. Should band adjustment be needed, this may be achieved simply by reaching and opening this box and modifying the length of the ball chain. The band materials permit easy follow-up by echocardiography. This device was tested in 3-kg rabbits during 24 days to see whether or not adjustments were easily feasible under echocardiographic control.
Results: Multiple adjustments were carried out without opening the chest, with simultaneous echocardiographic imaging showing correct device function.
Conclusion: We were able to demonstrate correct device function in an animal model with similar features to those of neonates. Further work is needed to consolidate our findings..

P2432 - IMMEDIATE RESULTS OF ANOMALOUS ORIGIN OF THE LEFT CORONARY ARTERY FROM THE PULMONARY ARTERY (ALCAPA) CORRECTION

Pedro Rafael Salerno[1], Juliana V. O. Salerno[2], Lúcia V. O. Salerno[3], Carolina V. O. Salerno[4], Thereza Lins[5], Catarina Cavalcanti[6], Ricardo Lins[1], Frederico Vasconcelos[1], Francisco Monteiro[1], Ricardo Lima[1]
UPE, Cardiovascular Surgery, Recife-Brazil[1]; FCMPB, Student, Recife-Brazil[2]; Esperança Hospital, Pediatric Cardiology, Recife-Brazil[3]; UFPE, Student, Recife-Brazil[4]; Esperança Hospital, Cardiology, Recife-Brazil[5]; UPE, Pediatric Cardiology, Recife-Brazil[6]

Background: ALCAPA, also known as the bland-white-garland syndrome, is a rare congenital coronary anomaly correlated with high early infant mortality and sudden death in adulthood. If intercoronary collaterals fail to develop, survival is highly unlikely due to severe myocardial ischemia or congestive heart failure unless corrective surgery takes place.
Material and Methods: From May 2007 to August 2016, four patients diagnosed with ALCAPA were operated at our service. Two female and two male. Weight varied from 5 to 78 kg (m = 48.7), age ranged from 5 to 456 months (m = 235). All patients had echocardiography performed, but it was the coronary cineangiography that lead to the diagnosis in all cases. Three patients also had myocardial scintigraphy and coronary angiotomography, which allows identification of the exact location of the coronary origin. In three of the patients, the left coronary artery (LCA) originated from the right-hand pulmonary sinus. Two of them were submitted to direct reimplantation of the anomalous LCA and the third to the Takeuchi technique. The last patient had the LCA originating from the nonfacing pulmonary sinus. Ligation of the ALCAPA at its origin and coronary artery bypass grafting with the left internal thoracic artery were performed.
Results: None of the patients suffered transoperative infarction or needed any kind of postoperative assisting device. No complications during or after surgery occurred, and the discharge ranged from 8 to 18 days after surgery (m = 10).
Conclusion: To implement the adequate technique for the ALCAPA correction it is crucial to identify from which sinus the coronary artery originates, and that is the role of the coronary angiotomography since it shows the best anatomic correlation.

P2469 - TIMING AND OUTCOME OF CARDIOTHORACIC SURGERY FOR ELLIS VAN CREVELD SHORT RIB THORACIC DYSPLASIATIMING AND OUTCOME OF CARDIOTHORACIC SURGERY FOR ELLIS VAN CREVELD SHORT RIB THORACIC DYSPLASIA

Devyani Chowdhury[1], Katie Williams[2], Millie Young[2], Aaron Chidekel[3], Catherine Preddy[4], Christian Pizarro[3], Kevin Strauss[2]
Cardiology Care for Children, Pediatric Cardiology, Lancaster-United States[1]; Clinic for Special Children, Pediatrics, Strasburg-United States[2]; Ai Dupont Children, Pediatrics, Wilmington-United States[3]; Ai Dupont Children, Pedaitrics, Wilmington-United States[4]

Background: Ellis-van Creveld syndrome (EVC) is a short-rib thoracic dysplasia common among the Amish population (EVC c. IVS13 + 5 G > T) and characterized by acromelic limb shortening, polydactyly, restrictive thorax and an increased incidence of congenital heart disease (CHD), particularly endocardial cushion defect. There is a high postoperative morbidity and mortality following cardiac surgery.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Methods: Clinical data from 51 EVC homozygotes born between 2005 and 2014 and managed at a single center was reviewed. Postoperative outcome for a subset of 18 children who underwent surgical correction of CHD is presented.
Results: 9 children born between 2005-2009 had corrective cardiac surgery at age 1.3 ± 1 months, whereas surgery was intentionally delayed until 50.1 ± 40 months (P = 0.009) for 9 children born between 2010 and 2014. Compared to the 2005-2009 cohort, delayed surgery was associated with reduced ventilator dependence (1.1 ± 2.4 days vs 49.6 ± 57.1 days, P = 0.075), fewer intensive care days (16 ± 24 days vs 48.6 ± 44, P = 0.155), (fig. 1) and complete prevention of tracheostomy (vs 60%, P = 0.028) and postoperative death (vs 44%, P = 0.082). Relative to age-matched controls subjects, EVC patients had increased respiratory rate that was independent of co-morbid CHD and normalized by 36-40 months of age. (fig. 1).
Conclusion: Delayed surgical repair of CHD in children with EVC decreases postoperative mortality and morbidity. Respiratory rate may be a useful indicator of thoraco-pulmonary maturation.

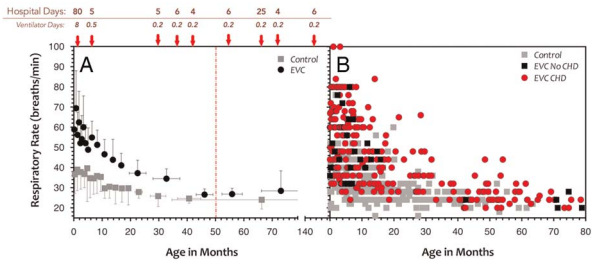

Figure.

P2478 - LONG TERM OUTCOMES FOLLOWING AORTIC ARCH REPAIR IN PAEDIATRIC PATIENTS. A RETROSPECTIVE STUDY

Andrew Ho[1], Khoon-li Kok[1], Genevieve Vanderslott[2], Antonio Ravaglioli[1], Tara Bharucha[1], Nicola Viola[1]
Southampton General Hospital, Wessex Congenital Cardiac Centre, Southampton-United Kingdom[1]; University of Southampton, Wessex Congenital Cardiac Centre, Southampton-United Kingdom[2]

Introduction: A number of surgical procedures can be adopted to repair coarctation of the aorta, depending on the extent of the lesion. We sought to review medium term reintervention rates and seek risk factors for death or reintervention.
Methods: All patients undergoing procedures from January 2007 to January 2017 involving surgical repair of coarctation of the aorta were retrospectively reviewed. Continuous variables were compared with the Student's t-test and binary variables with Fisher's exact test. Multivariable analyses were performed by logistic regression. A p value of <0.05 was regarded as statistically significant.
Results: 247 patients (96 female) underwent consecutive repair of coarctation. The median weight at primary repair was 3.5 kg (range 1.5–29 kg) and the median age 11 days (range 1 day to 7 years). 20 children were born prematurely and 27 had chromosomal or other genetic abnormalities. Additional structural lesions were present in142, including septation defects in 94 (66%), hypoplastic left heart syndrome (HLHS) in 33 (23%), and Taussig-Bing anomaly in 12 (5%). Surgical repairs included end-to-end or extended end-to-end anastomosis in 133 (54%), forward subclavian flap in 3 (1.2%), reverse subclavian flap in 21 (8.5%) and full arch patch reconstruction in 90 (36.4%). There were 24 deaths, and 26 reinterventions for recoarctation, overall. Excluding patients with HLHS, survival and freedom from reintervention at five years was 92% (95% CI 87-96%) and 89% (95% CI 84-94%), respectively. There was no difference in survival or reintervention by surgical procedure. Multivariable logistic regression identified HLHS (OR 11, p < 0.001), chromosomal abnormality (OR 5, p = 0.01) and presence of other, non-cardiac comorbidities (OR 8, p = 0.002) as risk factors for mortality, but not for arch reintervention.
Conclusions: Early and mid-term outcomes following surgical repair of coarctation of the aorta are excellent, but around 10% of patients require arch reinterventions within 5 years.

P2483 - MID TERM RESULTS OF THE IN SITU PERICARDIAL REROUTING TECHNIQUE FOR SCIMITAR SYNDROME REPAIR

Ignacio Lugones[1], Victoria Eugenia Zerpa Pacheco[1], María Fernanda Biancolini[2]
Children´s Hospital Buenos Aires "Pedro De Elizalde", Cardiac Surgery Unit, Buenos Aires-Argentina[1]; Children´s Hospital Buenos Aires "Pedro De Elizalde", Cardiology Department, Buenos Aires-Argentina[2]

Background: The main complication associated with surgical techniques in scimitar syndrome repair is pathway obstruction, which accounts for up to 50% of the cases. We describe our experience with the in situ pericardial rerouting technique.
Materials and Methods: Patients: 7 patients with history of recurrent respiratory infections, right cavities dilation and pulmonary overflow were operated on in our institution in the last 3 years. Mean age: 8 years-old (range: 1.9-20 years-old).
Surgical Technique: a) after median sternotomy, the right pleural space is opened; b) dissection of the scimitar vein (SV) c) the pericardium is opened and the right pulmonary artery is cross-clamped; d) the SV is transected above the diaphragm; e) its left lateral aspect is longitudinally opened; f) large incision in the right lateral wall of the pericardium; g) a wide anastomosis is performed between both incisions; h) CPB with aortic and usual bicaval cannulation and moderate hypothermia is established; i) aortic crossclamping; j) a large vertical left atriotomy is performed; k) the pericardium is sutured to the external surface of the heart, leaving the pulmonary venous return connected to the left atrium through a tunnel made of autologous pericardium.
Results: Mortality: 0%. Mean hospital stay: 7,3 days. No major complications. One patient developed transitory massive right atelectasis, which resolved in 72 hs. Mean follow-up: 25 months. Last echocardiogram showed unobstructed pulmonary venous return, with normal low-velocity blood flow throughout the pathway in all patients. Tomographic 3D reconstruction (4 patients) demonstrated wide elliptic connection between the left atrium, the pericardial sac and the SV. Catheterization (3 patients) also showed unobstructed pulmonary venous return.
Conclusions: This technique seems to achieve a wide connection between the pulmonary venous return and the left atrium, with no evidence of pathway obstruction or thrombosis in the mid-term follow-up.

P2549 - PRELIMINARY EXPERIENCE WITH THE USE OF POLYTETRAFLOUROETHYLENE MEMBRANE TO AUGMENT THE NATIVE PULMONARY VALVE DURING REPAIR OF TETRALOGY OF FALLOT

Anil Dharmapuram, Sudeep Verma, Nagarajan Ramadoss, Goutami Vejendla, Rao Ivatury
Kims Hospitals, Paediatric Cardiac Services, Secunderabad-India

Background: During repair of TOF when a trans-annular incision is required, we reconstructed the RVOT using a polytetraflouroethylene (PTFE) membrane to augment the native valve and create a competent valve in the RVOT to avoid pulmonary regurgitation.
Methods: From March 2013 to December 2016, we reconstructed the RVOT using PTFE membrane in 15 patients who required a trans-annular patch in TOF repair. The age ranged from 10 months to 26 years (median 12 years). The weight ranged from 8 kg to 47 kg (median 23.5 kg). In all patients, the trans-annular incision was made across the anterior cusp of the native valve preserving the hinge mechanism leaving the posterior cusp intact. A PTFE 0.1 mm thin membrane was used to augment the divided leaflet. The length of the patch was measured from the annulus to the most proximal extent of the ventriculotomy. A generous width was taken so that the valve would occupy the entire RVOT. The membrane was sutured to the endocardium of the ventriculotomy all around and distally to the divided anterior leaflet. The reconstructed PTFE valve would co-apt with the native posterior leaflet.
Results: There was no mortality. The median follow up was 20 months. All patients were doing well. 2D echocardiography showed good RV function with preserved volumes. There was no significant gradient in the RVOT. Pulmonary valve regurgitation was mild in 12 patients and absent in 3 patients.
Conclusions: PTFE membrane seems to be a good alternative to reconstruct the native pulmonary valve after a trans-annular incision in TOF repair to avoid pulmonary regurgitation. The thin nature of the membrane makes it pliable to use for suturing. Early experience with this material seems encouraging but long-term follow up is required to demonstrate the prevention of pulmonary regurgitation.

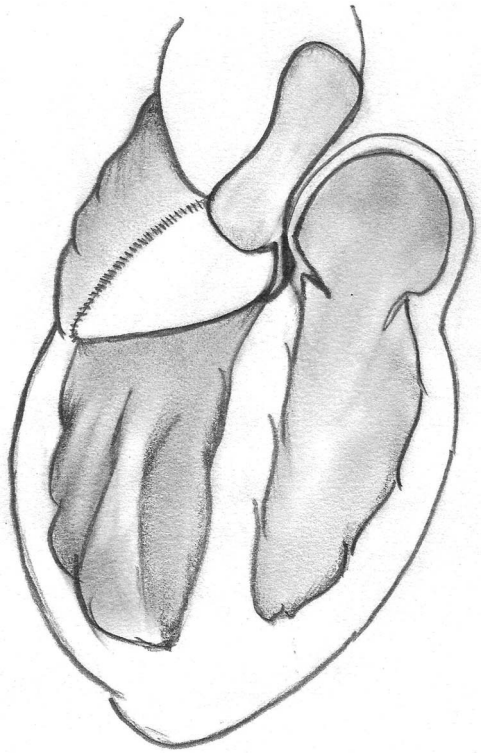

Figure 2.

P2557 - READMISSIONS FOLLOWING CONGENITAL HEART SURGERY AMONG INFANTS AND CHILDREN

Oscar Benavidez[1], Wei He[2], Manuella Lahoud-Rahme[3]
Massachusetts General Hospital/Harvard Medical School, Pediatric Cardiology, Boston-United States[1]; Massachusetts General Hospital/Harvard Medical School, Medicine, Boston-United States[2]; Massachusetts General Hospital/Harvard Medical School, Massachusetts General Hospital/harvard Medical School, Boston-United States[3]

Background/Hypothesis: Thirty-day readmission in after pediatric congenital heart surgery (CHS) has been under studied despite patient vulnerability. We hypothesized that readmissions after pediatric CHS are common and identifiable risk factors exist.
Materials and Methods: We obtained Inpatient Databases for Washington, New York, Florida, and California 2009-2011 and selected CHS admissions age <19 years. We defined readmission as non-elective hospitalization for a patient <31 days of discharge from index CHS admission. We defined complications using the Society of Thoracic Surgeons Congenital Heart complication list. Case mix was adjusted by using Risk Adjustment for Congenital Heart Surgery-1 (RACHS-1). We defined High Resource Use (HRU) admissions as those >90th percentile for total hospital charges. Multivariate analyses using generalized estimating equations estimated adjusted odds ratio (AOR) for readmission.
Results: Among 8,585 index admissions we identified 964 readmissions (11.3%). Median length of stay for readmissions was 5 days, median total charge of $31,973 and mortality rate 1.8%. Among readmissions, 1.6% underwent another CHS of which 44% were HRU, complication rate 88% and mortality 6.25%. On multivariable analysis age 1 month - 1 year AOR 1.3 $p = 0.01$; Hispanic AOR 1.2 $p = 0.03$; government-insurance AOR 1.3 $p = 0.01$; RACHS-1 3 complexity AOR 2.4 $p < 0.001$;

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

RACHS-1 4+ complexity 2.0 p = 0.001; HRU AOR 1.4 p = 0.02; complications AOR 1.1 p = 0.04; and emergent index admission AOR 2.0 p < 0.001 were risk factors.
Conclusions: Over 11% of pediatric CHS admissions result in an unplanned readmission. Hispanic race, government insurance, HRU, higher case complexity, complications and emergent index admission are risk factors for readmission.

P2564 - FEASIBILITY OF BIVENTRICULAR REPAIR FOR DOUBLE OUTLET RIGHT VENTRICLE (DORV) NON COMMITTED VENTRICULAR SEPTAL DEFECT (VSD) IN HETEROTAXY AND NON HETEROTAXY SUBSTRATES A CASE SERIES

Vishal Singh[1], Ashutosh Marwah[2], Rajesh Sharma[3]
Jaypee Hospital, Pediatric Cardiac Critical Care, Noida-India[1]; Jaypee Hospital, Pediatric Cardiology, Noida-India[2]; Jaypee Hospital, Pediatric Cardiac Surgery, Noida-India[3]

Double outlet right ventricle (DORV) physiology and suitability for biventricular repair is based on the routability and location of ventricular septal defect (VSD) in relation to aorta, pulmonary artery anatomy and left ventricle (LV) configuration. We present an analysis of 9 cases with extreme DORV, VSD, decreased pulmonary blood flow physiology , borderline LV and their outcomes after biventricular repair. Over a duration of 2 years, 9 cases of DORV physiology referred for univentricular repair, were committed for biventricular repair based on visual anatomic assessment on table, between the age range of 10 months to 18 years with seven patients doing well on mean one year follow up. Five patients had heterotaxy and four cases had associated complete atrioventricular septal defect (AVSD). In two additional cases, the VSD was perimembranous with inlet extension while the other three had large outlet VSD with perimembranous extension. Five cases underwent right ventricle to pulmonary artery (RV-PA) conduit, and four cases had right ventricle outflow tract augmentation (RVOT) augmentation with transannular patch. Low cardiac output state and prolonged ventilation was observed in 3 survivors, while permanent pacemaker implantation was required for post operative complete heart block (CHB) in one child. None of the cases were reported to have subaortic obstruction. An 18 year old female patient with fontan failure and a diagnosis of transposition of great arteries (TGA) DORV VSD PS, heterotaxy, pulmonary arteriovenous fistulas underwent biventricular repair, but expired due to severe myocardial dysfunction secondary to coronary artery injury. One case with heterotaxy expired 10 months after surgery with severe respiratory sepsis. To conclude Biventricular repair for DORV, non committed VSD is a viable treatment strategy with acceptable early and intermediate term results.

P2576 - OUTCOMES OF SYSTEMIC TO PULMONARY ARTERY SHUNTS IN A LOW INCOME AFRICAN COUNTRY

Andre Brooks[1], Matthew Amoni[1], Benjamin Lee[1], Paul Human[1], Amin Mazine[2], Nancy Poirier[2], George Committis[3], Peter Zilla[1]
University of Cape Town, Chris Barnard Division of Cardiothoracic Surgery, Cape Town-South Africa[1]; University of Montreal, Cardio Vascular Surgery, Montreal-Canada[2]; University of Cape Town, Division of Cardiology, Cape Town-South Africa[3]

Background/Hypothesis: Our unit still uses systemic-to-pulmonary artery shunts for initial palliation of cyanotic congenital heart defects when primary repair is regarded as unsafe. Shunts are thrombogenic and warrant close follow-up; difficult to achieve due to the socio-economic constraints prevalent in a low-income country. Poor follow-up contributes to a delay between the shunt and definitive repair. The study objective is to document the short- to mid-term outcomes.
Material and Methods: Single-centre retrospective review in an established academic unit in a low-income African country. Exclusion: Patients with Hypoplastic Left Heart Syndrome. Primary end points: Mortality (hospital, inter-stage, and at re-intervention); need for re-intervention; definitive repair. Between January 2007 – December 2014,142 consecutive patients underwent a total of 168 MBTS, followed up for 34 ± 27 months (mean ± SD). Age: median 3.1(IQR: 0.9–9.8)months; weight: median 4.5(IQR: 3.3–7.9)kg. Diagnoses: TOF/DORV: 37%; univentricular heart defects (UVH): 18%; pulmonary atresia with VSD(PA/VSD): 15%;TGA: 7%; AVSD with pulmonary stenosis/atresia: 6%; pulmonary atresia with intact ventricular septum (PA/IVS): 4%; miscellaneous: 12%.
Results: Mortality after 1st time shunt procedure (8%), inter-stage mortality (12%) and after 2nd time shunt procedure (5.6%). Cumulative mortality, prior to definitive repair, 20%. Shunt re-intervention prior to definitive repair in 19%. One year survival: PA/IVS 30%, UVH 70%, TOF/ PA-VSD 90%. Definitive correction achieved in only 33% at a median of 18.3 months.
Conclusion: Under conditions prevalent in a low-income country shunts remain a very high-risk procedure with a low yield of definitive repair within a reasonable time frame. Better outcomes may conceivably be achieved through implementing a system of vigilant patient follow-up; structured approaches to earlier definitive repair, or the next step of palliation. The adoption of alternative palliative surgical strategies is justifiable in face of the high overall mortality and warrants exploration.

P2586 - A PROSPECTIVE STUDY TO DETERMINE THE INCIDENCE OF VARIOUS CORONARY ARTERY PATTERNS IN PATIENTS UNDERGOING ARTERIAL SWITCH SURGERY FOR DEXTRO TRANSPOSITION OF GREAT ARTERIES

Sukanta Kumar Behera[1], Devika Thacker[1], Mrinalendu Das[1], Amitava Chattapadhyaya[2]
Rabindranath Tagore International Institute of Cardiac Sciences, Cardiac Surgery, Kolkata-India[1]; Rabindranath Tagore International Institute of Cardiac Sciences, Pediatric Cardiology, Kolkata-India[2]

Background: Understanding of coronary artery in dextrotransposition of great arteries is necessary for successful outcome of arterial switch operation. The study aims to observe the anatomic diversity of coronary arteries in patients undergoing arterial switch operation, and determine the commonest pattern seen intra operatively in India.
Methods: The study was carried out in a single centre from January 2012 to Jan 2016, 97 consecutive arterial switch surgeries performed during this period were included in the study. We used the Yacoub and Radley- Smith patterns in order to classify the different coronary distributions [A, B, C, D and E] as observed intra operatively.
Results: The commonest coronary pattern seen in the study was type A 57 out of 97[58.76%]. Interestingly, 24.74% of our patients had a type D coronary pattern which is extremely unusual as when compared to what is observed in other parts of the world. This was followed by type B and E [8.24%] each. Type C was not observed in any of the patients.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: In Indian population almost a quarter of the patients present with type D coronary pattern, which is significantly higher than what is observed in other parts of the world.

P2591 - PULMONARY ARTERY STENOSIS AFTER ARTERIAL SWITCH PROCEDURE

Artur Sharafutdinov[1], Dmitry Onegov[1], Vladimir Plechev[2], Irina Nikolaeva[3], Ruslan Tuguzbaev[1], Elena Larionova[4]
Republican Cardiac Center, Pediatric Cardiac Surgery, Ufa-Russia[1]; Bsmu, Hospital Surgery Dept, Ufa-Russia[2]; Republican Cardiac Center, Republican Cardiac Center, Ufa-Russia[3]; Republican Cardiac Center, Cicu, Ufa-[4]

The results of 51 arterial switch procedure were observed. Significant pulmonary artery stenosis in the remote period occurred in 9 patients (17,6%). All 9 patients were examined using CT in addition to routine methods. 6 patients underwent attempts of the balloon plasty of the pulmonary artery stenosis. Only in one case the procedure was successful. We came to conclusions of possible causes leading to the pulmonary artery stenosis: - inadequate dissection of branches of the pulmonary artery results in their low mobility, tension and deformation; - using a xenopericardial patch in the reconstruction of the pulmonary artery; - using of an autologous pericardium treated with glutaraldehyde; - using the trap-door coronary transfer forming increased aortic root which results in the compression of the pulmonary artery and its bifurcation. 8 patients with pulmonary artery stenosis were reoperated using cardiopulmonary bypass. In two patients the stenosis were located at the level of the pulmonary artery anastomosis. In six patients the stenosis were located at the level of the the pulmonary artery branches.
The postoperative period were uneventful. All the patients were disharged with a good results.

P2592 - SURGICAL OUTCOMES AFTER TWO YEARS OF ESTABLISHING A CONGENITAL HEART DISEASE PROGRAM IN A RESOURCE LIMITED COUNTRY USING A 'SINGLE CHARITY CENTRE' APPROACH

Intikhab Zafurallah[1], Calum Holden Cooper[2], Randa Blenden[3], Tyler Wallen[4], Travis Vesel[5], Marissa Seepersaud[6], Rodrigo Soto[7]
Birmingham Children, Paediatric Intensive Care, Birmingham-United Kingdom[1]; Great Ormond Street Hospital, Cardiac Critical Care, London-United Kingdom[2]; International Children, Chief Administrative Officer, Memphis-United States[3]; Mercy Catholic Medical Center, Cardiac Surgery, Darby-United States[4]; Duke University, Cardiac Critical Care, Phildelphia-United States[5]; Georgetown Public Hospital Corporation, Paediatric Surgery, Georgetown-Guyana[6]; International Children, Ceo, Clinical Operation, Memphis-United States[7]

Background/Hypothesis: Guyana, a developing nation in South America, has a neonatal mortality rate of 22.8 and an under five mortality of 39.4 respectively. With no established congenital heart disease or critical care programs, the morbidity and mortality of this group of disease contributes to the country's health burden. The International Children's Heart Foundation (ICHF), a charitable organisation with 22 years of providing paediatric cardiac services in developing countries, undertook the challenge of establishing a congenital heart disease program in Guyana.
Aim: The aim of this study was to evaluate the surgical outcomes over the first two years of introducing a pediatric cardiac surgical program in Guyana and to identify factors transferable to other resource limited countries.
Materials and Methods: This is a retrospective case series review of patients who underwent cardiac surgery by the ICHF team from January 2015 to December 2016.
Results: Ninety-five patients underwent corrective or palliative cardiac surgery. Ninety percent (n = 85) were children, 55% percent (n = 47) were less than 5 years old. Seventy percent (n = 80) had a RACHS-1 score of 2 or more. The range of cardiac diagnoses and interventions were comparable to established programs within developed countries (Table 1). Seventy percent (n = 55) of the cases returned intubated after surgery. The median time of mechanical ventilation on the PICU was 120 minutes (IQR 0, 247.5). Only twenty percent of the patients (n = 18) received analgesic infusions. The most frequent post-operative complication was bleeding (Table 2). In this series, 30 days mortality was 2.1%.The median PICU length of stay (LOS) was 2 days without and 3 days with any inotropic requirements.
Conclusion: Pediatric cardiac surgery can be performed with good outcomes in developing countries. Optimal use of analgesia, shorter periods of invasive ventilation, early mobilization, using an experienced team to supervise and train the local health care professionals may contribute to shorter PICU LOS.

P2603 - AN UNNOTICED PARTIAL PULMONARY VENOUS RETURN COMPLICATING SURGICAL CLOSURE OF A SWISS CHEESE VSD

Aybala Tongut[1], Ali Can Hatemi[2], Eylem Tuncer[2], Fusun Guzelmeric[3], Hakan Ceyran[2]
Mehmet Akif Inan Educational and Research Hospital, Pediatric Cardiac Surgery, Sanliurfa-Turkey[1]; Kartal Koşuyolu Educational and Research Hospital, Pediatric Cardiac Surgery, Istanbul-Turkey[2]; Kartal Koşuyolu Educational and Research Hospital, Clinic of Anesthesiology, Istanbul-Turkey[3]

PAPVC and VSD co-existence, both causing significant left to right shunt, is exceptionally rarely reported. We herein report a case of Swiss cheese VSD closed surgically with a peroperatively diagnosed PAPVC. To our knowledge there is only one report depicting such a case in the literature.
Material and Method: A 2-year old male with a history of pulmonary artery banding (PAB) in infancy, due to a swiss cheese VSD at another clinic, underwent patch closure of the VSD and debanding at 1 year old. However patient could not be weaned from cardiopulmonary bypass and surgical team made a decision to takedown the VSD patch with a loose re-PAB, but ECMO support to provide adequate systemic organ perfusion was mandatory. Patient was discharged on the 1st postoperative month under pulmonary anti-hypertensive therapy.
Results: Patient was referred to our clinic and transthoracic echocardiography (TTE) revealed a swiss cheese VSD and an uneffective PAB. Cardiac catheterization reported a defect unamenable for catheter closure thus the patient was scheduled for a total correction. Right upper pulmonary veins draining to superior vena cava was noticed peroperatively, therefore correction of the PAPVC and VSD closure was performed (Figure 1). Patient was extubated on the 2nd postoperative day and control TTE depicted no residual VSD with unrestrictive pulmonary vein flow. The post-operative course was uneventful and the child was discharged on the 7th post-operative day in good condition.
Conclusion: Although preoperative diagnostic studies are sine qua non for the congenital heart surgeon, meticulous peroperative evaluation of the patient with his/her unique history is vital for splendid results, exceptionally in redo cases.

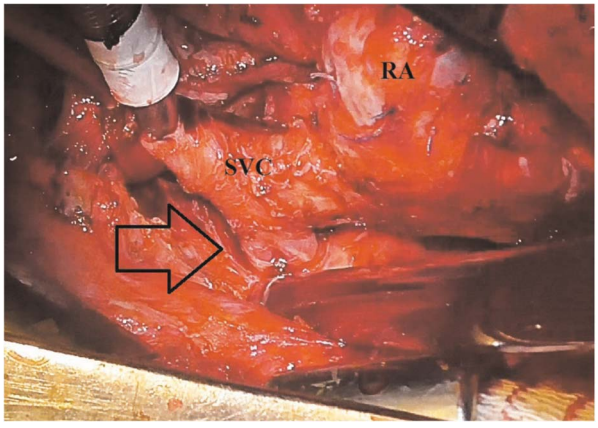

Figure.
Intraoperative photograph showing the cannulated SVC and right upper pulmonary veins draining to superior vena cava (arrow). Abbreviations: SVC, superior vena cava; RA, right atrium.

P2613 - NIKAIDOH PROCEDURE INITIAL EXPERIENCE FROM SINGLE CENTRE

Giridhar Gopal Dhandayuthapani[1], Roy Verghese[2], Ravi Agarwal[2], Ejaz Sheriff[2]
Madras Medical Mission Hospital, Paediatric Intensive Care, Chennai-India[1]; Madras Medical Mission Hospital, Paediatric Cardiac Surgery, Chennai-India[2]

Background: The Rastelli operation is the conventional procedure for TGA with VSD, PS. Its results, however, are suboptimal. Although short term results are good it has long term complications due to conduit obstruction, arrhythmia. Another surgical technique, the Nikaidoh procedure, appears as a good therapeutic option.
Objective: Review our initial experience using the modified Nikaidoh procedure consisting of aortic translocation and biventricular outflow tract reconstruction in the short term.
Methods: The study analyzed 5 consecutive patients operated on with the modified Nikaidoh procedure at our institution.
Results: The mean hospital stay duration was 15 days (11- 23 days). Ventilatory dependency was noted for mean of 5.4 days (2-9 days) and ionotropy for mean of 7 days (5-11 days). Only one patient developed moderate LV dysfunction. None of the patient had aortic valve regurgitation. One patient developed post operative JET which recovered in three days.
Conclusions: The Nikaidoh operation and its variants are a satisfactory surgical option for patients presenting with TGA,VSD, PS morphology who are inadequate candidates for a Rastelli procedure. In the short term follow-up, the left ventricular outflow tract remained without obstruction and there was no significant aortic valve regurgitation.

P2631 - ON TABLE EXTUBATION FACILITATES MANAGEMENT OF POSTOPERATIVE PULMONARY ARTERIAL HYPERTENSION A NOVEL APPROACH

Gaurav Kumar[1], Vipul Sharma[2], Saajan Joshi[2], Vivek Kumar[3], Nikhil Tiwari[1]
Army Hospital Research & Referral, Paediatric Cardiac Surgery, New Delhi-India[1]; Army Hospital Research & Referral, Cardiac Anaesthesia, New Delhi-India[2]; Army Hospital Research & Referral, Paediatric Cardiology, New Delhi-India[3]

Background: Past two decades have seen rapid improvement in outcome for congenital heart surgery after palliation and complete repair. Post operative pulmonary hypertensive crisis is a potentially fatal complication occurring unpredictably in the post operative period in patients with severe pulmonary arterial hypertension. The aim of this study was to evaluate the safety of extubation in the operating room after pediatric cardiac surgery in patients with severe pulmonary arterial hypertension using our institutional protocol.
Methods: A retrospective analysis of 122 patients aged 15 days – 7 years (median 12 months) with severe pulmonary arterial hypertension due to large left to right shunts having undergone corrective surgery was conducted. Patients on preoperative inotropes, emergency surgery, preoperative ventilation and spinal deformity or deranged coagulation profile precluding central neuraxial blockade were excluded from the analysis. Statistical analysis of factors influencing inability to extubate and risk factors were assessed. Induction of anaesthesia with a combination of Ketamine and midazolam, maintenance with sevoflurane, use of vasopressin, epidural analgesia with bupivacaine and postoperative sedation with combination of dexmedetomidine and epidural bupivacaine was the standard protocol adopted. Post extubation high flow nasal oxygen therapy was used in all cases.
Results: In our analysis, 107 out of 122(87%) patients having undergone corrective surgery with lesions with severe pulmonary arterial hypertension were extubated in the operating room. 3

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

patients (2.8%) required reintubation due to various reasons but not due to pulmonary hypertensive crisis. There was no mortality in the extubated group. Lower weight, lower age, high inotropic score with unstable hemodynamics and complex repairs with longer bypass time were factors preventing extubation.
Conclusion: On table extubation is a safe strategy in majority of patients after corrective surgery in lesions with severe pulmonary arterial hypertension and reduces the risk of pulmonary hypertensive crisis.

P2635 - UNIFOCALIZATION OF THE MAJOR AORTOPULMONARY COLLATERAL ARTERIES WITHOUT DIRECT ANASTOMOSIS IN PATIENTS WITH PULMONARY ATRESIA AND VENTRICULAR SEPTAL DEFECT USEFUL APPROACH

Joaquin Perez-Andreu[1], Joaquin Fernandez-Doblas[1], Dimpna C Albert[2], Ferran Gran[2], Gemma Giralt[2], Anna Sabate-Rotes[2], Pedro Betrian[2], Queralt Ferrer[2], Ferran Roses[2], Raul Abella[1]
Vall D´hebron University Hospital, Congenital Heart Surgery, Barcelona-Spain[1]; Vall D´hebron University Hospital, Pediatric Cardiology, Barcelona-Spain[2]

Background: The ultimate goal of the pulmonary atresia (PA) with ventricular septal defect (VSD) and major aortopulmonary collateral arteries (MAPCAs) is to create unobstructed and separate in series pulmonary and systemic circuits. The number of lung segments recruited and the status of the pulmonary microvasculature are the main influence factors for the post-repair peak right ventricular (RV) pressure. We present our experience with a 1-stage unifocalization technique that eliminates the need for anastomosis of individual MAPCAs.
Materials and Methods: Between 2008 and 2016,25 patients underwent a 1-stage unifocalization surgery consisting in 1) exclusion of the descending thoracic aorta segment containing the origin of all MAPCAs and 2) connection of this aortic segment to the native pulmonary artery with an interposition polytetrafluoroethylene conduit. The RV was connected to unifocalized pulmonary arteries using a valved conduit. 95% of MAPCAs were finally unifocalized. The median age at surgery was 8 months (range: 4-18). 11 patients needed a rehabilitative procedure of the hypoplastic pulmonary arteries before the definitive repair.
Results: All patients survived the operation with the exception of 1 death in a child with a complete absent of intrapericardial branch

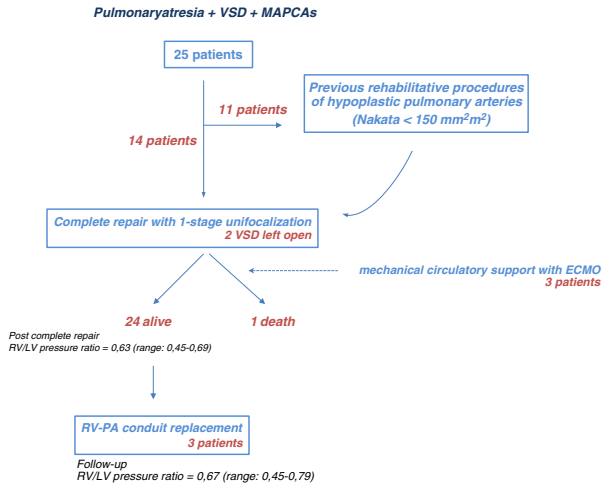

Figure 1.

pulmonary arteries. Postoperative complications included: infection (n = 3), bleeding (n = 2), pleural effusion (n = 1) and diaphragm paralysis (n = 2). The postoperative length of stay was 10 days (range: 7-16). Technetium99m lung perfusion scans in 15 patients one year after the operation showed uniform perfusion of all pulmonary segments. After 8 years of follow-up, all 24 patients are alive.
Conclusions: Complete repair of PA + VSD with unifocalization of all MAPCAs can be successfully accomplished. This approach provides optimal results in selected patients with MAPCAs originating from the descending thoracic aorta..

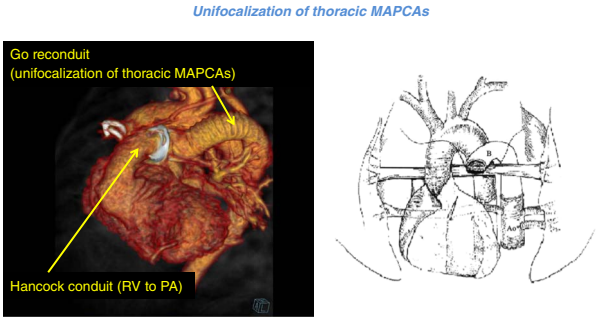

Figure 2.

P2647 - A 6 YEAR SINGLE CENTRE EXPERIENCE ON THE USE OF EXTRACORPOREAL MEMBRANE OXYGENATION IN PAEDIATRIC MYOCARDITIS PATIENTS

Julian Matingal[1], Jacqueline Soo May Ong[2], Win Maung Maung Aye[1], Sriram Shankar[1]
National University Hospital, Singapore, Cardiac, Thoracic and Vascular Surgery, Singapore-Singapore[1] National University Hospital, Singapore, Paediatrics, Singapore-Singapore[2]

Background: Paediatric myocarditis, although uncommon, carries significant morbidity and mortality if undiagnosed promptly. Extracorporeal membrane oxygenation (ECMO) has been employed as a rescue therapy since 2010 at our institution. We aim to analyze our experience, in terms of the outcome of its use on paediatric myocarditis patients.
Materials and Methods: This is a single centre study in a tertiary hospital on paediatric myocarditis patients treated medically and with ECMO over a 6-year period from Jan 2010 to Oct 2016. Patients were identified from the paediatric intensive care unit (PICU) admission book and institutional ECMO registry. Demographic data was collected retrospectively from the hospital database. The outcome for patient was classified as either survival to hospital discharge or death. Data on complications and ejection fraction (EF) were also collected.
Results: 9 children (3 boys and 6 girls, mean age 9.78 years) were diagnosed to have myocarditis. Two (22%) were medically managed in PICU, and they received both dobutamine and milrinone, and did not require invasive ventilation. They were the two eldest in the study group (ages 15.92 and 17.36 years), and also had a higher EF pre treatment (59% and 72%) and post treatment (73% and 72%). We used veno-arterial ECMO on seven (78%) children, one of whom (girl, age 6.83 years) died on day 15 of admission due to systemic bleeding and severe cerebral oedema. Complications in other patients included haemorrhagic stroke, vocal cord paresis, lung barotrauma, pleural effusion, pneumothorax, urinary tract infection, acute urinary retention, transaminitis, ileus, line

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

infection and sepsis. The majority of our myocarditis patients required ECMO, and they did well with a survival rate of 86%.
Conclusions: ECMO has good outcomes in myocarditis. ECMO should be considered as one of the treatment modalities in paediatric patients with myocarditis.

P2659 - LONG TERM OUTCOMES OF JATENE PROCEDURE

Camila Lino Martins, Natalia Jatene, Daniel Mascarenhas, Maira Weigel, Elaine Furquim, Rogério Souza, Patricia Elias, Ieda Biscegli Jatene, Marcelo Biscegli Jatene
Heart Hospital, Pediatric Cardiology, São Paulo-Brazil

Background: Transposition of the Great Arteries (TGA) is the most prevalent cyanogenic congenital heart disease in the neonatal period. It presents totally unfavorable evolution if it is not corrected surgically, and the Jatene Procedure is the gold standard for the treatment. The aim of this study is to describe clinical and functional characteristics of patients undergoing Jatene procedure during long-term outpatient follow-up.
Material and Methods: Retrospective study of patients submitted to Jatene procedure, in outpatient follow-up at a tertiary service. The following variables were evaluated: type of TGA, performance of Lecompte maneuver, development of arrhythmias during follow-up, need for pacemaker, presence of heart failure, major artery insufficiency or stenosis and residual ventricular septal defect (VSD).
Results: A total of 113 patients were included in the study, 73 (64.6%) were males, with a mean follow-up time of 9.8 ± 8.7 years. The mean age at surgery was 2.8 ± 8.4 months. Regarding the type of TGA, 63.5% were simple. Of the patients in whom the Lecompte maneuver was performed ($n = 81$), 22% evolved with neopulmonary stenosis compared to 47.8% of those who did not undergo the maneuver ($p = 0.033$). There was a need for definitive pacemaker implantation in 8.3% of the patients, signs of HF in 10.7%. Neoaorta dilatation was also observed in 49.1%, neopulmonary stenosis in 30% and neoaorta in 10.1% and residual VSD in 8.1% of patients.
Conclusion: In the long-term follow-up after Jatene procedure for anatomical correction of TGA, the incidence of neopulmonary stenosis was lower in those patients who underwent Lecompte maneuver. Approximately half of the patients evolved with dilation of the neoaorta and a small portion with definitive pacemaker implantation, residual IVC or heart failure.

P2672 - IMPACT OF CARDIAC SURGERY ON MALNOURISHED AANEMIC ANDHHYPOPROTEINEMIC INFANTS TO ADULTS OF INDIA

Sreemathi Seshadrinathan, Karunanidhi Jaikar, Vijayasankar Muthu, Saravanakrishnaraja Shanmugasundaram
Public Health Centre, Cardiovascular and Thoracic Surgery, Chennai-India

Objectives: To study the short and long term effects of cardiac surgery on malnourished, anaemic and hypoproteinemic infants to adults.
Background: There have been several studies but only a few on anemic, malnourished and hypoproteinemic infants to adults.
Methods: This is a Retrospective study of 280 infants to adults with Congenital and Acquired Cardiac abnormalities who had undergone cardiac surgery. There were 212 in the Paediatric age group and 68 in the adult age group. In the pediatric age group, Repair of Acyanotics was in 175, Coarctation of Aorta in 3, Cyanotics in 20, Anomalous Pulmonary Venous Drainage in 4, and Complex Anomalies in 6. Mitral valve Replacement was in 3 and AVR in 1. Among adults 7 Acyanotics had Repair, 42 had Mitral valve Replacement, 3 had Mitral Valve repair, 5 had Aortic valve Replacement, 4 had Double Valve Replacement and 7 had CABG. They have been followed up periodically after 1 month, 3, 6, and 12 months and every year after that with a view to estimate to what extent the preoperative risk factors impact the recovery of vital parameters. Role of each person in family and society is also being ascertained. Follow up has been from 1 month to 12 years.
Conclusion: Irrespective of the fact that they return to the same environment from which they hailed, symptomatically and in terms of growth, they have shown remarkable progress. Return of the parameters however varies. Only long term follow up can reveal the true outcome.

P2673 - REPAIR OF ANOMALOUS RIGHT CORONARY ARTERY FROM THE PULMONARY ARTERY TECHNICAL PEARLS AND PITFALLS

Srujan Ganta, Minoo Kavarana
Medical University of South Carolina, Surgery, Charleston-United States

Background/Hypothesis: Anomalous origin of the right coronary artery from the pulmonary artery(ARCAPA) is rare. Late thrombosis due to technical imperfection has been reported. Unique anatomical characteristics observed are tethering secondary to the extensive large collateral vessels, severe native coronary tortuosity and the side-by-side great vessel orientation which require specific technical considerations to ensure safe translocation.
Materials and Methods: A single center retrospective review of 5 patients with ARCAPA was performed. There were 4 children and 1 adult. Echocardiographic and computerized tomography (CT) scan data were analyzed for anatomical and functional cardiac characteristics. Operative techniques were analyzed which reflected an evolution towards a modified-trapdoor technique.
Results: Patient demographics are listed in table 1. Coronary artery echo characteristics are listed in table 2. CT angiography was used to assess coronary anatomy in all patients and detected a severe ostial stenosis in one. 4 children presented with asymptomatic murmurs and the adult patient with unstable angina. All patients underwent successful surgical correction without complications. The modified trapdoor technique provided the most ideal geometry for coronary transfer secondary to its unique anatomical characteristics. The average hospital stay was 5 days and there were no mortalities. Two patients had coronary button transfers above the sino-tubular junction (STJ) using a vertical stab incisions, one had the button implanted after excising part of the aortic wall and 2 patients had modified trapdoor incisions.

Table 1.

Patient	Age (years)	CPB (minutes)	XC (minutes)	Sex M = male, F = female	Presentation	Translocation Technique
1	4.2	140	73	M	Asymptomatic murmur	Coronary button with Aortic wall excision
2	41.5	208	154	F	Unstable Angina	Patch Augmented button
3	1.8	91	41	F	Asymptomatic murmur	Vertical Slit
4	3.3	188	100	F	Asymptomatic murmur	Modified Trapdoor
5	8.0	155	78	M	Asymptomatic murmur	Modified Trapdoor
Mean	11.8116.8	156 ± 40.5	89 ± 37.5	-	-	-

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: ARCAPA is often asymptomatic but can present with ischemia. Its unique anatomical characteristics require a coronary transfer technique different from that performed for aortic root replacement or arterial switch operations. The use of a modified trapdoor incision simplifies coronary transfer and may minimize late coronary thrombosis.

Table 2.

Patient	RCA Z-Score	LMCA Z-Score	LAD Z-Score	Ventricular function	Collateral Flow	Coronary Stenosis
1	1.45	8.4	5.4	Normal	Present	None
2	0.5	3.9	-	Normal	Present	Proximal RCA 90%
3	-	-	-	Normal	Present	None
4	2.7	3.7	2.4	Normal	Present	None
5	5.5	6.3	4.5	Normal	Present	None
Mean	2.5 ± 1.9	5.6 ± 1.9	4.1 ± 1.3	-	-	-

P2674 - NEUROSURGICAL INTERVENTION AFTER CARDIAC SURGERY FOR PEDIATRIC AND CONGENITAL CARDIAC CARE A SINGLE CENTER 17 YEAR EXPERIENCE

Luis Rodriguez[1], Jeffrey Jacobs[2]
Johns Hopkins All Children, Pediatric Neurosurgery, St. Petersburg-United States[1]; Johns Hopkins All Children, Cardiovascular Surgery, St. Petersburg-United States[2]

Background: Neurological injury after cardiac surgery can present as seizures, stroke, or hemorrhage. Very few strokes or hemorrhages result in the need for neurosurgical intervention. We reviewed all patients undergoing cardiac surgery at a single institution during a 17 year time interval and identified all patients who required neurosurgical intervention.
Materials and Methods: All pediatric and congenital cardiac operations were identified at a single institution between January 1, 2000 through December 31, 2016 using the institutional software Society of Thoracic Surgeons (STS) Congenital Heart Surgery Database. The records of patients undergoing neurosurgical intervention were reviewed.
Results: 5033 pediatric and congenital cardiac operations were performed. Only two of these patients (0.04%) required neurosurgical intervention. Patient 1 was born with transposition of the great arteries with ventricular septal defect and aortic arch narrowing. He underwent palliative Rashkind balloon septostomy on day one of life, and an arterial switch procedure on day 41, requiring extracorporeal membrane oxygenation (ECMO) after surgery. He developed an acute pan-hemispheric left subdural hematoma that required a left coronal burr hole and a subdural drain. The patient was separated from ECMO on postoperative day 4 and delayed sternal closure on postoperative day 6. The patent is now 7 years old and without significant neurological deficit. Patient 2 is a 3 year old who had undergone Norwood and Glenn procedures for hypoplastic left heart syndrome. She underwent an extracardiac Fontan operation complicated by postoperative bleeding. She developed a right holohemispheric infarct with midline shift and effacement of the ventricles. She underwent right frontotemporoparietal decompressive craniectomy. She survived with significant neurological deficits.
Conclusion: The need for neurosurgical intervention after pediatric and congenital cardiac surgery is quite rare; however, when indicated, it can offer the possibility of satisfactory outcome.

P2681 - CURRENT OUTCOME OF VENO ARTERIAL EXTRACORPOREAL MEMBRANE OXYGENTATION IN NEONATES AND INFANTS USING MAGNETIC LEVITATION CENTRIFUGAL PUMPS

Stiljan Hoxha[1], Riccardo Giuseppe Abbasciano[1], Alessio Rungatscher[1], Giulia Poretti[1], Tiziano Menon[1], Luca Barozzi[1], Camilla Sandrini[2], Mara Pilati[2], Giuseppe Faggian[1], Giovanni Battista Luciani[1]
University of Verona, Department of Surgery, Verona-Italy[1]; University of Verona, Department of Medecine, Verona-Italy[2]

Background: Outcomes of first generation centrifugal pumps has been controversial, thus latest generation pumps using magnetic levitation technology were developed in order to overcome mechanical properties of first generation devices.
Objective: This retrospective study aimed to assess the safety and efficacy of V-A ECMO for cardiac indications in neonates and infants using standard (SP) and latest generation magnetic levitation (ML) centrifugal pumps.
Methods: Between September 2002 and January 2017, 40 consecutive patients with a median age of 23 days (4 days-12 months) and a median body weight of 3.2 kg (1.9-12; 11/40 < 2.5 kg) were supported using V-A ECMO. Indication to V-A ECMO was circulatory collapse in ICU in 18 (45%), failure to wean after cardiac repair in 12 (30%), myocarditis in 4 (10%), sepsis in 3 (7.5%) and refractory arrhythmias in 3 (7.5%). Central cannulation was used in 32 (80%) patients. Seven patients were supported with SP and 33 with ML pumps.
Results: Median duration of support was 72 hours (range 24-672), with an overall weaning rate of 82% (33/40). Overall survival to discharge was 48% (19/40). Risk factors for hospital mortality included lower (<2.5 kg) body weight ($p = 0.02$) and rescue ECMO after cardiac repair ($p = 0.03$). During a median follow-up of 52 months (range 1-97), there were 4 (10%) late deaths and 2 late survivors with neurological sequelae. Comparison of weaning rate (5/7 versus 28/33, p = NS) and prevalence of renal failure requiring dialysis (4/7 versus 16/33, p = NS) were comparable between SP and ML ECMO groups. Patients supported with ML had a trend toward higher hospital survival (1/7 versus 18/33, $p = 0.05$) and significantly higher late survival (0/7 versus 15/33, $p = 0.02$).
Conclusions: The present experience shows that V-A ECMO for cardiac indications using latest generation centrifugal pumps may further improve end-organ recovery, hospital and late survival, even in very low body weight newborn.

P2684 - TOWARDS FAST TRACKING PAEDIATRIC CARDIAC SURGERY STRATEGY AND INITIAL EXPERIENCE WITH EARLY EXTUBATION

Nikhil Tiwari
Childrens Hospital ,Alder Hey, Ctvs, New Delhi-India

Objective: The aim of this study is to report our initial experience with early extubation (<6 hours)following congenital cardiac surgery, assessing its efficacy and safety and the potential for fast tracking through Paediatric Intensive Care Unit (PICU).
Methods: Early extubation was defined as intraoperative or within 6 hours from arrival to PICU. Between January 2014 till March 2016, 847 patients underwent congenital cardiac surgery at Alder hey Childrens Hospital with a 30 day mortality rate of 0.9 percent. The clinical records of 525 patients older than 90 days of age were reviewed. The mean age and weight was 1.04 years and 12.1 kg respectively. Redo-sternotomy accounted for 131 cases (25%). The management strategy involves a specific anaesthetic technique, warm cardiopulmonary bypass and intraoperative echocardiogram for evaluation of surgical repair.
Results: Out of 525 patients, early extubation was accomplished in 465 patients (88%)with an intraoperative extubation rate of (66%).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

There was no mortality or other adverse events related to early extubation. Reintubation was required in 3 patients (0.6%). Patients extubated earlier had a shorter PICU stay (3.1 + /-3.6 vs 5.1 + /- 2.7 days) and shorter hospital stays (5.9 + /- 10.7 days). It was noted that the PICU stay was artificially longer due to the bottle - neck effect along the patient flow.

P2686 - INITIAL CLINICAL MANIFESTATIONS AND RESULTS AFTER SURGICAL REPAIR OF DOUBLE CHAMBERED RIGHT VENTRICLE IN CHILDREN AND ADULTS

Murat Surucu[1], Ilkay Erdogan[2], Birgul Varan[2], Murat Ozkan[3], Kursad Tokel[2], Sait Aslamaci[3]
Ankara Children's Hematology Oncology Education and Research Hospital, Pediatric Cardiology, Ankara-Turkey[1]; Faculty of Medicine, University of Başkent, Pediatric Cardiology, Ankara-Turkey[2]; Faculty of Medicine, University of Başkent, Cardiovascular Surgery, Ankara-Turkey[3]

Background/Hypothesis: Double-chambered right ventricle (DCRV) is a rare congenital heart disease, characterized by division of the right ventricle by hypertrophy of the septoparietal trabeculations into two parts, the proximal chamber with higher pressure, and the distal chamber with low pressure. We aim to report our experiences regarding the DCRV symptomatic presentations, long-term prognosis, including the recurrent rate of DCRV and occurrence of arrhythmias after surgery.
Materials and Methods: We retrospectively investigated 89 consecutive patients who were diagnosed with DCRV and underwent a surgical intervention from 1995 to 2016. We investigated the following clinical characteristics before and after surgery: gender; age at the time of surgery; follow-up period; pressure data obtained using transthoracic echocardiography and cardiac catheterization; and co-existing conditions, such as ventricular septal defect (VSD), atrial septal defect (ASD). The surgical approaches, postoperative mortality rate, and occurrence of cardiac events were also evaluated.
Results: Mean age at the time of diagnosis was 1.96 ± 4.15 years (1 month - 30 years) and 5.3 ± 4.89 years (5 months - 30 years) at the time of operation. Concomitant cardiac anomalies; perimembranous VSD (78 patients), musculer VSD (2 patients), ASD (9 patients), right arcus aorta (3 patients), left superior vena cava (2 patients), patent ductus arteriosus (1 patient), peripheral pulmonary stenosis (1 patient). The mean follow-up period was 4.86 ± 4.6 years. In these patients, the systolic pressure gradient in the RV by echocardiography before, immediately, and long-term after surgical intervention was 49 ± 31, 11.8 ± 7.9 and 10.4 ± 6.9 mm Hg respectively. There were no deaths during the long-term follow-up period. Surgical reinterventions were performed for residual VSD (2 patients), residual pulmonary stenosis (1 patient), severe tricuspid insufficiency (1 patient).
Conclusion: The surgical outcomes and postoperative prognosis of DCRV are favorable, and neither recurrence of DCRV nor fatal arrhythmias develop during the long-term follow-up period.

P2687 - PSYCHOSOCIAL CONDITIONS AND QUALITY OF LIFE OF PATIENTS AFTER STAGED OPERATION FOR HYPOPLASTIC LEFT HEART SYNDROME AND THEIR FAMILIES ONE CENTER EXPERIENCE

Anna Mazurek-Kula[1], Barbara Wiśniewska[1], Jadwiga Moll[1], Jacek Moll[2], Piotr Kula[3], Tomasz Moszura[1]
Polish Mother's Memorial Hospital Research Institute, Department of Cardiology, Lodz-Poland[1]; Polish Mother's Memorial Hospital Research Institute, Department of Cardiosurgery, Lodz-Poland[2]; Medical University of Lodz, Department of Cardiac Surgery, Lodz-Poland[3]

Background: Improvement in results of staged palliation for HLHS indicates assessment of HLHS survivors quality of life (QoL).
Aim: To assess the QoL of patients with HLHS and their families.
Material and Methods: 98 mothers of patients with HLHS (73 boys – 75%) completed the questionnaire to assess their children QoL and impact of child's illness on the family. All children (age 3-17 years, mean 7 years) were operated at our institution. Prenatal diagnosis of HLHS was established in 43 (44%). Mean mother's age at the delivery was 28 years (17-41 years). In 52% child with HLHS was the first, in 28% - the only child.
Results: Development estimated as normal was reported in 89%. Limited physical activity in 80%, emotional problems in 24%, educational in 9%. Normal schools and kindergartens attendance in 78%. Learning progress estimated as good and very good in 70%. Child's illness indicated strong parental stress (93%), but 87% of responders estimated that they successfully cope with the problem. Only 11% of mothers looked for psychological care. In 94% familial atmosphere was assessed as good, in 78% child's illness strengthened parental marriage. In 18% of families mother was the only parent. Impact of child's illness on material situation was significantly negative in 79%. In 57% father was the only working parent. 97% of responders wouldn't change anything in their choice of the method and place of treatment.
Conclusions: 1. Patients with HLHS are active members of the society, they attend to normal schools and kindergartens although their physical activity is limited. 2. The family functioning is good but child's illness is a reason of strong parental stress and indicates material problems. 3. Increasing number of HLHS survivors indicates the need for continuation studies concerning neurodevelopmental outcome, quality of life, career and family planning and social functioning.

P2695 - COMPUTATIONAL FLUID DYNAMICS ANALYSIS PULMONARY BLOOD FLOW AFTER TOF REPAIR

Qin Yan[1], Jinlong Liu[1], Lei Zhang[1], Haibo Zhang[2], Jinghao Zhen[2], Zhiwei Xu[2], Jinfen Liu[2]
Shanghai Children's Medical Center, Medical School, Shanghai Jiao Tong University, Cardiovascular and Thoracic Surg, Shanghai-China[1]; Shanghai Children, Cardiovascular and Thoracic Surg, Shanghai-China[2]

Objectives: We hypothesize that patient-specific computed tomography (CT)-based morphometry with TOF repair followed by reconstruction of viable surgical options with hemodynamic function assessment using computational fluid dynamics (CFD) can guide surgical decisions.
Methods: Two TOF patients (Model 1 and 2) who underwent successful correction by one pericardial patch (PP) was selected as a reference for morphological characterization by 3D model of patient-specific pulmonary artery reconstruction from CT images. The third patient (VR) with residual left pulmonary artery (LPA) stenosis after repair, was selected for virtual re-correction LPA using the same strategy (i.e. PP) by computer-aided design. CFD was employed for hemodynamic analysis of pulmonary blood flow, including of streamlines, wall shear stress (WSS), energy loss and ratio of flow distribution.
Results: Compared with patient after VR, before one showed more vortex formation in the LPA, swirling flow (1.5 m/sec vs 0.2 m/esc), higher WSS area and energy loss of LPA blood flow, with lower distribution ratio. In the VR, the streamlines from

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

main PA to LPA was smoothly with more than rectangular position between main PA and LPA.
Conclusions: In patient-specific virtual re-correction LPA surgery followed by CFD evaluation has the potential in augmenting morphology-guided decisions on surgical strategy. Considering the limitations relate to the small number of patients, these data may provoke reconsidering the optimal surgical design to TOF repair.

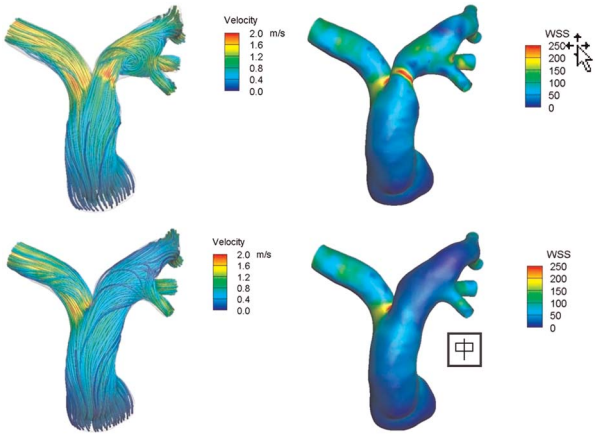

Figure.

P2702 - THE LEFT ANTERIOR MINI THORACOTOMY APPROACH FOR THE CLOSURE OF PATENT DUCTUS ARTERIOSUS IN PRE TERM NEONATES MID TERM RESULTS

Okan Yurdakok[1], Fatih Ozdemir[1], Mehmet Dedemoglu[1], Oktay Korun[1], Murat Cicek[1], Mehmet Bicer[1], Numan Ali Aydemir[1], Ahmet Sasmazel[1], Ali Riza Karaci[2]
Siyami Ersek Hospital, Pediatric Cardiac Surgery, Istanbul-Turkey[1]; Florence Nightingale Hospital, Pediatric Cardiac Surgery, Istanbul-Turkey[2]

Objectives: We hereby present the mid-term results of our series, using the left anterior mini-thoracotomy technique for closure of a patent ductus arteriosus (PDA) in pre-term neonates. Left anterior mini-thoracotomy is a surgical procedure that consists of an anterior mini-thoracotomy (~1.5 cm) below the clavicle, entering the thoracic cavity from the 2nd or 3rd intercostal space, clipping the PDA, and closing the thorax without a tube thoracostomy.
Methods: Between 2009 and 2017, we performed PDA closure in 88 pre-term neonates using this method. Logistic regression analysis of potential risk factors for mortality was determined.
Results: The mean weight of the patients at the time of operation was 801.49 ± 22.03(range 450g-1500g). The mean age at the operation was 26.44 ± 3.15 days. 1 surgery-related mortality occurred and it was due to respiratory and ventilatory difficulties. Ten short-term mortalities occurred after the operation (11.3%) before the patients could be discharged from newborn intensive care unit. Five were due to sepsis, two was due to necrotizing enterocolitis and 3 were due to multi-organ failure. According to the linear regression analysis, no other variables were found to be statistically significant for predicting mortality. A negative linear correlation was found between the weight of the patients at the operation and extubation time.
Conclusion: The surgical outcome of left anterior mini-thoracotomy for PDA closure in neonates is comparable to other methods with satisfactory results. This technique may be advantageous for extremely low birth weight infants, since it causes less traction and trauma on the congested lungs.

P2706 - PREVALENCE OF ARRHYTHMIAS IN POSTOPERATIVE PERIOD OF JATENE OPERATION FOR TGA

Natalia Jatene Baranauskas[1], Patricia Figueiredo Elias[1], Jaqueline Ribeiro Cardoso[1], Paula Machado Costa[1], Thalyta Madeira Correa[1], Camila Lino Martins[1], Elaine Gorobets[1], Rogerio Souza[2], Ieda Jatene[1], Marcelo Jatene[3]
Hospital Do Coração, Pediatric Cardiology, São Paulo-Brazil[1]; Hospital Do Coração, Pneumology, São Paulo-Brazil[2]; Hospital Do Coração, Pediatric Cardiac Surgery, São Paulo-Brazil[3]

Background: Jatene operation is considered the treatment of choice for most TGA anatomies; improviment in mortality and less long-term complications is becoming the usual evolution in most groups. Usually arrhythmias are associated with residual lesions or coronary arteries abnormalities.
Objective: To evaluate the prevalence and caractheristics of arrhythmias in postoperative period of Jatene operation for TGA.
Material and Methods: Retrospective study included 109 patients from a single center with complete follow-up (1 to 39 years), who underwent Jatene operation (from 1976 to 2015) for TGA (65 intact septum, 29 VSD, 9 subaortic or pulmonary stenosis).
Results: 17 (15.6%) presented arrhythmia, being AV block with pacemaker implant (9), supraventricular or ventricular tachycardia (7) and atrial flutter (1). A lower incidence of arrhythmias in patients with TGA with intact septum (9.2%), compared to other complex types (26.3%) (P = 0.025). Older age at the operation was related with higher arrhythmias prevalence (p = 0.03). Cardiac failure was more prevalent in patients with arrhythmias (29.4%), compared to patients without arrhythmia (7.6%) (P = 0.03). There was no relation between the prevalence of arrhythmia and the presence of residual lesions or coronary anomaly.
Conclusion: The development of arrhythmias was associated with more complex subtypes of TGA, older age at the time of the operation and was not associated with the presence of residual lesions or coronary anomalies.

P2709 - THE EARLY OUTCOME OF DELAYED CHEST CLOSURE AFTER COMPLEX PEDIATRIC CARDIAC SURGERY – REVIEW OF SINGLE CENTRE EXPERIENCE FROM SOUTHERN INDIA

Muthukumar Sundaram[1], Vijakumar Raju[1], Karthiga Unnikrishnan[1], Muthukumaran Subramanian[1], Soundara Valli[2], Madhav Roa[1], Anandhi Arul[2], Sai Gopal[2], Kalyana Sundaram[3]
Gknm Hospital, Cardiaothoracic Surgery, Coimbatore-India[1]; Gknm Hospital, Anaesthesia, Coimbatore-India[2]; Gknm Hospital, Cardiologist, Coimbatore-[3]

Background: Open chest followed by delayed chest closure is a standard of care in major centers after complex cardiac surgery in the pediatric age group. The Morbidity and Mortality in our center is examined.
Methods: Between July 2014 - December 2016, 545 children with age less than 18 yrs underwent cardiac surgery. Delayed chest closure was performed in 51 children (9.3%). The mean age and weight was 231 ± 6.6 days and 4.4 ±3.17 respectively. Male predominates (72%). Cardiac surgeries included Arterial switch operation in 16 pts (31.3%), TAPVC repair in 15 (29.4%) total intracardiac repair for TOF in 6 pts (11.7%),and others in 14pts (27.4%). The Mean CPB time was 176.58 ± 78 minutes and cross

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

clamp time was 102.39 ± 52.86 minutes. The chest was electively left open in 20pts (39%), for bleeding in 12(23%), long pump run in 6(11%), high PA pressure in 6 (11%),unsatisfactory haemodynamics in 4(7%)and for ECMO in 3(5%).
Results: The Mean number of days of open chest was 2.2 ±2.04. The mean number of re exploration in the ICU was 0.72 ±1.01. The mean number of Ventilation, ICU stay, antibiotic use and Hospital stay was 87.48 ±73 hours, 5.3 ± 3.8 days, 4.7 ± 3.14 days and 9.16 ±5.4 days respectively. Among these patients, 30 day mortality was observed in 22 pts (43%). Sepsis was the major cause of death (n = 8, 36.3%), followed by PAH crisis (n = 6, 27.2%) and cardiac failure (n = 5, 22.7%). The median Followup was 8 months (1 month – 30months). No late mortality.Only two patients (3.9%) developed deep mediastinal wound infection on followup and needed surgical intervention.
Conclusion: Delayed chest closure effectively optimizes the cardiac status after complex cardiac surgery in children.However delayed chest closure is associated with high postoperative sepsis and there by increases the 30 days mortality.Therefore judicious use of delayed chest closure is recommended.

P2714 - POVERTY & PERCEPTION OF HEALTH IN INTERNATIONAL PEDIATRIC CARDIAC SURGERY PATIENTS

Laura Schiff[1], Janine Henson[2], John Connett[3], Susan Lowry[4], Vantrang Nguyen[5], Emily Farkas[6], Vinivius Nina[7], William Zeman[8], Donna Doxsey Mcgrew[9], Aubyn Marath[10]
Enloe Medical Center, Data Collection, Cardiostart, Chico,-United States[1]; Cardiostart Intl., Director of Nursing, Lakeville, Minnesota-United States[2]; University of Minnesota, Biostats, Chairman, Minneapolis, Minnesota-United States[3]; University of Minnesota, Biostats, Programming, Minneapolis, Minnesota-United States[4]; Cardiostart International, Data Collection, Cardiostart, Minneapolis, Minnesota-United States[5]; Cardiostart International, Cardiac Surgeon, Los Angeles, California-United States[6]; University of Maranhao, Cardiac Surgeon, Sao, Luis-Brazil[7]; Peace Health Hospital, Cardiologist, Springfield, Oregon-United States[8]; Community Hospital, Nurse Practitioner, Milford, Connecticut-United States[9]; Cardiostart Interntional, Cardiac Surgeon, Eugene, Oregon-United States[10]

Introduction: CardioStart's international compassionate missions are structured to provide intensive teaching and equipment to support local congenital and acquired heart surgery program development. Determining how pediatric patients are selected and whether or not preventative care issues can be effectively addressed, is often uncertain.
Methods: Data from patients awaiting cardiac surgery by our visiting teams was examined in 13 missions to evolving tertiary care hospital centers in 8 countries, and in-depth direct interviews of 78 pediatric patients or their immediate accompanying relative carried out. Documentation included full cardiological evaluation and questions regarding patient's living conditions, time from first cardiac diagnosis until surgery, and their perception of current state of their health. Diagnoses included Atrial Septal Defect (18), Mitral Valve disease (4), Fallot's Tetralogy (8), Ventricular Septal Defect (30), Patent Ductus Arteriosus (10), and others (8). Patients' socio-economic and poverty status were identified by using typically used poverty indicators (including water obtained by well only, dirt floor, living in temporary shelters, electricity supply and food scarcity measures).
Results: Those identified as [1] 'extremely poor' reported lower perceptions of health when compared to other pediatric patients in the same geographic area [2], with similar diagnoses (2.14 vs 3.18 [3], p = .005). Gender and time from diagnosis until surgery were not correlated with differences in perceptions of health. Patient's poverty level did not correlate with longer waiting time between first cardiac diagnosis and surgery.
Conclusions: Mission locations have diverse cultural and medical specialist access issues: the lack of gender differences, and the comparable evaluation and referral times are encouraging. Our international missions already include structured Outreach rural clinic assistance. These Poverty and Health Perception results, however, underscore the need for emphasizing primary, preventative cardiac disease related education. This may help strengthen primary and tertiary cardiac care interaction [4].

P2731 - SURGERY FOR LEFT VENTRICULAR OUTFLOW TRACT OBSTRUCTION IN NEONATES AND INFANTS

Bram Van Wijk, Eveline Rooijakkers, Femke Van Der Stelt, Felix Haas, Paul Schoof
Wilhelmina Children's Hospital, Children's Heart Center, Utrecht-The Netherlands

Background: Infants and neonates with severe left ventricular outflow tract obstruction can be treated with pulmonary autograft replacement of the aortic root. In this retrospective single center cohort study, we present our experience with the Ross(-Konno) procedure in neonates and infants with a focus on survival, durability of the autograft and homograft, and left ventricular function.
Materials and Methods: Retrospective observational study of 23 infants (age <1 month (n = 8), <1 year (n = 15)) operated on in the Wilhelmina Children's Hospital, Utrecht, the Netherlands between 2004 and 2016. Echocardiography was used to determine left ventricular function in the post-operative follow-up.
Results: Patients had a pulmonary autograft replacement of the aortic valve with (17) or without (6) septal myectomy (Konno-procedure. Concomitant coarctectomy (5), correction of an interrupted aortic arch (6) and resection of endocardial fibroelastosis (6) was additionally performed. Median patient age at surgery was 72 days (5–342 days). All patient were available for follow-up. Median follow-up was 4 years (0,5-12 years). Overall mortality was (1) 5,9%. Freedom from autograft reintervention was 100%. Echocardiography demonstrated good LV function, even in poor contracting chambers with endocardial fibroelastosis at the time of initial surgery.
Conclusion: A Ross(-Konno) procedure can be performed with good results in neonates and infants for treatment of severe LVOT obstruction. The pulmonary autograft is a durable substitute. This procedure offers an effective desobstruction of the LV and may allow LV function to normalize.

P2735 - AN ALGORITHM FOR SURVIVAL OF THE CHALLENGING POSTOPERATIVE LATE PRESENTING FONTAN PATIENTS

Okan Yurdakok, Oktay Korun, Murat Cicek, Mehmet Bicer, Mehmet Dedemoglu, Fatih Ozdemir, Numan Ali Aydemir, Ahmet Sasmazel
Siyami Ersek Hospital, Pediatric Cardiac Surgery, Istanbul-Turkey

Objective: We hereby present our case series for a group of late presenting fontan patients, which had a challenging early postoperative course.
Methods: In the last 2 year period, we dealt with 6 late presenting fontan patients with a misleading postoperative course, age ranging between 6 to 18 years. Uneventful classic extracardiac fontan

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

procedures end-up with signs of a downhill multiorgan failure phase in the intensive care unit(ICU). We immediately applied an A-V extracorporeal membrane oxygenation system (ECMO) to stay one step forward, before evaluating the underlying cause. After the patients were stabilized hemodinamically, they all underwent cardiac catheterization under ECMO to evaluate the reason for the instability.
Results: All of the patients underwent ECMO for initial stabilization and in 1-2 days to cardiac catheterization in the cathlab for evaluation. According to the findings, the patients have either a surgical reconstruction or an interventional procedure like balloon dilatation of the fenestration and/or a dilatation or stenting of the pulmonary arteries. 2 of the patients were discharged uneventfully after almost 3 months in the ICU, 2 of them are still in the ICU (45 days and 3 months), and 2 of the patients did not survive because of multiorgan failure.
Conclusion: The late presenting Fontan patients are difficult to manage and needs the medical staff to think one step ahead for satisfactory results. We believe that when the patient is showing signs of multiorgan failure, acting immediately is mandatory, ECMO is essential and protecting the circulation of the endorgans with ECMO from the complications of cardiac catheterization and contrast dye is also important. We also prefer to use a side graft as chimney to the extracariac fontan conduit for venous cannulation of the ECMO, which not only helps with the uneventful drainage to the circuit, but also facilitates the interventions in the cathlab.

P2737 - OPTICAL TOOL TRACKING FOR SKILL ASSESSMENT IN OPEN SURGERY

Su-lin Lee[1], Nasko Radev[1], Juana Gonzales Bueno[1], Nairouz Shehata[1], Giovanni Pittiglio[1], Olivier Ghez[2]
Imperial College, The Hamlyn Centre, London-United Kingdom[1] Royal Brompton Hospital, Cardiac Surgery, London-United Kingdom[2]

Background/Hypothesis: Optical tool tip tracking for surgical skill assessment can be effectively performed on videos captured via mobile phones and processed using computer vision methods. By utilising an affordable and ubiquitous device for filming, the technology can be used for skill assessment without requiring an external observer.
Materials and Methods: An operator was set up to perform suturing on a synthetic suturing pad while wearing surgical gloves with specially designed chequerboard patterns and using tools (needle holder and forceps) modified with colour markers. The camera was first calibrated and then used to film the operator as they sutured. The videos were processed by detecting the chequerboards and using the Perspective-n-Point to recover their 3D orientation. From that, a kinematic chain was established from the chequerboards to the coloured markers on the tips of the tools, resulting in 3D positions and orientations for the tool tips.
Results: Validation results using a commercial electromagnetic tracking system showed that the hands could be tracked effectively using computer vision methods on mobile phone video. Further improvement is required on the kinematic chain due to variability in holding tools and movement during suturing.
Conclusions: A mobile phone can be used to effectively track the 3D positions and orientations of the hands during suturing. Our next steps are to improve the method to work in any lighting condition and to incorporate the developed framework into a mobile application for medical students to assess their suturing and knot tying skills.

P2739 - PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM EARLY MANAGEMENT AND MID TERM OUTCOMES

Gladys Salgado[1], Fernando Andres Diez Mori[1], Analía Martin[1], Florencia Romina Strawich[1], Julieta Irman Garrido[1], María Victoria Lafuente[1], Alberto Sciegata[1], Pablo García Delucis[2], Horacio Capelli[1] Hospital De Pediatría Garrahan, Pediatric Cardiology, Buenos Aires-Argentina[1]; Hospital De Pediatría Garrahan, Pediatric Congenital Heart Surgery, Buenos Aires-Argentina[2]

Background: Pulmonary atresia with intact ventricular septum (PAIVS) is a complex and uncommon congenital heart disease, with a wide morphologic spectrum. The aim of this study was to describe the surgical management and results according to the different anatomical variants.
Methods: Between 2000-2015, 67 patients (p) with PAIVS were operated on, with a median follow-up of 7,92 (IQRR 5-11-5 years) and 10p were lost in follow-up. Membranous atresia occurred in 81% of the patients. Right ventricular dependent coronary circulation was observed in 13% and tricuspid valve dysplasia in 14%.
Results: A shunt was performed in 54p (80%) at a median age of 17 days with an early mortality rate of 9.2% (5p, three of them with concomitant right ventricular outflow tract obstruction relief). It was indicated a biventricular approach as initial strategy in 30p: 16p (53%) reached a total biventricular stage and 14p (47%) partial repair. In 27p the final stage was univentricular pathway, at a median age of 5 years, 3p are awaiting for complete repair. The table 1 summarizes the morphologycal characteristics and different procedures.
Conclusions: Thorough evaluation of the morphology is essential to define the strategy of management. A favourable initial tricuspid annulus size (Z score > -3) was associated with a final biventricular repair, either total or partial. In contrast, bipartite right ventricle morphology was not related to final stage. Early right ventricular outflow tract obstruction relief allowed the possibility of a biventricular pathway. The choice of initial management and better selection of patients allows planning biventricular repair with good outcomes, despite the fact that it requires multiple reinterventions. Univentricular repair had larger mortality rate. Nevertheless, the three groups showed similar functional capacity in the mid-term follow up..

Table.

	Biventricular (16p) 28%	**One and a half (14p) 25%**	**Univentricular (27p) 47%**
Tricuspide Valve Z score			
>-3	85%	70%

P2741 - AUTOLOGOUS PULOMONARY ARTERY TUBE RECONSTRUCTION TO ESTABLISH DUAL CORONARY SYSTEM IN ALCAPA FROM NON FACING SINUS

Muthukumar Sivasubramanian[1], Periyasamy Thangavel[1], Rajesh Venkataraman[1], Ramkumar Jeyavelan[1], Ranjith Karthekeyan[2], Jebaraj Rathinam[3]
Sri Ramachandra University, Cardiothoracic Surgery, Chennai-India[1]; Sri Ramachandra University, Cardiac Anesthesia, Chennai-India[2]; Sri Ramachandra University, Paediatric Cardiology, Chennai-India[3]

Background: Various techniques have been described for establishing dual coronary system in ALCAPA repair. But management of ALCAPA from posterior non facing sinus is more challenging. We present our modest experience with pulmonary artery tube reconstruction in this condition.
Materials & Methods: From Jan 2013 to Sep 2016, eleven babies underwent ALCAPA in our institute. Out of 11, five babies had LMCA arising from posterior non facing sinus.Our study included only these five patients. Male : female ratio was 1:4. Age at presentation varied from 23 days to 7 months. All babies underwent ALCAPA repair under cardiopulmonary bypass using aortic and bicaval cannulation.
Results: Dual coronary system was created using autologous pulmonary artery tube in all the five babies. After harvesting LMCA from the pulmonary artery ,a pulmonary artery tube was created by suturing the pulmonary artery wall of the sinus portion. The mean CPB time and aortic cross clamp time were 179 minutes and 77 minutes respectively.The chest was left open in two babies.We had one postoperative death due to persistent low cardiac output. ECMO support was used in one patient.Left phrenic nerve palsy was noted in one bay who underwent diaphragmatic plication.
Conclusion: From our experience, we conclude that pulmonary artery flap tube repair of ALCAPA helps in creation of a long, tension free neo LMCA and perfect aortic reimplantation to establish the dual coronary system in babies with ALCAPA from non facing sinus.

P2751 - DUCTAL ASSOCIATED PULMONARY ARTERY STENOSIS (PULMONARY COARCTATION) WITH NEONATAL BLALOCK TAUSSIG SHUNT INCIDENCE AND MANAGEMENT

Kirk Kanter, Subhadra Shashidharan, Bahaaldin Alsoufi
Emory University School of Medicine, Pediatric Cardiac Surgery, Atlanta-United States

Background: Infants undergoing a modified Blalock-Taussig shunt (MBTS) can have stenosis at the ductal insertion site on the pulmonary artery (PA) termed pulmonary coarctation. We examined our experience with pulmonary coarctation at our institution.
Patients and Methods: From 2002, 311 infants aged <90d (0-87 days, mean 17.4 ± 21.2; weight 1.4-6.2 kg, mean 3.1 ± 0.7) had a primary MBTS; 161 (52%) had univentricular anatomy. Four diagnoses each with >10% of the total number of shunts accounted for 59% of the shunts: pulmonary atresia with intact ventricular septum (n = 65, 21%), pulmonary atresia with ventricular septal defect (PA/VSD; n = 47, 15%), tricuspid atresia (n = 38, 12%) and tetralogy of Fallot (n = 33, 11%). Pulmonary coarctation was identified by preoperative echocardiogram or catheterization or at direct intraoperative inspection and repaired at the time of the MBTS.
Results: 73 infants (23%) had pulmonary coarctation repair with the MBTS, 61 (86%) without cardiopulmonary bypass (Figure). Patients with PA/VSD or double-inlet left ventricle (DILV) had an increased incidence of pulmonary coarctation. Pulmonary coarctation patients were younger (11.2 ± 15.1d vs. 19.8 ± 22.7d); hospital mortality was not different. Sixteen (5.1%) had late recognition of pulmonary coarctation. 26 of 89 pulmonary coarctation patients (29%) had recurrent stenosis including 5 of 6 with situs inversus and right pulmonary arterioplasty.
Conclusions: Pulmonary coarctation is common in infants undergoing MBTS, especially with PA/VSD or DILV. It usually can be managed without CPB during the initial MBTS. Operative mortality is not different from patients with MBTS alone. Delayed recognition and late recurrence after pulmonary arterioplasty are not infrequent; ongoing vigilance is necessary.

P2758 - LEFT VENTRICULAR REMODELING AT ONE YEAR AFTER AORTIC VALVE REPAIR IN PATIENTS WITH CONGENITAL ISOLATED AORTIC REGURGITATION

Fatima I. Lunze[1], Meena Nathan[2], Kimberlee Gauvreau[1], Christopher A. Baird[2], Pedro Del Nido[2], Stephen P. Sanders[1], Gerald R. Marx[1], Steven D. Colan[1]
Boston Childrens Hospital, Harvard Medical School, Cardiology, Boston-United States[1]; Boston Childrens Hospital, Harvard Medical School, Department of Cardiology And Thracic Surgery, Boston-United States[2]

Background: Congenital isolated aortic regurgitation (AR) is a rare congenital defect in the young. Chronic left ventricular (LV) volume overload results in irreversible myocardial dysfunction. We aimed to examine changes in aortic valve and LV size and function from baseline prior to aortic valve repair (AVre) to discharge and 1 year follow-up after.
Methods: Single institution, retrospective review of subjects <25 years who underwent AVre initially for isolated AR between 1989 and 2014. Inclusion criteria were $\geq$ moderate AR and mean Doppler gradient ≤ 30 mmHg at baseline (BL). Aortic valve annular, aorta ascendance and LV size and LV functional echo variable Z-scores at BL, discharge (DC) and 1 year after AVre were evaluated. The AR was assessed by vena contracta diameter adjusted to body surface area.
Results: Of 47 subjects, 39 (79.5%) underwent repair. Median age was 14 years (range 2, 24). Patients with bi- (40%) and tri- (38%) commissural AV have a greater proportion of severe AR than those with unicommissural (21%, P = 0.08). At DC, AR decreased

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

to mild or less in the majority of patients (87%), resulting in significant acute decline in LV end-diastolic size and volumes, while LV mass didn't change (Table 1). The acute fall in preload resulted in increased LV mass/volume ratio and decreased ejection fraction (EF) at DC (both $P < 0.001$). At 1 year follow-up, LV end-diastolic and stroke volumes significantly increased due to AR recurrence, at least moderate grade in 62% of patients. Regardless, the LV mass significantly decreased, resulting in mass/volume ratio and EF normalization.

Conclusion: Moderate and severe AR declined to mild after aortic valve surgery, accompanied by acute LV preload reduction in the majority of patients at DC. Acute decline in LV pre-load led to ejection fraction deterioration early after aortic valve surgery, with full recovery after 1 year follow-up.

P2759 - TRACKING MORTALITY IN PEDIATRIC PATIENTS WHO RECEIVE OPERATIONS BY VISITING CARDIAC SURGICAL TEAMS

Laura Schiff[1], Janine Henson[2], John Connett[3], Susan Lowry[4], Van-Trang Nguyen[5], Emily Farkas[6], Vinicius Nina[7], William Zeman[8], Donna Doxsey-Mcgrew[9], Aubyn Marath[6]

Enloe Medical Center, Data Collector, Chico-United States[1]; Cardiostart International, Director of Nursing, Lakeville, Minnesota-United States[2]; University of Minnesota, Chairman, Biostats, Minneapolis, Minnesota-United States[3]; University of Minnesota, Programmer, Biostats, Minneapolis, Minnesota-United States[4]; Cardiostart International, Data Collector, Minneapolis, Minnesota-United States[5]; Cardiostart International, Cardiac Surgeon, Los Angeles, California-United States[6]; University of Maranhao, Cardiac Surgeon, Sao Luis-Brazil[7]; Peace Health Hospital, Cardiologist, Springfield, Oregon-United States[8]; Community Hospital, Nurse Practitioner, Milford, Connecticut-United States[9]

Introduction: Between 2011 and 2016, CardioStart International teams taught and performed pediatric and adult cardiac surgeries for patients in 8 severely healthcare restricted locations, addressing the poorest within the local communities. Local teams often took the primary surgical role to provide surgeries to those who would otherwise go without. Difficulties in obtaining post-operative tracking information of 30-day, and later morbidity/mortalitY estimations are frustrated by: • Lack of electronic medical record capability; • Similarity in family names;.

• Incomplete demographic information at admission; • Inadequate and varied access to patients following discharge; • Very long traveling distances between referral center and patient's home; • Lack of primary care support; • Non-attendance to specialist follow-up clinics; • A substantial fear that follow-up attendance will incur additional costs to the patient/family, • Non-permanent addresses, shared housing and/or internal migration by families for work. • Surgeons/cardiologists leaving one tertiary care center for better opportunities elsewhere;.

Methods: We successfully tracked 78 pediatric patients who underwent cardiac surgery between 2011 and 2016, in 13 missions to Brazil, Myanmar, Vietnam, Dominican Republic, Peru, India, Nigeria, and Uganda. Information regarding live status and well-being were obtained by contact with specialist doctors and patients through e mail and cellphone using a RedCap-based questionnaire.★.

Results: At 30 days, 70 patients were confirmed as alive, 5 were confirmed as mortalities, and only 3 remained unknown, confirming a successful tracking rate of 96%.

Conclusions: Tracking of patients in start-up programs or those centers seeking skill advancement is difficult in limited resource environments, but does remain possible. A significant improvement in tracking success was obtained by clearly stating to patients on discharge that no financial charges for follow-up information received would be made to them on any repeat evaluations. Connectivity through E mail and cellphone (direct/indirect through relatives) was surprisingly high. ★(Bio-Statistic Function of the Clinical and Translational Science Institute, University of Minnesota).

P2770 - NEW BIOSCAFFOLD USED FOR SURGICAL REPAIR OF COARCTATION OF THE AORTA IN NEONATES

Tomasz Mroczek, Elżbieta Wójcik, Magdalena Czerżyńska, Marcin Gladki, Janusz Skalski

University Children Hospital, Jagiellonian University, Pediatric Cardiac Surgery, Kraków-Poland

Background: In neonates with a low body weight with long segmental coarctation of the aorta (CoA), plastic repair technique might be useful. CoA commonly coexists which other heart defects, e.g. ventricular septal defect (VSD) or complex heart disease. To surgically correct CoA, surgeons can use several biomaterials. The newest is a decellularized bovine pericardial patch. The aim of the study is to present the results of CoA repair with the decellularized bovine pericardial patch.

Material and Methods: We retrospectively analyzed 11 neonates with coarctation of the aorta, in which the decellularized bovine pericardial patch was used to repair the defect. All the procedures were performed through the postero-lateral thoracotomy. The follow-up examination included echocardiography and clinical examination.

Results: The mean patient age was 9 days (range 4–116); mean body weight 3.3 kg (range 1.4–10.8). Nine patients (81%) had other heart defects, mainly presenting with VSD (nine patients), followed by transposition of the great arteries (2), aortic arch hypoplasia (2) and BAV (2). The mean ICU stay was 7 days (range 4–13). The mean time from surgery to follow-up was 7 months (range 4–13). Recoarctation of the aorta was found in three cases

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(27%), 4, 6 and 8 months after surgery. In echocardiography, the maximum gradient through CoA was in the range of 33-80 mmHg (mean - about 50 mmHg). These patients had balloon plasty and one of them had hypoplastic aortic arch. Balloon plasty was effective in all the patients. Only two of our patients were treated with aspirin. None of them had any problems with recoarctation.

Conclusion: A longer follow-up is needed to assess the usefulness of the decellularized bovine pericardial patch for aortic surgical repair in neonates.

P2774 - PROSPECTIVE ASSESSMENT OF STERNOTOMY WOUND RELATED COMPLICATIONS AFTER PAEDIATRIC CARDIAC SURGERY

Antonio Gonzalez-Calle[1], Adrian Crucean[2], John Stickley[3], Phil Botha[2], Nigel Drury[2], Natasha Khan[2], Tim Jones[2], David Barron[2]

Birmingham Children's Hospitalbirmingham Children's Hospital, Cardiac Surgery, Birmingham-United Kingdom[1]; Birmingham Children's Hospital, Cardiac Surgery, Birmingham-United Kingdom[2]; Birmingham Children's Hospital, Audit Department, Birmingham-United Kingdom[3]

Background: Many previous studies of wound-related complications post-paediatric cardiac surgery have focused primarily on unmodifiable risk factors or have used definitions non-specific to the sternal wound. This study aimed to prospectively identify the true incidence of infective and non-infective wound complications, providing a tool for comparison and monitoring of such complications.

Methods: A prospective 90-day surveillance programme was developed to identify all sternotomy wounds that failed to heal by primary intention in which at least one of the following were present: wound collections /dehiscence, abnormal or persistent inflammatory signs/symptoms with or without positive inflammatory markers or microbiology cultures. Sternum and/or mediastinum involvement placed the complication in the deep group. Frequently-cited associated variables were analysed and cumulative sum control charts (CUSUM) were derived for monitoring deviations from target values in real time. The impact of a wound care bundle on outcomes was assessed over a 2-year period.

Results: There were 105 wound-related complications in 1020 sternotomies with 88(8.63%) categorised as superficial and 17 (1.66%) as deep. These required 362 surgical wound reviews, and 58 surgical interventions (Table1). Only 13(14.4%) of superficial wounds elicited positive cultures whereas 14(82.35%) did so in the deep group, mostly Staphylococcus species (Table1). More than half of the complications in the deep group initially manifested superficially. Demographic variables associated with wound infections are displayed in table. The implementation of a new wound care bundle demonstrated a significant impact on the incidence of superficial wound complications, but not on those classified as deep.

Conclusions: A real-time surveillance programme of sternotomy wound complications provides a more comprehensive assessment of the true incidence of infective and non-infective delays in healing. This represents an important quality metric that informs resource allocation and allows long-term performance monitoring. The implementation of a wound care bundle reduced superficial wound complications but not those involving the sternum and/or mediastinum..

Table 1. All values are presented as median and IQR except for RACHS cotegaries (%) and Management, Neonotes, First sternotomy, and Positive culture (absolute values). Of note, 25% of the wound complications were diagnosed beyond the 3rd quortile

P2788 - CASE REPORT TRICUSPID ATRESIA WITH COMMON ARTERIAL TRUNK FIRST STAGE SURGICAL PALLIATION

Salem Deraz[1], Ahmed Afifi[2], Waleed Simry[2], Wesam El Mozy[3], Mahmoud Fathy[4], Magdi Yacoub[5]
Aswan Heart Centre and Menoufia University, Pediatric Cardiology Department, Aswan-Egypt[1]; Aswan Heart Centre, Cardiac Surgery Department, Aswan-Egypt[2]; Aswan Heart Centre, Radiology Department, Aswan-Egypt[3]; Aswan Heart Centre, Pediatric Icu Department, Aswan-Egypt[4]; Aswan Heart Centre And Imperial College-london, Cardiac Surgery Department, Aswan-Egypt[5]

Tricuspid atresia (TA) and common arterial trunk (CTA) are rare anomalies accounting for 2.5% and 0.7% of all congenital heart diseases, respectively. The coexistence of both anomalies is rare. This association constitutes only 0.01% to 0.02% of congenital heart disease.
Case Report: A Three-months-old female infant weighing 3.4 kg. A transthoracic echocardiogram performed at the time showed tricuspid atresia with a hypoplastic right ventricle, with truncus arteriosus type one, mild truncal valve regurgitation, an unrestrictive interatrial communication, and good-sized branch pulmonary arteries. Cardiac computerized topography (CT) angiography confirmed the diagnosis. The case was approached via median sternotomy, both pulmonary artery branches were snared, the VSD was closed using gortex patch, the right ventricular outflow was reconstructed with direct RV-PA conduit using aortic homograft size 11 which was the smallest size available, then banding of the homograft was done to get a mean pulmonary artery pressure of 25 mmHg. Pre discharge echocardiography revealed good ventricular function, moderate aortic regurgitation and mild regurgitation across the right ventricle to pulmonary artery homograft with a pressure gradient across the band 50 mmHg. The patient was discharged from the hospital in a stable condition.
Conclusion: The association of CTA and TA is an extremely rare finding and represents a particular challenge for the medical and surgical team. Without surgical palliation, the definite outcome is a neonatal death. Various approaches to the management of this morphology have been described with varying success, and consensus remains to be established. We demonstrate that successful first stage palliation of this condition can be undertaken with satisfactory results using a Sano shunt as primary palliation.

P2791 - AORTIC ARCH RECONSTRUCTION AND BILATERAL PULMONARY ARTERIES BANDING – NEW MODIFICATION OF THE NORWOOD OPERATION FOR TREATMENT OF HYPOPLASTIC LEFT HEART SYNDROME – EXPERIENCE OF OUR CENTER

Jacek Pajak[1], Piotr Stanek[2], Michal Buczynski[1], Grzegorz Zalewski[2], Marek Wites[2], Leslaw Szydlowski[3], Katarzyna Klimczak[2], Ewa Radziszewska[2], Lidia Tomkiewicz-pajak[4], Luiza Zalewska[5]
Medical University of Warsaw, Chair and Department of Pediatric Cardiac Surgery, Warsaw-Poland[1]; John Paul Ii Upper Silesian Child Health Centre, Department of Pediatric Cardiac Surgery, Katowice-Poland[2]; John Paul Ii Upper Silesian Child Health Centre, Department of Pediatric Cardiology, Katowice-Poland[3]; Jagiellonian University Medical College and John Paul Ii Hospital, Institute of Cardiology, Krakow-Poland[4]; Silesian Center for Heart Diseases, Department of Congenital Heart Diseases And Pediatric Cardiology, Zabrze-Poland[5]

Background: In the period from 2013 to 2016, 46 Stage I procedures were performed in our center on children with hypoplastic left heart syndrome (HLHS). The study sought to retrospectively evaluate early results of a new modification of the Norwood operation for treatment of hypoplastic left heart syndrome.
Material and Methods: The group analyzed included 46 children with HLHS after modification of the Norwood procedures, in whom the aortic arch was reconstructed with an extracellular matrix patch and bilateral pulmonary artery banding.
Results: The mean patient age was 16 days (1-47 days) and the mean body mass was 3025 g (1500 to 4200 g) on the day of operation. The overall hospital mortality rate was 15.2%. Twenty-one patients were discharged directly from our department to outpatient care after an average of 18 days. The remaining 18 patients were in stable condition and transferred to a pediatric clinic for follow-up treatment after an average of 25 days of postoperative care. The rates of death were: 1 patient (14,3%) due to bleeding, 2 patients (28,6%) due to sepsis, and 4 patients (57,1%) due to low cardiac output. Eight children (39,1%) underwent open-chest management postoperatively. Postoperative bleeding requiring chest revision occurred in 8 children (17,4%). Postoperative intubation in livingpatients lasted for an average of 8 days (from 2 to 28). Assisted circulation with ECMO was employed on 5 children (10.8%). In two of these cases, assisted circulation was discontinued with a positive effect.
Conclusions: According to the assessment of results in our center the initiation of this new surgical technique enabled reduction of postoperative bleeding rates as well as shortened operation time. This method also provides better outcome in children with low birth body weight, preterm neonates and children with complicated heart defects eg. HLHS with TAPVC. There is also a need of long-term assessment of this procedure.

P2795 - SURGICAL MANAGEMENT OF ADDITIONAL MUSCULAR DEFECTS BY 'TWO PATCH TECHNIQUE' FOLLOWING EN FACE RECONSTRUCTION OF VENTRICULAR SEPTUM

Gananjay Salve[1], Shreepal Jain[1], Manglesh Nimbalkar[1], Kshitij Sheth[1], Bharat Dalvi[1], Krishna Kumar[2], Sandip Katkade[1], Jeril Kurien[1], Vilson Choondal[1], Shivaprakash Krishnanaik[1]
Sir H.N. Reliance Foundation Hospital, Paediatric Cardiac Sciences, Mumbai-India[1]; Amrita Institute of Medical Sciences, Dept. of Paediatric Cardiology, Cochin-India[2]

Background: Closure of additional muscular ventricular septal defects (VSD) remains a challenge. The complex anatomy of muscular septum makes it difficult to identify and address

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

additional muscular VSDs. We addressed this issue by En Face reconstruction (EFR) of RV septum during pre-operative echocardiography and then a 'Two-Patch Technique' (TPT) to surgically close all additional muscular VSDs.
Materials and Methods: 39 patients (M:F = 25:14) underwent surgical repair by TPT for additional defects. All were located and mapped by pre-operative echocardiography and EFR. Mean age was 1year 9months (2 months- 10years), and mean weight 6.02 kg (2.3- 19 kg). Right-angled tip forceps was introduced through additional VSD from RV side of septum. Another forceps was introduced into LV through larger defect and a vessel loop was threaded across the defect. PTFE patch anchored to LV limb of vessel loop using 2 fine polypropylene sutures was placed on LV septum by pulling the vessel loop out through RV. Another PTFE patch was placed on RV side of defect using same polypropylene sutures- like a Hammock. Alternatively, we approached LV through inter-atrial septum across the mitral valve. Intra-operative echocardiography was done and RA-PA saturations checked. Morphological spectrum included multiple VSDs (perimembranous 36, anterior muscular 13, posterior muscular 16, apical 9, mid-muscular 9), TOF (n = 6), DORV (n = 2).
Results: Mean clamp time and bypass time was 93 mins and 14 mins respectively. Significant RA-PA step-up (n = 5) was confirmed by intraoperative echocardiography and all were banded in the same sitting. Mean hospital stay was 11.4 days with zero hospital mortality. On follow up, all patients remain in NYHA class I. All banded patients either have no residual shunt (n = 3) or tiny shunt (n = 2) awaiting debanding.
Conclusion: It is an easily reproducible technique (EFR with TPT) and can be employed for all types of additional muscular defects. Short-term results are satisfactory.

P2798 - TAKEUCHI TECHNIQUE IN FOUR CASES OF ANOMALOUS LEFT CORONARY ARTERY FROM THE PULMONARY ARTERY

Juan Miguel Mantilla[1], José Leonardo Cely-Andrade[2], José Leonidas Olaya Forero[3], Monica Moreno[3], Alfonso Velandia[4]
Hospital Cardiovascular Del Niño De Cundinamarca, Pediatric Cardiovascular Surgery, Soacha-Colombia[1] Hospital Cardiovascular Del Niño De Cundinamarca - Universidad Del Bosque - Universidad Manuela Beltran, Research Departement, Soacha - Bogota-Colombia[2] Hospital Cardiovascular Del Niño De Cundinamarca, Cardiovascular Surgery, Soacha-Colombia[3] Hospital Cardiovascular Del Niño De Cundinamarca, Cardiovascular Anesthesiology, Soacha-Colombia[4]

Anomalous left coronary artery from the pulmonary artery (ALCAPA), also known as Bland-White-Garland syndrome(1) is a rare congenital cardiac disease that can cause myocardial infarction, heart failure and even death in paediatric patients(2), is present in 1 of 300 000 live births and accounts for 0.05% of congenital cardiac malformations (3). Surgical treatment is ever the treatment election and success overlive is most than 90%; coronary reimplatation is now the elective treatment when it is not possible, takeuchi technique is the elective treatment; this technique repairs intrapulmonary tunnel and is a unique procedure for repairing anomalous origin of the left coronary artery with left and posterior possition from the pulmonary artery (3)Four female clinical cases are presented: a 4 years old, 5,8 y10-months all patients with dilated cardiomyopathy with severe ventricular dysfunction, LVEF 15%, 20% 20% and and 40%, respectively, with moderate mitral insufficiency secondary to anomalous origin of the left coronary artery Of the Pulmonary Artery Trunk (ALCAPA), Takeuchi surgery was performed in all cases, with excellent results given by recovery of ventricular function as a whole. Follow-up time of 6 to 3 years..

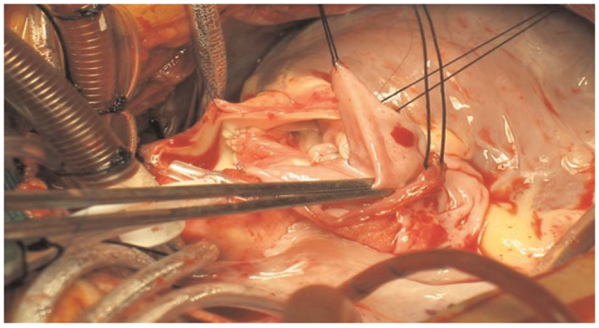

Figure 1.

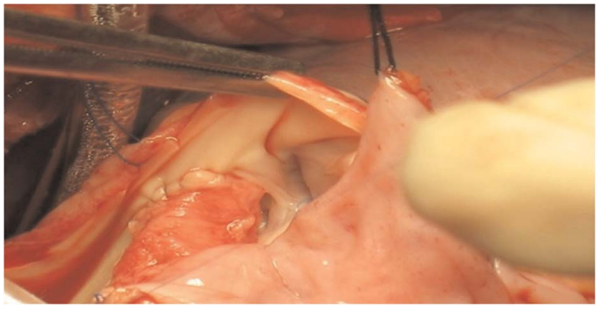

Figure 2.

Table 1. Characteristics of patients who underwent surgical repair with takeuchi technique.

Year	Age	Pre surgical LVEF	Post-surgical LVEF	Follow up LVEF (time)	Followup MI
2008	4 years old	15%	38%	65% (3 years)	Moderate
2013	8 months	20%	45%	60-70% (3 years)	Moderate
2015	5 months	20%	45%	65% (1 year)	Moderate
2016	9 months	40%	40%	65% (6 months)	Low

P2812 - CASE REPORT ORIGIN OF THE RIGHT PULMONARY ARTERY FROM THE ASCENDING AORTA

Carlos Guerrero[1], Guillermo Aristizabal[1], Jorge Cervantes[2], Jose Antonio Garcia-montes[1], Juan Calderon[3], Carlos Zabal[1], Juan Pablo Sandoval[1]
Ignacio Chavez National Institute of Cardiology, Pediatric Cardiology/ Catheterization Laboratory, Mexico City-Mexico[1]; Ignacio Chavez National Institute of Cardiology, Department of Pediatric Cardiac And Congenital Heart Disease Surgery, Mexico City-Mexico[2]; Ignacio Chavez National Institute of Cardiology, Pediatric Cardiology, Mexico City-Mexico[3]

Background: Origin of the right pulmonary artery (RPA) from the ascending aorta is an extremely rare congenital anomaly. It is anatomically different from discontinuos pulmonary arteries where one branch of the pulmonary arteries is supplied either by an arterial duct (PDA) or by major aortopulmonary collaterals. Furthermore, it is not unusual that while RPA pressure is evidently systemic, right ventricular (RV) and left pulmonary artery (LPA) pressure may be suprasystemic. The latter may reflect a discrepant degree of pulmonary vascular disease between the right and left lung increasing surgical risks along with a somewhat unpredictable outcome.
Case Presentation: A 3-year-old boy was admitted with symptoms of severe congestive heart failure. Diagnosis was non-conclusive

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

on echocardiogram. A diagnostic cardiac catheterization was performed finding an anomalous RPA arising from the aorta. Concomitant defects included a small PDA and atrial septal defect. RV pressure was suprasystemic (80 vs.70 mmHg). LPA pressure was 80/35-55 mmHg compared to 70/35-47 mmHg in the RPA. Left lung wedge angiography showed more advanced stages of pulmonary vascular disease when compared to the right lung. Provided signs of congestive heart failure were still present, surgical repair was advocated. Reimplantation via an end-to-side anastomosis of the anomalous RPA into the MPA was performed using a 16mm PTFE graft. In addition, PDA closure was performed along with a lung biopsy. Systemic and main pulmonary artery pressures in the immediate postoperative period were 100/55-70 mmHg and 43/18-26 mmHg respectively. The patient had a remarkable uneventful recovery and remains under surveillance as an outpatient.
Conclusion: Anomalous origin of the right branch pulmonary artery from the ascending aorta is a rare congenital anomaly. Significant pulmonary arterial hypertension is usually present with different degree of vascular involvement between the right and left. Surgical risks are considerably higher in this population but surgical repair remains an option in selected cases.

P2817 - EARLY PRIMARY REPAIR OF TETRALOGY OF FALLOT IN EARLY INFANCY – CHALLENGES & OUTCOMES !

Muthukumar Sivasubramnanian[1], Periyasamy Thangavel[1], Karthick Kavin[1], Ramkumar Jeyavelan[1], Ranjith Karthekeyan[2], Jebaraj Rathinam[3]
Sri Ramachandra University, Cardiothoracic Surgery, Chennai-India[1]; Sri Ramachandra University, Cardiac Anesthesia, Chennai-India[2]; Sri Ramachandra University, Paediatriac Cardiology, Chennai-India[3]

Background: The timing of intra cardiac repair for Tetralogy of Fallot keeps evolving. The practice of early primary repair of TOF is recommended in babies with adequate pulmonary anatomy. We present our experience in early primary repair of TOF in infants who are less than 3 months of age.
Materials & Methods: We performed an early primary TOF correction in 41 infants who were less than 12 weeks during a period of 5 years from Sep 2011 to Aug 2016. The age ranged from 23 days to 12 weeks. Based on the preoperative ECHO, 53 patients were selected for an early repair.But, we found near pulomanry atresia and hypoplastic branch pulmonary arteries in 12 babies. Hence they underwent BT shunt and were excluded from the study group. All babies underwent intra cardiac repair with conventional cardiopulmonary bypass using an aortic and bicaval cannulation at core temperature of 28 °C.
Results: We performed transatrial repair in 29 patients and 12 had transannular patch. Seven patients needed prolonged ventilation and the mean duration of icu stay was 127 hours. There were 4 hospital deaths and one late death. Left phrenic nerve palsy was noted in 3 patients and they underwent diaphragmatic plication. The mean hospital stay was 14 days.
Conclusion: We conclude that early primary repair of TOF can be safely performed in infants less than 3 months of age with recurrent hyper cyanotic spells. Babies with good pulmonary anatomy had better clinical outcomes.Precise surgical techniques and attentive post operative care play a vital role in these babies.

P2819 - THE ROSS AND ROSS KONNO PROCEDURE IN NEONATES AND INFANTS INTERMEDIATE TERM RESULTS FUNCTION AND GROWTH OF AUTOGRAFT

Joaquin Fernandez-Doblas[1], Joaquin Perez-Andreu[1], Queralt Ferrer[2], Gemma Giralt[2], Dimpna C Albert[2], Ferran Gran[2], Pedro Betrian[2], Anna Sabate-Rotes[2], Ferran Roses[2], Raul Abella[1]
Vall Hebron Hospital, Cardiac Surgery, Barcelona-Spain[1] Vall Hebron Hospital, Pediatric Cardiology,Barcelona-Spain[2]

Background: The Ross procedure is commonly used in children requiring aortic valve replacement with the possibility to enlarge small aortic root (Ross-Konno). However, is not clear the potential for growth and the durability of the autograft in neonates and infants. We assess a review our intermediate-term results of the Ross and Ross-Konno procedure.
Material and Methods: A retrospective analysis of all consecutive patients aged younger than 1 year who underwent the Ross or Ross-Konno procedure was recorded. We included 13 patients (8 Ross and 5 Ross-Konno; 4 neonates, 9 infants) The median aged was 150 days and median weight was 6 kg. 11 patients had aortic stenosis, 2 patients had isolated severe aortic insufficiency and 4 patients had other left-side heart lesions, such as arch obstruction (2 patients) or mitral valve disease (2 patients). 2 patients had left ventricle endocardial fibro-elastosis. The median aortic valve diameter z-score was -1,5 (1,5 to -3,5). Major study outcomes included patient survival, postoperative complications, autograft function and need for reoperation.
Results: The median follow-up was 60 months. No patients had 2 + or more aortic insufficiency and/or moderate aortic stenosis. 4 patients required concomitant aortic arch or mitral repair. 2 patients needed ECMO after surgery. 2 patients presented renal insufficiency with depuration therapy and 2 pacemakers were implanted due to postoperative av block. No patients suffered acute myocardial infarction. Actuarial survival rate was at 100% at 5 years. We assessed an increased of autograft diameter (-1,5 to 1,7 z-score, $p < 0,003$). There were 2 reinterventions, including 2 procedures on the right-side conduit. No reinterventions was in autograft.
Conclusions: The Ross and Ross-Konno procedure for neonates and infants has good results with low mortality and acceptable rates of reintervention with potential growth.

Table 1.

Number	Age	Weight	Diagnose	Previous procedure	Preoperative z-score	LHlesions
1	116	4,1	Shone syndrome	Aortic valvuloplasty	-2,6	Mitral stenosis, fibro-elastosis LV

P2825 - DIGEORGE SYNDROME DOUBLE AORTIC ARCH TOF AND PULMONARY ATRESIA – A CASE REPORT

Muthukumar Sivasubramanian[1], Periyasamy Thangavel[1], Ramkumar Shanmugasundaram[1], Ramkumar Jeyavelan[1], Ranjith Karthekeyan[2], Jebaraj Rathinam[3]
Sri Ramachandra University, Cardiothoracic Surgery, Chennai-India[1]; Sri Ramachandra University, Cardiac Anesthesia, Chennai-India[2]; Sri Ramachandra University, Paediatric Cardiology, Chennai-India[3]

Objective: To present a case report of successful management of DiGeorge syndrome with TOF and Double aortic arch.
Methods: A 12 days old male baby born as preterm was diagnosed to have DiGeorge syndrome by amniocentesis and FISH analysis. Echocardiogram revealed TOF with pulmonary atresia. CT pulmonary angio revealed a double aortic arch, forming a complete ring around the trachea and oesophagus with compression. Baby had a pre-op SpO2 of 80%.
Results: After pre-op evaluation, baby underwent division of posterior limb of aortic arch with central shunt and PDA interruption. Post-op recovery was uneventful. Ventilated for 71 hours and later inotropes were tapered and shifted to ward. Post-op SpO2 of 95%.
Conclusion: Antenatal evaluation and prompt neonatal surgical intervention can save these kids with complex cardiac anomaly.

P2826 - D TRANSPOSITION OF THE GREAT ARTERIES SINGLE CENTER EXPERIENCE WITH ARTERIAL SWITCH OPERATION IN THE CURRENT ERA

Nikolay Antsygin, Ruben Movsesian, Aleksei Shikhranov, Andrey Tsytko, Elena Mikhailova, Natalia Fedorova
Chilldren's City Hospital, Congenital Heart Surgery, St.petersburg-Russia

The neonatal arterial switch procedure has become the technique of choice for babies with TGA, including transposition with intact ventricular septum, with ventricular septal defect with or without aortic arch hypoplasia, with Taussig-Bing anomaly and with complex coronary artery variants.
Methods: Between 2010 and 2016, 126 consecutive patients who underwent ASO for D-TGA or Taussig-Bing anomaly were included in this study. The median age at the operation was 8 (1-28) days, and 96 patients (75%) underwent ASO less than 2 weeks. The median weight was 3.2 kg (minimal weight 1,5 kg). Eighty two patients with either simple (n = 54) or complex forms (n = 22) of TGA, diagnosed prenatally. Balloon atrial septostomy was performed in 11 cases. The patients were divided into groups: simple TGA (n = 89), complex TGA (n = 31) included those who had TGA with VSD or other anomalies, and Taussig-Bing anomaly with aortic arch obstruction (n = 6). Intramural coronary arteries were detected in 5 of them and single coronary artery in 2 babies. In two cases previously was performed abdominal surgical procedures: resection of Meckel's diverticulum and esophageal plasty. Median follow-up duration was 29 (0.2-72) months.
Results: There were 4 (3,1%) in-hospital deaths - 2 patient with complex coronary anatomy and 2 babies with aortic arch obstruction repair. There was no late deaths. 7 patients (5.7%) required reintervention during follow up: AV insufficiency repair - 1, ASD closure - 1, PA plasty - 1, PA stenting - 1 and PA ballon angioplasty in 3 patients.
Conclusions: Prenatal diagnosis and early neonatal clinical suspicion with adequate measures in the first hours after birth are essential to reduce the early mortality in TGA. ASO can be performed with a low risk of early mortality and satisfactory long-term outcomes. Close long-term surveillance is mandatory to detect hemodynamic changes.

P2829 - HEPATIC VENOUS OXYGEN SATURATION IS LOWER THAN MIXED VENOUS OXYGEN SATURATION IN LATE FONTAN CIRCULATION

Takayuki Hagiwara[1], Ikai Akio[1], Junichi Koizumi[1], Ryoichi Kondoh[1], Yurie Takizawa[2], Satoshi Nakano[2], Shin Takahashi[2], Kotaro Oyama[2], Hitoshi Okabayashi[1]
Iwate Medical Univesity, Cardiovascular Surgery, Morioka-Japan[1]; Iwate Medical Univesity, Pediatric Cardiology, Morioka-Japan[2]

Background: The decrease in hepatic venous oxygen saturation (ShvO2) was proposed to indicate the presence of acute liver dysfunction after cardiac operation especially in Fontan procedure. Hepatic venous oxygen saturation in late Fontan circulation has not been investigated. The purpose of this study is to evaluate the difference between hepatic and mixed venous oxygen saturation in late Fontan circulation.
Materials and Methods: 42 patients with Fontan circulation (F group) and 14 patients with biventricular repair (non-F group) were compared in their results of cardiac catheterization. APC Fontan and fenestrated Fontan, heterotaxy were excluded.
Results: The age at study were 7.2 ± 3.6 years in F group (5.5 ± 2.2 years after the Fontan operation) and 4.9 ± 5.2 years in non-F group. At catheterization, cardiac index was lower for the F group than non-F group (2.9 ± 0.8 ml/min/m2 vs. 3.4 ± 0.7 ml/min/m2; $p = 0.048$) and central venous pressure was higher for the F group (10.3 ± 1.5 mmHg vs. 4.7 ± 1.9; $p < 0.01$). Mixed venous oxygen saturation was lower for F group($65.0 \pm 6.5\%$ vs. $70.1 \pm 4.5\%$; $p = 0.013$) and hepatic venous oxygen saturation was lower for F group($48.8 \pm 14.2\%$ vs. $63.9 \pm 5.9\%$; $p < 0.01$). In F group hepatic venous oxygen saturation was significantly lower than mixed venous oxygen saturation ($p < 0.01$).
Conclusions: Lower cardiac output and higher central venous pressure in Fontan circulation has been interpreted as the cause of lower mixed venous oxygen saturation. In this study, however, we showed the discrepancy between mixed venous oxygen saturation and hepatic venous oxygen saturation. This implies the imbalance of the oxygen supply-demand relation in abdominal organs.

P2833 - INCIDENCE AND FACTORS INFLUENCING SPONTANEOUS CLOSURE OF FENESTRATION AFTER EXTRACARDIAC CONDUIT FONTAN PALLIATION

Sudheer Gorla[1], Nataley Jhingoeri[2], Abhishek Chakraborty[2], Sethuraman Swaminathan[1]
Jackson Memorial Hospital, Pediatric Cardiology, Miami-United States[1]; Jackson Memorial Hospital, Pediatrics, Miami-United States[2]

Background: Fontan operation is the last stage of single ventricle palliation. Most centers use fenestrated extracardiac Fontan procedure as the preferred modality. Some of these fenestration close spontaneously with time. There is limited data available about the incidence of spontaneous closure of this fenestration and the factors which influence this. The aim of this study is to identify the incidence of spontaneous closure of Fontan fenestration and the factors influencing it.
Methods: Retrospective review of patients who underwent fenestrated Fontan surgery at our center between January 1, 2001 and June 30, 2016 was done. Data extracted include age at Fontan, preoperative data including mean pulmonary artery pressure, transpulmonary gradient, pulmonary vascular resistance, ventricular end-diastolic pressure, Nakata and McGoon Pulmonary artery indices, presence of significant aortopulmonary collaterals. Perioperative and post-operative variables obtained include cardiopulmonary bypass, cross clamp time, pleural effusion lasting

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

>2weeks, ventricular function and atrioventricular valve regurgitation, thromboembolism. The last clinic visit was reviewed for NYHA class, arrhythmia history, oxygen saturation and evidence of protein losing enteropathy. The most recent echocardiogram/or MRI was reviewed for any evidence of Fontan pathway obstruction and patency of fenestration.
Results: Of 82 subjects who underwent fenestrated Fontan surgery, 15 did not have postoperative follow-up at our center. Of the remaining 67 patients, there was no echocardiographic evidence of patent fenestration in 27 patients (40%). Of these 27 patients, 16 (59%) had spontaneous closure of the fenestration and 10 patients (37%) underwent closure of fenestration in the cardiac catheterization laboratory and 1 (4%) had surgical closure of the fenestration. None of the variables evaluated had significant predictive value for spontaneous closure of the fenestration.
Conclusions: 24% of patients had spontaneous closure of fenestration after Fontan palliation. There was no variable in these patients which could have predicted the potential for spontaneous closure.

P2847 - EARLY EXPERIENCE USING COMPOSITE VALVED RV TO PA CONDUIT IN STAGE I RECONSTRUCTION

David Hoganson[1], Chris Baird[1], Aditya Kaza[1], Xiaoqi Tang[2], John Kheir[2], Sitaram Emani[1]
Boston Children, Cardiac Surgery, Boston-United States[1]; Boston Children, Cardiology, Boston-United States[2]

Background: Use of a valved right ventricle to pulmonary artery (RV-PA) conduit as part of the Stage I palliation (S1P) for univentricular heart heart disease may diminish ventricular volume loading, improve pulmonary blood flow, or lower mortality compared to a Sano shunt.
Methods: Infants with univentricular heart disease undergoing S1P using either a composite, valved RV-PA conduit (proximal ringed PTFE graft and distal cryopreserved femoral vein graft, n = 18) or standard Sano conduit (control, n = 53) at Boston Children's Hospital between 2013 and 2016. Endpoints included markers of oxygen delivery assessed by linear mixed model analysis accounting for repeated measures over time from postoperative day 0-7.
Results: On average from POD 0-7, the valved Sano group had a higher arterial (by 4.5%, P = 0.02) and venous oxyhemoglobin saturation (by 5.2%, P = 0.12), and a similar serum lactic acid (lower by 0.9, P = 0.24) than did standard Sano group. The time to cardiac catheterization was similar between groups (P = 0.38, log rank test). Of the valved Sano group, 5 patients required stenting of conduit (two at RV connection and three at femoral vein to PA anastomosis). There was evidence of valvar patency in all of the valved Sano group by echocardiography at the time of evaluation for the Glenn operation. Survival to hospital discharge was similar between groups (78.6% vs 88.9%, P = 0.63).
Conclusions: The use of a valved Sano conduit as part of S1P is safe and may improve acute postoperative hemodynamics. Further modifications to the distal anastomosis may diminish the need for stenting.

P2848 - FATE OF 775 MAPCAS IN 271 PATIENTS THE INTER RELATIONSHIP OF NATIVE PULMONARY ARTERIES WITH COLLATERAL VESSELS IN PULMONARY ATRESIA MAPCAS

Safak Alpat[1], Ramesh S. Kutty[1], John Stickley[1], Oliver Stumper[2], Nigel E. Drury[1], Phil Botha[1], Natasha E. Khan[1], Timothy J. Jones[1], William J. Brawn[1], David J. Barron[1]
Birmingham Children, Cardiac Surgery, Birmingham-United Kingdom[1]; Birmingham Children, Cardiology, Birmingham-United Kingdom[2]

Background: The relationship between native vessels and MAPCA supply is very variable. We utilised an individualised approach to maximise recruitment of the vascular bed, utilising both native PAs and MAPCAs and reviewed 30 year clinical outcomes and MAPCA patency/re-intervention.
Methods: Between 1988–2016, 271 patients with PA/MAPCAs were treated. The strategy aimed to achieve unifocalisation using native PAs if present and recruiting all MAPCAs where there was no dual supply. The VSD was left open if <15/20 lung segments recruited. Unifocalisation was categorised in 3 groups: (Group1) based on native system only, (Group2) combination of native system and MAPCAs; and (Group3) MAPCAs only (absent native PAs).
Results: Unifocalisation was achieved in 92% of patients with 30-day mortality of 2.8% and 1,5,10 and 15 year survival of 97.1, 95.69, 93.0 and 91.3% respectively. A total of 474 MAPCAs (29% Group1, 48% Group2 and 23% Group3) were recruited with the remainder ligated due to dual supply. In 22(8%) patients, unifocalisation was not achievable and they were palliated with shunt procedures, although 6(27%) now await unifocalisation. It was possible to close the VSD in similar numbers across the 3 groups: 81.9%, 78.1%, 79.3%, with survival at 10 years of 98.6%, 93.7%, 84.8% respectively(0.0607 log-rank test). There was no 'era effect' on survival. DiGeorge Syndrome was strongly associated with failure to close VSD(p = 0.02). Of 97 patients where the VSD was initially left open, 46(47.4%) underwent subsequent closure. Overall, VSD closure was achieved in 198 (79.5%) of patients, incorporating 364 MAPCAs.
Conclusion: Although native PAs provide the best substrate for unifocalisation, recruitment of MAPCAs is essential to achieve successful VSD closure. In a small proportion (6%) with intrinsically poor vasculature, unifocalisation cannot be achieved. A strategy of initial unifocalisation, leaving VSD open can be helpful in borderline cases with successful septation of the circulation being achieved in the majority.

Table.

Groups				
Unifocalised	**All patients (n = 249)**	**Group 1 (n = 72)**	**Group 2 (n = 119)**	**Group 3 (n = 58)**
DiGeorge	64 (25.7%)	15 (23.4%)	30 (46.9%)	19 (29.7%)
MAPCAs sum/mean	775 (3.11)	177 (2.45)	404 (3.39)	194 (3.34)
Shunt: mBT	73 (29.3%)	17 (23.3%)	36 (49.3%)	20 (27.4%)
Shunt: Melbourne	56 (22.5%)	33 (58.9%)	23 (41.1%)	0 (0.0%)
No shunt	120 (48.2%)	22 (18.3%)	60 (50.0%)	38 (31.7%)
VSD status (unifocalised)				
VSD primary closure	152 (61.0%)	52 (34.2%)	67 (44.1%)	33 (21.7%)
VSD closed: delayed closure	46 (18.5%)	7 (15.2%)	26 (56.5%)	13 (28.3%)
VSD remains open	51 (20.5%)	13 (25.5%)	26 (51.0%)	12 (23.5%)
Group 1	PA/VSD/MAPCAs : Native PA system only (no recruited MAPCAs)			
Group 2	PA/VSD/MAPCAs : Combination of native PA system and MAPCAs			
Group 3	PA/VSD/MAPCAs : MAPCAs only (absent native PAs)

P2851 - TRICULSPID VALVE DETACHEMENT DURING CLOSURE OF VENTRICULAR SEPTAL DEFECTS VALVULAR COMPETENCE AT LONG TERM FOLLOW UP

Sandeep Palepu[1], Narutoshi Hibino[2], Luca Vricella[2]
Johns Hopkins University School of Medicine, Cardiac Surgery, Baltimore-United States[1]; Johns Hopkins University, Cardiac Surgery, Baltimore-United States[2]

Background/Hypothesis: Tricuspid valve detachment (TVD) has been utilized during ventricular septal defect (VSD) repair for improved visualization of and access to the defect. The objective of this study was to determine if TVD was associated with increased tricuspid regurgitation at long-term follow-up.
Materials and Methods: 272 patients (age <18 years) undergoing perimembranous VSD repair at our Institution between 1995-2013 were identified. Eighty-six patients (31.6%) underwent concomitant TVD to enhance exposure. The degree of tricuspid valve regurgitation at latest echocardiographic follow-up (trivial, mild, moderate, and severe according to the 2003 Journal of the American Society of Echocardiography recommendations) was reviewed. Intergroup differences were evaluated with the Fisher exact test or the Mann-Whitney U test for categorical and continuous variables, respectively.
Results: Fifty-seven percent of subjects were male, with a mean age at intervention of 743 + 1101 days and no significant difference between TVD and non-TVD groups. Mean echocardiography follow-up was 7.5 + 5.2 years. There was no significant difference in degree of tricuspid regurgitation in subjects with and without TVD with the mean degree of tricuspid regurgitation of both groups falling within the trivial to mild range ($p = 0.54$). Furthermore, there was no significant difference in the incidence of residual VSD between the two groups ($p = 0.64$).
Conclusions: Tricuspid valve detachment is a valid technical adjunct to VSD closure and is associated with excellent long-term valvar competency and no increase in the incidence of residual VSD. Surgeons should not hesitate to detach the tricuspid valve when exposure of the defect is limited.

P2878 - LEFT ATRIAL ISOMERISM A LONG TERM OUTCOME STUDY

Srinidhi Jv Rao, Syed Asif Akbar Shah, Siva Rao, Vinay Bhole, Oliver Stumper, David Barron, Chetan Mehta
Birmingham Children, Heart Unit, Birmingham-United Kingdom

Left atrial isomerism (LAI) is a rare disorder associated with a wide variety of cardiac and extracardiac abnormalities with varying outcomes.
Objective: The aim of the study was to describe the cardiac and non-cardiac associations in patients with LAI. We also aimed to determine the long term outcomes and analyse the risk factors associated with adverse outcome.
Methods: Retrospective casenote review of cases with LAI managed at Birmingham Children's Hospital from 1980-2015. The outcome measures were overall survival and survival following surgical intervention.
Results: Over a 35 year period, 94 patients were identified with LAI. The cardiac abnormalities are described in table 1. Commonest extracardiac abnormalities were polysplenia in 57(61%) and biliary atresia in 11(12%). 48 (51%) had biventricular circulation (6 were not operated) while 46 (49%) were palliated along the univentricular route. Overall mortality was 30 (32%), with 13 (27%) in biventricular circulation and 17 (37%) in those with univentricular circulation. Overall survival following surgical intervention was 83% at 1year, 75% at 5yrs and 72% at 10yrs. There was no difference in the 1 and 5 year survival in both the groups, however the 10 year survival was 68% in the univentricular group and 75% in the biventricular group. Risk factors for adverse outcome were congenital complete heart block ($p = 0.03$), total anomalous pulmonary venous drainage ($p = 0.01$) and need for neonatal cardiac surgery ($p = 0.04$). Of those who underwent surgery, there was no statistically significant difference in the survival between the single and biventricular circulation groups ($p = 0.44$).
Conclusions: There is no difference in the medium term outcomes of the LAI, irrespective of univentricular or biventricular circulation. Survival in both groups is influenced by the presence of anomalous pulmonary venous drainage, complete heart block and need for neonatal cardiac surgery.

Table.

	Number (percentage)		Number (percentage)
Systemic veins	**Pulmonary artery**		
Bilateral SVC	51 (53)	Pulmonary atresia	11 (11)
Left SVC	9 (9)	Pulmonary stenosis	29 (31)

P2883 - RATIONALE AND DESIGN OF A STEM CELL TRIAL IN HYPOPLASTIC LEFT HEART SYNDROME PATIENTS

Brody Wehman[1], Nicholas Pietris[2], Sudhish Sharma[1], Rachana Mishra[1], Kristopher Deatrick[1], Allen Everett[3], Narutoshi Hibino[4], Luca Vricella[4], Joshua Hare[5], Sunjay Kaushal[1]
University of Maryland School of Medicine, Cardiac Surgery, Baltimore-United States[1]; University of Maryland School of Medicine, Pediatric Cardiology, Baltimore-United States[2]; Johns Hopkins Medical Institute, Pediatric Cardiology, Baltimore-United States[3]; Johns Hopkins Medical Institute, Cardiac Surgery, Baltimore-United States[4]; Miller School of Medicine, Cardiology, Miami-United States[5]

Background: The survival rate of hypoplastic left heart syndrome (HLHS) patients remains limited. We describe the rationale from a preclinical model and study design for the first Phase I trial in the United States to evaluate the safety and feasibility of allogeneic mesenchymal stem cell (MSC) therapy in HLHS patients.
Materials and Methods: Neonatal Yorkshire swine (n = 20, 6-9 kg) underwent pulmonary artery banding to induce RV dysfunction. Human stem cells were injected intramyocardially into the RV at

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

30 minutes post-banding (MSCs: n = 5, cardiac stem cells (CSCs): n = 5; MSCs/CSCs: n = 5; placebo: n = 5). RV size and function was monitored with serial transthoracic echocardiography.
Results: Four weeks post-injection, stem cell-treated myocardium had a smaller increase in RV end-diastolic area, end-systolic area, and tricuspid vena contracta width ($p < 0.01$), increased RV fractional area of change ($p < 0.01$), and improved myocardial strain mechanics ($p < 0.01$) relative to placebo. Myocardium from MSC-treated piglets exhibited several mechanisms of endogenous myocardial repair, including enhanced neovessel formation, recruitment of endogenous c-kit$^+$ CSCs and proliferation of cardiomyocytes and endothelial cells. Mechanistically, MSC treatment of porcine RV myocardium as well as an in vitro model of cardiomyocyte hypertrophy was associated with upregulation of the cardioprotective, anti-hypertrophic molecule growth differentiation factor 15. Based on these preclinical results, an FDA approved trial has been initiated in a total of 30 HLHS patients who will be randomized to receive intramyocardial allogeneic MSCs at the Stage II palliative bidirectional cavopulmonary connection (BDCPC) operation versus control. This study will examine safety and feasibility endpoints as well as preliminary efficacy to enhance RV performance. To date, three infants (n = 3) with HLHS have safely undergone allogeneic MSC injection at the time of the Stage II BDCPC operation.
Conclusions: This Phase I trial will provide important insights of allogeneic MSC therapy in HLHS patients. The lessons learned may be applied to other congenital heart diseases.

P2891 - LONG TERM FOLLOW UP OF BIDIRECTIONAL CAVOPULMONARY ANASTOMOSIS PATIENTS MULTI CENTER STUDY

Amal El-sisi[1], *Amira Esmat*[1], *Nevin Mamdouh*[2], *Rania El-kaffas*[1], *Hesham Shawky*[3]
Cairo University, Pediatric Cardiology, Cairo-Egypt[1]; *Ain Shams University, Pediatric Cardiology, Cairo-Egypt*[2]; *Cairo Universoty, Cardiothoracic Surgery, Cairo-Egypt*[3]

Background: The bidirectional cavopulmonary shunt is a step towards the Fontan operation in palliation of patients with single-ventricle heart.In Egypt, there is a delayed age of children undergoing Fontan procedure due to long waiting lists and budget restraints on pediatric cardiac surgeries.
Aim of the work: To assess long term follow up of patients with bidirectional cavopulmonary shunt and to determine their clinical and hemodynamic status.
Methods: A total of 125 patients with bidirectional cavopulmonary shunts from three centers in Egypt were followed up from January 2012 till July 2016. At follow up, mean age was 7.5 (1.7-16 years) and weight was 23.05 (9-58 Kg). Males were 61.5%, 64% had single ventricle morphology, 76% had additional pulmonary flow and 38.5% had prior palliative cardiac surgery.
Results: The mean age at Cavopulmonary shunt was 2.98 years (0.4–12 years). NYHA was class I in 82% and II in 15%, mean oxygen saturation was 81% (60-95). Cardiac catheterization was done in 45%, mean Glenn pressure was 15.5(6-28 mmHg) and mean Nakata index was 287 (108-910). Catheter interventions were done in 24%; eleven patients had procedures to minimize the extrapulmonary flow: closure of the shunts, collaterals, patent ductus arteriosuus and/or device occlusion of the forward flow, while thirteen patients had balloon and/or stent of pulmonary arteries, superior vena cava (SVC) or pulmonary veins. five patients had occlusion of venoatrial collaterals and/or left SVC to coronary sinus. The only significant difference was intensive care unit (ICU) stay which was shorter in patients with additional pulmonary flow (P value 0.016), and mean Glenn pressure which was lower in patients with single ventricle (P value less than 0.001). Mean follow up was 13.33 years with 5% late mortality.
Conclusion: Cavopulmonary shunt can be a long term palliative procedure for patients with single ventricle in developing countries..

P2903 - COMPREHENSIVE INTERSTAGE CARDIAC CARE PROGRAM FROM FETUS TO GLENN RESULTS IN IMPROVED SURVIVAL FOR COMPLEX SINGLE VENTRICLE INFANTS

Haleh Heydarian[1], Dennis Wells[2], Samuel Hanke[1], James Cnota[1], Bryan Goldstein[1], Laurel Stein[1], Roosevelt Bryant[2], James Tweddell[2], David Morales[2]
Cincinnati Children, Cardiology, Cincinnati-United States[1]; Cincinnati Children, Cardiothoracic Surgery, Cincinnati-United States[2]

Background: Interstage mortality for single ventricle (SV) patients is 10-20%. Care protocols have been reported to improve outcomes in this population.
Methods: In December 2012, a change in surgical strategy along with an interstage monitoring protocol following the Norwood operation was created in conjunction with our SV clinic. Guidelines from prenatal to stage-II palliation included a home surveillance program, trigger points for urgent office visits and admissions via a SV hotline, as well as frequent echocardiograms and nutrition evaluations. Outcomes for infants undergoing stage-I palliation before and after initiation of the care guidelines were reviewed. End points included operative mortality, postoperative length of stay, interstage discharge to home, interstage mortality, growth, and timing of stage II palliation.
Results: Forty-one infants between January 2008 and December 2012 comprised the pre-SV program cohort. Since the SV program, 54 patients have undergone stage I palliation with a significant reduction in operative mortality (16% vs. 5.7%). Notably, 26 Norwood procedures have been performed since September 2014 with no operative mortality (STS national benchmark 15.6%). Postoperative median length of stay in the post-SV program cohort is 26 days with 87% of patients discharged home. Interstage mortality decreased from 26% to 4% post-SV program. The last interstage mortality was in July 2014 with 28 Norwood operations performed since then. Time to bidirectional Glenn was shortened from 143 days (range 99-261 days) to 130.5 days (range 89-185 days) at a comparable patient weight. Furthermore, there was a significant reduction in growth failure (25% to 4.3%).
Conclusion: Outcomes have significantly improved at our institution for stage I palliation after changing surgical strategy and initiating a comprehensive care plan (inter-stage monitoring protocol and SV clinic). Although many centers already have interstage programs, this comprehensive fetus to Glenn program has improved the.

P2906 - PULMONARY AUTOGRAFT MITRAL VALVE REPLACEMENT (ROSS II) INTERMEDIATE AND LONG TERM FOLLOW UP OF A U.S. CENTER

David Blitzer, Jeremy Herrmann, John Brown
Indiana University School of Medicine, Surgery, Indianapolis-United States

Background: Mitral valve replacement (MVR) in pediatric and adolescent patients poses significant challenges, specifically regarding valve size, durability, and need for anticoagulation. The use of a pulmonary autograft or allograft for mitral replacement, the Ross II MVR, has been reported by centers seeking durable replacements without requiring anticoagulation. We report medium- to long-term follow-up in the largest reported experience with this procedure in North America.
Methods: We conducted a retrospective review of Ross II patients from January, 2003 to January, 2010. Autografts and allografts were constructed by suturing valves inside a 2.5 cm Dacron tube and covering the outside with pericardium. The composite prosthesis was sutured to the mitral annulus with interrupted sutures.
Results: Mean age at the time of surgery was 25.15 ± 15.72 years. 80% of patients were female. Mean follow-up was 11.74 ± 5.2 years. There were no in-hospital deaths. There were 3 late deaths post Ross II procedure, occurring at 11 months (respiratory failure), 5 years (unknown cause), and 11 years (cardiac arrest), respectively. Three patients required subsequent mechanical MVR at a median interval of 2 years after the Ross II procedure. Echocardiographic follow up was available for 5 of 7 patients who retained the Ross II prosthesis at a mean of 10.53 ± 3 2 years postoperatively and revealed mean mitral valve gradients ranging from 2.2 to 9.6 mmHg. One patient had greater than mild mitral regurgitation; all others had minimal-to-no mitral regurgitation.
Conclusions: The Ross II procedure may be a valid option for a select subset of older pediatric and adolescent patients for whom a durable tissue valve devoid of the bulk or need for anticoagulation is necessary or desired. Our experience indicates this technique may offer a durable solution for these challenging patients.

Table 1. Demographic and Echocardiographic Information.

Patient	Age at last follow up (years)	Age at Ross II (yrs)	Follow Up (yrs)	Echocardiopraphic Follow-up (years)	Mean Mitral Gradient (mm Hg)	Mitral Function
1^	60.91	46	14.91	–	–	–
2	56.83	43	13.83	12.66	2.2	Normal

P2919 - HYPOPLASTIC AORTIC ARCH REPAIR BY THORACOTOMY IS IT PLAUSIBLE

Juan B. Umana[1], Nestor F. Sandoval[2], Catalina Vargas[3], Carlos E. Obando[2], Albert F. Guerrero[2], Juan P. Umana[1], Jaime Camacho[1]
Fundacion Cardioinfantil Institute of Cardiology, Cardiac Surgery, Bogota-Colombia[1]; Fundacion Cardioinfantil Institute of Cardiology, Congenital Cardiac Surgery, Bogota-Colombia[2]; Pontificia Universidad Javeriana, Cardiac Surgery, Bogota-Colombia[3].

Objective: The aim of this study is to present the early clinical outcomes of patients with severe aortic coarctation and hypoplastic aortic arch that underwent repair through a thoracotomy.
Methods: A retrospective cohort of patients with aortic coarctation or coartation and hypoplastic aortic arch with complete echocardiographic evaluation of the aorta, who underwent repair by thoracotomy between 2009 and 2016 was analyzed. Pre-operative, post-operative, and echocardiographic characteristics were analyzed. Mortality and reintervention outcomes were evaluated by phone at one year follow up. Hypoplastic aortic arch was defined as distal transverse arch/ascending aorta ratio ≤ 0.6 and was compared to simple coarctation cases.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: In the study period 380 patients underwent combined or isolated aortic coarctation repair. For the analysis 55 patients meet the inclusion criteria. 40% (22/55) were newborn, 38.2% (21/55) infants and 21.8% (12/55) older than 1 year. 7.2% (4/55) had chromosomal anomalies. Preoperative ejection fraction was 68.6 ± 10.6%. Mean distal transverse arch/ascending aorta ratio was 0.6 ± 0.2. There was no global mortality or follow up 1 year mortality. Reoperation rate was 3.6% (2/55). 30.6% were termino-terminal repairs, 4.1% were subclavian flap repairs, 63.3% were extended termino-terminal repairs and 2% were extended termino-terminar repairs with subclavian flap. Re-coarctation rate for termino-terminal repair was 5.9% and for extended termino-terminal repair was 3.1% without any statistical difference.
Conclusion: Patients undergoing hypoplastic aortic arch repair through thoracotomy had similar outcomes when compared to patients undergoing isolated aortic coarctation repair. Taking into account the morbidity of a median sternotomy and extracorporeal pump needed to repair a hypoplastic arch through a sternotomy it is reasonable to use a thoracotomy for repair. Even though the proportion of patients with re-coarctation was higher with a termino-terminal approach, there was no statistical difference but extended termino-terminal is recommended.

Table.

	Distal transverse arch/ ascending aorta ratio	
Characteristic	**<0.6**	**>0.6**
Patients n (%)	14 (25.4)	41 (74.5)

P2920 - A SURVEY OF CURRENT PRACTICES FOR PRE BIDIRECTIONAL GLENN EVALUATION OF SINGLE VENTRICLE PATIENTS IN NORTH AMERICA

Proscovia Mugaba[1], Lindsay Ryerson[2], Lisa Hornberger[3]
University of Alberta, Division of Cardiology, Department of Pediatrics, Edmonton-Canada[1]; University of Alberta, Division of Critical Care, Department of Pediatrics, Edmonton-Canada[2]; University of Alberta, Division of Cradiology, Department of Pediatrics & Department Of Obstetrics And Gynaecology, Edmonton-[3]

Background: Cardiac magnetic resonance (CMR) is reported to be a less costly, effective alternative to cardiac catheterization (cath) in selected single-ventricle patients prior to bidirectional Glenn (BDG). To what extent CMR is used in routine pre-BDG evaluation at cardiac centres in North America is unknown.
Materials/Methods: We conducted an online survey from July to November 2016, exploring North American practices for pre-BDG evaluation among pediatric cardiologists and cardiovascular surgeons treating children with congenital heart disease.
Results: In total, 184(19.6%) practitioners responded (cardiologists: 89%, surgeons: 11%). Of these, 87% reported ≥10 years of practice and the majority were from centres performing ≥100 open-heart surgeries(88.1%) and ≥10 BDG(86%) operations annually. Sixty percent reported existance of an institutional policy for pre-BDG evaluation including: echocardiography with cath for all patients (76.4%), echocardiography with CMR for low-risk patients (14.5%), echocardiography with CMR for all patients (1%), and other modalities (8.1%). Individually, With 69.3% and 12.5% of practictioners, respectively recommended cath or CMR in >75% of instances. If any risk factor (aortopulmonary or venovenous collaterals, pulmonary vein stenosis, pulmonary hypertension, arch obstruction, ventricular dysfunction or restrictive atrial communication) was identified by pre-BDG echocardiography, 72% would refer for cath alone, 26% would refer for cath with CMR, and 2% would for other modalities. 96% and 99% estimated the frequency of a preoperatively missed diagnosis as <25% of instances with CMR or cath, respectively. The minority (17.3%) of practitioners felt that, in most cases, early unplanned re-operation following BDG resulted from missed diagnoses due to inadequacies of the pre-BDG imaging while 56.3% disagreed and 26.4% provided a neutral response.
Conclusions: There's practice variations across North America for pre-BDG evaluation of single-ventricle patients. Echocardiography combined with cath is most commonly used in spite of existing data to support use of CMR for at least low risk.

P2927 - AORTOPULMONARY WINDOW IN AN ADULT PATIENT. IS SURGERY POSSIBLE AT THIS STAGE OF LIFE

Oscar Andrés Eskola Villacís, Henry Ortega Espín
Carlos Andrade Marín Hospital, Cardiothoracic Surgery, Quito-Ecuador

Introduction: In concept, an aortopulmonary window is a communication between the main pulmonary artery and the ascending aorta in the presence of two semilunar valves separately. There are no large series collected specifically for adults with this pathology because of their fatal nature within the first year of life, but surgical correction has been described and feasible, with certain particular considerations and with good results in the short, medium and long term.
Case: A female patient of 22 years of age presents with flat dyspnea and palpitations sensation, cyanosis labial to the effort. She is originally from a rural sector of the capital. A radiographic study determined cardiomegaly GIII with biventricular growth and increased pulmonary vasculature. It is diagnosed by Transthoracic Echocardiography and Cardiac Catheterization of a congenital Aortopulmonary Window type II, with systolic pressure of the pulmonary artery between 80 and 90 mmHg and a short circuit from left to right, QP/QS 2.87, RPT 634.3 dynes, 7.9 uw, RST 1960. The only treatment option was surgical. The finding of the surgery was a aortopulmonary window type III. The total time used for the surgical correction was 197 min, with a cardiopulmonary bypass time of 96 minutes, aortic clamping of 62 minutes and reperfusion in 18 minutes, working with hypothermia up to 32 °C. She remains hospitalized in intensive care unit for 24 hours. Was discharged within 4 days of leaving the unit. The final echocardiogram at the end reports a pulmonary artery pressure of 36 mmHg, without short circuits, without aortic and pulmonary insufficiency. Currently in a postoperative period of 12 months, with good general condition, without cyanosis, she does his daily activities without problem and does not require oxygen. The patient lives in a rural parish that is 2830 meters above sea level.

P2939 - LONG TERM SURVIVAL BY PHYSIOLOGIC CLASSIFICATION AFTER SURGICAL OR TRANSCATHETER INTERVENTIONS FOR CONGENITAL HEART DISEASE (CHD) A STUDY FROM THE PEDIATRIC CARDIAC CARE CONSORTIUM (PCCC)

Lazaros Kochilas[1], Jeremiah Menk[2], Jeffrey Vinocur[3], James St Louis[4], Brian Harvey[5], Matthew Oster[1], James Moller[6], Logan Spector[5]
Emory University-Children, Pediatrics, Atlanta-United States[1]
University of Minnesota, Clinical and Translational Science Institute, Minneapolis-United States[2]; University of Rochester, Pediatrics, Rochester-United States[3]; Children, Surgery, Kansas City-United States[4]; University of Minnesota, Pediatrics, Minneapolis-United States[5]; University of Minnesota, Internal Medicine, Minneapolis-United States[6];

Background: We examined the long term survival of patients surviving interventions for CHD as reported in the PCCC between 1982 and 2003. The PCCC is the longest standing registry of outcomes for pediatric cardiac interventions in the world containing data from surgical and trans-catheter procedures from 48 centers in 27 U.S. states.
Methods: We linked the PCCC dataset with the National Death Index and the United Network for Organ Sharing using direct identifiers to evaluate long term vital status of individuals with repaired or palliated CHD. A total of 56,834 subjects were registered prior to April 15, 2003 and matched through December 31, 2014. Time from birth to first transplant or death was compared using Cox Proportional Hazards Regression and Kaplan-Meier survival plots to compare major physiologic classifications. Follow-up time was administratively censored after 50 years.
Results: A total of 9,049 deaths or transplants (15.9%) were identified within 50 years of birth. Time to event or censoring ranged from 1 day to 50 years with a median time of 21.1 years. Analysis by physiologic group revealed a hazard ratio of 0.167 (95% CI: 0.160-0.175) for two-ventricular conditions compared to single-ventricle lesions. Within the group with two ventricle physiology, hazard ratios relative to complete mixing were: 0.30 for impaired pulmonary flow (95% CI: 0.27-0.33), 0.53 for impaired pulmonary venous return (95% CI: 0.44-0.64), 0.21 for impaired systemic flow (95% CI: 0.19-0.25), 0.14 for pulmonary left-to-right shunt physiology (95% CI: 0.12-0.16), and 0.50 for TGA physiology (95% CI: 0.43-0.57).
Conclusions: Mortality is higher for patients with single ventricle physiology. Within patients with 2-ventricle physiology mortality differs significantly based on the underlying main physiology with the highest mortality observed in the group of complete mixing and the lowest for left-to-right shunt physiology..

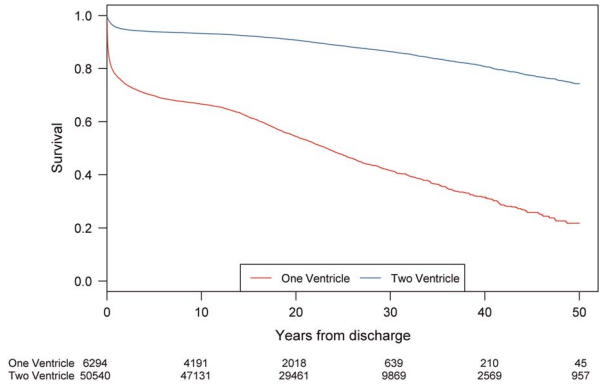

Figure.

P2942 - CORONARY ARTERY PATTERN IN TRANSPOSITION OF THE GRAT ARTERIES AND ITS INFLUENCE IN ARTERIAL SWITCH

Martin Alfonso Saldaña Becerra, Alejandra Valeria Iturriaga Hernández, Dagoberto Muñoz Serret, Jorge Luis Cervantes Salazar, Antonio Benita Bordes, Julia María Martínez Morales, Edgar Samuel Ramirez Marroquin
Instituto Nacional De Cardiología Ignacio Chávez, Pediatric Cardiac and Congenital Heart Disease Surgery, Saltillo-Mexico

Clinical background: Now on days arterial switch is the election treatment for surgical correction of transposition of the great arteries. For the success of anatomical correction of transposition of the great arteries it is essential to transfer the coronary ostia to the posterior vessel without undue tension, torsion, or kinking of the proximal coronary arteries or their early branches, requiring understanding the anatomical disposition and variations of the coronary arteries in the cited disease.
Objetive: Describing the origin and the anatomical variations of the coronary arteries in patients with transposition of the great arteries, and its relation with the mortality in anatomical correction.
Material and Methods: Retrospective and descriptive study. The anatomy of the coronary arteries was examined and described during operation of arterial switch, between January 2007 and December 2016, in 155 patients (99 male/56 female), with a mean age of 8 months. (1 day – 7 years).
Results: Coronary artery nomenclature was based on the Leiden Convention Classification. The usual coronary distribution and the most common variant (1LAD,CX; 2RCA) was found in 77.4% of the patients. Eight patients (5.2%) had a 1LAD,CD; 2CX pattern, six patients (3.9%) had 1LAD; 2CX,RCA; a pattern 1LAD,CX,RCA in a unique ostium in 4 subjects(2.6%), and a 2LAD,CX,RCA in a unique ostium in four patients; other patterns were less frequent. During the correlations of the pattern and mortality of the subjects, no statistic significance was found. (p 0.89).
Conclusion: The anatomic variants frequency was similar to the reported in literature. A great diversity of isolated patterns with a complex origin and trajectory was found; however, no relationship between mortality and coronary pattern was observed.

P2945 - CHARACTERISTICS AND EVOLUTION OF THE SURGICAL MANAGMENT FOR THE TRANSPOSITION OF THE GREAT ARTERIES

Martín Alfonso Saldaña Becerra, Alejandra Valeria Iturriaga Hernández, Dagoberto Muñoz Serrat, Jorge Luis Cervantes Salazar, Antonio Benita Bordes, Julia María Martínez Morales, Edgar Samuel Ramirez Marroquin
Instituto Nacional De Cardiología Ignacio Chávez, Pediatric Cardiac and Congenital Heart Disease Surgery, Saltillo-Mexico

Transposition of great arteries is one of the most common cardiovascular congenital malformations, with an incidence of 1 in 3500-5000 newborns. In the last three decades, a survival increase has been reported in this patients, due to an earlier diagnosis, prostaglandine e1 administration on a regular basis, and a strong progress in the technical aspects of the cardio surgical units and cardiac catheterization.
Objective: describe the background and evolution of affected subjects who were through surgery, and determine possible prognostic factors in morbility and mortality in a short and midterm.
Material and Methods: retrospective and descriptive study. Review of clinical files of subjects with great arteries transposition who were operated between 2007 and 2016.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: 192 subjects diagnosed with great arteries transposition were selected (105 IVS/85 VSD). In 127 of the patients, a surgical correction during the first surgical procedure was achieved (anatomical 91%/physiological 9%), with a mortality of 22.8%. In 24 patients, the anatomical correction was done after ventricular preparation (mortality of 33.3%). A higher mortality is observed in patients with transposition with aggregates malformations, mainly coarctation of the aorta. In the linear regression analysis, we found significant significance for mortality in the following variables: cardiopulmonary bypass time, aortic cross clamp time, postoperative mechanical ventilation time, and the age of surgery.
Conclusion: In our institution, the mortality in the surgical management of the transposition of the great arteries is higher than the reported in the literature; this is closely related to the learning curve and improvement of the surgical technique over the years.

P2954 - TOTAL RIGHT VENTRICULAR EXCLUSION FOR END STAGE ARVD AND EBSTEIN ANOMALY

Ahmad Ali Amirghofran[1], Farah Peiravian[2], Saeed Abtahi[3], Mohammad Reeza Edraki[4], Ghlamhossein Ajami[4], Hamid Amoozegar[4]
Shiraz University, Cardiac Surgery, Shiraz-Iran[1]; Azad University, Cardiology, Shiraz-Iran[2]; Mashhad University, Cardiology, Mashhad-Iran[3]; Shiraz University, Cardiology, Shiraz-Iran[4]

Introduction: The best maagement for end stage RV dysfunction is under debate. This condition can be seen as Arrhythmogenic RV dysplasia or in extreme cases of Ebstein anomally.Total RV exclusion has been introduced as a final management modality in these patients. We report our experience in 2 patients.
Method and Result: A 13 y/o girl who presented with severe dyspnea and CHF and a 2 year old girl with extreme form of non repairable Ebstein anomaly are reported. Both patients had very dilated dysfunctional right venricles pushing the interventricular septum towards left. Both had right to left shunts through ASDs causing relative cyanosis.The first patient was candidate for heart transplant and had frquent admissions due to severe sympyoms. Echo, Angiography & MRI confirmed the diagnosis in both patients. The diagnosis of ARVD(arrhythmogenic right ventricular dysplasia) was made in Patient 1 although full criteria could not be met. The whole RV was excised and the tricuspid valve closed by fenestrated patch and Extra-cardiac ferestrated TCPC performed at the same stage in both patients. A patch used to replace the RV wall in patient 1 and direct closure done inpatient 2.Fortunately they tolerated the operation well and discharged on the 12th and 14th post op days.
Conclusion: Total right ventricular exclusion can be done with satisfactory result in patients with exceptionally non-functional RV disease.

P2955 - INITIAL EXPERIENCE IN THE SURGICAL MANAGEMENT OF CONGENITAL HEART DISEASE IN NORTHWESTERN MEXICO

Alexander Gurahua[1], Samuel Ramirez[1], Jorge Cervantes[1], Hugo Martinez[2], Alfredo Fuentes[3], Jose Garcia Montes[4]
Instituto Nacional De Cardiologia, Pediatric Cardiac Surgery, Mexico-Mexico[1]; Hospital General De Mexicali, Cardiac Anesthesia, Mexicali-Mexico[2]; Hospital General De Mexicali, Pediatric Cardiology, Mexicali-Mexico[3]; Instituto Nacional De Cardiologia, Interventional Pediatric Cardiology, Mexico-Mexico[4]

Objectives: To evaluate the 5-year results of the beginning of activities of a surgical center for congenital heart disease in Northwestern Mexico.
Methods: We collected data from all patients who underwent congenital heart disease correction surgery from January 2012 to December 2016, classifying them by age, weight, complexity of heart disease and risk of mortality RACHS-1 and Aristoteles.
Results: During 5 years of operation, 165 surgical procedures were performed. The age range ranged from 9 days to 14 years, with a mean age of 3 years. (57%) were male. Regarding the complexity of heart disease (17%) Complex heart disease, (51%) heart disease of moderate complexity and the rest (32%) Simple heart disease. Mortality associated with procedural complexity and stratified risk corresponds to the international average.
Conclusions: It is possible to decentralize the surgical management of congenital heart disease in Mexico, adequately addressing cases of simple and moderate complexity with similar results to the international average. Complex cases still have to be treated in national reference centers.

P2956 - SURGICAL REPAIR OF THE COMMON ARTERIAL TRUNK IN THE NATIONAL INSTITUTE OF CARDIOLOGY OF MEXICO

Alexander Gurahua Sebastian[1], Samuel Ramirez Marroquin[1], Jorge Cervantes Salazar[1], Antonio Benita Bordes[1], Juan Calderon Colmenero[2], Alfonso Buendía Hernandez[2], Jose Garcia Montes[3]
Instituto Nacional De Cardiologia, Pediatric Cardiac Surgery, Mexico-Mexico[1]; Instituto Nacional De Cardiologia, Pediatric Cardiology, Mexico-Mexico[2]; Instituto Nacional De Cardiologia, Interventional Pediatric Cardiology, Mexico-Mexico[3]

Objective: To describe the anatomical characteristics, surgical treatment and evolution of patients who underwent surgical correction by diagnosis of Common Arterial Trunk at the National Institute of Cardiology Ignacio Chávez, from Mexico City from January 2003 to December 2016.
Material and Methods: A descriptive, longitudinal and retrospective study was carried out. The study population consisted of all patients of the National Institute of Cardiology Ignacio Chavez, who underwent surgical correction by Diagnosis of Common Arterial Trunk from January 2003 to December 2016.
Results: Of the total of the sample, 59 patients were submitted to surgical correction by Diagnosis of Common Arterial Trunk. Of these, 31 were females and 28 males, the mean age was 8 months with a maximum age of 15 months and a minimum of 1 month, the average weight was 5.6 kg, with a maximum of 10 kg and one Minimum of 2.5 kg, the type of correction was with Rastelli technique in 86% of cases and with Barbero Marcial technique in the remaining 14%, the average diameter of the Rastelli tube was 10.85 mm in diameter, and the material used Was Dacron in 60.8%, Goretex in 16.3% and 22.9 xenograft, 4.5% of patients required interventionism in the immediate postoperative period due to a significant gradient of obstruction in the Rastelli tube or in the pulmonary branches. The need for reoperation was present in 22% of the patients during the follow-up to change the Rastelli tube.

P2963 - SURGICAL STRATEGY FOR PA VSD MAPCA WITH ABSENT OR HYPOPLASTIC CENTRAL PULMONARY ARTERY

Takako Miyazaki, Masaaki Yamagishi
Kyoto Prefectural Universit Y of Medicine, Department of Pediatric Cardiovascular Surgery, Kyoto-Japan

Objectives: Pulmonary atresia and ventricular septal defect with major aortopulmonary collaterals (PA/VSD/MAPCA) is a

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

complex lesion that is challenging to manage surgically, especially when the central pulmonary artery (cPA) is absent or hypoplastic. We report our experience with one-stage unifocalization of the MAPCA, cPA plasty and palliative right ventricular outflow tract reconstruction (pRVOTR), followed by definitive repair at a later stage.
Methods: From 2000 through 2016, the cPA was reconstructed under cardiopulmonary bypass in 26 patients (mean age 1.2 years, mean weight 8.8 kg) using a Y-shaped autologous pericardial roll. MAPCAs were anastomosed directly to the roll by pRVOTR, resulting in an RVOT diameter 75% that of the normal pulmonary annulus. MAPCA banding was proceded in one patient and Blalock-Taussig shunts in five. The strategy for unifocalization of the MAPCA and pulmonary reconstruction was planned preoperatively using 3D-CT angiographic images.
Results: The mean follow-up period was 6.9 years. There was one surgical death and one late death. Nineteen patients achieved definitive repair with complete VSD closure after 1.3 ± 0.4 years, and 3 patients were waiting. No patient required reoperation. The PA systolic pressure was 27.5 ± 11.4 mm Hg after unifocalization + pRVOTR, decreasing to 23.9 ± 5.6 mm Hg after definitive repair. Oxygen saturation was 79% before and 88% after unifocalization + pRVOTR.
Conclusions: Staged surgical treatment of PA/VSD/MAPCA with absent or hypoplastic cPA resulted in excellent early to mid-term results. pRVOTR might be a good option to obtain adequate pulmonary blood flow.

P2969 - LATE RESULTS AND 4D FLOW MRI EVALUATION OF DOUBLE DECKER TECHNIQUE FOR PARTIAL ANOMALOUS PULMONARY VENOUS RETURN TO THE SUPERIOR VENA CAVA

Hisayuki Hongu[1], Masaaki Yamagishi[1], Takako Miyazaki[1], Yoshinobu Maeda[1], Satoshi Taniguchi[1], Shuhei Fujita[1], Eijiro Yamashita[1], Hitoshi Yaku[2], Keiichi Itatani[2]
Kyoto Prefectural University of Medicine, Pediatric Cardiovascular Surgery, Kyoto-Japan[1]; Kyoto Prefectural University of Medicine, Division of Cardiovascular Surgery, Department of Surgery, Kyoto-Japan[2]

Objective: Conventional procedures for PAPVR to the SVC still have problems such as late SVC obstruction, supraventricular arrhythmia, and PVO. We developed a new procedure with minimum right atriotomy and double-barreled arrangement of both systemic and pulmonary venous channels (double-decker technique).
Methods: Between November 1998 and October 2016, 18 patients underwent this operation. The median age was 4.0years, and body weight was 17.5 kg. The right atrial wall was incised from the appendage to few millimeters short of the SVC-atrial junction. The external upper wall of the proximal SVC was covered with the appendage, taking care to avoid injury to the sinus node and sinus nodal artery. New SVC channel was reconstructed onto the proximal SVC external wall. The atrial septal flap or autologous pericardium was used for intra-atrial rerouting. Surgical ASD was created in patients who had intact atrial septum. The anomalous PV was baffled into LA through the ASD. New PV channel was accomplished from the anomalous right upper PVs via the proximal SVC and the created tunnel in RA to LA. CFD analysis of both venous channels was performed with 4D Flow MRI.
Results: The median follow-up period was 10.7years. There was no early mortality and late death. Nobody required reoperation. All patients maintained sinus rhythm and supraventricular arrythmias didn't occur. The median blood flow velocity of the neo-SVC channel was measured 0.47 m/s, and that of the neo-PV channel was measured 0.41 m/s. Among the 6 patients who underwent CFD analysis, the straight and non-restrictive flow stream line was visualized in both pathways, and low wall share stress was detected in all regions.
Conclusion: Newly developed double-decker technique is useful alternative surgical procedure for PAPVR to the SVC. Late complications can be completely avoided by this technique. Growth potential of both channels are maintained. CFD analysis is an useful method for such a complicated hemodynamics evaluation.

P2980 - THE EFFECTIVENESS OF LASSO TECHNIQUE IN BILATERAL PULMONARY ARTERY BANDING

Eijiro Yamashita[1], Masaaki Yamagishi[1], Takako Miyazaki[1], Yoshinobu Maeda[1], Hitoshi Yaku[2]
Kyoto Prefectural University of Medicine, Pediatric Cardiovascular Surgery, Kyoto-Japan[1]; Kyoto Prefectural University of Medicine, Cardiovascular Surgery, Kyoto-Japan[2]

Purpose: We evaluated the effectiveness of Lasso technique in bilateral pulmonary artery banding (PAB).
Methods: Lasso technique:A expected size of bougie is catched with Lasso of Gore-Tex suture CV-4. The CV-4 are passed through the tourniquet (4Fr. ATOM tube), preoperatively marked with 7-0 prolene at the edge of the tourniquet. The right and left pulmonary arteries are encircled by this CV-4. After tourniquetting, Hemoclips are applied to the CV-4 at the marked site. Hemoclips are added to adjust the PA constriction. Intraoperative epicardial echography is performed to adjust the velocity at the PAB site, aiming to 3.0-3.5 m/s. We performed retrospective review of 29 patients who underwent bilatelara PAB from 2000 to 2016 at our institution.
Result: Bilateral PAB was performed at the age of 7.2 ± 4.7 days. The velocity and PA circumference at the banding site was 3.2 ± 0.5 m/s and 8.9 ± 1.0mm in right, 3.3 ± 0.6 m/s and 8.9 ± 1.0mm in left respectively. Preoperative SpO2 were declined from 92.4 ± 4.5% to 83.2 ± 5.3% after bilateral PAB. No reoperation was required for migration of the PA banding. Reoperations for additional adjustment of the PA band were required in 4 cases due to excessive pulmonary blood flow or systemic desaturation. Each adjustment was performed easily by adding or removing the hemoclip. At the second stage operation, PAB was removed easily by cutting the CV4. In 5 cases, PA reconstructions were required to release PA stenosis at the banding site. PA index at the banding site was 198.6 ± 66.2(110.3 ± 41 in right, 88.3 ± 32.3 in left).
Conclusion: Lasso technique is attractive method in terms of feasibility, re-adjustability and PA growth.

P3010 - CAN MONOCUSP VALVES BE DISPENSED WITH IN YOUNGER PATIENTS WHILE DOING RVOT RECONSTRUCTIONS

Zeena Makhija[1], Mahesh Bhatt[2]
SK Hospital and PMMC, Congenital Cardiothoracic Surgery, Anand-India[1]; SK Hospital, Pediatric Cardiology, Anand-India[2]

Background: Transannular patching (TAP) of the right ventricular outflow tract results in pulmonary insufficiency (PI) The objective of this study was to (i) compare early outcomes after TAP with monocusp valve reconstruction or TAP alone and (b) assess the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

mid-term results after polytetrafluoroethylene (PTFE) membrane monocusp reconstruction.
Methods: From 2014 through 2016, 62 patients (mean age, 2.3 + /- 5.0 years) underwent right ventricular outflow tract reconstruction with a TAP. Data was retrospectively obtained to compare clinical outcomes among two groups: patients receiving monocusp with TAP (group A, n = 21) and patients undergoing TAP without monocusp (group B, n = 41).
Results: Overall, there were 1 early and 4 late deaths (5/62; 8.1%). There was a significant reduction of the preoperative right ventricular outflow tract gradient postoperatively following TAP (96.2 vs 16.1; P < .0001). Postoperatively, the RV/LV pressure ratio was <0.5 in all groups. Mechanical ventilation time, fluid drainage duration and total ICU stay showed no significant difference between Groups A and B. The incidences of moderate or severe PI on discharge were 9.5% in Group A, 7.3% in Group B (P = 0.7). None of the patients underwent reoperation for monocusp replacement. There was one death secondary to infective endocarditis of monocusp valve (4.7%). Two (9.5%) patients had moderate right ventricular outflow tract stenosis across the monocusp patch (mean gradient, 36.5 + /- 20.3 mm Hg). These gradients showed a inverse linear correlation with the age of the patient.
Conclusions: Use of a PTFE-monocusp valve prevents immediate PI, though no significant improvement in early or mid-term clinical outcomes is noted. There is a significant risk of pulmonary embolization, infective endocarditis which should be considered before implanting a monocusp valve. There is an increased risk of residual PS especially in younger patients which may increase the risk of reoperations.

P3021 - THE ROLE OF PALLIATIVE SURGERY IN THE ERA OF THE CORRECTIVE SURGERY. ANALYSES OF RESULTS AND FUTURE PERSPECTIVE

Esteban Sarria[1], Enrique Ruiz[1], Francisco Vera[1], Victorio Cuenca[2], Lourdes Conejo[2], Beatriz Picazo[2], Cristina Yun[3], Pilar Sanchez[3], Guillermo Milano[3], Ignacio Zabala[2]
Hospital Regional Universitario, Cirugía Cardiovascular, Málaga-Spain[1]; Hospital Regional Universitario, Cardiología Pediátrica, Málaga-Spain[2]; Hospital Regional Universitario, Cuidados Intensivos Pediátricos, Málaga-Spain[3]

Objective: To evaluate the results in surgical procedures of univentricular hearts.
Patients and Methods: Retrospective analysis of the 42 patients operated from 2013 to 2016.
Results: Neonatal palliation (16 patients): Blalock-Taussig shunt: 7 cases; Norwood procedure: 5 patients; Banding 4 cases. BT shunt: age 23 days (2-40); Aristoteles 7.5. Medium stay at PICU 12 days (5-32) and hospital 32 days (10-97). 1 reintervention due tu acute thrombosis. No mortality. Norwood procedure: 5 patients. Age 29 (6-90) days. Aristoteles 20.8. Stay at PICU 35 (19-57) days and hospital 48 days. Morbidity: 1 case of inferior vena cava thrombosis. Mortality: 1 case due to refratory septic shock. All cases have reached the Glenn procedure. Glenn procedure: 11 patients (1 case associated to Damus-Kaye-Stansel procedure). Age: 8(4-135) months. Aristoteles 9. Stay at PICU 17 (3-90) days and hospital 27 (7-119 days). Morbidity: 1 case of phrenic nerve paralysis. Fontan procedure: 15 patients. Age 56 (40-113) months. Aristoteles 11. Stay at PICU and hospital: 7 (4-81) and 24 (14-90). Morbidity: 1 case of cardiac tamponade due to chylopericardium, 1 case of persistent pleural effusion (reintervention and embolization of thoracic duct and 1 case of thrombosis of inferior vena cava. No mortality. Overall mortality: 2.3% In one particular case, the use of a MRI 3D printed model redirect a case from a Glenn procedure to a biventricular heart.
Conclusions: Surgery of univentricular hearts means complex high risk procedures. Currently, they can be performed successfully and patients are able to reach the definitive palliation with the Fontan procedure. The use of new methods for accurate diagnostic could help patients to be reconsidered from single ventricule-surgery to biventricular surgery.

P3033 - ACQUIRED LEFT VENTRICLE TO RIGHT ATRIUM COMMUNICATION AFTER CARDIAC SURGERY

Yun Jin Lee[1], Eun Joo Kim[1], Hong Ryang Kil[2]
Chungnam National University, Pediatrics, Daejeon-Korea, South[1]; Chungnam National University Hospital, Pediatrics, Daejeon-Korea, South[2]

Background: Left ventricular (LV) to right atrial (RA) communication is very rare congenital defect, but sometimes caused by complications of cardiac surgery, infectious endocarditis, trauma or myocardial infarction. Acquired LV to RA communication after surgery is rare complication but can be hazardous for the patient. Recently, awareness of this complication has been increased.
Methods: We analyzed medical records of 6 patients complicated by acquired LV to RA communication after cardiac surgery for congenital heart disease (CHD) at Chungnam National University Hospital (4) and others (2), retrospectively. We investigated the underlying CHD and surgical procedures. In addition, clinical manifestation, course and outcome of LV to RA communication were analyzed.
Results: Underlying CHDs were ventricular septal defect (VSD) (4), VSD, atrial septal defect and persistent ductus arteriosus (1) and transposition of great arteriosus with VSD(1). All patients performed autologous patch closure for VSD. All LV to RA communication were occurred postoperatively except one by infective endocarditis at patch closure region. The diagnosis was confirmed with transthoracic echocardiography. In addition, cardiac catheterization was done for shunt evaluation in two patients. Three patients underwent patch closure for LV to RA communication. In one patient, phrenic nerve palsy was complication by operation for LV to RA communication.
Conclusion: Acquired LV to RA communication is very rare and not well-known but significant complication after cardiac surgery for CHD. In many cases, the symptom and sign are not clear and variable. So, detailed and careful cardiac evaluation is needed to detect the LV to RA communication after cardiac surgery.

P3044 - ANOMALOUS ORIGIN OF THE CORONARY ARTERY FROM THE PULMONARY ARTERY DIAGNOSIS AND SURGICAL RESULTS IN 16 PAEDIATRIC PATIENTS OVER A 13 YEARS PERIOD

Ioanna Giannakopoulou[1], B. Claro[2], R. Onita[1], A. Spanaki[1], G. Di Salvo[1]
Royal Brompton Hospital, Department of Paediatric Cardiology, London-United Kingdom[1]; Royal Brompton Hospital, Department of Perfusion, London-United Kingdom[2]

Background: Anomalous origin of the coronary artery is rare, the origin of the left main coronary from the pulmonary artery (ALCAPA) is 0.25% of all congenital heart disease and even more rare is the origin of the right coronary artery from the pulmonary artery (ARCAPA). The aim of this study was to describe a single-

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

centre experience with surgical repair of this condition and determine the midterm outcome.
Materials and Methods: We studied 14 patients (11 females) with ALCAPA and 2 ARCAPA (males) who underwent surgical correction between 2003-2016 in our institution. All patients underwent chest radiography, ECG, and echocardiogram. In 5 patients CT angiogram or angiography was also performed. All patients underwent surgical reestablishment of a dual coronary system with direct aortic reimplantation of the anomalous origin coronary artery into the aorta.
Results: The patients' mean age at presentation was 2.25 ± 4 years (range, 1mo–15 yr). Eleven were infants (age, <1 yr); of these 1 was neonate and 7 were <4 months old. Clinical presentation in ALCAPA patients was heart failure in 5 infants, failure to thrive in 2 infants, cardiogenic shock in 1 neonate, ventricular fibrillation in one child and incidental murmur in the remaining ones. All the infants aged <6mo had dilated cardiomyopathy. The 2 ARCAPA patients were diagnosed following incidental finding of a murmur. At the last follow-up (mean 6.7 + 3.6years, range 3-12 yr), all the patients were alive, left ventricular systolic function was normal (EF > 55%) and all were asymptomatic. Mitral valve (MV) repair, performed in 6 (38%) ALCAPA patients with ≥ moderate MV incompetence, resulted in mild incompetence at the last echo evaluation.
Conclusions: Although initial presentation can be severe, the outcome of this cohort's patients after successful direct reimplantation was favourable. Additional MV repair is commonly required. High level of suspicion is crucial for improving diagnosis.

TRANSPLANT/HEART FAILURE/PULMONARY HYPERTENSION

P1004 - OUTCOMES IN PAEDIATRIC POST MYOCARDITIC AND PRIMARY DCM

Anna Argiolas[1], Elena Reffo[2], Ornella Milanesi[2]
Aou Parma, Dipartimento Materno Infantile, Parma-Italy[1]; Aou, Dipartimento Materno Infantile, Padova-Italy[2]

We compared basal data and outcomes of children with primary DCM and myocarditis. All patients (0-18 yrs.), referred in 2000-2016 to a single University Hospital for LVEF < 55%, and/or LVEDD >2 Zscores forBSA, were reclassified as: 32/72 myocarditis (11/72 definite, 8/72 probable, 13/72 possible) or unlikely 40/72(DCM). Admittance to ICU and inotropes use were similar (16/32 and 14/32 M vs 13/40 and 10/40 DCM) (p = 0,1 and 0,3 respectively), as was the need for ECMO or VADs (6/32 M vs 4/40 DCM p = 0,3). LVEF at onset was significantly lower (p = 0,01) for M patients (29,6% vs 39,1%) while mean LVEDDz was comparable (4,1 ± 2,1 M vs 3,5 ± 2,6 DCM p = 0,3). 4 patients were lost to follow-up. 6/30 patients in the M group and 8/38 in the DCM group reached the primary end point of death or transplant(p = 0,21). LVEF was significantly lower in patients progressing to this primary endpoint (32 ± 11,7 vs 17 ± 8 p = 0,09 for M, and 44,8 ±17 vs 25 ± 9 p = 0,07 for DCM), independently on the LVEDDZ score (3,6 ± 2 vs 5,8 ±1 p = 0,6 for M, and 3,5 ± 2,3 vs 5,4 ± 2,1 p = 0,2 for DCM). Onset below 2 years was associated with death or transplant in the DCM group only (7/22 vs 1/18 p = 0,02 vs 3/18 vs 3/14 p = 0,5). Recovery to normal LV was observed in 17/68 patients, with a non significant trend (p = 0,18) for better outcomes in the M group (10/30 vs 7/38). Higher LVEF at diagnosis was associated with a higher chance of recovery in the M group (29,6 ± 14 vs 41,7 ± 6,9 p = 0,008 inM, 26 ±11,8 vs 38,9 ± 9,7 p = 0,11 in DCM). Hence, it is not possible to confirm a strikingly better outcome for paediatric M patients.

P1048 - SCHOOL INTERVENTION THE MISSING LINK IN FOLLOW UP CARE

Kyle Herma
Children, Cardiology- Heart Transplant, Milwaukee-United States

Background: Children with congenital heart disease (CHD) are at risk for neurodevelopmental delays and differences due to changes in blood flow affecting brain development. Children with CHD score lower in hand-eye coordination, fine and gross motor skills, social-emotional functioning, and language development than their typically developing peers. Frequent attention problems and behavioral concerns are additionally reported. The Children's Hospital of Wisconsin, Herma Heart Center established their School Intervention Program (SIP) in February 2015 to address these educational risk factors. The SIP conducted a pilot study designed to promote academic success of pediatric heart transplant patients by providing individualized assessments and implementing intervention strategies in collaboration with their school. Services expanded to support all areas of pediatric cardiology in May 2016. No data currently exists on the benefits of structured school intervention as a comprehensive support service for pediatric cardiology patients.
Materials and Methods: We performed a retrospective, single center analysis of pediatric cardiology referrals to the SIP from 2/2015 to 10/2016. Referral rates, assessment results and interventions were reviewed and catalogued for descriptive analysis.
Results: Of 63 total school-age patients referred for enrollment, 57 (90.5%) required interventional follow-up. Special education support was the most common school need, while bullying was the most common secondary concern. General fear and lack of knowledge leading to poor communication, low expectations for the student resulting in low achievement and motivation, and an overall identification of missed opportunities for utilizing care coordination were significant trends. Through structured intervention facilitation, 54% of school concerns were resolved with no further action needed, while 40% remain on-going with improvements reported.
Conclusions: Integration of a SIP as part of multidisciplinary follow-up care provides standardized structure to address these known educational and developmental needs. Future research on programmatic correlation to medical outcomes and overall quality of life is needed.

P1111 - THE AORTIC PERFUSION SCORE A NOVEL SCORING SYSTEM TO PREDICT DEATH OR TRANSPLANT IN CHILDREN WITH PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM

Rohit Loomba[1], Andrew Pelech[2]
Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-United States[1]; UCSD, Pediatric Cardiology, Sacramento-United States[2]

Background: Pulmonary atresia with intact ventricular septum (PAIVS) is a unique congenital malformation. Various factors can impact the selection of appropriate palliative strategy. We developed the aortic perfusion score (APS), a novel scoring system based on anterograde coronary perfusion with the aim of being able to identify patients at risk for death or transplant.
Material and Methods: A retrospective study of patients at our institution was conducted. Patients were included if an initial catheterization was done prior to any intervention. Each patient was assigned an APS. In this system, each of the named coronaries (left anterior descending, left circumflex, right main, and posterior descending) had a maximum of 100 points they could be assigned.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

If the entire length of the coronary was being supplied via the aortic root then the coronary would receive 100 points, if only a percentage of it were receiving supply from the aortic root then it would receive that many points. If there was to-fro flow in the coronary due to VCCs then the coronary artery's score was halved. These were then summated for a maximum score of 400. ROC analysis was done to determine a cutoff point predictive of a composite endpoint of death or transplant.
Results: A total of 64 patients were included in the analysis with 10 reaching the endpoint of death or transplant. An APS of 227.5 predicted the endpoint with a sensitivity of 90% and a specificity of 83%.
Conclusion: The APS is a scoring method which can be used to predict a composite endpoint of death or transplant in patients with PAIVS and may be helpful in selecting patients that should be listed for transplant. Additional multicenter studies may help further refine the scoring system.

P1165 - PROGNOSTIC VALUES OF HEART RATE AND OXYGEN SATURATION IN PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION BEFORE AND AFTER SIX MINUTE WALK TEST

Serdar Kula, Vildan Atasayan, F. Sedef Tunaoğlu, Deniz Oğuz, Fatma Canbeyli
Gazi University Faculty of Medicine, Pediatric Cardiology, Ankara-Turkey

Objective: This study aims to determine the prognostic values of heart rate (HR) and transcutaneous oxygen saturation (Sat) which were measured before six minute walk test (6MWT), at the end of 6MWT and 5 minutes after 6MWT in children who are undergoing pulmonary arterial hypertension specific treatment (PAH-Rx).
Methods: 29 children (age 7 -17 years) were evaluated. Sat and HR were measured before 6MWT, at the end of 6MWT and 5 minutes after the completion of 6MWT (Sat0, Sat1, Sat2; HR0, HR1, HR2 respectively). HR increase was defined as HR1 minus HR0 and decrease in Sat was defined as Sat0 minus Sat1.
Results: The mean age was 129 ± 45 months and the mean follow-up time was 58 ± 40 months. The mean pro-BNP concentrations did not change significantly before and after the PAH-Rx (946.4 ± 1754.8 pg/ml vs 917.6 ± 1920 pg/ml $p = 0.11$). However, the mean 6MWT distance increased significantly after the PAH-Rx (400.2 ± 107.8 m vs 436.2 ± 119.2 m, $p = 0.012$). The 6MWT distance was significantly longer and HR1 was significantly higher in survivors (453.3 ± 96.5 m vs 250 ± 135.2 m, $p = 0.025$ and 122.8 ± 18.4 /min vs 94.3 ± 19.1 /min, $p = 0.034$). HR1 increased significantly but Sat1and Sat2 decreased significantly after PAH-Rx ($p = 0.017$, $p = 0.03$ and $p = 0.017$ respectively). While there was no significant correlation between WHO-FC and Sat1 before treatment, WHO-FC and Sat1 correlated negatively after treatment ($r = -0.435$, $p = 0.021$). Although WHO-FC and pro-BNP did not correlate before treatment, they correlated positively after treatment ($p = 0.0001$). There was no association between survival and HR increase whereas survival was positively associated with the decrease in Sat. If the decrease in Sat was 14.6%, sensitivity increased to 100% and specifity was 58.3%.
Conclusions: PAH is a chronic disease which continues to progress despite the administration of specific therapy. The measurement of Sat with pulse oximeter during 6MWT might have prognostic importance in the follow up of children undergoing PAH-Rx.

P1209 - CORRELATION OF HEART FAILURE SEVERITY AND N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE LEVEL IN CHILDREN AGED ONE MONTH TO 14 YEARS

Ria Nova, Yasmien -
The Department of Child Health Faculty of Medicine, Sriwijaya University, DR. Mohammad Hoesin Hospital Palembang-Indonesia

Background: Heart failure affects the morbidity and mortality in children with heart disease. There is no single specific test to diagnose heart failure. The modified Ross Reithmann scoring system has been used to classify heart failure severity, but it is limited due to its subjectivity. The N-terminal-pro brain natriuretic peptide (NT-proBNP) is secreted by the ventricles during heart failure.It has been suggested as a possible marker for diagnosing heart failure.
Objective: To investigate the correlation between heart failure severity and plasma NT-proBNP concentration in children aged one month to 14 years.
Methods: A cross-sectional study was performed in Pediatric Department of Mohammad Hoesin Hospital Palembang, Indonesia from August to October 2016 on children with congestive heart failure, aged one month to 14 years. Heart failure severity was assesed using the modified Ross Reithmann scoring system. Plasma NT-proBNP measurements were done in all subjects. Statistical analysis was done by Spearman's test.
Results: Subjects median plasma NT-proBNP concentration was 1.703 pg/ml (range 310 - 9.000 pg/ml). The NT-proBNP level and severity of heart failure had a significant positive correlation ($r = 0,87; P < 0,001$). The NT-proBNP minimum levels in subjects with mild, moderate and severe heart failure were 310 pg/ml, 1.251 pg/ml, and 2.610 pg/mL respectively.
Conclusion: Plasma NT-proBNP level has a significant, positive correlation with the severity of heart failure in children. As such NT-proBNP level may be useful as a biochemical marker for the diagnosis and grading of severity of heart failure in children.

P1212 - COMPARISON OF CLINICAL PROFILES BETWEEN PATIENTS WITH PROTEIN LOSING ENTEROPATHY WITH AND WITHOUT FONTAN CIRCULATION

Shin Ono[1], Hideo Ohuchi[2]
Kanagawa Children's Medical Center, Pediatric Cardiology, Yokohama-Japan[1]; National Cerebral and Cardiovascular Center, Pediatric Cardiology and Adult Congenital Heart Disease, Osaka-Japan[2]

Background: Protein losing enteropathy (PLE) is one of life-threatening complications in patients after Fontan operation. However, PLE sometimes occurs in patients with congenital heart disease (CHD) after biventricular repair (BVR). Objectives: Our study was conducted to compare clinical profiles of PLE patients with and without Fontan circulation.
Materials and Methods: We retrospectively reviewed clinical charts of all our postoperative CHD patients with PLE.
Results: We had a total of 42 PLE patients (BVR in 14, Fontan in 28). Postoperative follow-up period was significantly shorter in the Fontan group than in the BVR group (14 ± 2 years vs. 8 ± 1 years, $p = 0.02$) despite there were no difference in age at the onset of PLE between the two groups. Prevalence of clinically relevant arrhythmias was equivalent between the two groups. Regarding hemodynamics, although there were no differences in cardiac output or central venous pressure at the onset of PLE between two groups, percentage of treatable structural lesions (valve regurgitation and stenotic lesions) by non-pharmacological interventions

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

was higher in the BVR group than in the Fontan group (93% vs 50%, $p < 0.01$). During the follow-ups, 2 BVR and 8 Fontan patients died. There were no differences in the 5 to 10-year survival after the onset of PLE (81% vs 81%, 81% vs 66% for the BVR and Fontan, respectively). However, the complete remission rate from PLE was higher in the BVR group than in the Fontan group (38% vs. 7%, $p = 0.02$).
Conclusions: Mortality of CHD patients with PLE was substantially high regardless of the postoperative hemodynamics, BVR or Fontan physiology. BVR patients might have a chance of remission from PLE because of the possible treatable responsible lesions.

P1246 - FROM PATIENT TO PROFESSIONAL A TALE OF TWO PERSONAL JOURNEYS IN A PAEDIATRIC HEART TRANSPLANT CENTRE

Claire Kerr[1], Rebecca Peters[2]
Royal Children's, Paediatric Intensive Care Unit, Melbourne-Australia[1]; Royal Children's, Adolescent Transition Support Service, Melbourne-Australia[2]

Background: Heart transplantation is an accepted therapy for children with end-stage heart disease. The Royal Children's Hospital, Melbourne is the nationally designated paediatric heart transplant service for all children aged 0-18 years.
Methods: This abstract presents the experiences and challenges for two former patients who have returned to RCH, CK as a PICU nurse and RP as an adolescent transition support worker. CK was diagnosed with dilated cardiomyopathy at age 14 and relocated to Melbourne from South Australia, for VAD placement. She underwent transplantation several months later. CK graduated from nursing and works in the RCH PICU. RP was diagnosed with LVNC at 8 weeks of age. She relocated from the Northern Territory at age 7 and underwent heart transplantation. RP now works at RCH assisting young people with chronic illness, transitioning to adult care.
Results: 70% of all transplants at the RCH are performed from circulatory support and the number of transplants has increased to 12/year. Paediatric donor utilisation is 71%, with excellent post-transplant outcomes. Both RP and CK can relate to all aspects of the transplantation journey. For CK this involves a deeper understanding of the hopes and fears of families requiring ICU or circulatory support. For RP this involves understanding the challenges facing adolescents with a chronic illness, preparing to transition into adult life. This knowledge allows RP and CK to care for these patients at a higher level. Protective strategies include not discussing their personal history, diversifying their academic and clinical roles and setting personal goals to promoting physical and mental health.
Conclusions: Improving transplant rates and outcomes has led to more transplant patients working in the healthcare sector. This unique background enables them to provide a personalised level of professional support to transplant recipients, and to offer guidance in managing chronic illness with resilience.

P1267 - TIPS AND PITFALLS IN TRANSPLANT AFTER FONTAN

Juan-Miguel Gil-jaurena[1], Ramón Pérez-Caballero[1], Ana Pita[1], María-Teresa González-lópez[1], Manuela Camino[2], Constancio Medrano[2]
Hospital Gregorio Marañón, Pediatric Cardiac Surgery, Madrid-Spain[1]; Hospital Gregorio Marañón, Pediatric Cardiology, Madrid-Spain[2]

Background: Heart transplantation after Fontan completion poses a unique surgical challenge. Twelve patients are presented, stressing the technical hints performed in the five anastomoses to match the graft in the recipient.
Methods: Data are collected from ten Fontan and two takedown patients along 4 consecutive years. Age (9 years), weight (30 Kg.) and time interval between Fontan and transplant (3 years) are presented as median. Extra cardiac conduit (size 18/20) was implanted in 8 patients, whereas atriopulmonary connection was found in three and lateral tunnel in one. Three patients developed protein losing enteropathy. Ten stents have been previously deployed in left pulmonary artery (6), inferior vena cava (3) and right pulmonary artery (1). One patient was on Levitronix for two weeks before transplant.
Results: The five anastomoses underwent some changes. Left atrium once (enlargement with recipient both atria), aorta three times (hemi-arch repair), superior vena cava three times (one case with double superior vena cavae), pulmonary branches eight times (hilum to hilum pasty with donor´s aorta/pericardium patch after thorough stent removal) and inferior vena cava eight times (conduit sleeve anastomoses). Follow-up was complete for a median of 35 months (range 1-48) One patient died. ECMO was needed in four cases for pulmonary hypertension. Three patients had collateral vessels occluded in the cath-lab and stents placed in superior vena cava (1) and aorta (1). Protein losing enteropathy resolved in two children. Interestingly, our latest patient was on systemic assist device before transplant and right assistance (ECMO) afterwards.
Conclusions: Transplant in Fontan patients is actually challenging. Hints in every of the five proposed anastomoses must be anticipated, including stents removal. Extra tissue from the donor (innominate vein, aortic arch, pericardium) is strongly advisable. ECMO for right ventricular disfunction was needed in one third of cases. Overall results can match other transplants cohorts.

P1270 - INITIAL IMPLANTATION OF LEVITRONIX VENTRICULAR ASSIST DEVICE PRIOR TO CONVERSION TO BERLIN HEART; A COMPARITIVE STUDY

Jade Savins, Katie Allison, Donna Kelly
Freeman Hospital, PICU, Newcastle Upon Tyne-United Kingdom

Background/Hypothesis: Scarcity of donor hearts has increased the demand for reliable mechanical support. We are one of two centres in the United Kingdom who use Ventricular Assist Devices (VAD) as a bridge to transplant. In previous years the most common VAD used was a BERLIN HEART; however, due to visible fibrin and clot deposition and risk of systemic embolism we required numerous ventricle changes. The cost of this, led us to change our policy in that we now use the LEVITRONIX centrifugal VAD from implantation, therapeutic heparinisation and platelet inhibition is achieved prior to conversion to a BERLIN HEART device. Several implications have been recognised for a child being on LEVITRONIX opposed to a BERLIN HEART.
Materials and Method: We hypothesised that patients <10 kg would have the highest incidence of clot deposition requiring ventricle change and that using LEVITRONIX in this group would lead to fewer pump changes at the expense of reduced morbidity. Following a comparative study, using a representative sample of our VAD patients since 2010, patients selected met the following criteria: <10 kg, supported for > two weeks on mechanical support, with a minimum of seven days on a BERLIN HEART with the ventricle size 10-15mls. This information is derived from Freeman Hospitals ECMO/VAD as a bridge to transplant database.
Results: Comparison between patients implanted with the BERLIN HEART device against patients implanted with

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

LEVITRONIX prior to conversion to BERLIN HEART and looking at the number of ventricle changes carried out.
Discussion/Conclusion: Our study is not representative of all VAD patients however it demonstrates that stabilising children on LEVITRONIX leads to more manageable coagulation when converted to a BERLIN HEART. There's an increased risk to patients on mechanical support with unstable coagulation therefore it is important that it is stabilized as soon as possible to reduce risk of morbidity.

P1271 - LEFT VENTRICULAR END DIASTOLIC DIAMETER OBTAINED DURING FOLLOW UP ECHOCARDIOGRAPHY PREDICTS MORTALITY IN CHILDREN WITH HYPERTROPHIC CARDIOMYOPATHY

Taiyu Hayashi[1], Ryo Inuzuka[2], Takahiro Shindo[2], Hiroshi Ono[1], Hitoshi Kato[1]
National Center For Child Health And Development, Division of Cardiology, Tokyo-Japan[1]; Graduate School of Medicine, University of Tokyo, Department of Pediatrics, Tokyo-Japan[2]

Background: In children with hypertrophic cardiomyopathy (HCM), the septal and free wall thickness at diagnosis predicts mortality. However, few studies have reported the clinical relevance of left ventricular measurements during follow-up echocardiography. We aimed to identify echocardiographic parameters that predict mortality during the follow-up of children with HCM.
Materials and Methods: After searching the echocardiography database for examinations performed from March 2013 to September 2016, we included 21 patients (11 boys) with HCM who were younger than 20 years of age when examined. Echocardiographic data from the latest examination were included for the analysis. Linear measurements of the left ventricle were standardized using z-scores based on body surface area. The echocardiographic data were compared for survivors and non-survivors.
Results: Ten patients had Noonan syndrome, 2 had LEOPARD syndrome, and and 2 had familial history of HCM. The median age at echocardiographic evaluation was 7.1 (0.4-19.1) years. During a median follow-up period of 4 (1-41) months, 5 deaths (2 due to heart failure and 3 sudden deaths outside the hospital) occurred at a median of 4 (1-9) months after echocardiographic examination. Left ventricular end-diastolic diameter z-score was significantly larger in non-survivors than in survivors (1.2 ± 0.6 vs. -1.5 ± 1.9, $p < 0.05$). Non-survivors showed significantly smaller left ventricular fraction shortening z-score than survivors (-0.6 ± 5.0 vs 4.8 ± 4.3, $p < 0.05$). There were no significant differences in septal and free wall thickness z-scores between the groups.
Conclusions: A less compressed left ventricular cavity size is associated with mortality, which suggests that congestive heart failure is a pivotal contributor to death in children with HCM. In the follow-up of children with HCM, a left ventricle with a preserved internal diameter and decreased contraction despite concentric hypertrophy might imply poor outcome, and warrants further evaluation and therapeutic intervention.

P1361 - GENETIC ETIOLOGIES OF ACUTE HEART FAILURE IN PRE ADOLESCENTS

Emily Brown[1], Anne Murphy[2], William Ravekes[2], Kristen Nelson[2], Daniel Judge[1], Jane Crosson[2]
Johns Hopkins, Cardiology, Baltimore-United States[1]; Johns Hopkins, Pediatric Cardiology, Baltimore-United States[2]

Background/Hypothesis: There are a variety of causes of acute heart failure in pre-adolescent patients including myocarditis, genetic/metabolic conditions, and congenital heart defects. In cases with a structurally normal heart and a negative personal and family history, myocarditis is often presumed to be the cause, but we hypothesize that genetic causes are a significant portion of these cases.
Materials and Methods: We reviewed our cases of patients 12 years-old and younger who presented with acute heart failure and underwent genetic testing from 2008 to 2016.
Results: We present five cases of children from four families presenting with acute heart failure, who were determined to have a genetic etiology. Myocarditis was originally presumed to be the cause in all four families. First, a 12 year old female presented with acute heart failure. A cardiomyopathy panel revealed she has a pathogenic variant in TNNT2 (p.Lys210del). Secondly, a 3 month-old presented with dyspnea and cardiomegaly. Genetic testing showed two pathogenic variants in IDUA (p.Trp402* and p.Gln70*) in trans which have been shown to cause Hurler syndrome. In the third family, a pair of siblings presented with heart failure and underwent heart transplant during infancy. Limited genetic testing on the proband was uninformative, but when the second child presented, exome sequencing revealed two pathogenic variants in ALMS1 (c.1111_11134del19 and c.1794_1801dup8) in trans which cause Alstrom syndrome. Finally, a 2 month old presented with cardiomegaly. A cardiomyopathy panel revealed a "likely pathogenic" frameshift in TTN (p.Pro28826fs). Significantly, there was no history of dysmorphic features or prior cardiac disease in any of the cases and only a family history in the third family.
Conclusions: Genetic etiologies should be considered in children with acute heart failure even if there is no significant history to suggest a genetic cause.

P1380 - ABSTRACT FOR TRAFFIC LIGHTS SYSTEM TOOL FOR PAEDIATRIC INHERITED CARDIAC CONDITIONS PATIENTS PRODUCED BY NURSE SPECIALISTS FOR PATIENTS AND THEIR FAMILIES

Lucy Green[1], Charlene Casey[2]
The Royal Brompton Hospital, Inherited Cardiac Conditions, London-United Kingdom[1]; Royal Brompton Hospital, Inherited Cardiac Conditons, London-United Kingdom[2]

Background/Hypothesis: NHS England (2016) recognises that Early Warning Scores (EWS) aid identification of children at risk of clinical deterioration. NICE (2007) have strongly advised that EWS should be utilised for all inpatients. However, there is limited evidence to support the use of EWS within outpatient care for patients with chronic conditions. Literature recommends teaching patients symptom monitoring skills to recognise elevated heart failure risk. It is imperative that patients are able to identify signs of deterioration and seek appropriate help. Use of a symptom management tool can aid timely identification and management of symptoms, and access to relevant health services (Vincent and Mutsch, 2015).
Materials and Methods: A Traffic Light System is being trialled within the Paediatric Inherited Cardiac Conditions (ICC) Service at Royal Brompton Hospital, developed with the view to act as a EWS for patients to use once discharged post inpatient care. It aims to; identify the severity of patient symptoms, relieve patient anxieties and support patients in taking appropriate actions in response to symptoms.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: Feedback from the patients and families has yet to be collected in relation to the utilisation of the Traffic Light System. A questionnaire will be distributed to families who have used the tool, for the purposes of collecting and analysing data. This will assist in examining the effectiveness of the tool, and will ascertain whether or not it is beneficial for this patient group. Further improvements and developments can then be made in light of the findings.
Conclusions: Working with patients with chronic conditions involves a considerable amount of time supporting them with symptom advice and management. The Traffic Light System aims to empower patients to recognise symptoms, track them, identify early warning scores and for the patient/parents to act appropriately, is potentially beneficial for the patients and also for service development.

P1381 - MUSCLE STRENGTH IN CHILDREN WITH PULMONARY ARTERIAL HYPERTENSION IS DECREASED

S. Pepplinkhuizen[1], W.M.H. Zijlstra[1], C.Y. Timmer[2], M.J. Ploegstra[1], O.T.H.M. Lelieveld[2], R.M.F. Berger[1]
University Medical Center Groningen, Center For Congenital Heart Diseases, Beatrix Children's Hospital, Groningen-The Netherlands[1]; University Medical Center Groningen, Center For Rehabilitation, Groningen-The Netherlands[2]

Background: Pulmonary arterial hypertension (PAH) is a rare, severe disease of the pulmonary arteries and has a poor prognosis. PAH is characterized by exercise intolerance due to impaired cardiovascular function. Recently, muscle strength was shown to be decreased in adults with PAH and may thus play a role in the exercise intolerance. To date, data in children are lacking. We aimed to assess whether muscle strength is decreased in children with PAH and to explore its correlation with physical functional parameters.
Methods: In this prospective study, eligible children with PAH aged 4-18 years who visited the Dutch National Referral Center for Pulmonary Hypertension in Childhood between October 2015 and March 2016 were included. Peripheral skeletal muscle strength was evaluated using maximum voluntary isometric contractility (MVIC) of the elbow flexor and extensor, hip flexor, knee extensor and grip strength. The contribution of muscle strength to motor proficiency was evaluated with the Bruininks-Oseretsky test of motor proficiency – 2nd edition (BOT-2). These measurements were compared with age and sex matched reference values and correlations with 6-minute walk distance (6MWD) and World Health Organization Functional Class (WHO-FC) were assessed.
Results: In total, 18 children were included. Peripheral skeletal muscle strength and BOT-2 were significantly decreased compared to mean reference values. MVIC of the elbow extensor, grip strength and BOT-2 significantly correlated with 6MWD ($r = 0.688$, $p = 0.002$; $r = 0.587$, $p = 0.017$ and $r = 0.520$, $p = 0.032$, respectively). Only BOT-2 correlated with WHO-FC ($r = -0.602$, $p = 0.010$).
Conclusion: Peripheral skeletal muscle strength and BOT-2 scores of children with PAH were significantly decreased compared to healthy references and correlated with 6MWD and WHO-FC. This decreased muscle strength may contribute to decreased functional capacity in children with PAH. The pathophysiologic mechanisms of this reduced peripheral muscle strength in children with PAH remain to be clarified.

Table 219. P1381 Table 1. Patient and disease characteristics at moment of muscle strength tests of the total study population (N = 18)

	All patients (n = 18)
Female (%)	12 (67%)
Age at tests (yrs)	14.0 (9.9 – 16)
Age at diagnosis (yrs)	6.2 (2 -12.2)

NT-proBNP (ng/l)	131 (48.8 – 247.3)

BMI, body mass index; IPAH, idiopathic pulmonary arterial hypertension; HPAH, heritable pulmonary arterial hypertension; PAH-CHD, pulmonary arterial hypertension associated with chronic heart disease; PAH-CTD, pulmonary arterial hypertension associated with congenital tissue disease; WHO-FC, World Health Organization Functional Class; 6 MWD, six minute walking distance. Data are presented as mean (± standard deviation), median (interquartile range) or number (percentage).

P1391 - LONG TERM BENEFITS OF INTRAVENOUS EPOPROSTENOL IN IDIOPATHIC PULMONARY ARTERIAL HYPERTENSION; A PERSONAL EXPERIENCE

Tegan Dunmall[1]
Royal Children, Oncology, Melbourne-Australia[1]

Introduction: In the past 15 years, medical therapy for patients with idiopathic pulmonary arterial hypertension (IPAH) has improved outcomes, including functional status and quality of life. Intravenous Epoprostenol is initiated when there has been an inadequate response or clinical deterioration with oral therapy, prior to consideration of lung transplantation. Despite these advances, patients with IPAH have considerable morbidity with many life altering challenges.
Method/Results: TD was diagnosed with IPAH in 1995 at the age of 6, presenting with symptoms of syncope, dizziness and shortness of breath. At that time there were no effective therapies available in Australia and the median life expectancy for affected children was less than one year from diagnosis. After a medical work-up she was commenced on Diltiazem with an initially good result, but several years later developed symptoms of heart failure. She improved somewhat with the addition of Bosentan in early 2001, but remained highly symptomatic. In late 2001 she was placed onto intravenous Epoprostenol via centrally inserted Hickman catheter and placed onto the wait list for lung transplantation. Within a few months the changes were profound; there were no further syncopal episodes, her exercise tolerance increased and she was able to return to school. Although not symptom free, TD now faces the challenges of her disease and the side-effects of her medication in such a way that she exceeds the expectations of a patient with IPAH. With strict medication management, self-observation and attention to detail, TD is able to work as a Clinical

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Nurse Specialist in Oncology, has a passion for travel and has explored over 20 countries, including 3 months visiting Northern Europe.
Conclusion: The use of intravenous Epoprostenol combined with appropriate self-care has allowed TD to lead a busy and independent life over many years.

P1396 - MODELING CARDIAC REGENERATION INDUCED BY RIGHT VENTRICULAR PRESSURE LOAD IN INFANT RATS

Guido Pl Bossers[1], Quint Aj Hagdorn[1], Anne-Marie C Koop[1], Diederik E Van Der Feen[1], Lysanne M Jorna[1], Tom Van Leusden[1], Marinus Aj Borgdorff[1], Herman Hw Silljé, Rolf Mf Berger[1], Beatrijs Bartelds[3]
University Medical Center Groningen, University of Groningen, Center For Congenital Heart Diseases, Beatrix Children's Hospital, Groningen-The Netherlands[1]; University Medical Center Groningen, University of Groningen, Department of Cardiology, Groningen-The Netherlands[2]; Erasmus University Medical Center, Department of Pediatrics, Division of Pediatric Cardiology, Sophia Children's Hospital, Rotterdam-The Netherlands[3]

Background: Right ventricular (RV) pressure load plays a major role in the development of RV failure in congenital heart diseases (CHD). Recent studies reveal a regenerative capacity of cardiomyocytes that can be addressed to find new treatment targets. We hypothesize that regeneration and proliferation plays a cardioprotective role in CHD that depletes progressively during childhood. Comprehension of these mechanisms could provide new insights to aid the prevention or treatment of RV failure in CHD. We developed a rat model of progressive RV failure during infancy due to pressure load (PL) to study the role of proliferation and regeneration in the heart.
Materials and Methods: Wistar rat pups (30-45 g) were subjected to PL (n = 10) or sham surgery (n = 7) and studied during childhood (~8 weeks). We reported symptoms of RV failure (e.g. bodyweight, dyspnea, pleural effusion/ascites) and performed analysis of functional and structural adaptation by means of sequential echocardiography and immunohistochemistry.

Table.

	2 weeks		4 weeks		8 weeks	
Weights	**SHAM (n = 7)**	**PL (n = 10)**	**SHAM (n = 7)**	**PL (n = 10)**	**SHAM (n = 7)**	**PL (n = 10)**

Immunohistochemistry						
RV Ki67 (positive nuclei)	#	#	#	#	4.3 ± 0.6%	8.6 ± 0.6%*
RV CCSA (um^3)	#	#	#	#	320 ± 23	697 ± 26*
RV Masson's Trichrome	#	#	#	#	0.6 ± 0.2%	5.8 ± 1.1%*

Supplemental table. PL = pressure load. RV = right ventricle. LV = left ventricle. IVS = interventricular septum. TAPSE = tricuspid annular plane systolic excursion. CO = cardiac output. EI = eccentricity index. TI = tricuspid insufficiency. CCSA = cardiomyocyte cross-sectional area. Values are ± SEM, * = < 0.05 vs. SHAM. # = measurements were performed only after sacrifice.

Results: Severity of PL was confirmed by a clinical pattern characterized by failure to thrive, dyspnea and pleural effusion (see data in supplemental table). Chronic RV PL lead to decreased cardiac output and tricuspid annular plane systolic excursion after 2 weeks and septal bulging after 4 weeks. At sacrifice, after 8 weeks, RV hypertrophy and increased fibrosis were observed, both signs of pathological remodeling. However, in these ventricles, loaded during infancy, also increased cardiomyocyte proliferation, defined as cardiac cell-cycle activity (defined by Ki67) occurred.
Conclusion: This model of chronic RV PL in infant rats induces failure to thrive and RV failure, resembling CHD. The increased cardiac cell-cycle activity suggests a regenerative potential of the heart. This model can now be used to identify which cardiac cells can regenerate in response to pressure load and how this potential can be stimulated to prevent or treat RV failure in patients with CHD.

P1401 - CONTEMPORARY SURVIVAL OF PATIENTS WITH PULMONARY HYPERTENSION ASSOCIATED WITH CONGENITAL COMBINED AND COMPLEX SYSTEMIC TO PULMONARY SHUNT

Densiri Bositthipichet, Chodchanok Vijarnsorn, Kritvikrom Durongpisitkul, Paweena Chungsomprasong, Prakul Chanthong, Supaluck Kanjanauthai, Jarupim Soongswang
Faculty of Medicine, Siriraj Hospital, Mahidol University, Pediatrics, Bangkok-Thailand

Background: Combined systemic to pulmonary shunt and complex shunt such as atrioventricular septal defect, truncus arteriosus, transposition of great arteries, single ventricle allow unrestricted flow to pulmonary circulation resulting in rapid progressive pulmonary arterial hypertension (PAH). Advanced management of PAH has been reported. However, cohort data in this anatomic-pathophysiologic group is still limited.
Objective: To compare the hemodynamic characteristics and survival of PAH associated with combined and complex shunt lesions.
Methods: Records of patients who had hemodynamic confirmation by cardiac catheterization of PAH with combined and complex shunt in 1995 – 2015 were reviewed. Patients who had single ventricle following any staged operation were excluded. Treatment and clinical at a recent follow-up were recorded. Mortality risk was performed using multivariate analysis. Kaplan-Meier curve were constructed and compared between the lesions.
Results: At a median follow up of 6.3 years (1-20.6 years), 181 patients (49% male) were reviewed. The median age of diagnosis was 4 years (0.4-69 years). There were 103 patients with combined shunt and 78 patients with complex shunt. Defect closures were performed in combined shunt more than complex shunt (77% vs 45%; $p < 0.01$) at the median age of 2.5 and 7.3 years, respectively. Comparing between groups, persistent PAH after correction occurred 38.7% and 28.5% and mortality rate was 7.8% and 14.1%. Survival rates of patients with combined shunt at 1, 5 and 10 years following diagnosis were 96%, 96% and 83.6% whilst complex shunt were 94.7%, 87.8% and 82.2%, respectively. Significant risk of mortality was baseline PVR >8 WU•m2 (p 0.03).
Conclusion: PAH associated with combined and complex shunt has a modest long term survival. Following defect correction, PAH persists in 1/3 of patients, despite deliberately selected patients. However, baseline PVR may be a useful marker in identifying patients requiring further aggressive medical therapy.

P1420 - PULMONARY HYPERTENSION IN PEDIATRIC PATIENTS DUE TO LEFT HEART'S DESEASE

Jorge Bleiz[1], Sabina Garobbio[1], Analía Pardo[1], Andrea Cueli[1], Paula Campana[1], Victoria Corradi[1], Rodrigo Egues[1], Soledad Manciola[2], Eugenia Sabbione[2], Mercedes Dittler[2]
Children's Hospital, Cardiology, La Plata-Argentina[1]; Children's Hospita, Cardiology, La Plata-Argentina[2]

Background/Hypothesis: Little is known about the evolution of pediatric patients (P) with pulmonary hypertension (PH) due to the left heart's disease (LHD) [PH-LHD]. We hypothesized that they are underdiagnosed and would benefit from timely treatment.
Objetives: To evaluate incidence, clinical and hemodynamic characteristics of the PH-LHD, response to treatment and its long term evolution.
Materials and Methods: After retrospective analysis of 132 clinical records of pediatric P with PH, 15 with PH-LHD were checked, evaluating sex, age and functional class (FC) at the moment of diagnosis, comorbidities, performed procedures, medical treatment used and survival. Left heart function was assessed by ejection fraction and tissue Doppler measures and hemodynamic assessment (pulmonary vascular resistance- PVR, diastolic pressure gradient-DPG) was performed to classified HP-LHD in isolated poscapillary and combined postcapillary and precapillary. Variables were analyzed by chi square test and Fisher's exact test.
Results: 11% of incidence PH-LHD. Average age 4 years (0.5-12), male (66%), average follow-up time 3 years (0.6-7). 55%, 35% and 10% were in FC II, III and IV respectively at the time of diagnosis. 12% of the P presented genetic syndromes. LHD was 8%/92% congenital obstruction at the inflow/outflowtract of the left heart respectively, 20% combination of both. 78% presented left ventricle sisto-diastolic dysfunction. 38% of PH-LHD was combined ($p < 0.05$). 13 P (86%) ($p < 0.05$) underwent heart surgery, 33% ($p < 0.05$) of them underwent Interventional catheterization during the follow-up time, 47% ($p < 0.05$) were then treated with vasodilators with 28% and 15% average decrease in the previous values of GDP and PVR respectively ($p < 0.05$). They went from FC III-IV to I-II, without late deaths. The untreated group remained on poor FC with two deaths ($p < 0.05$).
Conclusions: The incidence of PH-LHD is not negligible and timely vasodilator therapies improve FC and survival of the pediatric P.

P1443 - RESTRICTIVE CARDIOMYOPATHY IN CHILDHOOD RISK FACTORS AND OUTCOMES

Alejandra Villa[1], Marisa Di Santo[1], Erica Stelmaszewski[1], Rodrigo Oribe[1], Alberto Charroqui[2], Marisa Gagioli[1], Horacio Vogelfang[3]
Hospital JP Garrahan, Cardiology, Buenos Aires-Argentina[1]; Hospital JP Garrahan, Pediatric Intensive Care, Buenos Aires-Argentina[2]; Hospital JP Garrahan, Cardiac Transplant, Buenos Aires-Argentina[3]

Restrictive Cardiomyopathy (RCM) accounts for 2.5 to 5% of all idiopathic cardiomyopathies in childhood. RCM is a serious, progressive disease, with a mortality rate of up to 50% within the first two years after diagnosis. Children with RCM develop progressive heart failure, arrhythmias, stroke, and sudden death.
Objective: to assess risk factors and progression in a group of patients diagnosed with RCM in a public institution.
Material and Method: In a retrospective analysis of a 36-patientcohort diagnosed with RCM, who were admitted to the Cardiomyopathy Unit at our hospital, clinical, echocardiographic, and hemodynamic findings, along with anatomical pathology, survival data,and cause of death were assessed.
Results: The overall survival rate was of 86 months (95% CI: 59 to 113). The multivariate analysis indicated that risk factors with the poorest prognosis were:the Shortening Fraction less than 28% (p 0.002), the LA:Ao ratio > to 2.5 (p 0.04), the S/D ratio less than 1 and the DT less or equal to 100 ms(p 0.05), and the age. The survival rate in children under 5 years of age was 43 months (95% CI: 35 to 57),whereas children above 5 years of age had a mean of 104 months (95% CI: 69 to 139). The other assessed variables, such as the types of cardiomyopathy, arrhythmias, and other echocardiographic parameters, were not significant. Causes of death were: progressive heart failure (16p), sudden death (2p).Nine patients were transplanted, whereas three patients were enrolled on the waiting list.Four out of the nine transplanted patients had a PVR of 6 WU/M with severe heart failure and were placed on VAD (Berlín Heart) as a bridge to transplantation.
Conclusions: Younger patients were the ones with the lowest survival rate. The Shortening Fraction, the LA:Ao ratio, the DT and S-D ratio were predictive risk factors.Sudden death caused by arrhythmias should be considered in asymptomatic patients.

P1446 - ROLE OF KALIISTATIN AND PRO ANTI INFLAMMATORY CYTOKINES IN PULMONARY HYPERTENSION

Ozge Pamukcu[1], Derya Ay[1], Kazim Uzum[1], Mehmet Kose[2], Ali Baykan[1], Didem Barlakketi[3], Suleyman Sunkak[1], Onur Tasci[1], Zeynep Baykan[1], Nazmi Narin[1]
Erciyes University, Pediatric Cardiology, Kayseri-Turkey[1]; Erciyes University, Pediatric Pulmonology, Kayseri-Turkey[2]; Erciyes University, Biochemistry, Kayseri-Turkey[3]

Introduction: Kallistatin, serin proteinase inhibitor exhibits its properties in inhibiting inflammation, oxidative stress and apoptosis, angiogenesis. Severe pulmonary hypertension caused by left to right shunt congenital heart disease and Eisenmenger syndrome is progressive obliterative vasculopathy; the pathogenesis endothelial dysfunction and function of ion channels, calcium homeostasis, changes in platelet and endothelial function, intravascular thrombosis proliferation reactivity increased vascular inflammation and remodeling. In this study, we aimed to show the possible relationship between kalistatin levels, pro-inflammatory TNF-alfa and anti-inflammatory cytokine IL-10 levels in pulmonary arterial hypertension.
Methods: The study was performed in Erciyes University Medical Faculty Hospital. Patient group was formed from pulmonary hypertensive patients (Eisenmenger syndrome and primary Pulmonary Hypertension). We enrolled the patients with pulmonary arterial hypertension diagnosis that confirmed by the angiocardiography in our center. Pulmonary arterial hypertension is defined as mean pulmonary arterial pressure greater than 25 mmHg. Serum kallistatin, TNF-alfa, IL-10, NtProBNP levels were studied in each patient.
Results: The study included total 50 patients:25 patients in pulmonary hypertension group (16with Eisenmenger syndrome, 9 with primary pulmonary arterial hypertension). Control group consisted 25 patients with innocent murmur. Median value of kallistatin in pulmonary hypertension group was 1.42(1.0-1.58), control group 2.27(1.57-3.38). Serum levels of kallistatin were significantly lower ($p < 0.05$) in pulmonary hypertensive patients. Negative correlation was detected between mean pulmonary arterial pressure and serum kallistatin levels. However no correlation was found for proinflammatory cytokine TNF-alfa and anti-inflammatory cytokine IL10.
Conclusion: Anti-inflammatory and anti-apoptotic features of Kallistatin were shown in various diseases like arthritis, pneumonia etc.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Our study is the first one that shows the anti-inflammatory effect of kalistatin in pulmonary hypertension. Kallistatin levels were low in pulmonary hypertension because of increased lung inflammation. Since no correlation between IL10 and TNF-alfa was found, probably they used different pathways in the pathogenesis of inflammation.

P1459 - MECHANICAL VENTRICULAR SUPPORT AS A BRIDGE TO HEART TRANSPLANT IN PEDIATRIC PATIENTS

Gerardo Naiman[1], Luis Quiroga[1], Gustavo Sivori[1], Maria De La Riva[1], Ignacio Berra[1], Alejandra Villa[2], Marisa Gaioli[3], Fernando Mascareño[2], Horacio Vogelfang[1]
Garrahan Hospital, Heart Trasplant, Buenos Aires-Argentina[1]; Garrahan Hospital, Cardiology Service, Buenos Aires-Argentina[2]; Garrahan Hospital, Clinic Unit, Buenos Aires-Argentina[3]

Introduction: Since July 2000 to November 2016, 119 pediatric patients where listed for cardiac transplant. Due the lack of suitable donors and the huge mortality rate during the waiting list we started with the use of mechanical cardiac support (MCS) as a bridge to transplant. This MCS, provides long time assistance in very young patients. Before using the MCS the mortality rate in this group was 50.%.
Material and Method: From March 2006, we assisted 44 patients. 43 with a Pulsatile Systems Berlin Heart (R) that consist in paracorporeal pumps and a pneumatic impulse consolé (Ikus(R),and one intrathoracic, with a continuos flow system (HeartWare®). Biventricular MSC 24 (55%); univentricular 20 (45%), when is usted by this way is necessary a strict monitoring to decide to assist or not the right ventricle. Diagnostics were: Dilated Cardiomyopathies 35 (80%), Restricted Cardiomyopathies 6 (14%) and Congenital Heart Disease 3 (6%). The continuos flow intrathoracic device (Heartware®) was used to provide left ventricular mechanical assistance in a 15 years old male patient, with high pulmonary pressure, transplanted after 10 months of support.
Results: The MCS time range was 3 to 954 days (X = 150). The age range of assisted patients was 10 to 192 months (X = 87). Survival on MCS: 67%, 27 were transplanted. One patient still remains on MCS, waiting for a suitable heart. Major complications: Neurological events due to Coagulopathie N = 10 (26,3%), Infections N = 4 (9%), Aortic pseudoaneurism N = 1 (2%). The mortality rate in waiting list drop off into a 20% (50/30%).
Conclusion: Mechanical Ventricular Support is an effective system to maintain alive the pediatric patients waiting a suitable heart donor. The artificial heart gives better results and improves condition of the pediatric patients before and after the transplant.

P1475 - MYCOTIC ANEURYSM AFTER BIVENTRICULAR ASSISTANCE DEVICE IN PATIENT SUBMITTED TO PEDIATRIC HEART TRANSPLANTATION

Andréa Consuelo De Oliveira Teles[1], Candice Torres De Melo Bezerra Cavalcante[1], Klebia Magalhães Castello Branco[1], Ronald Guedes Pompeu[1], Isabel Cristina Leite Maia[1], Valdester Cavalcante Pinto Júnior[2], Jeanne Araújo Bandeira Bandeira[1], Deborah Mont'alverne Dias[1], Silvania Braga Ribeiro[1], Henrique Campos[1]
Messejana's Hospital, Pediatric Cardiology, Fortaleza-Brazil[1]; Messejana's Hospital, Pediatric Cardiovascular Surgery, Fortaleza-Brazil[2]

Background: Aneurysm of the ascending aorta, particularly mycotic pseudoaneurym, is a very rare and potentially fatal complication in pediatric patients after heart transplantation, They are frequently associated with rupture and sepsis, with increased morbidity and mortality. Its management still remains a clinical and surgical challenge.
Objectives: To present the management of pediatric heart transplanted patient with mycotic aortic aneurysm after use of biventricular assistance device.
Case Presentation: A 8 year old girl was submitted to heart transplantation (HTX) in 2012 due to complex congenital heart disease. After four years of HTX, she presented with acute humoral rejection and cardiogenic shock, requiring circulatory assistance for 11 days, with complete recovery of cardiac function. After 6 months, she returned to our service with arterial hypertension, osteomyelitis in the right knee and superior vena cava syndrome. Echocardiogram showed a giant aortic aneurysm in ascending aorta. She was sent to the operating room and underwent an in situ graft replacement. Histological study revealed fungical infection. The postoperative course was uneventful and she was discharged after complete treatment of the mycotic infection.
Conclusion: Although the treatment of mycotic aortic aneurysm is difficult, surgical and clinical approach may present good results.

P1479 - CLINICAL OUTCOMES OF HEART TRANSPLANTATION IN A SMALL NORTHEAST CARDIAC PEDIATRIC CENTER IN BRAZIL

Background: Heart transplantation (HTx) has become the standard care for children with end-stage heart failure refractory to medical or conventional surgical therapy, whether secondary to underlying congenital heart disease (CHD) or cardiomyopathy (CMP). Early and late mortality have significantly improved during recent decades in pediatric patients after HTx, although small center volumes are still associated with poorer outcomes. In Brazil, according to data of The Brazilian Registry of Transplants in 2014, pediatric HTx represents 11,25% of all heart transplants.
Objectives: To presente a 14-year experience of pediatric HTx of a northeast small referral center in Brazil, focusing on survival and long-term results.
Methods: All consecutive patients submitted to HTx from january 2002 to december 2016 were included in the study. Data collection consisted of demographic data, main indications and complications, immunosuppression therapy and mortality.
Results: There were 45 HTx in 43 patients during a period of 14 years. The two cases of re-transplants were due to graft dysfunction. Mean age at the time of HTx was 9,82 ± 5,58 years and the mean weight was 28,74 ± 15,92 kg. Twenty six (57,8%) patients were male. The indications of heart transplantation were cardiomyopathy (CMP) in 21 (46,7%) and CHD in 22 (48,9%) patients. The main complications were anemia (15,6%), systemic hypertension (11,1%) and hypercholesterolemia (11,1%). The main drugs for immunosuppression were cyclosporine (57,6%) and mycophenolate (60,6%). The mean follow up was 47,91 ± 34,81 months and the mean overall survival was 90,37 ± 8,35 months, without differences between patients with diagnosis of CMP or CHD.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: HTx is an acceptable therapeutic option for children and young adults, even in small centers with outcomes comparable to large centers.

P1533 - ACUTE CARDIOTOXICITY SECONDARY TO CHEMOTHERAPY TYPE SAINT JUDE ABOUT FOUR CASES

Regaieg Haifa[1], Chouichi Yosraa[1], Achour Bechir[1], Ben Sayeh Nessrine[1], Ajmi Houda[2], Ben Youssef Yosraa[1], Khelif Abderrahim[1]
Farhat Hached University Hospital, Department of Hematology, Sousse-Tunisia[1]; Sahloul University Hospital, Department of Pediatrics, Sousse-Tunisia[2]

Background: Among the forms of leukemia affecting children, acute lymphoblastic leukemia (ALL) is by far the most common. It is treated with chemotherapy, the most common, type Saint Jude. However, anthracycline cardiotoxicity remains the most risk to fear.
Objective: The aim of this study is to show the cardiotoxicity risk of chemotherapy type Saint Jude in children with acute leukemia.
Methods: This is a retrospective study of 04 cases with ALL, treated by chemotherapy type Saint Jude and complicated by cardiotoxicity. These patients were collected in clinical hematology department, Farhat Hached hospital-Sousse between 2011 and 2016.
Results: We collected four male children with a median age of 10 years [5 years -14 years], suffering from ALL. The diagnosis of acute leukemia was confirmed by myelogram. Immunophenotyping was in favor of a LLA-B in three children and of a LLA-T in a single patient. The karyotype objectified translocation (1.19) in a single patient. The pre-chemotherapy cardiac ultrasound was normal with a fraction of left ventricular ejection correct in all patients. These children were treated by chemotherapy type Saint Jude. The evolution was marked by the onset of respiratory symptoms such as orthopnea associated with a dry cough. Thus, the diagnosis of heart failure secondary to cardiotoxicity of anthracyclines was suspected and confirmed by echocardiography which objectified: LVEF altered (15-30%), a global hypokinesis with a left ventricular dilatation in all patients. Adequate medical treatment was instituted. Three children achieved complete remission of the acute leukemia with regression of respiratory symptoms and improving heart function. A child was died by his heart failure.
Conclusion: Anthracyclines (doxorubicin, daunorubicin. .) have largely proven effective in treating acute leukemia. However, they exert a dose-dependent, cumulative and often irreversible cardiotoxicity. Hence, the need for its early detection is the only effective way to improve the prognosis.

P1540 - PULMONARY HYPERTENION IN EXTREME PRETERM BORN INFANTS A SYSTEMATIC REVIEW AND META ANALYSIS

S. Arjaans[1], E.A.H. Zwart[1], M.J. Ploegstra[1], A.F. Bos[2], J.l. Hillege[3], R.M.F. Berger[1]
University Medical Center Groningen, Department of Pediatric Cardiology, Groningen-The Netherlands[1]; University Medical Center Groningen, Department of Neonatology, Groningen-The Netherlands[2]; University Medical Center Groningen, Department of Epidemiology, Groningen-The Netherlands[3]

Background/Hypothesis: Pulmonary Hypertension (PH) is known to complicate the course of extreme preterm born infants and is associated with poor outcomes in Bronchopulmonary Dysplasia (BPD). Prevalence, risk factors and outcome of PH are insufficiently known. Therefore our aim was to provide an up-to-date synthesis to examine these factors by performing a systematic review.
Materials/Methods: Databases Medline, EMBASE and The Cochrane Library were searched on the 12th of July 2016. Two authors reviewed titles/abstracts and full-text. Eligible studies reported one of the following: 1) PH prevalence, 2) patient characteristics of infants with and without PH, or 3) mortality. Studies without extreme preterm born infants were excluded. Thereafter data extraction and meta-analysis of prevalence, characteristics and mortality were performed. Heterogeneity was assessed using Cochran's Q-test and I^2 quantity.
Results: 1623 unique articles were identified, 22 articles were eligible for analysis. Meta-analysis, shown in table 1, assessed prevalence rates, risk factors and mortality. Prevalence of PH in severe BPD was 39% and infants with severe BPD were significantly more at risk for PH (Risk Ratio (RR) = 4.16). Infants with PH were also more at risk for mortality (RR = 4.17).
Conclusions: PH appears most prevalent in infants with severe BPD. However, due to heterogeneity between the eligible articles, prevalence rates for PH in infants with or without BPD could not be accurately estimated. Severe BPD appears a prominent risk factor for PH. Other risk factors for PH, were also risk factors for BPD. Available data did not allow for a distinction in risk factors between infants with and without BPD. Finally, PH increases risk of mortality. However, the effect of PH on mortality for infants without BPD remains unknown. In conclusion, current literature does not allow confirmatory conclusions on incidence, risk factors and outcome. Therefore, properly designed, prospective studies are needed.

Table 1. Results meta-analysis

Prevalence rate PH	**% (CI)**	***P-value***
No BPD	2 (0 - 8)	0.11
Mild BPD	4 (0 - 9)	0.01**
Moderate BPD	8 (2 - 16)	<0.001**
Severe BPD	39 (27 - 51)	<0.001**
Risk factors PH	**RR (CI)**	
Severe BPD	4.2 (2.9 - 6.0)	<0.001
SGA	2.1 (1.5 - 2.9)	<0.001
	SMD (CI)	
Low birth weight	-0.8 (-1.0 - -0.6)	<0.001
Low birth weight in BPD	-0.3 (-0.5 - -0.01)	0.060
Mortality	**RR (CI)**	
Infants with PH	4.2 (2.2 - 7.8)	<0.001

** p value < .01 for heterogeneity
Definition of abbreviations: RR = risk ratio; CI = 95% confidence interval; PH = pulmonary hypertension; BPD = bronchopulmonary dysplasia; SGA = small for gestational age; SMD = standardized mean difference.

P1547 - RISK FACTORS FOR LONG TERM ADVERSE EVENTS IN PEDIATRIC HEART TRANSPLANTATION IN SINGLE CENTER

Hyun Ok Jun, Eun-Jeong Shin, Jae Suk Baek, Jeong Jin Yu, Young-Hwue Kim, Jae-Kon Ko
Asan Medical Center Children's Hospital, Division of Pediatric Cardiology, Department of Pediatrics, Seoul-Korea, South

Introduction: Pediatric heart transplantation, the ultimate treatment option for end-stage heart failure has undergone major changes

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

over the past three decades. However, some long-term complications are still left. We conducted this study to determine the relative risk factors for long-term adverse event associated with pediatric heart transplantation.
Method: The medical records of pediatric patients with heart transplantation in Asan Medical Center Children's Hospital, since 1997 were reviewed retrospectively. We classified long-term adverse events as death, re-transplantation, hemodynamically compromised rejection including cardiac allograft vasculopathy (CAV), persistent renal dysfunction, infection and post-transplant lymphoproliferative disease (PTLD). We assumed possible risk factors for major adverse events as age of transplantation, waiting time, primary diagnosis (cardiomyopathy or congenital heart disease), Severity of heart status(Korean Network for Organ Sharing system), CMV or EBV serology, type of immune suppressant and apply of mechanical circulatory support.
Result: For 62 eligible patients (36 males, median age at transplant is 10.9 months), overall mortality was 22.6%(n = 14; 10 year survival rate = 70.1%) and 5 patients underwent re-transplantation. Among these patients, 19 had rejection, 11 had infection, 7 had persistent renal dysfunction and 1 had PTLD. Nineteen patients (30.6%) had critical adverse event (CAE; death or re-transplantation) and the only risk factor for CAE is the type of immune suppressant; cyclosporin increase the risk of CAE than tacrolimus (p = 0.004, Odds ratio, 9.041; 95% CI 2.035-40.165). The other presumed-risk factors did not increased the prevalence of CAE significantly. In 6 patients who transplanted due to Fontan failure, only 1 died from graft failure. No other CAE was reported in this group.
Conclusion: Although the overall outcome of heart transplantation has been improved largely attributed to advance of immune suppressant, several risk factors, especially CAV is left and its evaluation in children has some limitations. The novel surveillance method suitable for pediatric transplant group should be studied.

P1560 - PEDIATRIC CARDIAC TRANSPLANTATION EXPERIENCE FROM INITIAL 30 CASES

Ganapathy Subramaniam[1], Balakrishnan Komarakshi[1], Arul Narayanan[2], Venkataswamy K[2]
Fortis Malar, Cardiac Surgery, Chennai-India[1]; Fortis Malar, Cardiology, Chennai-India[2]

Introduction: Heart transplantation is the only definite therapy for children with end stage heart failure or those with irreparable complex single ventricle defects, not responding to optimal medical therapy. We present our experience with transplantation in patients <18 years of age.
Methods: 30 patients <18 yrs underwent cardiac transplantation between Jan 2012 and Nov 16. The Youngest was 11 months old. 24(80%) patients had idiopathic dilated cardiomyopathy, 3(10%) had restrictive cardiomyopathy, 3(10%) had previous palliation for single ventricle one of whom had only single lung perfused. 3 had familial cardiomyopathy, with 2 siblings receiving successful transplantation after bridging with assist device. 4(13.3%) patients were bridged with assist device prior to transplantation. Cardiac catheterisation was performed preoperatively and they were listed for tranplantation only if the PVRI was less than 5 woods units, with or without pulmonary vasodilators. All of them received protocolised immunosuppression with inductioin with basiliximab and maintanence with steroid, tacrolimus and mycophenolate. Donors age ranged from 12 to 40 years. 75% of the donors were outside the state, the mean ischemic time was 190 minutes. Custodial cardioplegia was used in all. 2 (6.6%) required post op ECMO support for RV failure of whom one survived.
Result: The mean duration of ventilation was 50 hrs and ICU stay was 8 days. There were 3(10%) early mortality (<30 days) and 2 (6.6%) late mortality after 6 months duration. 3 developed posterior reversible encephalopathy syndrome. Of whom one had early and one late death. All the three single ventricle patients including one with single lung had successful transplantation with excellent functional outcome.

P1561 - TRANSPLANTATION IN SINGLE VENTRICLE PATIENTS

Ganapathy Subramaniam[1], Balakrishnana K R[1], Arul Narayanan[2], Venkatasamy K[2]
Malar, Cardiac Surgery, Chennai-India[1]; Malar, Cardiology, Chennai-[2]

Heart transplantation as an option in the management of patients with single ventricle has long been in vogue. It can be introduced at any stage in the management of patients with single ventricle, at the first stage before any palliation or after Fontan failure. We present our experience in 3 young patients who received heart transplantation for single ventricle, one of them had heart transplantation into single lung. Patient 1 – 11 yr old girl with no previous palliation with, common AV canal, severe AV valve regurgitation, unbalanced ventricle with dysfunction, TAPVC supracardiac TAPVC with PS, underwent cardiac transplantation-her postoperative course was totally uneventful. Patient 2 – This 15 yr old boy had previous shunt and bilateral bidirectional glenn shunt, he had increased PVRI and ventricular dysfunction and was considered unsuitable for two ventricle repair or Fontan. He received cardiac transplantation and ligation of the left superior venacava as there he was discharged on day 30 after eventful postop course. Patient 3 – 18 yr old boy who had previous BT shunt and glenn. His right pulmonary artery was totally occluded and all forms of investigation failed to show any usable pulmonary artery segment. This was replaced by a leash of collaterals entering the right lung. He had heart transplantation to the single left lung after creating a PFO. He did well and was discharged on oxygen which was tapered and stopped after 40 days.
Conclusion: Transplantation into single lung is possible in patients with single ventricle. transplantation provided excellent palliation for single ventricle patients and can be considered in preference to high risk interim procedures.

P1575 - INSERTION OF LVAD STERNOTOMY AND THORACTOMY APPROACH – TECHNIQUE AND RESULTS

Ganapathy Subramaniam[1], Balakrishnan Komarakshi[1], Arul Narayanan[2], Venkataswamy K[2]
Fortis Malar, Cardiac Surgery, Chennai-India[1]; Fortis Malar, Cardiology, Chennai-India[2]

Temporary mechanical support to a failing heart nonresponsive to inotropes is necessary either as a bridge to decision or bridge to transplantation. The available options are limited by their cost or lack of availability in small sizes. We present our technique which we believe is economical, easily reproducible and applicable in wide variety of situations. A sternotomy with limited pericardiotomy and thoracotomy approach is used to access the ascending aorta and the apex of the heart and also as a means for initiation of cardiopulmonary bypass if necessary. A conduit is sutured to both the areas, and a single lumen cannula is inserted into the apex, both are connected with appropriate connectors and

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

after deairing is connected to centrifugal pump (Levitronix). The procedure was used in 8 patients with imminent decompensation due to end stage heart failure refractory to inotropes. One patient succumbed to intracranial bleeding. One patient died due to renal failure following heart transplantation. The youngest is 11 month 7 kg child awaiting transplantation. Adequate flows could be attained in all the patients. There was significant and in some cases dramatic improvement in end organ function following institution of LVAD. LVAD insertion using centrifugal pump and combined sternotomy, thoractomy approach is a useful lifesaving option for patients with endstage heart failure awaiting transplantation or as a bridge to decision.

P1592 - MYOCARDIAL FUNCTION ECHOCARDIOGRAPHIC EVALUATION IN HEART TRANSPLANTATION WITH LONGITUDINAL PEAK SYSTOLIC STRAIN

Márcio Miranda Brito[1], Andrea Diniz[1], Talita Aires[1], Adailson Siqueira[2], Glaucia Maria Tavares[1], Estela Azeka[2]
SBC, Ecocardiografia, São Paulo-Brazil[1]; SBC, Cardiologia Pediátrica, São Paulo-Brazil[2]

Introduction: Acute cellular rejection is responsible for great morbidity after heart transplantation and its early detection is important in patient prognosis. The longitudinal peak systolic strain (LPSS) echocardiographic evaluation detects systolic dysfunction earlier than the commonly used ejection fraction measured by Teicholz method. There are few studies using the former method in pediatric heart-transplanted patients.
Objective: To evaluate the use of LPSS in early detection of myocardial dysfunction after heart transplantation in pediatric patients.
Methods: A retrospective study in pediatric heart-transplanted patients who underwent LPSS echocardiographic evaluation and myocardial biopsy within two months before or after echocardiography.
Results: In 22 patients evaluated, 12 (52.1%) had no acute cellular rejection in biopsy and 10 (43.5%) had mild cellular rejection (1 R). Mean LPSS values were -13.7% and -12.5% in patients with negative and positive biopsy results respectively. Student T test found no statistical significance between acute cellular rejection and LPSS value ($p = 0.508$).
Discussion: Previous studies have shown that heart-transplanted patients with no coronary artery disease have reduced LPSS values despite of normal global myocardial function. The present work showed reduced LPSS values in acute cell rejection, but also the same tendency among all patients, in accordance with literature. Other studies are necessary to find an association between LPSS values and myocardial dysfunction in pediatric heart transplantation.

Table.

Variable	Degree	n	Average	SD	Medium	Minimum	Maximum	P*

P1606 - POST TRANSPLANT LYMPHOPROLIFERATIVE DISEASE IS ASSOCIATED WITH STERNOTOMY DURING INFANCY AND LEFT VENTRICULAR HYPOPLASIA A POPULATION BASED RETROSPECTIVE REVIEW

Britt-Marie Ekman-Joelsson[1], Håkan Wåhlander[1], Mats Synnergren[1], Madeleine Sager[2], Karin Mellgren[1]
Institution For Clinical Sciences, Pediatric Department, Gothenburg-Sweden[1]; Institution For Clinical Sciences, Södra Älvsborg Hospital, Borås-[2]

Background/Hypothesis: Pediatric heart transplantation has been available in Sweden since 1989; it is centralized to two centers, Gothenburg and Lund. As our unit in Gothenburg faced an increased rate of Post-transplant lymphoproliferative disease (PTLD), the objective of the study was to identify possible risk factors in our cohort of children.
Materials and Methods: This is a retrospective study of all 71 children who underwent heart transplantation (0–18 years of age) in Gothenburg, Sweden from 1989 to 2014.
Results: The overall incidence of PTLD was 15% (11/71). Mean age at transplantation was 9 years (0–17) and mean post-transplant follow-up time was 5,5 years (0.5–21.9) in the group that developed PTLD, compared with 10,2 years (0.02–25.2) for those who did not develop PTLD ($p = 0.062$). In our study group risk factors for PTLD were surgically palliated congenital heart defects ($p = 0.0003$), sternotomy during infancy ($p = < .0001$), hypoplastic left ventricle ($p = < .0001$), number of surgical events ($p = 0.0001$), mismatch concerning Epstein Barr virus infection ($p = 0.0001$), induction therapy with Antithymocyte globulin produced by Fresenius Medical Care (ATG-FRESENIUS) compared to Antithymocyte globulin produced by Genzyme (THYMOGLOBULINE) ($p = 0.028$) and immunosuppressive treatment with Tacrolimus compared with Ciklosporine ($p = 0.028$).
Conclusions: This study has three major findings. First, PTLD only developed in subjects born with congenital heart defects, especially univentricular defects with a hypoplastic left ventricle. Second, the vast majority (10/11) of subjects developing PTLD had undergone sternotomy as infants. Third, the number of surgical events carried a higher risk of PTLD.

P1610 - BOSENTAN FOR SEVERE PULMONARY HYPERTENSION ASSOCIATED WITH CONGENITAL HEART DISEASE IN CHILDREN A SINGLE CENTER OPEN LABEL PROSPECTIVE STUDY

Yan Zhu, Chen Zhang, Qiangqiang Li, Wangui Zhao, Hong Gu
Beijing Anzhen Hospital, Capital Medical University, Department of Paediatric Cardiology, Beijing-China

Background: Bosentan has been used in adult patients with pulmonary arterial hypertension(PAH). This open-label, prospective study was to evaluate the effectiveness and safety of Bosentan in children with severe PAH associated with congenital heart disease (PAH-CHD).
Methods and Results: Patients were enrolled from Department of Paediatric Cardiology of Beijing Anzhen Hospital and received Bosentan therapy for a minimum of 24 weeks. They were assessed by 6-minute walking distance (6MWD), transcutaneous oxygen saturation (SaO2), New York Heart Association functional class (NYHA-FC), haemodynamic parameters assessed by right- and left-heart catheterization and liver function before and after therapy. Of the 35 children diagnosed with severe PAH-CHD, mean

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

age of (11.9 ± 5.0) years (1.5-18.9 years), 33 completed all follow ups (13 males and 20 females). After 24 weeks Bosentan treatment, the pulmonary vascular resistance index (PVRI) decreased from (16.9 ± 6.1) Wood units•m2 to (15 ± 5.6) Wood units•m2 (p = 0.012). In 28 children (>7 years), 6MWD increased from (452.5 ± 105.5) m to (502.8 ± 74.8) m (P = 0.003). NYHA-FC either improved or remained stable in all the patients. The mean SaO2 increased from (91.4 ± 3.6)% to (91.6 ± 4.1)% (P = 0.690), systemic vascular resistance (SVR) decreased from (20.4 ± 6.8) Wood units to (20.3 ± 4.9) Wood units•m2 (P = 0.966), and mean systolic PAP (PAPs) increased from (79.9 ± 11.0) mmHg to (83.7 ± 10.5) mmHg (P = 0.057). However, these differences were not statistically significant. All patients tolerated Bosentan therapy well with only one patient developed a transient increase in transaminase.
Conclusion: Bosentan has beneficial effects on haemodynamic parameters, exercise capacity, and is well tolerated by children diagnosed with severe PAH-CHD.

P1622 - IMPROVING RESULTS OF HEART TRANSPLANTATION FOR THE FAILING FONTAN

Carl Backer[1], Michael Monge[1], Osama Eltayeb[1], Katheryn Gambetta[2], Philip Thrush[2], Courtney Hardy[3], John Costello[4], Elfriede Pahl[5]
Ann & Robert H. Lurie Children, Cardiovascular-Thoracic Surgery, Chicago-United States[1]; Ann & Robert H. Lurie Children, Cardiology, Chicago-United States[2]; Ann & Robert H. Lurie Children, Pediatric Cardiac Anesthesia, Chicago-United States[3]; Ann & Robert H. Lurie Children, Pediatric Cardiac Critical Care, Chicago-United States[4]; Ann & Robert H. Lurie Children, Heart Transplantation Program, Chicago-United States[5]

Background/Hypothesis: The reported mortality of heart transplantation for patients with a failing Fontan circulation ranges from 10 to 50%. To determine if results have improved at our institution, we compared the outcomes of an early cohort (Group 1, 1990-2011, n = 18) with a recent cohort (Group 2, 2012-2016, n = 20).
Materials and Methods: Between 1990 and 2016, 238 patients underwent heart transplantation (OCT) at our institution. Of these, 38 patients had heart transplantation for a failing Fontan circulation. Sixteen patients (Group 1, n = 8; Group 2, n = 8) had a Fontan conversion or revision (with cardiopulmonary bypass) at a mean of 4.3 ± 4.2 years (median, 2.6 years) prior to OCT. Seven of these patients had their OCT within 18 months of the conversion/revision operation. Cross-sectional follow-up for survival status was obtained for all patients on October 16, 2016.
Results: Median age at OCT was 12.7 (Group 1) versus 10.9 years (Group 2) (p = 0.26*); mean age at OCT was 16.3 ± 12.4 (Group 1) versus 11.6 ± 7.4 years (Group 2) (p = 0.30, t-test). Median interval of Fontan to OCT was 7.3 (Group 1) versus 8.1 years (Group 2) (p = 0.91*). Operative mortality was 5 (28%, Group 1) versus 0 (Group 2) (p = 0.017*). *Wilcoxon rank sum test was used. Overall survival for the 38 Fontan patients was 87% at 1 year, 77% at 5 years, and 62% at 10 years.
Conclusions: In the recent era the results of heart transplantation for failed Fontan patients has improved markedly. These improved results should be considered in evaluating patients prior to Fontan conversion or revision attempts. Earlier referral of failing Fontan patients for OCT will improve patient outcomes.

P1653 - SYSTEMATIC LITERATURE REVIEW ON THE INCIDENCE AND PREVALENCE OF HEART FAILURE IN CHILDREN AND ADOLESCENTS

Robert Shaddy[1], Aneesh George[2], Thomas Jaecklin[3], Eimear Nic Lochlainn[4], Lalit Thakur[2], Rumjhum Agrawal[2], Susan Solar-yohay[5], Joseph Rossano[1], Thomas Severin[6], Michael Burch[7]
Children's Hospital of Philadelphia, Pediatric Cardiology, Philadelphia-United States[1]; Novartis Healthcare Pvt. Ltd, Patient Access, Hyderabad-India[2]; Shire International Gmbh, Global Clinical Development, Zug-Switzerland[3]; Novartis Pharma Ag, Worldwide Heor, Basel-Switzerland[4]; Novartis Pharmaceuticals Corporation, Cardio-metabolic, East Hanover-United States[5]; Novartis Pharma Ag, Cardio-Metabolic, Basel-Switzerland[6]; Great Ormond Street Hospital For Children, Cardiorespiratory Division, London-United Kingdom[7]

Background: To assess the incidence and prevalence of heart failure (HF) in children and adolescents (age <18 years) over the last 20 years (1996-2016).
Methods: Cochrane Collaboration methodology was used to undertake this narrative systematic review. A search strategy was designed to retrieve studies in English from sources including Embase, Medline, recent conference proceedings, NHSEED, HTA, and WHO databases. Observational studies reporting incidence and/or prevalence of pediatric HF were included.
Results: 83 unique studies were included and categorized according to the method of reporting HF diagnosis: 1) primary diagnosis (n = 10); 2) HF associated with other cardiovascular diseases (CVDs) (n = 49); 3) HF associated with non-CVDs (n = 24). Most publications were from single-center studies. For primary HF, the incidence ranged from 0.87/100,000 (UK/Ireland) to 7.4/100,000 (Taiwan). A prevalence of 83.3/100,000 was reported in one large population-based study (Spain). HF etiology varied across regions. In lower income countries, lower respiratory tract infections and severe anemia were major causes, whilst in higher income countries, major causes of HF were cardiomyopathies and congenital heart disease. Key findings for categories 2 and 3 included a prevalence of HF associated with cardiomyopathies ranging from 36.1% (Japan) to 79% (US); associated with congenital heart disease from 8% (Norway) to 82.2% (Nigeria); associated with rheumatic heart diseases from 1.5% (Turkey) to 74% (Zimbabwe); associated with renal disorders from 3.8% (India) to 24.1% (Nigeria); and associated with HIV from 1% (US) to 29.3% (Brazil).
Conclusions: To our knowledge, this is the first systematic review of the incidence and prevalence of HF in children and adolescents, providing valuable insights into, and strengthening current knowledge of, pediatric HF. Although many studies were identified, heterogeneity in study design and diagnostic criteria limits the ability to compare regional data. There is a need to standardize definitions of pediatric HF to facilitate cross-regional data comparisons.

P1658 - THE ROLE OF CIRCULATING PROGENITOR CELLS AND CIRCULATING ENDOTHELIAL CELLS BEFORE AND AFTER CORRECTION OF CONGENITAL HEART DEFECTS

Juan Pablo Sandoval[1], Juan Calderon[1], Felipe Masso[2], Carlos Guerrero[1], Araceli Paez[2], Jose Garcia Montes[1], Carlos Zabal[1], Jorge Cervantes[3], Alfonso Buendia[1], Julio Sandoval[4]
National Institute of Cardiology, Pediatric Cardiology, Mexico City-Mexico[1]; National Institute of Cardiology, Molecular Biology, Mexico City-Mexico[2]; National Institute of Cardiology, Cardiovascular Surgery, Mexico City-Mexico[3]; National Institute of Cardiology, Cardiopulmonary Department, Mexico City-Mexico[4]

Background: Circulating progenitor cells (CPC) and circulating endothelial cells (CEC) have been proposed as useful markers of severity and disease progression in patients with pulmonary arterial hypertension (PAH) associated with congenital heart disease (CHD). Limited information exists regarding CPC and CEC

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

values after so-called definitive repair has been established. We sought to investigate these biomarkers in the setting of CHD with L-to-R shunts.

Methods: We are prospectively quantifying CPC and CEC before and after repair in a cohort of patients with CHD (n = 75). We report preliminary findings in 14 children (median age 4 years (2-12)) who have completed follow-up(FW). CPC (CD45dim,CD34 + , KDR2 +) and CEC (CD45-,CD31 + ,CD146 + ,CD105 +) were quantified in the SVC, pulmonary artery and femoral artery during catheterization prior and at least 6 months after repair. Values are expressed as median (range) or meanSD. Paired-t test was used accordingly. Statistical significance was accepted as p0.05.

Results: Defects included: VSD(n = 4); PDA(n = 7); ASD, AVSD and truncus arteriosus (n = 1 each). PDA and ASD patients underwent transcatheter device occlusion; the remainder underwent surgical repair. Median time for FW catheterization was 8 months(6-14). Table 1 shows hemodynamic variables and cellular counts before and after intervention; pulmonary artery pressure (PAP) normalized in all patients at FW. Most patients showed significant reduction of both CPC and CEC counts in all sample sites. However, in 4 children CEC counts increased, did not decrease and/or remained above reference value. In these patients, PAP at FW, although normal, was significantly higher than in the rest.

Conclusions: CPC and CEC levels decrease in patients with reversible PAH-CHD within few months after repair. This highlights the capacity of the pulmonary endothelium to mend once the hyperkinetic phase of cardiac L-to-R shunts is no longer present. Furthermore, it may guide appropriate management in patients that remain with elevated CEC counts, hence at risk of persistent or recurring PAH.

Table.

Variable	Before	After	p-value
Systolic PAP, mm He	53 ± 20	29 ± 3	.001
Mean PAP, mmHg	33 ± 15	15 ± 2	.001

P1659 - CLINICAL PROFILE AND OUTCOME OF PERIPARTUM CARDIOMYOPATHY AMONG TEENAGER PATIENTS AT THE UNIVERSITY OF THE PHILIPPINES PHILIPPINE GENERAL HOSPITAL (UP PGH)

Bee Jane Martinez, Maria Concepcion Sison, Cecilienne Acosta
University of The Philippines- Philippine General Hospital, Pediatrics, Manila-Philippines

Background: Peripartum Cardiomyopathy (PPCM) is a rare new-onset disease of the myocardium occurring in the peripartal period (within the last month of pregnancy to 5 months postpartum) resulting to decreased ventricular contractility (LVEF ≤ 45%) and heart failure. Multiparity, advanced maternal age, multifetal pregnancy, preeclampsia, gestational hypertension, and African-American race have been associated with peripartum cardiomyopathy. There is inadequacy of epidemiologic data of PPCM patients less than 19 years old. We determined the clinical profile and outcome of peripartum cardiomyopathy among teenagers admitted to our institution.

Materials and Methods: All 14-18 years old patients referred to the UP-PGH Section of Pediatric Cardiology from 2004-2013 diagnosed to have PPCM based on the criteria set by National Heart, Lung and Blood Institute (NHLBI) were included in the study. The demographic and clinical profile including age, parity, co-morbid conditions, and outcome; and 2D-Echocardiogram findings were extracted from the medical records. Mean and standard deviation were computed for continuous data, and frequency and percentages were presented for categorical data.

Results: Twenty five patients (mean age = 17years) diagnosed with PPCM were included in the study. Six patients (24%) had twin delivery. The most common co-morbidity was preeclampsia (10/25). Twenty-one developed symptoms of heart failure after birth. Most (24/25) presented in NYHA functional class III-IV. Majority had poor LV contractility (mean EF = 29%). Most (92%) had term deliveries, and 21 delivered vaginally. LV function improved in 18 mothers after 6 months. Four died from intractable heart failure.

Conclusion: PPCM occurred not infrequently among 14-18 year old patients. Pre-eclampsia is the most common co-morbidity which is consistent with other studies. More in-depth study on risk factors of PPCM in this particular population is warranted.

P1670 - HEART TRANSPLANTATION IN PEDIATRIC AND ADULT WITH CONGENITAL HEART DISEASE CURRENT STATUS

Karla Coutinho[1], Adailson Siqueira[1], Nana Miura[2], Marcelo Jatene[3], Estela Azeka[1]
Heart Institute (HCFMUSP), Pediatric Heart Transplantation, São Paulo-Brazil[1]; Heart Institute (HCFMUSP), Pediatric Cardiologist, São Paulo-Brazil[2]; Heart Institute (HCFMUSP), Cardiac Surgery, São Paulo-Brazil[3]

Introduction: Cardiac transplantation is considered the therapeutic treatment for refractory heart failure. Endomyocardial biopsy (EMB) is the gold standard for diagnosis, allowing adequate treatment in cases of graft rejection.
Materials and Methods: Retrospective study of patients submitted to EMB from January 1, 2015 to December 31, 2015, at the Heart Institute (HCFMUSP). The objective of the study was to correlate the EMB with the time of transplantation, clinical and echocardiographic findings.
Results: A total of 117 biopsies were evaluated in 51 patients in this period. 56 (47.8%) did not present cell rejection (0 R), 36 (30.7%) presented mild rejection (1 R), and in 18 biopsies (15.3%) there was moderate (2 R) rejection. Of the 51 patients who underwent biopsy, 17 (33.3%) were in the first year after transplantation. 5 (9.8%) of the patients were in the immediate postoperative period. Rejection 2 R occurred in 13 cases, and in 5 (38.4%) more than one episode occurred. One of the patient (7.6%) died. Of these 13 patients, 10 (76.9%) used tacrolimus, 3 (23.1%) of cyclosporine and all cases were taking mycophenolate sodium. We also observed that of the 13 cases with cell rejection (IIR), 8 (61.5%) presented echocardiographic changes. These were ventricular hypertrophy in 62.5% of the cases, ventricular diastolic dysfunction in 37.5%, ventricular systolic dysfunction in 25% and worsening of atrioventricular valve regurgitation in 25% of cases. There was no complication after the EMB procedure.
Conclusions: EMB is a low risk procedure that allows the diagnosis and treatment of pediatric and adult patients undergoing cardiac transplantation. The echocardiogram is a noninvasive method that has shown promise tool for rejection diagnosis.

P1714 - PEDIATRIC HEART TRANSPLANTATIONS IN A NATIONAL PEDIATRIC HOSPITAL IN ARGENTINA

Horacio Vogelfang[1], Maria Del Carmen De La Riba[1], Gerardo Naiman[1], Luis Guillermo Quiroga[1], Alejandra Villa[2], Marisa Gaioli[3], Gustavo Sivori[1], Ignacio Berra[1]
Hospital Garrahan, Heart Transplant Unit, Buenos Aires-Argentina[1]; Hospital Garrahan, Cardiology, Buenos Aires-Argentina[2]; Hospital Garrahan, Clinical Follow Up, Buenos Aires-Argentina[3]

Background: Heart transplantation is the most appropriate surgical option for terminal heart failure in childhood. The lack of suitable donors is the biggest problem to develop Pediatric Cardiac Transplant Program.
Materials and Methods: This is a prospective, retrospective, transversal and observational paper. From July 2000, 119 patients have been listed for heart transplantation. Age: 1 to 230 months; Female: 52% ; Male: 48%. Range in waiting list: 1 to 3351 days. Diagnosis: Dilated Cardiomyopathy 85; Congenital Heart Disease 18; Restrictive Cardiomyopathy 13; Pulmonary Hypertension 2 ; Retransplant 1.
Results: Three Patients (16, 32, 7, months old) were transplanted with an ABO incompatible heart donor using the "West Protocol". Due to the lack of suitable donors and its consequence of high mortality on waiting list, in 2006 we have started to use Mechanical Assistance to let patients, in terminal condition, survive and have a chance for transplantation. Fifty-four heart transplants where done in 53 patients The actuarial survival rate in waiting list showed a huge improvement with the use of the Mechanical Cardiac Support (MCS); 26 patients were assisted with the MCS before transplantation. Age: 13 to 198 months; weight: 6 to 90,0 kg.; univentricular MCS: 14 (54%) and biventricular MCS: 12 (46%). No surgical deaths and no REDO because surgical bleeding in the MSC series. Five patients where assisted with ECMO after transplantation, due to primary heart failure; with good results in all of them after ECMO weanning. The triple scheme treatment for immunosuppression was: azathioprine, cyclosporine and steroids.
Conclusions: A Cardiac Transplant Program in a Pediatric Public Hospital; in Argentina; provides the opportunity for heart transplantation to infants and pediatric population with terminal heart failure.

P1735 - ECHOCARDIOGRAPHIC ASSESSMENT OF INFANTS WITH CONGENITAL DIAPHRAGMATIC HERNIA AND ASSOCIATED PULMONARY HYPERTENSION

Mohammad Abumehdi[1], Jamie Woods[2], Neil Patel[3], Lindsey Hunter[1]
Royal Hospital For Children, Paediatric Cardiology, Glasgow-United Kingdom[1]; Royal Hospital For Children, Paediatrics, Glasgow-United Kingdom[2]; Royal Hospital For Children, Neonatal Medicine, Glasgow-United Kingdom[3]

Introduction: Congenital diaphragmatic hernia (CDH) remains a challenging neonatal condition with a number of sequelae. In particular there is a lack of published evidence documenting the long term effects and outcomes of pulmonary hypertension (PH) in repaired CDH patients.
Aim: The aim was to document the long term echocardiographic assessment of patients with repaired CDH, in particular those showing evidence of post-operative PH.
Method: Retrospective analysis of infants with CDH treated at the Royal Hospital for Children, Glasgow between February 2009 and February 2015. The pre discharge; first discharge and most recent echocardiogram were identified. Parameters were identified that would delineate evidence of PH and assess left/right ventricular

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

function. These included tricuspid regurgitation (TR); right ventricular size; systolic and diastolic functional assessment, including LV global speckle strain imaging and tissue Doppler imaging.
Results: Data was available for 62 patients of whom 47 (75.8%) survived to discharge. Median number of scans performed during hospital admission was 4.3 (IQ range 1-3), with final scans performed a median of 19 days before discharge (IQ range 3-24). 11 (17.5%) children were discharged on oral sildenafil, none were discharged on Bosentan therapy. The most common echocardiographic measurements assessed were the presence and velocity of TR, fractional shortening and ejection fraction, (82.3%, 75.8%, 66.1%, and 66.1% respectively). TR was present in 27 patients (43.5%), with a mean Vmax of 2.0 m/s (IQ range 0-3.2). Following discharge, 13 patients (21.0%), underwent an echocardiogram; median 117 days post discharge (IQ range 20-181).
Conclusion: There is currently no standardised approach for echocardiographic assessment of CDH patients. Our findings support the development of a standardised protocol for long term echocardiographic assessment of patients with repaired CDH.

P1744 - PULMONARY HYPERTENSION AMONG 5 TO 18 YEAR OLD CHILDREN WITH SICKLE CELL ANEMIA IN NIGERIA

Ogochukwu Sokunbi[1], Ekanem Ekure[2], Edamisan Temiye[2], Roosevelt Anyanwu[3], Christy Okoromah[2]
Department of Paediatrics, Lagos University Teaching Hospital, Lagos-Nigeria[1]; Department of Paediatrics, College of Medicine, University of Lagos, Lagos-Nigeria[2]; Central Research Laboratory, College of Medicine, University of Lagos, Lagos-Nigeria[3]

Background: Pulmonary Hypertension (PHT) is a significant cause of mortality in patients with sickle cell anemia (SCA). Few studies on PHT in SCA have been carried out in children. This study aimed to estimate the prevalence of PHT in children with SCA and determine its clinical and laboratory correlates.
Materials and Methods: In this cross sectional study, evaluation involved obtaining bio-data, history and physical examination findings in 175 SCA subjects with genotype SS aged 5 to 18 years and 175 age and sex matched controls with genotype AA. PHT was determined using echocardiography derived peak Tricuspid Regurgitant Velocity (TRV) > / = 2.5 m/s as a marker. Complete blood count (CBC), lactate dehydrogenase (LDH) assay, reticulocyte count, fetal hemoglobin estimation as well as Human Immunodeficiency Virus (HIV) I and II, Hepatitis B Virus (HBV) and Hepatitis C Virus (HCV) screening were done for patients with SCA.
Results: The mean peak TRV of subjects with SCA and controls was 2.2 ± 0.4 m/s and 1.9 ± 0.3 m/s respectively and prevalence of PHT among children with SCA and controls was 22.9% and 2.3% respectively. PHT in SCA correlated negatively with Body Mass Index, hematocrit and hemoglobin. A loud second heart sound was independently associated with PHT.
Conclusion: This study affirms that PHT prevalence is high in children with SCA and a loud second heart sound is associated with its occurrence.

P1753 - THE ROLE OF ACE2 ANG (1 7) MAS PATHWAY ON CARDIAC REMODELING IN PRESSURE OVERLOADED LEFT VENTRICLE MODEL

Zen-Kong Dai, Yi-Ching Liu, Jong-Hau Hsu, Yen-Hsien Wu, I-Chen Chen, Jiunn-Ren Wu
Kaohsiung Medical University Hospital, Department of Pediatrics, Kaohsiung-Taiwan

Background: In the pressure overloaded left ventricle, left ventricular remodeling and retrograde pulmonary hypertension (PH) will develop. Subsequently, PH will lead to right ventricular remodeling and failure. And, the decreased cardiac expressions of ACE2-Ang-(1-7)-Mas related proteins in both ventricles are hypothesized simultaneously. The activator of ACE2 will attenuate the development of cardiac remodeling.
Methods: In ascending aora-banded (AOB) Wistar rat for six weeks, the hemodynamic measurements including left atrial pressure and pulmonary arterial pressure are arranged in the AOB rats and sham-operated rats. The cardiac expressions of ACE2, Ang-(1-7) and Mas will be checked.
Results: There were pressure-overloaded left ventricular hypertrophy, interstitial fibrosis and perivascular fibrosis, increased left atrial pressure, and increased pulmonary arterial pressure noted in the aortic banded rats. In addition, the cardiac expression of ACE2, Ang-(1-7) and Mas in both ventricles were decreased simultaneously. Very importantly, DIZE, ACE2 activator, could exert preventive and therapeutic effects on pathological findings such as hypertrophy and fibrosis, and hemodynamics such as left atrial pressure and pulmonary arterial pressure.
Conclusions: The ACE2/ Ang-(1-7)/Mas pathway could play an important role of pathophysiology of hypertrophic ventricle, and their pharmacologic modification exert the beneficial effects on the development of cardiac hypertrophy especially in pulmonary hypertension.

P1756 - METABOLIC REMODELLING IN RIGHT VENTRICULAR ADAPTATION TO PRESSURE LOAD

Anne-Marie C. Koop[1], Quint A.J. Hagdorn[1], Guido P.l. Bossers[1], Tom Van Leusden[1], Diederik E. Van Der Feen[1], Lysanne M. Jorna[1], Debby P.Y. Koonen[2], Herman H.W. Silljé, Rolf M.F. Berger[1], Beatrijs Bartelds[1]
Center for Congenital Heart Diseases, Beatrix Children, Department of Pediatric Cardiology, Groningen-The Netherlands[1]; University Medical Center Groningen, University of Groningen, Department of Pediatrics, Section Molecular Genetics, Groningen-The Netherlands[2]; University Medical Center Groningen, University of Groningen, Department of Cardiology, Groningen-The Netherlands[3]

Background: Because of improved techniques, more patients with congenital heart diseases are exposed to right ventricular (RV) chronic pressure load (PL) which makes them prone to develop RV failure. Disturbed cardiac metabolism, observed in end-stage RV failure, has been hypothesized as mechanism of deterioration. Most animal models of RV PL are focused on end-stage RV failure. However, to stop pathological processes contributing to failure, early intervention is necessary. We aimed to characterize time dependent remodelling and metabolic changes in a rat model of RV PL.
Material and Methods: Male Wistar WU rats (160-180 gram) were subjected to pulmonary artery banding (PAB, n = 25) or sham surgery (n = 13). RV adaptation to pressure load, including remodelling and metabolism were assessed at three different time points (two, five and twelve weeks). We assessed mitochondrial respiratory capacity with fatty acids (FA) or glucose as substrates (Oroboros). RV function was assessed by clinical score and echocardiography. RV remodelling was assessed by weights, echocardiography, histology and qPCR.
Results: PAB induced significant RV PL, reflected in RV hypertrophy and fibrosis, reduced RV function, septal bulging and upregulation of mRNA levels NPPA (see table for data). All animals showed preserved cardiac output, congruent with absence of overt clinical failure. At early adaptation to PL (two weeks), mitochondrial

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

respiratory capacity for both glucose and FA tended to decrease. During prolonged PL (five and twelve weeks) the ratio of mitochondrial respiratory capacity of glucose vs. FA increased. At twelve weeks, glucose respiration was significantly increased, suggesting compensatory mechanisms in glucose metabolism.
Conclusion: This model of chronic RV PL suggests an early dysregulation of mitochondrial respiration with respiratory compensation overtime build on glucose metabolism. These data may help target therapeutic metabolic remodelling in the chronically PL RV.

P1773 - CURRENT ERA OUTCOMES OF POST TRICUSPID SYSTEMIC TO PULMONARY SHUNT WITH PULMONARY HYPERTENSION

Salisa Ketsara[1], Kritvikrom Durongpisitkul[1], Paweena Chungsomprasong[1], Prakul Chanthong[1], Supaluck Kanjanauthai[1], Jarupim Soongswang[1], Chodchanok Vijarnsorn[1]
Faculty of Medicine, Siriraj Hospital, Mahidol University, Pediatrics, Bangkok-Thailand[1]

Background: Simple post-tricuspid systemic to pulmonary shunt such as ventricular septal defect (VSD), patent ductus arteriosus (PDA) and aortopulmonary window (APW) is common. Untreated significant shunt subsequently leads pulmonary arterial hypertension (PAH).
Objective: To define survival and prognosis of patients with isolated post-tricuspid systemic to pulmonary shunt and PAH. *Methods:* Data of consecutive patients with hemodynamic confirmation by cardiac catheterization of PAH due to isolated post-tricuspid systemic to pulmonary shunt in 1999 - 2015 were collected. Clinical outcomes and survival were recorded. Risks of mortality and functional class (Fc) worsening were performed.
Results: At a median follow-up of 4.6 years (1-16.1 years), 116 patients having PAH associated with VSD (n = 78), PDA (n = 37) and APW (n = 2) were reviewed. The age at the diagnosis was 19.1 ± 17.1 years. The mPAP measured 69.9 ± 17.5 mmHg and baseline PVR was 19.6 ± 16.4 WU•m2. 26 patients were initially defined as Eisenmenger syndrome. 84 patients (72.4%) underwent defect closure and 20 had persisted PAH after correction (22.8%). Overall, worsening Fc and mortality was 6.9% and 2.6%. Risk of adverse events was final PVR >8 WU•m2 (p = 0.01) and elevated right atrial pressure (p 0.04). Survival at 10 and 15 years was entirely 100% in patients with PVR <8 WU•m2 while it was 93.4% and 90.3% in patients with PVR >8 WU•m2 (p = 0.01) regarding of anti-pulmonary hypertensive drugs.
Conclusion: PAH associated with isolated post-tricuspid systemic to pulmonary shunt has a high survival rate in contemporary era. PVR modulates the strategies of treatment and outcomes. Aggressive medical therapy should be considered in patients with PVR >8 WU•m2 after pulmonary vasodilator testing.

P1777 - ANGIOTENSIN CONVERTING ENZYME INHIBITORS MAY CAUSE THE NON OSMOTIC RELEASE OF PLASMA ARGININE VASOPRESSIN

Tomohiro Nawa, Tomoaki Murakami, Masahiro Shiraishi, Shinichiro Sakaki, Yukie Ito, Ryo Mafune, Koji Higashi, Hiromichi Nakajima, Hiroyuki Aotsuka
Chiba Children, Cardiology, Chiba-Japan

Background: Angiotensin-converting enzyme inhibitors (ACEI's) are an important medication in the treatment of congestive heart failure. However, ACEI's may cause harmful side effects, such as the non-osmotic control of plasma arginine vasopressin (pAVP) secretion, leading to the syndrome of inappropriate secretion of antidiuretic hormone (SIADH).
Materials and Methods: Thirty-two pediatric patients who received ACEI between January 2015 and November 2016, were enrolled in this study. The laboratory parameters were measured before and after ACEI administration. Among 10 patients with the osmotic regulation of pAVP release before ACEI administration, we compared pAVP levels between before and after ACEI administration. The non-osmotic release of pAVP was defined that pAVP levels were not suppressed when plasma osmolality (pOsm) was below the osmotic threshold for pAVP secretion. Patients were diagnosed as SIADH with the diagnostic criteria; serum sodium concentration (sNa) <135 mEq/L, pOsm <280 mOsm/kg H2O, urinary osmolality >100 mOsm/kg H2O, and urinary sodium concentration >20 mEq/L.
Results: The mean age was 4.0 ± 5.3 years. Seven patients received cilazapril, and three patients received enalapril. There were no differences between before and after receiving ACEI in pOsm (284.4 ± 7.1 vs. 283.5 ± 7.3 mOsm/kg H2O; p = 0.81), sNa concentration (138.1 ± 3.8 vs. 137.6 ± 2.9 mEq/L; p = 0.78), and pAVP levels (2.0 ± 1.2 vs. 2.6 ± 2.2 pg/mL; p = 0.38). Four patients (40.0%) had the non-osmotic release of pAVP, and one of them was diagnosed as SIADH without symptoms.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: This study suggested that ACEI could cause the non-osmotic secretion of pAVP.

P1830 - CARDIAC TRANSPLANTATION IN SURVIVORS FOLLOWING TREATMENT FOR PEDIATRIC MALIGNANCY

Marie Steiner[1], Brian Joy[1], Michaela Richardson[1], Sara Shumway[2], Logan Spector[1], Anthony Azakie[2]
University of MN, Pediatrics, Minneapolis-United States[1]; University of MN, Surgery, Minneapolis-United States[2]

Background/Hypothesis: Outcomes from malignancy occurring during infancy and childhood are improving. However, secondary side-effects can compromise quality of life and survival, including cardiac failure from chemotherapy/radiation. The timing of when cardiac transplant is performed, how patients are supported after listing but before transplant and the transplant outcomes in cancer patients are unknown. This data could inform use of temporary/destination extracorporeal support devices and impact the practice of cardiac transplant following malignancy diagnosis.
Materials & Methods: A retrospective analysis of patients ≤25 years old receiving cardiac transplants in the United States following their malignancy diagnosis was undertaken. The comprehensive United Network for Organ Sharing (UNOS) database from 1988-2015 was queried and abstracted. Patients were analyzed by: age ≤25 or >25 years old; pre-transplant malignancy diagnosis; type of any extracorporeal support pre-transplant; post-transplant recurrent malignancy; survival at censoring of database, among other attributes explored.
Results: From complete records 1988-2014, 59,705 total cardiac transplants were performed in the United States. Pre-transplant malignancy occurred in 2,265 patients, 2064 adult and 201 pediatric. The most common pediatric malignancy diagnoses included 55 leukemia/lymphoma and 37 sarcoma patients; 77 were "unknown". 105 pediatric patients were supported with extracorporeal devices pre-transplant including extracorporeal membrane oxygenation (ECMO) and multiple varieties of ventricular assist devices (VAD). There were 340 recurrent malignancies post-transplant occurring in 291 adult and pediatric patients; only 13 recurrences occurred in 9 pediatric patients.
Conclusions: Cardiac transplant for cardiac failure from chemotherapy/radiation can result in positive outcomes for pediatric cancer patients. However, not all potential transplant candidates may have been offered the option and thus are not included in UNOS database. Further systematic analysis of all patients' courses, perhaps linking UNOS to other registries, could optimize candidate selection and define potential role of long-term or destination VAD support in their management.

P1890 - DIAGNOSTIC CRITERIA OF HEMODYNAMICALLY SIGNIFICANT PATENT DUCTUS ARTERIOSUS IN PRETERM NEWBORNS

Margaryta Gonchar[1], Alona Boichenko[1], Irina Kondratova[1], Olena Riga[1], Victoria Komova[2]
Kharkiv National Medical University, Department Pediatrics No.1 and Neonatology, Kharkiv-Ukraine[1]; Regional Perinatal Center, Kharkiv-Ukraine[2]

Objective: To improve the accuracy of diagnosis of hemodynamically significant ductus arteriosus (HSDA) in preterm infants by determining objective clinical and Doppler echocardiographic criteria. The study involved 93 newborns of 24-35 weeks gestation (WG). Doppler echocardiography was conducted in the first days of life on a daily basis. The newborns were grouped into: Group 1 (n = 26) with weight 779.5 ± 63.4 g of 24-29 WG, Group 2 (n = 29) – weight 1297.1 ± 112.6 g of 30-34 WG, Group 3 (n = 38) with weight 1859.1 ± 118.1 g of 32-35 WG.
Results: Doppler echocardiography showed HSDA in 13 (50.0%) ($p < 0.05$) Group 1 children in accordance with the criteria elaborated by A.Sehgal, P.J.McNamara (2009); LV dilatation with hypertrophy of the wall and interventricular septum in 77.4% (p1\2; 1/3 < 0.05), RV dilatation in 82.8% (p1\2; 1/3 < 0.05), LA dilatation in 100% (p1\2; 1/3 < 0.05), 1st-2nd degree regurgitation on the tricuspid and pulmonary valves in 65.6% (p1\2; 1/3 < 0.05), increase in the average pressure in the pulmonary artery in 78.5% (p1\2; 1/3 < 0.05), disturbance of ventricular diastolic function by slow relaxation in 100% (p1\2; 1/3 < 0,05) of children. We identified additional Doppler echocardiography data in neonates who were rendered respiratory care with FiO2 40% or more, particularly the probability of false-negative result due to temporary functional closure of PDA. Furthermore, lack of reverse flow in the anterior cerebral artery and/or middle cerebral artery.
Conclusion: Morphological changes in cardiac chambers and clinical deterioration of newborns' state demonstrate the need to address the issue of hemodynamic significance ductus arteriosus. It is important to focus on the morphological changes in heart chambers, clinical condition of the patient and oxygen dependence.

P1955 - IMPLEMENTATION OF A CLINICAL PRACTICE GUIDELINE FOR GENERAL ANAESTHESIA OR PROCEDURAL SEDATION FOR CHILDREN WITH IDIOPATHIC PULMONARY ARTERIAL HYPERTENSION

Bronwyn Norman[1], Michelle Rose[1], Peta Alexander[2], Robert Weintraub[1]
The Royal Children's Hospital, Cardiology, Melbourne-Australia[1]; Boston Children's Hospital, Cardiology, Boston-United States[2]

Background: Children with idiopathic pulmonary arterial hypertension (IPAH) are a high-risk group who require diagnostic and invasive procedures with general anaesthesia (GA) or procedural sedation (PS). Complications including death, are reported more frequently in this population, but the true risk has not been quantified.
Aim: Review clinical outcomes, considering major complications, mortality and impact of a clinical practice guideline (CPG) for IPAH patients from a single paediatric tertiary centre (RCH, Melbourne).
Methods: A retrospective review using medical records and institutional databases was undertaken on patients with IPAH who underwent GA or PS as part of the state-wide pulmonary hypertension (PH) service. Patients were stratified into 3 groups: before availability of PH specific therapies (1.1.1980-31.12.1999), after (1.1.2000-31.12.2012) and following implementation of an institutional CPG (1.1.2013-1.12.2016). Data collected included disease severity, details of clinical management, and major complications occurring within 30 days of GA or PS. Major complications were defined as death, unplanned intensive care, cardio-pulmonary resuscitation, ECMO, intubation and pulmonary hypertensive crisis. Standard statistical methods were applied.
Results: During the study period, 41 patients underwent 107 procedures including 17 performed in the era without specific PH therapy, 62 in the era of available PH specific therapy and 28 utilizing the new CPG. Death occurred in 12% of untreated cases

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

and 5% of treated era patients (p = 0.16). There were no deaths post CPG implementation. Major complications were significantly greater in the untreated era, representing 41% of cases, reducing to 6% and 11% respectively in the treated era and post CPG era (p = 0.002).

Conclusions: Mortality and morbidity in the form of major complications has markedly reduced over time as interventions undertaken in children with advanced disease increased. Implementation of a specific CPG for this vulnerable group with IPAH has promoted institutional awareness, education and overall improved care.

Table.

Descriptive Variable	Untreated era patients (1980-1999)	Treated era patients (2000-2012)	Treated era patients post CPG (2013-2016)
Patient numbers	11	17	13
Median age at IPAH Diagnosis (years)	10.3 (4.2, 11.7)	6.9 (4.8, 11.2)	7.3 (4.2, 11.3)
Median age at Time of Intervention (TOI)	9.5 (6.6,11.9)	11.2 (7.3, 14.3)	10.4 (5.0, 16.4)
Median duration of follow-up (years)	0.65 (0.1, 4.9)	5.14 (3.1, 9.5)	5.2 (2.7, 7.9)
Interventions with GA or PS	17	62	28

P1975 - RIGHT VENTRICULAR VASCULAR COUPLING RATIO IN PEDIATRIC PULMONARY ARTERIAL HYPERTENSION COMPARISON OF INVASIVE AND NONINVASIVE MEASUREMENTS

Karel Breeman[1], Melanie Dufva[2], Mark-jan Ploegstra[1], Vitaly Kheyfets[2], Tineke Willems[1], Jens Wigger[1], Kendall Hunter[2], Dunbar Ivy[3], Rolf Berger[1], Uyen Truong[3]

University Medical Centre Groningen, Pediatric Cardiology, Groningen-The Netherlands[1]; University of Colorado, Bioengineering, Aurora, CO-United States[2]; Children, Pediatric Cardiology, Aurora, CO-United States[3]

Background/Hypothesis: In pediatric pulmonary arterial hypertension (PAH), right ventricular (RV) failure is the main cause of death. RV-vascular coupling ratio (VVCR) is gaining interest as it describes contractile response to afterload. Conventional measurement of VVCR by cardiac catheterization (VVCRs) is invasive with associated risks. Therefore, noninvasively estimated VVCR (VVCRm) using cardiac magnetic resonance (CMR) may offer advantages in children with PAH. We aimed to compare VVCRm to VVCRs in pediatric PAH and tested two hypotheses: 1) VVCRm corresponds with VVCRs; and 2) both represent disease severity.

Methods: Patients diagnosed with idiopathic and associated PAH without post-tricuspid shunt, who underwent catheterization and CMR within 90 days at two specialized centers for pediatric PAH were retrospectively studied. VVCRs by single-beat pressure method was compared with VVCRm defined as stroke volume/end-systolic volume ratio, using correlation, regression analysis and Bland-Altman plots. Both were correlated with clinical measures of disease severity (World Health Organization functional class [WHO-FC], pulmonary vascular resistance index [PVRi], mean pulmonary artery pressure [mPAP], mean right atrial pressure [mRAP], RV cardiac index [RV CI]).

Results: Twenty-seven patients were included with median age at diagnosis 9 years (IQR: 3,7–14) and at enrollment 14 years (IQR: 11–17), PVRi 7,6 WU × m2 (IQR: 4,1–12,0) and median mPAP 40 mmHg (IQR: 28–55) (table 1). VVCRs and VVCRm showed a strong correlation (r = 0,81, p < 0,001) with a mean difference of 0,2 and 95% of the differences between -0,2 and 0,6. Both correlated with WHO-FC and hemodynamics (table 2).

Conclusion: Non-invasively measured VVCRm is feasible in pediatric PAH and comparable to invasively assessed VVCRs. Both VVCRm and VVCRs correlate with functional and hemodynamic measures of disease severity. The role of VVCR in predicting outcome and its use as treatment goal in pediatric PAH requires further clinical investigation.

Table 1. Patient characteristics

	N	Value (percentage) or median (IQR)
Age at PAH diagnosis (years)	27	9,0 (3,7- 14,0)

P1986 - EXPLORING PARENTS' EXPERIENCES BRIDGING TO CARDIAC TRANSPLANT ON A BERLIN HEART

Holly Clisby[1], Vicky Kelly[2], Jo Wray[1], Michael Evangeli[3]

Great Ormond Street Hospital, Critical Care and Cardiorespiratory Division, London-United Kingdom[1]; Great Ormond Street Hospita, Critical Care and Cardiorespiratory Division, London-United Kingdom[2]; Royal Holloway University of London, Clinical Psychology, London-United Kingdom[3]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Devices such as the Berlin Heart, a mechanical circulatory support device, are increasingly being used to support children in cardiac failure whilst they wait for a suitable donor heart. Although the medical benefits of these devices have been established, studies have largely neglected the psychological impact of this experience on parents and their children. This study aimed to explore parents' experiences of supporting a child on a Berlin Heart as a bridge to cardiac transplant. Secondly, this study aimed to understand the impact these experiences had on parental quality of life, parental adjustment to their child's condition and family dynamics.
Methods: Semi-structured interviews were completed with eight parents of children who were supported on the Berlin Heart as a bridge to cardiac transplant. Interpretative Phenomenological Analysis was used to identify themes and connections across parents' accounts.
Results: Three superordinate themes were identified: 'Loss of Control on the Berlin Heart', 'Life in the Berlin Heart Bubble' and 'Transitioning Forward'. The findings highlight the complex process of decision-making for these parents and difficulties managing distress in a restricted and isolated environment. Loss of control was a defining feature of parents' experience. The importance of their support system in transitioning forward to a more positive and hopeful position with their child was also emphasised. There was a significant impact on parental quality of life and family dynamics throughout the experience.
Conclusion: The study provided a unique insight into the parental lived experience of having a child supported on a Berlin Heart through the collection of rich narrative data. There are a number of research and clinical implications for healthcare professionals including: how parents can be more adequately supported whilst their child is on a Berlin Heart, coping with uncertainty and the challenges of decision-making.

P2002 - PULMONARY HYPERTENSION AND ASSOCIATED FACTORS IN SICKLE CELL DISEASE

Sharon E Obrien[1], Kristen Sheppard[2], Patricia Kavanagh[1]
Boston Medical Center, Boston University, Pediatrics, Boston-United States[1]; Boston University, Pediatrics, Boston-United States[2]

Background: Sickle cell disease (SCD) affects ~100,000 people in the United States. Pulmonary hypertension (PHTN) is found in 6-11% of SCD adults and is associated with 40% mortality within 3 years. Less is understood about PHTN in the pediatric SCD population. Studies have estimated a prevalence of PHTN up to 30%, defined as tricuspid regurgitation velocity (TRV) ≥ 2.5 m/s on echocardiogram. The objective of this study is to describe PHTN in children with SCD.
Methods: Retrospective chart reviews were performed at an academic center caring for 450 children and adults with SCD. Subjects were eligible if they were 8 to 30 years during the period 7/1/2003 to 6/30/2015 and had their first screening echocardiogram before age 21. Patients with PHTN-predisposing comorbidities were excluded. Baseline hemoglobin (Hb), reticulocyte counts (RC), SCD-related complications, history of asthma, hydroxyurea (HU) use, and chronic blood transfusions (CBT) were assessed. Categorical and continuous data were analyzed using Fisher's exact test and 2-tailed t-test, respectively.
Results: Of 118 eligible subjects, 83 (70%) had a TRV measured (Table). Eleven of 83 (13%) had one or more TRV values ≥ 2.5 m/s. The average age at first elevated TRV was 15.9 years, and of these, nine (79%) had been prescribed HU at some point and 6 (55%) were prescribed HU at the time of elevated TRV. No statistically significant difference was found in TRV and genotype, Hb, HU use, SCD-related complications, asthma, or CBT. However, RC was significantly higher in the elevated TRV group.
Conclusion: Only 13% of patients with SCD had TRV ≥ 2.5 m/s, lower than published estimates. While other studies have found associations between TRV and genotype, Hb or SCD-related complications, these were not seen in this study. Prospective longitudinal studies beginning in childhood are needed to understand the development of PHTN among SCD patients.

Table. SCD-related factors associated with PHTN in previous studies

Factor	% of subjects with measured TR jet (N = 83)
HbSS	73
History of SCD-related conditions	
Acute chest syndrome	60
Splenic sequestration/splenectomy	22
Sepsis/bacteremia	17
History of Asthma	22
Hydroxyurea use	64
Chronic blood transfusion	8

P2003 - FRAGMENTED QRS COMPLEXES IN PEDIATRIC PATIENTS WITH IDIOPATHIC DILATED CARDIOMYOPATHY A SINGLE TERTIARY CENTER EXPERIENCE

Younghwa Kong, Yiseul Kim, Heirim Lee, Jinyoung Song, I-seok Kang, June Huh
Samsung Medical Center, Department of Pediatrics, Seoul-Korea, South

Background: Fragmented QRS complex (fQRS) is an easily evaluated noninvasive electrocardiographic parameter. Presence of fQRS has been associated with alternation of myocardial activation due to myocardial scar and myocardial fibrosis. Some literatures suggest that the parameter may affect prognosis and risk of sudden cardiac death, risk of implantable cardioverter-defibrillator therapy and response to cardiac resynchronization therapy. In this retrospective study we investigated the difference between presence and absence of fQRS.
Methods/Results: We retrospectively reviewed the records of pediatric patients <19 years of age who were diagnosed with idiopathic DCMP from 2003 to 2014 at Samsung Medical Center. Sixty-five patients were enrolled in this study according to the inclusion criteria: (1) pediatric idiopathic dilated cardiomyopathy patients aged <19 years, (2) performed the electrocardiography at diagnosis and recent follow-up. Median age at diagnosis was 14.5 months (range 1-237 months) and gender ratio was nearly 1.0 (male 32, female 33). In 25 patients (36/65, 55.4%), fQRSs were appeared at diagnosis. There were no statistically significant difference between fQRS positive and negative patients except the age at diagnosis (positive group: 81.49months; negative group: 41.28 months). In 41 patients (41/65, 63.0%), fQRSs were appeared at recent follow-up electrocardiography. Same as above, there were no statistically significant difference between positive and negative of fQRSs patients including mortality, cardiac death, cardiac contractility, and left ventricle dimensions. In our study, there were two cases of ventricular arrhythmia. One was a

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

mortality case due to ventricular fibrillation, and the other case was frequent ventricular premature beats and non-sustained ventricular tachycardia. All cases of the ventricular arrhythmias, fQRSs were appeared.
Conclusion: Presence of fQRS is not always a strong independent predictor of clinical outcome in our experience. Despite of statistically non-significant findings, we will have to carefully observe the newly appeared ventricular arrhythmia in patients with fQRS.

P2005 - THE MID TERM RESULTS OF PEDIATRIC HEART TRANSPLANTATION

Jia-Kan Chang, Kuo-Chen Lee, Chung-Yi Chang, Yi-Cheng Chuang, Jeng Wei
Cheng-Hsin General Hospital, Heart Center, Taipei-Taiwan

Background: Heart transplantation (HTx) is a life-saving therapy for infants, children, adolescents and adults with end-stage heart failure or complex, inoperable congenital cardiac defects. Our team performed the first case of orthotopic HTx in July 1988 and first pediatric case (recipient's age under 18 years) in March 1996. By December 2016, a total of 467 cases have been performed with acceptable results. The aim of this study was to review retrospectively 21 pediatric patients who underwent orthotopic HTx. The mid-term survival results in pediatrics and adults were compared.
Materials and Methods: From July 1988 to December 2016, the total number of HTx cases was 467 in this program. Twenty-one of these 467 patients were pediatrics. Average age was 14.2 ± 3.5 years, ranging from 2 to 18 years, fourteen were male and seven female. The etiologies of end-stage heart disease are dilated cardiomyopathy in 15 patients, congenital heart disease in 4, and valvular cardiomyopathy in 2.
Results: Actuarial survival rates in pediatric cases at 1, 5, 10 years were 81.0%, 59.9%, and 28.1%, respectively. On the other hand, actuarial survival rates in adults at 1, 5, 10 years were 85.7%, 74.7%, and 59.5%, respectively.
Conclusions: Our results revealed that HTx is a feasible alternative for pediatric patients who suffered end-stage heart disease. With careful choice of the recipients and selection of appropriate immunosuppressive agents, durable mid-term result could be achieved. The actuarial survival rate in pediatrics after 5 years is relatively worse than that in adult cases, indicating the scarcity of pediatric donor hearts remains a serious problem and hemodynamic instability before HTx is relatively more common in pediatric cases. To improve the results, cooperation between the transplant team and the primary care pediatrician and well-organization of the pediatric donation resources are crucial.

P2020 - MYOCARDIAL PERFUSION ABNORMALITIES IN EISENMENGER SYNDROME

Saurabh Gupta Gupta[1], Anunay Gupta[1], S Ramakrishnan[1], Rajnish Juneja[1], Shyam S Kothari[1], Anita Saxena[1], Chetan Patel[2], V K Bahl[1]
All India Institute of Medical Sciences, Cardiology, New Delhi-India[1]; All India Institute of Medical Sciences, Nuclear Medicine, New Delhi-India[2]

Background: Compared to idiopathic pulmonary hypertension (IPAH), patients with Eisenmenger syndrome (ES) are known to have preserved right ventricular (RV) function for a longer period. While this difference is attributed largely to preservation of a fetal phenotype, the exact contribution of myocardial ischemia is not known.
Objective: We sought to examine the prevalence of myocardial ischemia in patients with Eisenmenger syndrome using stress nuclear studies.
Materials and Methods: In this prospective study, twenty consecutive patients with Eisenmenger syndrome were evaluated from 2014 to 2016. These patients underwent clinical evaluation, six minute walk test, echocardiography and stress myocardial scintigraphy using technetium 99 m sestamibi.
Results: Majority (60%) of patients were in were in NYHA functional class II. All patients had RV hypertrophy. Four (20%) patients had RV dysfunction while LV function was normal in all. Two (10%) patients showed perfusion defects in the anterior wall of right ventricle while one patient had perfusion defect in the interventricular septum. Four (20%) patients had perfusion defect in the LV apical area of whom it was reversible in two patients.
Conclusion: Myocardial perfusion defects both in RV and LV occur even in asymptomatic or mildly symptomatic patients with Eisenmenger syndrome. However, they are less frequent than reported in patients with IPAH, which may be partly responsible for the better prognosis observed in ES.

P2021 - APICAL RECOIL A SIMPLIFIED MEASURE OF UNTWIST MAY BE USED AS AN INDEX OF DIASTOLIC DYSFUNCTION IN CHILDREN WITH DILATED CARDIOMYOPATHY

Putri Yubbu[1], Renzo Calderon-Anyosa[2], Anirban Banerjee[2]
University Putra Malaysia, Pediatric, Serdang-Malaysia[1]; Children Hospital of Philadelphia, Pediatric Cardiology, Philadelphia-United States[2]

Backgrounds/Objectives: Untwisting of helical left ventricular (LV) myofibers during early diastole is defined as recoil. Recoil may be a precursor of LV apical "suction". Previously we identified apex as the "engine" of the LV. The purpose of this study was to simplify untwist by measuring recoil from a single view, the LV apex. We also evaluate the feasibility of utilizing apical recoil in children with dilated cardiomyopathy (DCM), to measure diastolic dysfunction.
Methods: Fifty-one healthy subjects (mean age 13.8 years age match + 2.9) were studied prospectively at rest and exercise. To increase lusitropy, subjects performed repeated straight leg raising from the hip to elevate their heart rates by > 40 beats per minute. Peak apical recoil rate and time to peak recoil were measured using 2DE speckle-tracking of LV apex. Application of this index in diseased states was tested in 18 DCM patients at rest (mean age 9.5 years, range 9 months to 18 years) with 30 sex and age matched control.
Results: In healthy subjects, peak apical recoil rate increased with exercise, -63.07 + 19.4°/s to -97.82 + 39.02°/s ($p < 0.01$) and time to peak recoil became shorter, 424.4 + 60.3 ms to

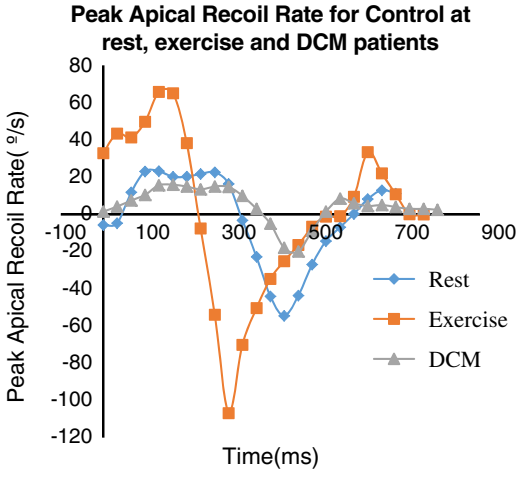

Figure.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

337.4 + 51.1 ms ($p < 0.0001$). Compared to controls, peak apical recoil rate was significantly lower in DCM cohort, -38.5 + 18.6 °/s vs -63.07 + 19.4 °/s ($p < 0.001$).
Conclusion: Apical recoil is new concept that may provide insight into LV untwisting and diastolic dysfunction. It was successful in detecting both increased and decreased lusitropic states. Commercial ultrasound machines could potentially automate this index for future clinical applications.

P2033 - ECMO THERAPY IN A CRITICAL PATIENT WITH TRANSPOSITION OF GREAT ARTERIES AND PERSISTENT PULMONARY HYPERTENSION

Francisco Vera[1], Esteban Sarria[1], Juan Ignacio Zabala[2], Lourdes Conejo[2], Victorio Cuenca[2], Beatriz Picazo[2], Jose Manuel González[3], Raquel Gil[3], Vanesa Rosa[3], Enrique Ruiz[1]
Hospital Materno Infantil, Congenital Cardiovascular Surgery, Málaga-Spain[1]; Hospital Materno Infantil, Pediatric Cardiology, Málaga-Spain[2]; Hospital Materno Infantil, Pediatric Intensive Care Unit, Málaga-Spain[3]

Background/Hypothesis: Persistent pulmonary artery hypertension (PPAH) occurs in 1-3% of neonates with transposition of great arteries (TGA). This can dramatically increase mortality of TGA, due to persistent cyanosis and heart failure.
Material and Methods: We report a case where ECMO therapy was successfully employed to reduce pulmonary artery pressure and to improve oxygenation in a TGA-PPAH patient. A new born of 2,5 Kg with TGA presented severe desaturation and increasing levels of lactate, in spite of mechanical ventilation, prostaglandins, and inhaled NO. Rashkind atrioseptostomy didn't produce any changes in clinical situation. Echocardiogram showed a patent ductus arteriosus shunting right to left. Increasing dosage of adrenaline (1,5 mcg/Kg/min) was needed to maintain arterial blood pressure higher than 40 mmHg, while peripheral and cerebral saturation remained under 20%. To manage this critical situation, a venous-arterial ECMO (centrifugal pump) was implanted through cervical vessels (Arterial: 8 F, Venous: 10 F).
Results: After ECMO implantation, hemodynamic and respiratory function improved rapidly. Lactate levels normalized, and adrenaline requirements decreased. Echocardiogram showed a reduction of pulmonary pressure. We maintained a low dosage of prostaglandin in order to avoid the LV deconditioning. After 48 h of ECMO support, Arterial Switch Operation (ASO) was performed without complications. CPB weaning was made under low dosage of inotropes and no further mechanical assistance was needed in the postoperative period. Chest was left open prophilactically, and could be closed the 4th postoperative day. Patient was extubated the 12th day and discharged from ICU the 18th day. No complications were registered, except mild distal inferior limb ischemia. The patient was discharged home the 47th postoperative day.
Conclusion: ECMO therapy should be considered in TGA-PPAH critical patients, in order to improve the clinical and hemodynamic situation and to reduce pulmonary vascular resistances, so that ASO could be performed in optimal conditions.

P2107 - REPAIR OF ISOLATED ATRIAL SEPTAL DEFECT (ASD) IN INFANTS LESS THAN 12 MONTHS IMPROVES SYMPTOMS OF BRONCHOPULMONARY DYSPLASIA OR SHUNT RELATED PULMONARY HYPERTENSION

Dafni Charisopoulou[1], Shahin Moledina[2], Roberta Bini[2], Gillian Riley[3], Jan Marek[1]
Great Ormond Street Children's Hospital, Paediatric Cardiology, London-United Kingdom[1]; Great Ormond Street Children's Hospital, Pulmonary Hypertension, London-United Kingdom[2]; Great Ormond Street Children's Hospital, Echocardiography, London-United Kingdom[3]

Introduction: Infants with isolated ASDs are usually minimally symptomatic and repair is typically performed after infancy. Early repair may be considered in certain circumstances e.g. patients with reduced respiratory reserve or early signs of pulmonary hypertension (PH). Our aim was to review the characteristics and outcomes of a large cohort of infants who underwent infant ASD repair at our institution.
Methods: The study included 56 infants (28 female, 19 trisomy 21) with isolated ASD [age: 8 months (1.5-12), weight 6 kg (2.8-7.5), echo Qp/Qs:1.9 ± 0.1], who underwent surgical closure (20 fenestrated) between 2006-2016. Three groups of patients were identified: i) bronchopulmonary dysplasia of prematurity and PH (BPD-PH: n = 27) ii) Acutely unwell infants with PH but no chronic lung disease (non CLD-PH: n = 20, 36%) iii) Infants with refractory congestive heart failure (HF) without either PH or CLD (high-flow, n = 9, 16%). There were no major surgical complications. PH status was defined by echo (systolic PAP > 35 mmHg/ indirect markers).
Results: Postoperatively, PH infants (47/56) showed improvement in TAPSE z-score (BPD-PH:-1.74 ± 1.24 vs 1.04 ± 1; nonCLD-PH:-0.03 ± 2 vs 1.02 ± 0.1, $p < 0.001$) and right ventricular systolic/diastolic duration ratio (BPD-PH:1.37 ± 0.12 vs 1.1 ± 0.31; non CLD-PH:1.2 ±0.2 vs 0. 84 ± 0.1, $p < 0.05$). All ventilator (14,25%) or O2 dependent (31,55%) children could be weaned within two weeks after ASD closure. One year after repair, weight z-score increased in all patients and by +1 (0.5-1.5) in BPD-PH, +1.3 (0.7-1.7) in nonCLD-PH and +2 (1-2) in high-flow group. Over a median follow-up of 1.4 yrs (0.2-8.5), 3 patients died. Only 4 of 47 PH patients continued to have PH echo evidence at last follow-up. Only two of them remain on anti-PH medication.
Conclusion: This cohort suggests that ASD repair within the first year of life may improve the clinical status and growth.

P2127 - PHYSICAL ACTIVITY IN PEDIATRIC PULMONARY ARTERIAL HYPERTENSON MEASURED BY ACCELEROMETRY A CANDIDATE CLINICAL ENDPOINT

Willemijn Zijlstra[1], Mark-jan Ploegstra[1], Theresia Vissia-kazemier[1], Marc Roofhooft[1], Gideon Du Marchie Sarvaas[1], Beatrijs Bartelds[1], Annette Rackowitz[1], Freek Van Den Heuvel[1], Hans Hillege[2], Guy Plasqui[3], Rolf Berger[1]
Beatrix Children's Hospital, University Medical Center Groningen, University of Groningen, Center For Congenital Heart Diseases, Groningen-The Netherlands[1]; University Medical Center Groningen, University of Groningen, Department of Epidemiology, Groningen-The Netherlands[2]; University of Maastricht, Maastricht University Medical Center, Maastricht-The Netherlands[3]

Background: The development of evidence-based treatment guidelines for pediatric pulmonary arterial hypertension (PAH) is hampered by lack of pediatric clinical trials. Trial-design is hampered by lack of a feasible clinical endpoint in this population. We aimed to evaluate the use of accelerometry for measuring physical activity (PA) in pediatric PAH and to investigate its correlation with clinical disease severity markers.
Materials and methods: We included children from the Dutch National Network for Pediatric Pulmonary Hypertension. Controls were recruited from the outpatient cardiology clinic of the Beatrix Children's Hospital. Children were asked to wear the accelerometer for 7 days. Vector magnitude counts per minute (VM CPM) and time per day spent in different PA intensity levels were defined as accelerometer outcomes.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: VM CPM was lower in children with PAH (n = 29) than in controls (n = 60) (647 vs. 921; $p < 0.001$) (Figure 1). Children with PAH spent less time in moderate and vigorous PA (13 vs. 29 minutes, 2 vs. 13 minutes per day; $p < 0.001$). Time spent in moderate and vigorous PA correlated inversely with WHO-functional class. Time spent in moderate PA correlated positively with 6-minute walk distance. In post hoc analyses, higher VM CPM and more time spent in moderate/vigorous combined and vigorous PA were associated with favorable outcome ($p \leq 0.044$).
Conclusion: PA is markedly decreased in children with PAH. Accelerometer output correlated with clinical disease severity markers and may predict outcome. We showed an exciting potential of PA as meaningful endpoint for clinical trials in pediatric PAH, although its clinical utility and prognostic value needs to be further validated.

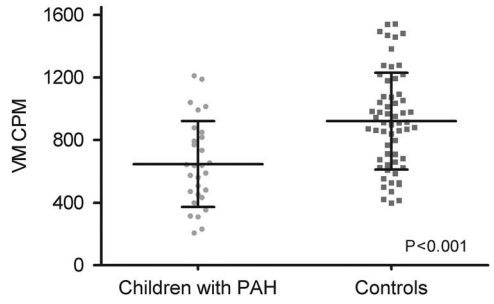

Figure.

P2128 - SYSTEMATIC LITERATURE REVIEW ON THE CLINICAL ECONOMIC HUMANISTIC AND SOCIETAL BURDEN OF HEART FAILURE IN CHILDREN AND ADOLESCENTS

Michael Burch[1], Thej Nallagangula[2], Eimear Nic Lochlainn[3], Thomas Severin[4], Lalit Thakur[2], Thomas Jaecklin[5], Aneesh George[2], Susan Solar-yohay[6], Joseph Rossano[7], Robert Shaddy[7]
Great Ormond Street Hospital for Children, Cardiorespiratory Division, London-United Kingdom[1]; Novartis Healthcare Pvt. Ltd., Patient Access Services, Hyderabad-India[2]; Novartis Pharma Ag, Basel, Heor, Basel-Switzerland[3]; Novartis Pharma Ag, Basel, Cardio-metabolic, Basel-Switzerland[4]; Shire International Gmbh, Global Clinical Development, Zug-Switzerland[5]; Novartis Pharmaceuticals Corporation, Cardio-metabolic, East Hanover-United States[6]; Children's Hospital of Philadelphia, Pediatric Cardiology, Philadelphia-United States[7]

Background: Pediatric heart failure (HF) is associated with substantial morbidity and mortality. However, to date, there has been no systematic assessment of pediatric HF burden.
Methods: This narrative systematic review used Cochrane methodology to assess the evidence on the HF burden in children and adolescents (<18 years) over the past 10 years (2006–2016). Sources searched included Embase, Medline; selected congresses; and WHO, NHSEED, and HTA databases.
Results: 18 observational studies were included. Six studies reported mortality rates. In a UK/Ireland study, the 1-year mortality rate for patients admitted with a first HF episode was 18.3%, while a US study reported 71% mortality over 10 years for in-hospital HF following cardiac arrest. Based on three studies, 16.4%–82% of end-stage HF patients underwent heart transplantation. Four studies reported HF-related hospitalization rates of 18.2%–63.9% in infants (<1 year) and 18.7%–45.7% in children aged 1–12 years. Across six studies, mean length of hospital stay was 15 days overall, but was up to 26 days for infants. Five studies reported cost data. US studies reported mean hospital charges/year that were higher for infants (US$176,000) than for children aged 1—10 years (US$132,000) and total hospitalization costs for all US pediatric HF admissions in 2006 of US$753,149,082 (mean hospital cost per patient: US$49,354). In Germany, DRG-based hospital allowances per HF case were €3,498 in 1995 and €4,250 in 2009. In a Nigerian study, out-of-pocket expenses for HF treatment were 0.7%–122% of family income (mean US $17.6 ± 10.6/month); indirect costs (transportation/man hours) were 0.1%–57.1% of monthly income; and mean man-hour loss was 85.2 hours/year. No study reporting on patient quality of life fulfilled the selection criteria.
Conclusions: This review demonstrates the substantial burden of pediatric HF. However, the small number of studies, heterogeneity, and limited geographical coverage indicates the need for further research.

P2132 - REGIONAL SEPTAL HINGE POINT INJURY DRIVES ADVERSE BIVENTRICULAR INTERACTIONS IN PULMONARY HYPERTENSION

Eva Amalie Nielsen[1], Kenichi Okumura[2], Mei Sun[2], Vibeke E. Hjortdal[1], Andrew N. Redington[2], Mark K. Friedberg[2]
Aarhus University Hospital, Cardiothoracic Surgery, Aarhus-Denmark[1]
Hospital for Sick Children, Cardiology, Toronto-Canada[2]

Background: Death and morbidity in pulmonary arterial hypertension (PAH) are often due to right ventricular (RV) failure and associated left ventricular (LV) dysfunction. We investigated regional myocardial remodeling and function as the basis for adverse ventricular-ventricular interactions in experimental chronic RV pressure overload.
Methods and Results: Two distinct animal models were studied: A) a rabbit model of increased RV pressure-load through progressive pulmonary artery banding B) A rat model of monocrotaline (MCT)-induced pulmonary arterial hypertension (PAH). Regional myocardial function was assessed by speckle-tracking strain echocardiography and ventricular pressures measured by catheterization before termination. Regional RV and LV myocardium was analyzed for collagen content, apoptosis and pro-fibrotic signaling gene and protein expression. Although the RV developed more fibrosis than the LV; in both models the LV was substantially affected (fig. A). In both ventricles, particularly the LV, fibrosis

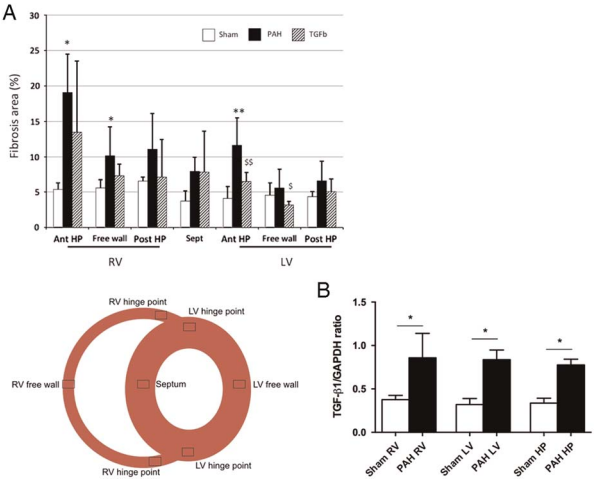

Figure.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

developed predominantly at the septal hinge-point regions in association with decreased regional and global circumferential strain, reduced global RV and LV function and up-regulation of regional transforming growth factor-β1 (TGFβ1) (Fig B) and apoptosis signaling. A group of PAH rats who received the TGFβ blocker SB431542 showed improved RV function and reduced regional hinge-point myocardial fibrosis.
Conclusion: RV pressure-loading and PAH lead to biventricular TGFβ1 signaling, fibrosis and apoptosis, predominantly at the septal hinge-point regions, in association with regional myocardial dysfunction. This suggests that altered geometry and wall stress lead to adverse RV-LV interactions through the septal hinge-points to induce LV fibrosis and dysfunction..

P2141 - STATUS OF PULMONARY ARTERY PRESSURES ON ECHOCARDIOGRAPHY IN HIGH RISK NEWBORNS

Shaad Abqari, Tauqueer Ahmed, Tabassum Shahab, Syed Manazir Ali
Amu, Pediatrics, Aligarh-India

Background: Persistent pulmonary hypertension of newborn (PPHN) is associated with various risk factors and there is paucity of data about the outcome of newborns who have one or more risk factors for PPHN and have some degrees of PAH not significant enough to cause hypoxemia and desaturation to be labelled as PPHN.
Objective: Prevalence of Pulmonary Arterial Hypertension in High Risk Newborns.
Material and Methods: This was a prospective observational study in which newborns (including both inborn and outborn deliveries) up to 1 month of age having risk factors for PPHN were included, a detailed history of mother and newborn was taken and after meticulous examination neonates having one or other risk factors for PPHN were selected for the study. Finally pulmonary hypertension was identified on echocardiography in neonates more than 48 hours of life with one or another risk factors. Second screening was done at 6 weeks of life independent of cases having PAH or not at the first screening.
Result: Total 410 neonates were screened and 10 cases were of congenital heart disease and hence excluded from the study. Out of remaining 400 cases 26 patients lost to follow up, 2 cases left against medical advice and 18 patients expired after first screening. Finally a total of 354 cases came for follow up at 6 weeks and repeat echocardiography was done in all cases. PAH was found in 54 cases on first screening, 12 neonates had reversal of shunt at the level of PDA or PFO and only 2 cases had persistence PAH on second screening at 6 weeks. Perinatal asphyxia (43.9%), respiratory distress (31%) and MSAF (30%) has shown a significant association with the development of PAH in these neonates.
Conclusion: Newborns with risk factors have some degree of PAH and should be screened early.

P2142 - INTERDISCIPLINARY APPROACH IN CHILDREN WITH PULMONARY HYPERTENSION (WHO GROUP 1)

Dimpna C. Albert[1], Lucas Degano[1], Alba Torrent[2], Anna Sabate[1], Raul Abella[3], Maria Morillo[4], Pedro Betrian[1], Marcos Lines[5], Joan Balcells[6], Antonio Moreno[2]
University Vall De Hebron Hospital, Pediatric Cardiology, Barcelona-Spain[1]; University Vall De Hebron Hospital, Pediatric Pneumology, Barcelona-Spain[2]; University Vall De Hebron Hospital, Pediatric Cardiac Surgery, Barcelona-Spain[3]; University Vall De Hebron Hospital, Nurse Department, Barcelona-Spain[4]; University Vall De Hebron Hospital, Neonatology, Barcelona-Spain[5] University Vall De Hebron Hospital, Intensive Care Unit, Barcelona-Spain[6]

Background: Children with pulmonary hypertension (PH) require special expertise to diagnose and properly treat to improve long-term prognosis. Our Pediatric PH Unit is integrated by a team of pediatric pneumologists, cardiologists, neonatologists, intensivists, thoracic and cardiac surgeons and nurse practitioners experts in pediatric PH, with possibility to treat them with ECMO, atrial septostomy (AS) and lung transplantation (LT). We present our results of children diagnosed with pulmonary arterial hypertension (PAH): idiopathic or heritable PAH, associated with congenital heart disease (CHD) and veno-occlusive disease.
Main Methods: Retrospective, observational study. Data of our 27 children below 14 years with PAH controlled in our center from 2012 to 2014. The primary outcome was death, others outcomes were need for ECMO, AS or LT.
Results: We included 9 cases of idiopathic PAH, 16 of CHD-associated PAH, 1 veno-occlusive disease and 1 persistent PH. Mean age was 2.9 years(1 d-11.7 years; only 5 cases were older than 5 years); 15 (55.5%) females and 12 (44.5%) males. Eight children were diagnosed during this period, and the others were retrospective cases. AS was performed in 6(4 using diabolo fenestrated stent technique for mounting a stent; 1 by Amplatzer atrial septal-occluder with self-made fenestration and 1 was surgical). Time between diagnosis of PAH and AS was on average 20.4 months. ECMO was used in 3 (1 after LT) and LT was performed in 2. At follow-up 2 died (one at the moment of diagnosis and other after LT). The remaining 22 after a median follow-up time between 2 months and 14 years are stable on pulmonary vasodilator treatment (see figure).
Conclusions: To optimize the quality of life and the outcome of children with PAH, a specific interdisciplinary management is required. Strategies of physicians specialized on congenital heart diseases and PH should be warranted .

P2149 - PHARMACOKINETICS AND HEMODYNAMIC RESPONSES TO RECTAL TADALAFIL IN CHILDREN WITH PULMONARY HYPERTENSIVE VASCULAR DISEASE EARLY AFTER CARDIAC SURGERY

Kanta Kishi[1], Ashida Atsuko[1], Odanaka Yutaka[1], Ozaki Noriyasu[1], Katayama Hiroshi[1], Kamiyama Naoya[2], Tasaki Yoshikazu[2], Sugimoto Masaya[3], Nemoto Shintaro[4], Konishi Hayato[4], Shimada Ryo[4], Hiroshi Tamai[1]

Osaka Medical College, Department of Pediatrics, Takatsuki-Japan[1]; Asahikawa Medical University., Department of Hospital Pharmacy and Pharmacology, Asahikawa-Japan[2]; Asahikawa Medical University., Department of Pediatrics, Asahikawa-Japan[3]; Osaka Medical College, Department of Pediatric Cardiovascular Surgery, Takatsuki-Japan[4]

Background: There is no report demonstrating the plasma concentrations of tadalafil in children with pulmonary hypertensive vascular disease (PHVD) after cardiac surgery. We assessed the pharmacokinetics and hemodynamic responses to rectal tadalafil for PHVD early after congenital cardiac surgery in pediatric patients.
Methods: Tadalafil is administered at a dose of 0.5 mg/kg every 12 hours rectally following admission to the intensive care unit. PHVD is defined as mean pulmonary pressure (mPAP) >25 mmHg for biventricular circulation and mPAP >15 mmHg or the mean transpulmonary pressure gradient (mTPG) >10 mmHg for single ventricle physiology. We retrospectively reviewed five patients treated with rectal tadalafil and measured tadalafil concentrations.
Results: Five patients with PHVD were included. Two patients were undertaken biventricular repair and 3 patients were undertaken bidirectional cavopulmonary shunt. The characteristics of patients were as below. Age:8.2 months (0.7-12.7), body weight: 5.3 kg(3.0-8.0), diagnosis: aortopulmonary window, complete atrioventricular septal defect (biventricular circulation)/pulmonary atresia with intact ventricular septum, tricuspid atresia, single ventricle (single ventricular physiology). Percentage of change in mPAP and mTPG significantly reduced eight hours after administration (-23.3 + /- 4.7%, $p = 0.03$) and further reduction was observed 12 hours after administration (-33.7 + /- 4.7%, $p = 0.005$). Systemic blood pressure did not change significantly during study period. Plasma concentrations of tadalafil increased gradually until second administration 12 hours after first administration. After second administration, the tadalafil concentrations increased further until third administration. The tadalafil concentrations were 48.0 + /- 9.2 ng/ml ($p = 0.019$) at 12 hours and 144.9 + /- 10.2 ng/ml ($p < 0.001$) at 24 hours after first administration. Moreover, there was negative correlation between tadalafil levels and percentage change of mPAP and TPG ($p = 0.01$, $r = -0.46$). No significant adverse events occurred.
Conclusions: Rectal tadalafil is a safe and effective treatment for children with PHVD early after cardiac surgeries.

P2218 - THE USE OF AN IMPLANTABLE CONTINUOUS FLOW VENTRICULAR ASSIST DEVICE IN A YOUNG SCHOOL AGE CHILD

Melanie Muller[1], Ana Lia Graciano[1], Casey Naughton[1], Caroline Bauer[1], Sunjay Kaushal[2]

University of Maryland, Children's Heart Center-Pediatric Critical Care., Baltimore, MD-United States[1]; University of Maryland, Children's Heart Center, Division of Cardiothoracic Surgery., Baltimore, MD-United States[2]

Background: The use of ventricular assist devices (VADs) as a bridge to transplant (BTT) in children with heart failure is expanding but still limited. We describe the use of an implanted continuous flow VAD as a BTT in a small pediatric patient who presented with dilated cardiomyopathy and cardiogenic shock.
Methods: An 8 year old 23 kilogram female with a body surface area (BSA) of 0.68 m^2 presented with diffuse abdominal pain, vomiting, and cough. Chest radiograph revealed massive cardiomegaly. Echocardiogram showed severe left ventricular dysfunction with an ejection fraction of 20%. She was admitted to a mixed pediatric cardiac intensive unit, initiated on inotropic support and evaluated for heart transplantation. Her precarious cardiorespiratory status deteriorated requiring intubation after which VAD support was decided. Four days after admission she underwent implantation of a HeartWare® ventricular assist device (HVAD). Device flows ranged between 2.2-2.4 revolutions per minute, providing an output of 2.9-3.6 liters/minute. The immediate postoperative course was complicated by a pericardial hematoma requiring mediastinal re-exploration and evacuation. Initial anticoagulation regimen included unfractionated heparin infusion. While being transitioned to an oral anticoagulation regimen with aspirin and warfarin her lactic dehydrogenase and plasma free hemoglobin levels were increasing. Due to concerns for hemolysis versus thrombus formation, the anticoagulation regimen was changed to bivalirudin and dipyridamole.
Results: She was extubated on postoperative day four after LVAD implantation. After 54 days on LVAD support she underwent orthotopic heart transplantation without complications and was discharged home on post-transplant day 11. She continues to do well, undergoing routine cardiac catheterization for biopsy with no evidence of rejection.
Conclusion: HVAD implantation was successful as a BTT in this young, thin patient without long-term complications or sequelae. Through the use of an expert multidisciplinary approach, detailed protocols and expedited decision making, these complex children can be successfully managed.

P2227 - ELECTRICAL CHANGES IN RESTING ECG IN CHILDREN WITH IDIOPATHIC PULMONARY ARTERIAL HYPERTENSION

Johannes Krämer[1], Felix Kreuzer[1], Michael Kaestner[1], Peter Bride[1], Jannos Siaplaouras[1], Heiner Latus[2], Dietmar Schranz[2], Christian Apitz[1]

University Children's Hospital Ulm, Division of Pediatric Cardiology, Ulm-Germany[1]; University of Giessen, Pediatric Heart Center, Giessen-Germany[2]

Introduction: Idiopathic pulmonary arterial hypertension (IPAH) is a rare condition in pediatric patients. Gold standard for diagnosis is invasive hemodynamic assessment. The role of electrocardiographic (ECG) changes in IPAH in children is still neglected. ECG ist widely available and easy applicable, even in small children. This study should systematically observe the role of ECG as a diagnostic and prognostic tool in pediatric IPAH.
Methods: Pediatric patients with suspected PAH who visited our tertiary referral center from 1999 to 2011 in order to obtain diagnostic cardiac catheterization were screened retrospectively. 42 children and adolescents were identified to have IPAH, a corresponding 12-lead-ECG was done during the same hospital stay. The follow-up after baseline examination was 59 ± 17 months. Kaplan-Meier analysis was used to assess predictive value of ECG changes regarding morbidity and mortality in these patients.
Results: In 12 patients (29%) severe cardiovascular events (defined as death, lung/heart-lung transplantation or Potts shunt) were observed after 20 ± 22 months. Patients with event showed higher baseline ratio of mean PA pressure to mean systemic arterial

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

pressure (1.02 ± 0.26 vs. 0.84 ± 0.25, $p < 0.05$). Most patients (n = 37) showed a positive RV-Sokolow-Lyon index (RVSLI ≥1.05) at baseline ECG. Patients with event showed higher values (3.6 ± 1.2 mV vs. 2.6 ± 1.6 mV; $p < 0.05$). Relative risk for any event with an index more than double the common reference value (>2.1 mV) was 1.76 (95% Ci 1.21-3.20). Relative risk for death with RVSLI >2.1 mV was 2.01 (95% CI 1.61-4.80). RVSLI ≥2.1 mV was able to distinguish patients on risk for events with a sensitivity of 75% and a specificity of 56% (AUC 0.73, $p < 0.05$).

Conclusion: ECG with common reference values is not sufficient for staging and diagnosis of IPAH in children. IPAH-patients with elevated RVSLI >2.1 mV are at risk for cardiac events and should receive closer follow-up assessment, including repeated invasive evaluation allowing timely escalation of specific PAH-treatment.

P2237 - USING HEARTWARE DEVICE IN PAEDIATRIC PATIENTS WITH LEFT VENTRICULAR HEART FAILURE AS BRIDGE TO TRANSPLANTATION PROVIDES IMPROVED OUTCOMES AND BETTER QUALITY OF LIFE – UK BASED EXPERIENCE

Abbas Khushnood[1], Zdenka Reinhardt[2], Andres Rico Armada[2], Teresa Chila[2], Fabrizio De Rita[2], Tain-Yen Hsia[1], Ann Karimova[1], Matthew Fenton[1], Michael Burch[1]

Great Ormond Street Hospital, Paediatric Cardiology, London-United Kingdom[1]; Freeman Hospital, Paediatric Cardiology, Newcastle-United Kingdom[2]

Background: The HeartWare Ventricular Assist Device (HVAD) is an implantable, centrifugal design, continuous-flow blood pump. Unlike EXCOR Berlin Heart, patients on HVAD are ambulatory and can be discharged home.

Method & Results: Retrospective review of 16 patients from 2 UK transplants centres [8 from each centre, mean age 11.3 (3-15) years, mean weight 39.3 (14-76) kg] underwent implantation of HVAD as left ventricular assist device, between 2014-2016, as bridge to transplant for end-stage heart failure. Median duration on HVAD was 187 (7-620) days. Table 1 shows the clinical background and outcomes following HVAD implantation. Of the 16 patients that received HVAD, there were no deaths. 15 patients have had successful transplantation and one remains alive on support. Most (13/16) children were discharged home, 2 were hospitalized long-term because of social reasons and 6/16 children returned to school. Complications following device implantation – 6 patients had driveline related infections requiring antibiotics. 3 patients had thrombo-embolic phenomenon causing reversible focal weakness but no patients have residual neurological deficit. 3 patients had sepsis with positive blood cultures requiring long-term antibiotics. One patient had thrombus in LV after VAD insertion and one had fungal infection with epistaxis and intracranial haemorrhage requiring neurosurgical evacuation. There were 2 pump blockades, one requiring emergency pump change and one transitioned onto cardiopulmonary bypass and urgent transplantation.

Conclusion: Our early experience shows that HVAD provides a relatively safe and efficient form of circulatory assistance for children awaiting heart transplant. Most of our patients on HVAD were able to go home, attend school and have community-based follow up, with overall good quality of life while awaiting transplantation. Further research is needed to prevent complications like infection, thrombo-embolism and haemorrhage in these patients..

Table 1. Demographics, clinical diagnosis and outcomes following HVAD implantation

P2245 - PEDIATRIC PALLIATIVE CARE IN ADVANCED HEART DISEASES

Sergi Navarro[1], Joan Sanchez De Toledo[2], Jose Antonio Porras[1], Lucía Navarro[1], Fredy Prada[2], Gemma Gelabert[3], Sara Pérez[3], Maria Del Rocío Escobar[4], Silvia Ciprés[4], Marta Palomares[4], Ester Fernandez[4]

Hospital Sant Joan De Déu, Pediatric Palliative Care, Barcelona-Spain[1]; Hospital Sant Joan De Déu, Pediatric Cardiology, Barcelona-Spain[2]; Hospital Sant Joan De Déu, Clinical Documentation And Archives, Barcelona-Spain[3]; Hospital Sant Joan De Déu, Pediatric Palliative Care Unit, Barcelona-Spain[4]

Background/Hypothesis: Advance Heart Disease (AHD), continues to be a Life-Limiting condition and a leading cause of dead in pediatrics. Despite advances in the surgical and medical management of children suffering cardiac conditions little attention is paid to the end-of-life period. Uncertainties in prognosis and discrepancies in treatment goals between staff and family members have been described as barriers that interfere with optimal end-of-life care. The main objective was to analyze the model of care of patients attended by cardiologists and the Pediatric Palliative Care Team (PPCT).

Materials and Methods: Retrospective review of children with heart diseases attended by the PPCT in a tertiary care pediatric hospital from September 2009 to December 2016. Data is presented as Median (range).

Results: 18 patients with AHD (Structural Congenital Heart Disease (uni/biventricular), Cardiomyopathy, Arrhythmia and Pulmonary Hypertension) were attended. Median age: 6 years (8 days-18 years) at the time of palliative care consultation. Eight (45%) were females. Fifteen (85%) died [9 (60%) at home and 6 (40%) at the hospital]. The difference between survival times (1,48 month cardiac population and 5,8 months in the non-cardiac population) was not significant (p = 0,22)⋆. All children were

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

surrounded by their parents at the time of death. Thirteen (72%) had comorbidities. PPCT activity was: 109 home visits, 150 inpatients visits and 467 phone calls. The primary care team was involved in 9 (50%) cases.
Conclusion: PPCT Facilitates The End-Of-Life Follow Up Of Patients Suffering AHD. In Our Series, A Multidimensional Approach Allowed Patients To Be At Home During The End-Of-Life Period Surrounded By Their Families. Future Studies Should Evaluate Patient And Family Perspectives Of Patients Dying From AHD In Order To Implement Strategies Directed To Ease The Healing Process Of A Children Death.

P2270 - PEDIATRIC CARDIOMYOPATHY EXPERIENCE OF A UNIVERSITY HOSPITAL IN MARRAKESH MOROCCO

Nadia El Idrissi Slitine[1], Ouidad Louachama[1], Abdellatif Daoudi[1], Fatiha Bennaoui[1], Mariam Makkaoui Alaoui[1], Ghizlane Draiss[2], Fadel Maoulainine[1]
Nicu, Mother and Child Hospital, Med Vi Hospital, Marrakesh Medical School, Cadi Ayyad University, Pediatrics, Marrakesh-Morocco[1]; Pediatrics A, Mother and Child Hospital, Med Vi Hospital, Marrakesh Medical School, Cadi Ayyad University, Pediatrics, Marrakesh-Morocco[2]

Background: Pediatric cardiomyopathy is a rare and severe heart condition that affects infants and children. Specifically, cardiomyopathy means disease of the heart muscle (myocardium).
Objective: To evaluate the frequency, diagnostic difficulties, the management and outcome of this disease. Materials and methods: A retrospective study of all cases of cardiomyopathy hospitalized in the pediatrics department at the university hospital Mohamed VI Marrakech, from January 2011 to October 2016.
Results: Cardiomyopathy was found in 32 of 7627 hospitalized children, which represents a prevalence of 0.4%. The mean age was 1.9 years (Extremes [1 month; 8 years]), with a male predominance (18 boys and 13 girls). All patients were symptomatic, 78% of them had heart failure. According to the ultrasound data: 26 dilated cardiomyopathy (DCM), 4 hypertrophic (HCM) and 2 case of restrictive cardiomyopathy (RCM). The etiological investigation confirmed a carnitine deficiency in one patient only, myocarditis was diagnosed in 41% of cases. Treatment was essentially symptomatic in all cases except in one case of DCM where treatment involved carnitine as well, one patient received a heart transplant. The Evolution was favorable under symptomatic treatment in 75% of cases with complications in 15% of cases, 9% of which resulted in death.
Conclusion: Cardiomyopathy is a rare, yet serious disorder of the heart that stands as a frequent cause of heart failure and the most common cause of heart transplantation in children, with substantial negative impacts on children and their families, as well as significant healthcare costs. The management of this disease is tough in Morocco because of financial problems, the difficulty for accurate diagnostic, the absence of some treatment in the country, and the lack of pediatric cardiologist.

P2300 - PREVALENCE OF PULMONARY ARTERIAL HYPERTENSION IN NEWBORNS WITH PERINATAL ASPHYXIA

Shaad Abqari, Tauqueer Ahmed, Tabassum Shahab, Syed Manazir Ali Amu, Pediatrics, Aligarh-India[1]

Background: Pulmonary arterial hypertension in adults is usually described as a pulmonary artery pressure of 25 mm of Hg or more. However neonates form a unique group in which there is a transition from systemic PA pressures to normal adult value and clear cut off value which is clinically significant is not well defined and situation gets more complicated when neonate have one or the other risk factor for pulmonary hypertension.
Objective: Prevalence of Pulmonary Arterial Hypertension in Newborns with Perinatal Asphyxia.
Material and Methods: This was a prospective observational study in which newborns up to 1 month of age having history and clinical features of perinatal asphyxia were included in the study. Both newborns delivered in our hospital and neonates delivered outside our hospital but admitted in our neonatal high dependency were enrolled in the study. Echocardiography was done after 48 hours of life and children with PAH were identified, second screening was done at 6 weeks of life independent of cases having PAH or not at the first screening.
Results: Total numbers of cases of perinatal asphyxia screened were 41 out of which 18(43.9%) cases had PAH. Out of 18 cases 11 neonates expired after first screening. A total of 7 cases came for follow up at 6 weeks. We also found that out of 18 neonates 8 had reversal of shunt at the level of PDA or PFO and hence were classified as cases of PPHN. Only 1 case had persistence PAH at 6 weeks screening.
Conclusion: Newborns with perinatal asphyxia had significant association with development of PAH which dramatically changes the prognosis as mortality was quite high in patients who developed PAH and even worse in those who developed reversal of shunt and systemic desaturation.

P2301 - ELIGIBLE CANDIDATE FOR LEFT VENTRICULAR ASSIST DEVICE AND OR HEART TRANSPLANTATION SUPPORTED WITH EXTRACORPOREAL MEMBRANE OXYGENATION IN CHILD AFTER CARDIAC SURGERY

Miki Asano[1], Hidekazu Matsumae[2], Norikazu Nomura[2], Akira Mishima[2]
University of Tokoha, Health Promotional Sciences, Hamamatsu-Japan[1]; Nagoya City University, Cardiovascular Surgery, Nagoya-Japan[2]

Background: Although extracorporeal membrane oxygenation (ECMO) has served as one of the effective care for children

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

requiring mechanical support as a bridge-to-heart transplantation, initial indication of ECMO as a bridge-to-recovery might affect posttransplantation mortality in child of congenital heart disease after cardiac surgery. We aim to assess the morbidity and mortality in children requiring ECMO after cardiotomy and determine the eligible candidate for left ventricular assist device (LVAD) or heart transplantation.
Methods: Fifty-six infantile ECMO operations relating to congenital heart surgery were reviewed to analyze prognostic risks for the weaning of ECMO, the discharge of hospital and long-term survival were employed between January 2002 to December 2016.
Results: Age and weight were 13 ± 18months and 6.6 ± 3.3 kg, respectively. The mean follow-up was 5.6 ± 3.9year (0.4-13.6years). Twenty patients had single ventricle and 36 had biventricular physiology. The duration of ECMO was 8.1 ± 4.5 days. Forty-eight (85%) were successfully weaned off ECMO and 33 (59%) survived to hospital discharge. Eventually, 27 (48%) survived after hospital discharge. The weaning from ECMO was affected by peak serum lactate ≧ 60 mg/dl during ECMO (OR = 7.2, 95% CI: 1.5-1.8, p = 0.014) and the duration of ECMO ≧ 8days (5.0, 1.0-36.7, 0.046). Factors associate with failure of hospital discharge despite successful decannulation were as follows: weight ≧ 7 kg (0.24, 0.5-0.9, 0.024), ECMO duration ≧ 9days (3.6, 1.9-13.5, 0.041), the peak serum lactate ≧ 50 mg/dl of post ECMO (12.0, 1.5-5.2, 0.017). Ventricle physiology was not significant predictor. Survivor vs. non-survivor to the hospital discharge was 6.9 ± 4.1 vs. 9.8 ± 4.5 (day) in ECMO duration (p = 0.021). Post ECMO lactate ≧ 15 mg/dl was also affected in long-term survival.
Conclusions: Higher lactate levels more than 50 mg/dl and longer ECMO operation more than 8days are significant factors associated with mortality during ECMO and after successful decannulation. Patients with these conditions after cardiac surgery supported by ECMO are eligible candidates of LVAD and/or heart transplantation.

P2304 - PROFILE OF NEONATES WITH PULMONARY HYPERTENSION

Shaad Abqari, Tauqueer Ahmed, Tabassum Shahab, Syed Manazir Ali
Amu, Pediatrics, Aligarh-India

Background: Persistent Pulmonary Hypertension of Newborn (PPHN) is defined as a failure of normal fall in pulmonary vascular resistance (PVR) at or shortly after birth, leading to shunting of unoxygenated blood into the systemic circulation across foramen ovale or ductus arteriosus. Several risk factors are described which have association with PPHN in a newborn but there is little data on children with only PAH not severe enough to cause desaturation.
Objective: To study the outcome of neonates with risk factors having pulmonary hypertension on echocardiography.
Material and Methods: This was a prospective observational study in which newborns up to 1 month of age having risk factors for PPHN were included. Echocardiography was done after 48 hours of life and neonates with PAH were identified. Second screening was done at 6 weeks of life independent of cases having PAH or not at first screening. The spectrum and outcome these neonates was studied.
Result: Total numbers of neonates with PAH were 54 and out of these, 22(40.7%) cases were of Respiratory distress Syndrome (RDS), 18(33.9%) of perinatal asphyxia, 15(27.8%) of MSAF, 9 (16.7%) cases were of sepsis and twin delivery respectively. There were only 4(7.4%) cases of hypocalcemia, 3 cases were VLBW and 1 case of PIH. 12 cases had reversal of shunt and hence were classified as cases of PPHN. 13(24%) cases had expired of which 12 (22.2%) had perinatal asphyxia, 8(14.8%) had RDS, 3(5.5%) cases had MSAF and 4(7.4%) had sepsis. Neonates with multiple risk factors had the worst prognosis.
Conclusion: Various risk factors like RDS, perinatal asphyxia had significant association with development of PAH and mortality was significantly high in neonates with these risk factors after development of PAH.

P2318 - GROWTH DIFFERENTIATION FACTOR 15 AS A NOVEL BIOMARKER OF HEART FAILURE IN CONGENITAL HEART DISEASE WITH LEFT TO RIGHT SHUNT

Yoshiyuki Kagiyama, Yusuke Koteda, Shintarou Kishimoto, Kenji Suda
Kurume University, Pediatric Cardiology, Kurume City-Japan

Background: Growth differentiation factor-15 (GDF-15) is a member of transforming growth factor–beta superfamily. Recent studies suggested that GDF-15 is an early diagnostic marker of heart failure in repaired congenital heart disease (CHD) and dysfunction of Fontan circuit. To our knowledge, there is no study about GDF-15 in unrepaired CHD.
Aim: To determine the efficacy of GDF-15 as a marker of HF with unrepaired CHD with left to right shunt.
Method: Plasma GDF-15 levels were measured in 45 patients (19 males) with left to right shunt CHD that received cardiac catheterization from March 2016 to December 2016. Median patients' age was 6 years old (range 0 - 71). Diagnosis was atrial septal defect in 28, patent ductus arteriosus in 11, ventricular septal defect in 4, coronary artery fistula in 1, and double outlet right ventricle in 1, respectively. From medical record, we determined the correlation between GDF-15 and clinical HF score (Ross and New York Heart Association classification), hemodynamic variables determined in catheterization, and NT-pro BNP.
Result: Patient's Ross/NYHA class was I in 40, II in 2, III in 3, and IV in none. Median concentration of GDF-15 was of 260 pg/mL (11-1024), NT-proBNP was 127 pg/mL (10-7922), and Qp/Qs was 2.1 (1.1-5.8). Mean SvO2 was 69.0 ± 5.8%, cardiac index was 3.0 ± 1.1 L/min/m2, and oxygen extraction ratio (OER) was 28 ± 5.6%. Because the distribution of NT-proBNP was not normal, NT-proBNP was log transformed. GDF-15 positively correlated with Ross/NYHA class (r = 0.54, p < 0.0001), Log NT-proBNP (r = 0.68, p < 0.0001), and OER (r = 0.48, p = 0.0008), but negatively correlated with SvO2 (r = -0.58, p < 0.0001). There was no correlation between GDF-15 with other hemodynamic variables including Qp/Qs.
Conclusion: Growth Differentiation Factor-15 can be an early diagnostic marker of heart failure in unrepaired congenital heart disease with left to right shunt in wide age range and different diagnosis.

P2328 - ECHOCARDIOGRAPHIC ASSESSMENT OF PAH AND CORRELATION OF ECHO PARMETERS WITH ITS SEVERITY AND SYMPTOMATOLOGY

Rajesh Ramasamy, Sivakumar Kothandam, Sreeja Pavithran, Ramya Chandrasekar
Madras Medical Mission, Pediatric Cardiology, Chennai-India

We present various echo parameters of the right heart from our institutional registry of patients with PH, evaluate right heart anatomy, hemodynamics and correlate with clinical features. Patient symptomatology, echo parameters of all patients were analysed for this study. 210 patients aged 27.415.7 years registered

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

in our registry. Females dominated the registry. CHD associated PH constitutes (66.6%) and Idiopathic PH (30.4%). 72.2% were in NYHA II and 20.6% in NYHA III. Mean RVSP was 83.58. mean and diastolic PA pressures were 35.720 and 21.411.5 respectively. Estimated mean RA pressure was 12.5 + 8.9 mmHg. Increased RA area (>15.5 cm2) was seen in 76.4% patients and mean RA area was 20.81 cm2. Increased RV EDA >28 cm2 was seen in 38.7% and 36.4% had abnormal RV ESA >15 cm2.Mean FAC was 33 + 5.4% and 29% had FAC <32%. Abnormal RV strain <-18% was seen in 44% patients;mean strain was -17.73.74%. Abnormal PAT < 90 ms was seen in 39.2%; mean PAT value was 978ms. Pericardial effusion was seen in 13.8%. Study showed significant association of pericardial effusion with NYHA class III symptoms (p = 0.001), elevated RA pressure (p = 0.005, RA area >22 cm2 (p = 0.004), FAC <25% (P = 0.001), RV strain < -10% (p = 0.001), PAT <60 ms (p = 0.004). TAPSE <1.0 cm was associated with severe RV dysfunction (FAC 25 vs. 32%), right heart remodeling (RA area, 22 vs 15.5 cm2).Using logistic regression analysis,PE [p = 0.006,OR 4.03,95% CI(1.4-10.9)], RA area [p = 0.02, OR 3.1, 95% CI(1.1-8.0)] and PAT [P = 0.009, OR 0.34 95% CI(0.1-0.7)] were the 3 variables having significant correlation with symptoms. Our study identifies easily performed multiple echo parameters helpful in assessing the severity of PAH. With its close correlation to symptoms (NYHA class), echo parameters might be useful to assess outcomes, monitor the efficacy of therapy.

P2347 - OUTCOMES AND CHALLENGES IN 25 YEARS OF PEDIATRIC HEART TRANSPLANT IN A SINGLE INSTITUTION IN BRAZIL

Guilherme Viotto Rodrigues Da Silva[1], Carla Tanamati[1], Luiz Fernando Caneo[1], Aida Luiza Turquetto[1], Leonardo Augusto Miana[1], Juliano Gomes Penha[1], Estela Azeka[2], Nana Miura Ikari[2], Fabio Biscegli Jatene[3], Marcelo Biscegli Jatene[1]
Incor, Pediatric Cardiac Surgery, Sao Paulo-Brazil[1]; Incor, Pediatric Cardiology, Sao Paulo-Brazil[2]; Incor, Cardiac Surgery, Sao Paulo-Brazil[3]

Background: Pediatric heart transplants (PHTX) continue to be the therapy of choice for children with end-stage heart failure. Since 1992, we have been experiencing challenges facing the interplay of limited donor supply and resources for mechanical circulatory support (MCS) and increase in growing-up congenital heart (GUCH) population. Recent reports suggest worse outcomes in congenital heart disease (CHD), specially in post-Fontan patients.
Hypothesis: Review our outcomes and risk factors in three distinct etiologies: cardiomyopathy (CMP), congenital heart disease (CHD) and Post-Fontan (s/p Fontan) patients. Casuistic and Methods: From 1992 to december 2016, 198 PHTX were performed in 190 patients:133 CMP (67,2%), 54 CHD (27,3%) and 11 post Fontan (5,6%) patients. The median age was 7,4 years (interquartile range 2,92-12,43 y), 49.7% male. Ten patients with GUCH diagnosis. Retrospective analysis was done using our medical record databank (Si3). Kaplan-Meier actuarial survival curve was obtained. Cox proportional-hazard regression method was used for univariate and multivariate risk analysis with 95% confidence interval using SPSS 23.0 (IBM,USA).
Results: Overall survival was 62,1% in 25 years. 30-day survival was 90,2%, 77,8% and 54,5% for patients with CMP, CHD and s/p Fontan respectively. One-year survival were 81,2%, 66,7% and 54,5% respectively and 10-year survival 71,4%, 55.6% and 54.5% respectively (log-rank p = 0,027). Re-transplants were done in 8 patients. The requirement for MCS after PHTX was greatest in patients with CHD (p = 0,001). Multivariate analysis revealed two significant risk factors for mortality: cardiopulmonary bypass time (hazard ratio[HR], 1.009; p = 0.027) and MCS as a bridge to PHTX (HR, 5.544; p = 0.003). CHD was a risk fator for early mortality (Odds Ratio 2.924, p = 0,006).
Conclusion: CHD and specially post-Fontan patients are higher risk groups in PHTX.

P2358 - THE PROGNOSTIC VALUE OF ECHOCARDIOGRAPHIC DIASTOLIC FUNCTION PARAMETERS IN PAEDIATRIC DILATED CARDIOMYOPATHY

Sabrina Bressieux-Degueldre[1], Matthew Fenton[1], Troy Dominguez[2], Michael Burch[1]
Great Ormond Street Hospital for Children, Paediatric Cardiology, London-United Kingdom[1]; Great Ormond Street Hospital for Children, Paediatric Cardiac Intensive Care, London-United Kingdom[2]

Background: Predicting the clinical course of paediatric dilated cardiomyopathy (DCM) remains challenging. Diastolic dysfunction is thought to be an important determinant for prognosis and survival in several paediatric heart diseases; however, its role has not been investigated in children with DCM.
Methods: We reviewed the first echocardiogram with diastolic function assessment for all children with dilated cardiomyopathy due to myocarditis, familial or idiopathic DCM from January 2006 to present. The association between diastolic function parameters and outcome was analyzed. Outcome was defined as recovery, stabilization and transplant or ventricular assist device for bridge-to-transplant. A univariable and multivariable analysis was performed using Cox regression to determine predictors of outcome.
Results: 44 echocardiograms of children with DCM were reviewed. The cause of DCM was familial for 8 patients, idiopathic for 26 and myocarditis for 10. Eight patients required cardiac transplant or mechanical assist devices (18%), 24 had persistently abnormal left ventricular function and/or dilatation (55%) and 12 patients recovered (27%). Median age was 1.7 years (range 0.17 to 16.08 years) and median duration of follow up was 3.0 years (range 0.17 to 8.6 years). Smaller values for lateral and septal E wave velocities on TDI and higher lateral E/E' ratios were associated with worse outcome (Table 1). Higher left ventricular end diastolic diameter z-scores (LVEDDz) and lower indices for left ventricular systolic function (fractional shortening (FS) and lateral S wave velocities on TDI) predicted for worse outcome. In a final multivariable model lower lateral S wave velocities were

Table.

	Univariable Analysis			Multivariable Analysis		
Variable	Hazard Ratio	95% CI	p-value	Hazard Ratio	95% CI	p-value
FS (%)	0.95	0.90-0.99	0.03			
LVEDDz	1.27	1.10-1.47	0.001	1.25	1.08-1.46	0.003
LVESD	1.05	1.01-1.09	0.01			
E/E'	1.05	1.0-1.10	0.02			
$E_{lateral}$	0.90	0.82-0.97	0.01			
E_{septum}	0.85	0.74-0.97	0.01			
$A_{lateral}$	0.90	0.74-1.10	0.31			
A_{septum}	0.98	0.90-1.06	0.6			
$S_{lateral}$	0.79	0.66-0.95	0.01	0.83	0.69-1.0	0.05
S_{septum}	0.81	0.65-1.02	0.08			
MV_A	0.79	0.16-3.80	0.77			
MV_E	0.99	0.98-1.0	0.06			
MV_{slope}	0.13	0.03-0.61	0.01			
E/A ratio	0.75	0.44-1.29	0.30			

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

significantly associated with persistent or worsening disease (Hazard ratio, 0.83; p = 0.05) after adjusting for LVEDDz (Hazard Ratio, 1.25; p = 0.003).
Conclusions: Systolic function remains the most powerful predictor of outcome in paediatric DCM, but selected echocardiographic measurements for diastolic function can also help to predict outcome and warrant consideration in the assessment of these children..

P2360 - CARDIAC EXAMINATION IN CHILDREN WITH LARON SYNDROME TAKING MECASERMIN TREATMENT

Nurdan Erol[1], Metin Yildiz[2], Ayla Güven[2], Ayse Yildirim[3]
Istanbul Medeniyet University Goztepe Education and Research Hospital, Pediatric Clinics, Istanbul-Turkey[1] Istanbul Medeniyet University Goztepe Education and Research Hospital, Pediatric Endocrinology Clinic, Istanbul-Turkey[2]; Kartal Kosuyolu Research and Training Hospital, Pediatric Cradiology, Istanbul-Turkey[3]

Introduction: Laron syndrome (primary growth hormone resistance or insensivity) is a rare genetic disease inherited autosomal recessive, although indistinguishable from growth hormone deficiency, it has high level growth hormone but IGF-1(insuline-like growth factor) and its related molecules can not syntesize.IGF-1 axis is important for cardiac development and cardiac protection. Mecasermin treatment is the only option for this patient. This study aims to research cardiac findings of children with Laron Syndrome taking mecasermin.
Materials and Method: The children with Laron Syndrome included in this study were diagnosed by applying growth hormone induction and IgGF-1 generation tests to children who have growth failure, at the pediatric endocrinology clinic. Their demografic data was obtained from their family and files. The children have taken mecasermin at 0,04-0,12 mcg/kg dose twice dubcutan injection per day, except for one child, who is going to take treatment after a six month follow-up. All of them were examined clinically, by electrocardiogram and echocardiogram.
Results: The study includes six children (4 male, 2 female). Three of them are siblings.Their ages were 5,76 + /-2,39 years. The treatment's duration was 8 to 53 months. Sistolic sufl was diagnosed in one child on the cardiac exam. They did not have arytmia. The echocardigrams did not show congenital cardiac anomaly, except patent foramen ovale in two patients. The echocardiogram of the child with sufl, showed pulmonary hipertension findings. These findings were proven angiographically. The patient's vasoreactivity test results were negative. Bosentan terapy was started. The reason of the ethiology of pulmonary hypertension is unknown.
Conclusion: In the literature we could not find pulmonary hipertension in childrin with Laron Syndrome, with or without mecasermin treatment. Cardiac findings and pulmonary pressures should be investigated on bigger series.

P2363 - AN OVERVIEW OF CURRENT PULMONARY HYPERTENSION TREATMENT IN SPAIN

Natalia Rivero Jiménez[1], Alejandro Rodríguez Ogando[2], Carlos Labrandero De Lera[3], Antonio Moreno[4], Alberto Mendoza Soto[5], Javier Gavilán[6], Antonio Moya[7], E Gómez[8], Marta López[9], María Jesús Del Cerro Marín[1]
Ramón Y Cajal Hospital, Pediatric Cardiology, Madrid-Spain[1]; Gregorio Marañón Hospital, Pediatric Cardiology, Madrid-Spain[2]; La Paz Hospital, Pediatric Cardiology, Madrid-Spain[3]; Vall D´hebron Hospital, Pediatric Neumology, Barcelona-Spain[4]; Doce De Octubre Hospital, Pediatric Cardiology, Madrid-Spain[5]; Virgen Del Rocío Hospital, Pediatric Cardiology, Sevilla-Spain[6]; La Fe Hospital, Pediatric Cardiology, Valencia-Spain[7]; Reina Sofía Hospital, Pediatric Cardiology, Córdoba-Spain[8]; Miguel Servet Hospital, Pediatric Cardiology, Zaragoza-Spain[9]

Backgound: Treatment options for pulmonary hypertension (PH) have evolved considerably in the past decade. However, the management of pediatric PH remains challenging as treatment decisions depend largely on experience of clinicians treating children. The aim of our study was to give a current view of PH treatment in our country.
Materials and Methods: A national, multicenter, retrospective, descriptive study was designed with the data collected in the Spanish Registry for Pediatric PH (REHIPED) about targeted therapies (TT).
Results: In April 2016, a total of 514 patients were registered in REHIPED (157 were dead, underwent lung transplantation or lost of follow up, and 357 were alive). Alive patients were classified into 2 groups: patients with a single ventricle physiology (Fontan group: mPAP <25 mmHg; n = 156; 44%) and patients with a biventricular circulation (PH group: mPAP >25 mmHg, PVRI >3 WU.m2; n = 201; 56%). Classification of Pulmonary Hypertension (WHO, Nice) in PH group was: 70% group I, 10%, group II, 17%, group III, 1% group IV and 2% and group V. TT were present in 75% of Fontan patients (117/156) and 71.6% of PH patients (144/201; 104 patients (73.8%) belonging to group I). Different treatments classified by groups are shown in the table. Monotherapy was present in 46% (n = 67) of PH patients treated, double therapy in 32% (n = 46, 72% Sildenafil + Bosentan; 78.7% group I) and triple therapy in 22% (n = 31; 39% Sildenafil + Bosentan + Treprostinil; 39% group I). In Fontan patients treated, 85% (n = 99) were in monotherapy, 14% in dual therapy (n = 17; 100% Sildenafil + Bosentan) and 1% in triple therapy (n = 1; Sildenafil + Bosentan + Iloprost).
Conclusions: In 2016 Spain, about 2/3 of patients received TT, most with Phosphodiesterase inhibitors. TT use is increasing in Fontan patients last years. Combined therapies were commonly used in PH patients.

Table.

Hospital, Pediatric Cardiology, Madrid-Spain[3]; Virgen Del Rocío Hospital, Pediatric Cardiology, Sevilla-Spain[4]; Doce De Octubre Hospital, Pediatric Cardiology, Madrid-Spain[5]; La Fe Hospital, Pediatric Cardiology, Valencia-Spain[6]; A Coruña Hospital, Pediatric Cardiology, A Coruña-Spain[7]; Gregorio Marañón Hospital, Pediatric Cardiology, Madrid-Spain[8]; Marqués De Valdecilla Hospital, Pediatric Cardiology, Cantabria-Spain[9]

Backgound: Prostacyclin therapy has formed the main stay of pulmonary hypertension (PH) therapy for many years and has improved functional status and survival for both adult and pediatric patients. The aim of our study was to describe the use of prostacyclins in children in our country.
Materials and Methods: A national, multicenter, retrospective, descriptive study was designed with the data collected in the Spanish Registry for Pediatric PH (REHIPED) about the use of prostanoids.
Results: In May 2016, a total of 492 patients were registered in REHIPED, 19% of them (n = 95) received /have received prostanoid therapy (PT). 3 cases were excluded for having univentricular circulation. Mean age at PH diagnosis was 3.3 ± 3.8 years (55% female). Mean time from diagnosis to start PT was 14.5 ± 25.5 months. Etiology Classification of Pulmonary Hypertension (WHO, Nice) included: 63% group I (41.3% idiopathic PH), 7.6% group II, 22.8% group III (66.6% bronchopulmonary dysplasia) and 6.5% group V (100% metabolopathies). Most patients (67%) before PT took 1 or 2 oral targeted theraphies (39% combined therapy, 28% monotheraphy) and 61% were in functional class III-IV. Distribution of PT by etiology groups is showed in the graphic. 7 patients received combined treatment with 2 prostanoids (85.7% Iloprost + Treprostinil). Most frequent adverse event with Iloprost was facial flush, Epoprostenol pulmonary edema and Treprostinil headache. Outcomes of PT after mean follow up of 3.9 ± 3.9 years were: 56.5% alive, 33.6% dead, 7.6% lung transplanted and 2.1% Potts shunt (n = 2; 1 alive; 1 dead). First cause of death was heart failure, followed by infection. Best survivals were found in group I and III, with no statistically significant differences.
Conclusions: In Spain, about 1/5 of PH patients have received prostanoids, most as a second/third line treatment. We have more experience in group I and with Iloprost and Treprostinil.

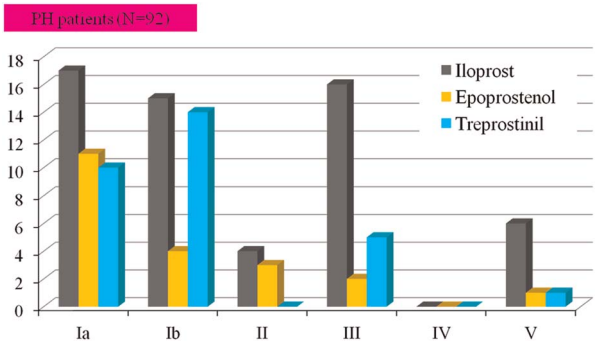

Figure.

P2395 - MECHANICAL CIRCULATORY SUPPORT STRATEGY OF BRIDGING TO PULSATILE FLOW IN PEDIATRIC PATIENTS IMPACT ON EARLY NEUROLOGIC EVENTS

Maryanne Chrisant, Gerald Lavandosky, Steve Bibevski, Megan Zakrzewski, Robert Winchester, Kak-Chen Chan, Frank Scholl
Joe Dimaggio Children, Heart Institute, Davie-United States

Background: Elective mechanical circulatory support (MCS) is used as triage as well as bridge to heart transplant (HTx). The incidence of neurologic (CNS) events, defined as having lasting motor or functional deficit, remains high, with clustering of events early post-implant when anticoagulation is not stabilized & post-operative bleeding predominates. Centrifugal MCS with Pedi or Centrimag (PM) support allows for less intense anticoagulation & a period of recovery immediately post-implant.
Methods: We compared our pts receiving MCS as triage or bridge to HTx: Group 1 (G1) pts received support from 1/10/2011 through 12/31/2014, N = 6; Group 2 (G2) pts received MCS 1/1/15 through 1/29/17, N = 6. G1 pts were placed on Berlin Heart Excor (BH) as chronic support until HTx (N = 6); G2 pts were placed on PM, if age < 15 yr, until adequately anticoagulated, then transitioned to BH (N = 5). Baseline demographics shown in Table 1.
Results: Incidence of CNS events in G1 was 67% (4/6) & in G2 was 33% (2/6). Time to CNS event in G1 was 7.75 d, range 1-11 d, & in G2 occurred at 4 & 9 d (6.5 d avg). Anticoagulation at CNS event in G1 & G2 was sub-therapeutic in all instances. Outcomes: In G1, all pts survived to HTx; in G2, 3/6 pts received HTx, 2/6 pts are waiting HTx on BH, 1 pt died after major CNS event while still on PM.
Conclusions: Elective MCS support with PM, as bridge to decision, HTx or BH conversion, shows promise resulting in fewer early CNS events in this small cohort of pts.

Table 1.

	Age (Avg, Med, R), yr	Diagnosis DCM: LVNC	CPR & ECMO prior to MCS	Atrial Communication at MCS implant	Normal CNS exam 24 hr prior to MCS	Listed 1st : MCS 1st	Duration PM Support (Avg, Med, R), d

Background: Heart transplantation is a therapeutic option for refractory heart failure. Graft vascular disease (GVD) is one of the limitations of long-term survival and may require new heart transplantation.
Patients and Methods: It was a retrospective observational study in cohort of children and adults with congenital heart disease submitted to heart transplantation between 1992 and 2017 at the Heart Institute (InCor) University of Sao Paulo Medical School. The incidence of re-transplantation and clinical outcome were analysed.
Results: Of the 190 patients who underwent heart transplantation, 6 required re-transplantation for GVD. The diagnosis of GVD was made by coronary angiography. The interval between the first and second transplants ranged from 9 to 19 years. The principal lesions were the right coronary artery (80%) and the anterior descending artery (60%). Two of the patients had renal failure as co-morbidity and required renal transplantation. One patient had renal transplant simultaneously and the other after cardiac transplantation. Two patients (33%) died in the immediate postoperative period after re-transplantation. The remaining patients (66%) were well and followed up at outpatient clinics.
Conclusion: The development of a coronary disease (GVD) is one of the main complications that limit the survival of cardiac transplant patients in the long term and re-transplantation is a successful therapeutic option.

P2411 - COMPARISON OF THE HEMODYNAMIC EFFECTS OF DOBUTAMINE AND NOREPINEPHRINE IN RIGHT VENTRICULAR PRESSURE OVERLOAD FAILURE

Janus Adler Hyldebrandt[1], Camilla Omann[2], Nikolaj Bøgh[3], Peter Agger[4]
Akershus University Hospital, Dept. of Anaesthesia And Intensive Care, Oslo-Norway[1]; Aarhus Unversity Hospital, Dept. of Cardiothoracic and Vascular Surgery, Aarhus-Denmark[2]; Aarhus Unversity Hospital, Mr Research Center, Aarhus-Denmark[3]; Aarhus Unversity Hospital, Dept. Pediatrics, Aarhus-Denmark[4]

Background: Right ventricular (RV) failure due to chronic pressure overload is an important determinant of outcome in congenital heart disease. Optimal inotropic therapy in the perioperative setting is challenging by the notion that not only contractility but also the interventricular interaction and arterio-ventricular relationship is manipulated. Several studies indicates that by increasing left ventricular (LV) afterload RV contractility can be improved, due to ventricular-ventricular interaction, hence improving cardiac index (CI).
Materials and Method: RV pressure overload was induced by pulmonary artery banding (PAB) for 16 weeks in 5 animals, and compared to 6 controls. Biventricular performance and hemodynamics were evaluated using biventricular conductance catheters, pulmonary catheter, and pressure transducers during infusion of norepinephrine (0,05–0,1–0,25-0,5 µg/kg/min) and dobutamine (0,5-1,0–2,5-5,0 µg/kg/min). We used a cross-over design and analyzed the results using repeated ANOVA analysis.
Results: After 16 weeks of RV pressure overload, Pmax was higher (45 vs 27 mmHg, $p = 0{,}001$) and Left ventricular volume (65 Vs 105 ml/m^2, $p < 0{,}001$), systolic pressure (78 Vs 98 mmHg) and cardiac index (CI) (4,0 Vs 5,4 L/m2/min, $p = 0{,}04$) were lower in PAB. During incremental inotrope infusions norepinephrine produced higher MAP ($p < 0{,}0001$) compared to dobutamine, increases in CI, HR and SV were equal between the groups. LV Arterial elastance (Ea) was significantly greater in norepinephrine treated PAB animals ($p > 0{,}001$), and the inotropic effect (PRSW) of norepinephrine in the LV was greater in PAB animals compared to control ($p < 0{,}05$), hence upholding the arterio-ventricular coupling and stroke volume.
Conclusion: In right ventricular pressure overload failure, with reduced LV volumes, CI and MAP, norepinephrine provided the same increase in CI but with higher MAP compared to dobutamine due to unchanged aterio-ventricular relationships in both ventricles.

P2417 - MECHANICAL CIRCULATORY SUPPORT IN PEDIATRIC HEART TRANSPLANTATION AND IN ADULTS WITH CONGENITAL HEART DISEASE SINGLE CENTER EXPERIENCE

Vanessa Guimarae[1], Marcelo Jatene[2], Luis Caneo[2], Adailson Siqueira[3], Leonardo Miana[2], Juliano Penha[2], Carla Tanamati[2], Nana Miura[3], Estela Azeka[3]
Heart Institute (Incor) University of Sao Paulo, Anesthesiology, Sao Paulo-Brazil[1]; Heart Institute (Incor) University of Sao Paulo, Cardiac Surgery, Sao Paulo-Brazil[2]; Heart Institute (Incor) University of Sao Paulo, Pediatric Cardiology, Sao Paulo-Brazil[3]

Background: Heart transplantation is the option therapy for patients with refractory heart failure. However, cardiogenic shock may occur before and after transplantation and the use of mechanical assistance circulatory support may be required. The objective of this study was the analysis of the use of mechanical cardiopulmonary support in pediatric patients and in adults with congenital heart disease before or after cardiac transplantation.
Patients and Methods: A retrospective clinical study of patients hospitalized with a diagnosis of pre or post transplant cardiogenic shock who used mechanical circulatory support (ECMO ™, Biopump ™ or Berlin Heart ™) from September 1999 to August 2016. Results: We included 44 patients submitted to mechanical circulatory support pre or after transplantation. The majority of patients were female (n = 26. 5%), aged 4 months to 27 years and weight of 5 to 48 kg. Short mechanical circulatory support (ECMO) was used in 28 (63.6%) patients, being in 16 (57.14%) of these as a bridge for transplantation. Biopump was installed in 17 (38.63%) and Berlin Heart in four (9%) patients. The shortest period in circulatory support care was 6 hours and the highest one was in one patient who used Berlin Heart for 334 days until transplantation. Heart transplantation was performed in 33 patients (75%) and 2 (4.5%) underwent re-transplantation. Renal insufficiency requiring dialysis, SIRS and stroke were the most frequent causes of death after transplantation, with the current survival of this group - 6 patients.
Conclusion: The installation of a mechanical circulatory support in patients with heart failure refractory to clinical treatment could be an option as a bridge for heart transplantation and helped to manage complications after the procedure.

P2419 - NOVEL NON INVASIVE ECHOCARDIOGRAPHIC MARKERS OF DISEASE PROGRESSION IN PEDIATRIC PULMONARY HYPERTENSION

Manish Aggarwal[1], Swati Choudhry[1], Philip Levy[2], R. Mark Grady[1], Gautam Singh[1]
Washington University School of Medicine, Pediatrics, St Louis-United States[1]; Goryeb Children, Pediatrics, Morristown-United States[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background and Hypothesis: Pulmonary hypertension (PH) carries a poor prognosis due to eventual right ventricular (RV) failure. Although pulmonary artery systolic pressure (PASP) is used as a marker of PH severity, it is a poor prognostic marker of disease progression and for risk stratification. We sought to evaluate RV work from length-force relationship and pulmonary artery (PA) compliance and load as novel markers of PH disease progression in pediatric patients.
Method and Material: In a retrospective study, we analyzed echocardiographic indices in 20 children with confirmed PH (by catheterization). We measured tricuspid annular plane systolic excursion (TAPSE) for length shortening to assess RV systolic function, tricuspid regurgitation (TR) jet velocity to estimate PASP, and PA acceleration time (PAAT) to evaluate PA compliance and resistance. TAPSExPASP and TAPSExPAAT were calculated to develop length-force relationship as indices of RV work. The children were divided into two groups based on who reached a composite endpoint (intravenous pulmonary vasodilator, Potts shunt, lung transplant, or death) (group 1, n = 8) and those who did not (group 2, n = 12). Comparisons of the echocardiographic indices were made to an age/weight- matched controls (n = 11), and ANOVA was used to compare the indices amongst the three groups.
Result: TAPSE, PAAT, TAPSExPAAT were all significantly reduced in PH patients who reached the composite endpoints compared to PH patients who did not reach the endpoint and controls ($p < 0.01$ for all). Although PASP and TAPSExPASP were significantly reduced in PH patients when compared to the controls ($p < 0.01$ for both), they were similar between two PH groups ($p = 0.43$ and $p = 0.99$) (Table 1).
Conclusions: TAPSExPAAT as indices of RV work and PAAT as an index of PA load and compliance offer quantitative markers of disease progression in pediatric patients with PH that may be useful for risk stratification for intervention.

Table 1. Comparison of Echocardiographic Measures

		Pulmonary Hypertension		
	Pediatric Controls (n = ll)	**Do not reach endpoints* (n = 12)**	**Reach endpoints* (n = 8)**	**P values**
RV function TAPSE (cm)	2.0 (0.1)	1.6 (0.3)§	1.3(0.1)**†	p < 0.001
Pulmonary Hemodynamics				
PASP (mmHe, derived byTR jet velocity)	20‡	62 (27)§	76 (24)	p = 0.43
PAAT (msec)	127(16)	90(15)§	65(13)** †	p < 0.001
RV Work (length x force)				
TAPSE x PASP (cm x mmHg)	41 (2)	96 (46)§	96(25)†	p = 0.003
TAPSE x PAAT (cm x msec)	262(43)	152(40)§	82(16)** †	p < 0.001

Values are presented as mean (standard delation). One way ANOVA was used to compare the measures amongst the 3 groups
R.V. right ventricle; TAPSE. tricuspid annular plane systolic excursion (cm)
‡PASP. pulmonary artery systolic pressure. PASP was assumed to be normal for controls (~20mmHg) TR; tricuspid regurgitation (meters/sec); PAAT. pulmonary artery acceleration time (msec)

★Composite endpoints. defined as me need for intravenous medication, hang transplantation. Potts shunt, or death
** $p < 0.05$. PH patients who reach composite endpoint compared with PH patients who do not reach endpoints;

§$p < 0.01$. PH patients who do not reach composite endpoint compared with pediatric controls;
†$p < 0.05$ PH patients who reach composite endpoints compared with pediatric controls

P2428 - HEART TRANSPLANTATION IN CHILDREN AND ADULTS WITH CONGENITAL HEART DISEASE CHARACTERISTICS OF EFFECTIVE DONORS – SINGLE CENTER EXPERIENCE

Vanessa Guimaraes[1], Marcelo Jatene[2], Adailson Siqueira[3], Juliano Penha[2], Leonardo Miana[2], Ana Tanaka[3], Ana Thomaz[3], Leina Zorzanelli[3], Estela Azeka[3]

Heart Institute (Incor) University of Sao Paulo, Anesthesiology, Sao Paulo-Brazil[1]; Heart Institute (Incor) University of Sao Paulo, Cardiac Surgery, Sao Paulo-Brazil[2]; Heart Institute (Incor) University of Sao Paulo, Pediatric Cardiology, Sao Paulo-Brazil[3]

Introduction: Cardiac transplantation is a safe and effective alternative in the treatment of refractory heart failure. In order to ensure the integrity of the organ obtained and reduce risks to the recipient, some criteria must be respected.
Objective: To evaluate the characteristics of donors accepted for children for heart transplantation as well as the refusal of potential donors. Methods: A retrospective descriptive study was carried out in which the records of potential donors for children and adults with congenital heart disease were evaluated from October 2014 to August 2016 for anthropometric, clinical and laboratory findings.
Results: A total of 225 donors, aged between 6 months and 59 years, of which 118 (52.44%) were male. The main causes of donor brain death were: hemorrhagic stroke in 86 (38%) cases, trauma in 76 (34%), encephalopathy pos- cardiac arrest in 15 (7%), bacterial meningitis in 8 (4%) and Firearm accident in 8 (4%). Among the main criteria for refusal of the organs were: incompatibility in 76 (34%) cases, echocardiogram and/or electrocardiogram abnormalities in 71 (32%) cases, sepsis in 40 (18%), systemic arterial hypertension in 36 (22%), the occurrence of cardiac arrest in 23 (10%),hemodynamic instability in 22 (10%), difficulties related to logistics (distance between cities, availability of aircraft and climatic conditions for landing and takeoff) on 16 (7%) occasions, in 8 cases (4%) due to virtual positive cross-match and other issues (11%). Twenty-nine transplants were performed in this period, making a 13% utilization rate of the organs offered.
Conclusion: The majority of donors were male, died due to central nervous system diseases, of vascular or traumatic causes and the main criteria of refusal of the organs were anatomical disproportion, cardiac function alterations and sepsis.

P2434 - AUTOMATIC IMPLANTABLE CARDIOVERTER DEFIBRILLATOR IN CHILDREN WITH DILATED CARDIOMYOPATHY

Arpit Agarwal[1], Nurin Jivani[1], Ming-Ion Young[2], Paolo Rusconi[1] University of Miami/Jackson Memorial Hospital, Pediatric Cardiology, Miami-United States[1]; Joe Dimaggio Children's Hospital, Pediatric Cardiology, Hollywood-United States[2]

Background: Sudden cardiac death (SCD) is a known risk in patients with dilated cardiomyopathy (DCM). Predictors of SCD in children with DCM are not well defined. In children with DCM we looked for predictors of fatal arrhythmias and efficacy of automatic implantable cardioverter-defibrillator (AICD).
Methods: From 1999 to 2011,out of 300 children with heart failure, we identified 100 children with DCM. Medical records were reviewed for demographic information, New York Heart Association (NYHA) or Ross functional class, left ventricular ejection fraction (LVEF), left ventricular diastolic diameter dimension indexed by BSA (LVDDz), NTproBNP levels and outcome. The patients were divided into 2 groups: Group 1, with no AICD implantation; Group 2, with AICD implantation.
Results: Mean age of presentation was 7.6 ± 6.6 years, mean follow-up was 6 ± 5.3 years. AICD was placed in 23 patients (23%) because of ventricular tachycardia. The median time from presentation to AICD placement was 667 days. There was no difference in sex, ethnicity or race between the two groups. The age of presentation was significantly higher in Group 2 (Table-1). There was no significant difference in LVEF, NTproBNP,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

LVEDDz and NYHA/Ross class at presentation. At the last follow up (endpoint), NYHA/Ross class, NTproBNP and LVEF were significantly worse in Group 2 compared to Group 1 (Figure-1). Significantly higher number of patients in Group 2 required heart transplant. In the patients with AICD, there were 56 appropriate shocks in 10 patients and 9 inappropriate shocks in 7 patients.
Conclusions: Based on the information analyzed, we were not able to distinguish patients at risk of arrhythmia at time of initial presentation. Patients requiring AICD placement were older and showed worsening LVEF, NYHA/Ross class and higher NTproBNP, reflective of more severe disease. AICD can effectively rescue patients from VT and avoid sudden cardiac death; the number of inappropriate shock was small.

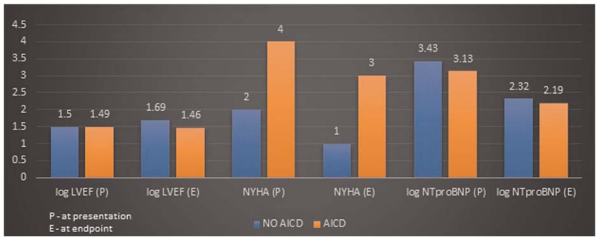

Figure.
Heart Failure Parameters in Children with and without AICD

P2441 - MANAGEMENT OF PULMONARY HYPERTENSION ASSOCIATED WITH A LARGE PATENT DUCTUS ARTERIOSUS IN EXTREMELY PRETERM INFANTS WITH BRONCHOPULMONARY DYSPLASIA

Kaitlin Balduf, Ranjit Philip, Alejandro Arevalo, Rush Waller, Shyam Sathanandam
Lebonheur Children's Hospital, University of Tennessee, Pediatrics, Memphis-United States

Background: Children born premature often have a patent ductus arteriosus (PDA), which in association with broncho-pulmonary dysplasia (BPD) in these patients leads to early onset pulmonary hypertension (PHT). The objective of this study was to evaluate the hemodynamics and determine the effects of pulmonary vasodilation and PDA closure in these patients.
Methods: Premature infants that had severe PHT, defined as a pulmonary artery systolic pressure (Pap) > 50% of the systolic blood pressure (SBP), with severe BPD (ventilator and oxygen dependency) and a large PDA were evaluated over a 4-year-period. Those with another level of left-right shunting were excluded. All patients underwent cardiac catheterization. Hemodynamic assessment at baseline, followed by pulmonary vasodilatory therapy with and without test occlusion of the PDA was performed.
Results: Twenty patients born prematurely (26.2 ± 3.5 weeks' gestation, birth weight = 739 ± 324 grams), underwent cardiac catheterization at 102.6 ± 50 days of age, weighing 2.1 ± 0.68 Kg. At baseline ventilator support, the Qp:Qs was 1.5 ± 0.5, Pap was 74 ± 14% of SBP, and PVR was 3.94 ± 2 Wu•m2. With 100% oxygen and inhaled nitric oxide, the Qp:Qs increased to 2.6 ± 1, Pap decreased to 54 ± 10% of SBP, and the PVR decreased to 1.9 ±1.2 Wu•m2. At this stage when the PDA was test occluded, the shunt was eliminated with further decrease in the Pap and PVR (in all but one patient). Based on these findings, the PDA was closed in nineteen of the twenty patients.
Conclusions: Pulmonary vasodilator therapy for PHT increases the PDA shunt in the premature infants which could worsen BPD. Therefore, closure of the PDA could be beneficial in the effective management of PHT and BPD in these patients. Transcatheter PDA closure can be accomplished during the time of the hemodynamic catheterization.

P2468 - HEART TRANSPLANTATION IN CHILDREN AND ADULTS WITH CONGENITAL HEART DISEASE POST TRANSPLANT LYMPHOPROLIFERATIVE DISORDER – 25 YEARS OF SINGLE CENTER EXPERIENCE

Estela Azeka[1], Vicente Odone[2], Adailson Siqueira[1], Vera Aiello[3], Nana Miura[1], Marcelo Jatene[4]
Heart Institute (Incor) University of Sao Paulo, Pediatric Cardiology, Sao Paulo-Brazil[1]; University of Sao Paulo, Oncology, Sao Paulo-Brazil[2]; Heart Institute (Incor) University of Sao Paulo, Pathology, Sao Paulo-Brazil[3]; Heart Institute (Incor) University of Sao Paulo, Cardiac Surgery, Sao Paulo-Brazil[4]

Background: Heart Transplantation has been the option for treatment of patients with refractory heart failure or inoperable congenital heart disease. However after the procedure, one of the main complications is post-transplant lymphoproliferative disorder (PTLD). The aim of this study is to report the incidence of PTLD after heart transplantation using double immunosuppressive maintenance therapy.
Patients and Methods: It is a retrospective observational study from a cohort of 190 patients who were submitted to heart transplantation at the Heart Institute (InCor) University of Sao Paulo Medical School from 1992 to 2017. The immunosuppressive therapy was calcineurin inhibitor and citostatic drugs. The diagnosis of PTLD was made by pathology findings and imaging methods.
Results: 21 of 190 (11%) patients developed PTLD. 7 (33%) were male. The sites of the disease were: 9 (42.8%) cervical lymph nodes, gastrointestinal 7 (33%) and 4 in the lungs. The treatment consisted of reduction of immunosuppressive drugs, the use of rituximab and sirolimus. The survival was 71.4%. The causes of mortality were 5 (83.3%) infection and 1 sudden death.
Conclusions: PTLD is a challenging complication after transplantation. The management of immunosuppressive drugs improved the survival.

P2481 - ANEURYSMATIC FISTULAS IN PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM IN CHILDREN CANDIDATES FOR HEART TRANSPLANTATION

Gabriel Carmona[1], Marcelo Jatene[2], Adailson Siqueira[1], Raul Arrieta[1], Walter Ishikawa[1], Nana Miura[1], Estela Azeka[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Heart Institute (Incor) University of Sao Paulo, Pediatric Cardiology, Sao Paulo-Brazil[1]; Heart Institute (Incor) University of Sao Paulo, Cardiac Surgery, Sao Paulo-Brazil[2]

Introduction: The presence of anomalous coronary pathways has been seen in pathological studies of children for more than 60 years. There is a broad spectrum of coronary lesions in patients with pulmonary atresia with intact ventricular septum, the most common being the presence of ventriculo- coronary fistulas observed in 45% of the cases. The objective of this study is to report two patients diagnosed with pulmonary atresia with intact ventricular septum with coronary sinusoides in the postoperative period of Glenn's surgery and Blalock-Tausing surgery with aneurysmal dilatation of the right and left coronary arteries and candidates for heart transplantation.
Case 1: Female patient, 14 days old, performed Blalock-Taussig due to pulmonary atresia with intact septum and right coronary fistulas dependent on the right ventricle listed for cardiac transplantation. She developed heart failure and arrhymthymia (bigeminism). Cardiac transplantation was performed in 1993 and aneurysms of right ventricular coronary fistulae were detected during heart transplantation procedure. Patient is clinically well after 23 years and 10 months after heart transplantation.
Case 2: A 17-year-old female patient with a diagnosis of intact septum pulmonary atresia and late postoperative Glenn surgery referred for heart transplantation due to significant ventricular dysfunction and listed for heart transplantation. Coronary artery angiography shows the presence of a tortuous pathway of the right and left coronary arteries, with an aneurysmal dilatation of the left artery measuring 26 mm, visualized in the coronary sinus, left and right coronary arteries, and directly communicating with the right ventricle cavity.
Conclusion: Coronary aortic aneurysmatic fistulas can be severe and may evolve with the need for heart transplantation.

P2488 - TEMPORARY RIGHT VENTRICULAR ASSISTIVE DEVICE (RVAD) POST LEFT VENTRICULAR ASSISTIVE DEVICE (LVAD) IMPLANTATION

Nida Tejada[1], Menchee Berris[1], Janet Scheel[2], Justine Fortkiewicz[3] Children, Nursing, Poolesville-United States[1] Children, Cardiology, Washington, Dc-United States[2] Children, Nursing Education, Washington, Dc-United States[3]

Introduction: Mechanical circulatory support as either bridge to transplant or destination therapy remains a viable option for heart failure in pediatric patients. While outcomes shows improving survival rates, the management of right ventricular failure (RVF) after Left Ventricular Assistive Device (LVAD) implantation remains a challenge (Mansfield et al, 2015).
Background: Our patient was a previously healthy 27 kg, six year old male, newly diagnosed dilated cardiomyopathy with an ejection fraction of 25%, positive for mutations in MYH6 and LMNA and with no active inflammation on MRI. Heartware LVAD implantation was performed following ECMO deployment secondary to decompensation. Patient subsequently developed RV failure that necessitated rotaflow RVAD support.
Discussion and Implication for Clinical Practice: Pulmonary vasodilators, afterload reducers and the use of inotropes do not guarantee success in preventing the progression of RVF. The use of temporary RVAD may be considered to support medical management. Various options such as Berlin Heart, Total Artificial Heart, Heartware RVAD were considered but decided to be unfavorable on this case. Among the challenges met on a patient with temporary RVAD and Heartware LVAD are neurologic complications specifically Horner's syndrome, a nerve injury due to cannula placement, arrhythmia and frequent suction events on LVAD. Patient's mobility limitations required a complex multidisciplinary planning. Also, the rotaflow is prone to fibrin and clot formations making anticoagulation management difficult. After 45 days, patient was able to completely come off RVAD and two days later was successfully transplanted.
Nursing Implications: The patient's mobility restrictions, skin issues, suction events, unfamiliarity on the use of the rotaflow device and educational needs in managing both devices posed as some of the nursing challenges. The success of this case points to the strong collaboration among the multidisciplinary team, the development of educational tools and strategies, the enthusiasm and the strong conscientious work of all involved.

P2489 - THE EPIDEMIOLOGY OF CHILDHOOD DILATED CARDIOMYOPATHY IN SINGAPORE

Shi Yan Lee[1], Wai Lin Ang[2], Ching Kit Chen[2] National University of Singapore, Yong Loo Lin School of Medicine, Singapore-Singapore[1]; KK Women's and Children's Hospital, Cardiology Service, Department of Paediatric Specialties, Singapore-Singapore[2]

Introduction: The epidemiology of dilated cardiomyopathy in children is not well established. Little is known about the causes, outcomes and overall survival of childhood dilated cardiomyopathy in Singapore. Hence, we undertook a retrospective study to document the epidemiology of dilated cardiomyopathy in children who presented to a tertiary children's hospital in Singapore.
Methods: This was a single-centre, retrospective review of all cases of dilated cardiomyopathy in children who presented between 2005 and 2015 to the cardiology service at KK Women's and Children's Hospital, Singapore. All diagnoses of dilated cardiomyopathy were made using echocardiographic criteria.
Results: A total of 43 dilated cardiomyopathy patients were analyzed. There was a slight male predominance (n = 24, 56%) among the children who were diagnosed. The commonest race included Chinese (n = 23, 54%), followed by Malay (n = 7, 16%) and Indian (n = 3, 7%). The mean age at diagnosis was 5.4 years. Most children presented before the age of 6 years (n = 29, 67%), with 37% being diagnosed before 1 year (n = 16, 37%). The majority of children had idiopathic dilated cardiomyopathy (n = 18, 42%). Out of the known causes, most were secondary to neuromuscular disorders (n = 8, 19%) and myocarditis (n = 7, 16%). The mean follow-up time was 3.8 years. The mortality rate in this cohort was 30% (13/43). In multivariable analysis, age at diagnosis <1 year, and lower baseline left ventricular fractional shortening were associated with increased risk of death.
Conclusion: Without the availability of pediatric heart transplantation, death occurred in 19% of patients with childhood dilated cardiomyopathy within 1 year of diagnosis. Risk factors for death include age at diagnosis and severity of left ventricular dysfunction. This data is pertinent as Singapore moves to develop a pediatric heart transplant program.

P2504 - RETROSPECTIVE STUDY OF OPTIONAL TREATMENT STRATEGY USING PULMONARY VASOREACTIVITY IN BORDERLINE EIGENMENGER SYNDROME USING PULMONARY VASOREACTIVITY

Jo Won Jung[1], Myung Jin Cha[1], Chang Shin Kim[1], Se Yong Jung[1], Jae Young Choi[1], Yu Rim Shin[2], Han Ki Park[2], Young Hwan Park[2]

Severance Cardiovascular Hospital Yonsei University College of Medicine, Pediatric Cardiology, Seoul-Korea, South[1]; Severance Cardiovascular Hospital Yonsei University College of Medicine, Pediatric Cardiovascular Surgery, Seoul-Korea, South[2]

Background: This study aimed to evaluate the feasibility, clinical application of pulmonary vasoreactivity testing with inhaled iloprost and to determine the treatment strategy in patients with pulmonary arterial hypertension (PAH) associated with congenital heart diseases (CHD).
Method: This retrospective study was done in single center for 139 cases with CHD diagnosed as PAH through the right heart catheterization from Jan. 2011 to Jul.2016. Inhaled iloprost was delivered during cardiac catheterization by ultrasonic nebulizer via a flow-inflating bag with 0.02 or 0.04 mg. The hemodynamic results and post-catheterization treatment results were reviewed.
Results: The median age of the patients was 32.48 years. The average numbers of systolic pulmonary artery pressure (sPAP) and mean pulmonary artery pressure (mPAP) were 67.39 ± 35.77 mmHg and 44.39 ± 26.30 mmHg. The median pulmonary vascular resistance index was 7.42 Wood units. Among those patients, 58 patients had underwent the pulmonary vasoreactivity test with inhaled iloprost plus oxygen during catheterization (testing group). The average numbers of sPAP and mPAP were 88.32 ± 22.77 mmHg and 57.34 ± 18.37 mmHg in testing group. The median pulmonary vascular resistance index (PVRi) was 10.8 Wood units. 32 (55%) patients were regarded as responder group. The mean PVRi was also significantly decreased in responder group (9.6 to 5.6 vs 12.3 to 11.0 Wood units). After pulmonary vasoreactivity testing, 27 patients had undertaken complete/partial corrective procedure, 4 patients had undertaken one more procedure/operation followed initial procedure after catheterization, and in only 1 patient, palliative coronary stenting was done. The others were treated with single or combined pulmonary vasodilators without any procedure/operation.
Conclusion: We suggest that even in patients with PAH associated with CHD, pulmonary vasoreactivity test in RHC is essential to determine the treatment strategy of closure or not for borderline Eigenmenger syndrome.

P2506 - CAUSES OF HEMOPTYSIS IN EISENMENGER SYNDROME – A CT ANGIOGRAPHY STUDY

Saurabh Kumar Gupta, Jo Joseph, S Ramakrishnan, Gurpreet Singh Gulati, Anita Saxena, Priya Jagia, Rajnish Juneja, Shyam S Kothari, Sanjiv Sharma, V K Bahl
All India Institute of Medical Sciences, Cardiology, New Delhi-India

Background: Hemoptysis is a common cause of morbidity in Eisenmenger syndrome, but the causes of hemoptysis are not well defined. We analyzed the clinical predictors and causes of hemoptysis in a cohort of patients with Eisenmenger syndrome using computerized tomographic pulmonary angiography (CTPA).
Materials and Methods: Of the 95 patients of Eisenmenger syndrome studied (mean age 23.7 ± 7.7 years; 57 male), 38 patients (40%) had presented with hemoptysis, and all of them underwent a CTPA within two weeks of index bleed.
Results: Patients with hemoptysis had a reduced 6 minute walk distance (356.2 ± 92.5 meters) as compared to patients without hemoptysis (395.1 ± 126.9 meters) ($p = 0.03$). However, other baseline demographic characteristics including diagnosis, complexity of lesion, functional class, and symptoms did not differ among patients with and without hempotysis. Of the 38 patients, 17 had a treatable cause of hemoptysis and received appropriate treatment. The identifiable causes included aorto-pulomanray collaterals, pulmonary thrombosis (2 patients), pulmonary tuberculosis (2 patients), pulmonary artery dissection (1 patient). Treating an identifiable cause reduced the risk of recurrence of hemoptysis by 0.46 (95% CI 0.28–0.64).
Conclusion: Hemoptysis remains a major cause of morbidity in patients with Eisenmenger syndrome. Hemoptysis occurs more frequently in patients with greater exercise limitation. CT pulmonary angiogram immediately following an episode of hemoptysis could identify a potentially treatable cause in nearly half of the patients and such treatment results in lesser recurrence of hemoptysis.

P2515 - RETROSPECTIVE STUDY OF OPTIONAL TREATMENT STRATEGY USING PULMONARY VASOREACTIVITY IN BORDERLINE EIGENMENGER SYNDROME

Jo Won Jung[1], Myung Jin Cha[1], Chang Shin Kim[1], Se Yong Jung[1], Jae Young Choi[1], Yu Rim Shin[2], Han Ki Park[2], Young Hwan Park[2]
Severance Cardiovascular Hospital Yonsei University College of Medicine, Pediatric Cardiology, Seoul-Korea, South[1]; Severance Cardiovascular Hospital Yonsei University College of Medicine, Pediatric Cardiovascular Surgery, Seoul-Korea, South[2]

Background: This study aimed to evaluate the feasibility, clinical application of pulmonary vasoreactivity testing with inhaled iloprost and to determine the treatment strategy in patients with pulmonary arterial hypertension (PAH) associated with congenital heart diseases (CHD).
Method: This retrospective study was done in single center for 139 cases with CHD diagnosed as PAH through the right heart catheterization from Jan. 2011 to Jul.2016. Inhaled iloprost was delivered during cardiac catheterization by ultrasonic nebulizer via a flow-inflating bag with 0.02 or 0.04 mg. The hemodynamic results and post-catheterization treatment results were reviewed.
Results: The median age of the patients was 32.48 years. The average numbers of systolic pulmonary artery pressure (sPAP) and mean pulmonary artery pressure (mPAP) were 67.39 ± 35.77 mmHg and 44.39 ± 26.30 mmHg. The median pulmonary vascular resistance index was 7.42 Wood units. Among those patients, 58 patients had underwent the pulmonary vasoreactivity test with inhaled iloprost plus oxygen during catheterization (testing group). The average numbers of sPAP and mPAP were 88.32 ± 22.77 mmHg and 57.34 ± 18.37 mmHg in testing group. The median pulmonary vascular resistance index (PVRi) was 10.8 Wood units. 32 (55%) patients were regarded as responder group. The mean PVRi was also significantly decreased in responder group (9.6 to 5.6 vs 12.3 to 11.0 Wood units). After pulmonary vasoreactivity testing, 8 patients had undertaken complete corrective procedure, 19 had received corrective procedure with either fenestration or banding, 4 had undertaken one more procedure/operation followed initial procedure after catheterization, and in only 1 patient, palliative coronary stenting was done. The others were treated with single or combined pulmonary vasodilators without any procedure/operation.
Conclusion: We suggest that even in patients with PAH associated with CHD, pulmonary vasoreactivity test in RHC is essential to determine the treatment strategy of closure or not for borderline Eigenmenger syndrome.

P2517 - LVAD IMMPLANTATION IN DCM CHILDREN

Tetsuhiro Takaoka, Yasutaka Hirata, Akihiro Masuzawa, Tomoyuki Iwase, Minoru Ono
University of Tokyo, Crdiothoracic Surgery, Tokyo-Japan

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Objective: To report the usefullness of Excor for DCM children.
Method(s): We have immplanted LVAD (Excor) in 7 DCM children.Age was from 2 month to 12 years old, and body weight was from 2.7 kg to 25 kg. LVAD immplantation was performed using cardiopulmonary bypass under beating heart. 10cc pump were used in 5 children, 15cc in one children, and 30cc in two child. One child has underwent pump exchange from 10cc to 15cc due to body weight gain. INR was controlled from 3.0 to 3.5.
Result(s): 1. Five of 7 children have underwent heart transplantation successfully, one child in Japan, and the other four in the USA. 2. Four of seven children sufferred from infection, and needed antibiotics infusion for a long time. One child sufferring from hemi-paralysis of the leg was free from infection. 3. Children who were immplanted 10cc pump needed 4 times of pump exchange due to pump thrombus during 6 month, and the other 8 times during 11 month.
Conclusion: 1. Excor is a usefull device for DCM children as the bridge to heart transplantation. 2. 10cc pump needed several times of pump exchange due to the thrombus. 3. Fixation of cannula is most immportant to prevent the infection.

P2558 - HEART FAILURE IN CHILDREN B TYPE NATRIURETIC PEPTIDE AS A BIOMARKER FOR INDICATION FOR HEART TRANSPLANTATION AND LONG TERM FOLLOW UP

Anna Ribeiro[1], Celia Strunz[2], Desiderio Favarato[3], Estela Azeka[1]
Heart Institute (Incor) University of Sao Paulo, Pediatric Cardiology, Sao Paulo-Brazil[1]; Heart Institute (Incor) University of Sao Paulo, Clinical Laboratory, Sao Paulo-Brazil[2]; Heart Institute (Incor) University of Sao Paulo, Cardiology, Sao Paulo-Brazil[3]

Background: Little is known about B-type natriuretic peptide (BNP) in children. The purpose of this study was to evaluate BNP levels profile in children and candidates for heart transplantation.
Patients and Methods: It is a prospective observational study at Heart Institute (InCor) University of Sao Paulo Medical School. The following data was analysed: demographics, ejection fraction (EF), BNP level, clinical outcome (event: transplantation or death). Receiver operating characteristic (ROC) curve were generated to determine the accuracy and optimal threshold of BNP for predicting future outcomes; sample size was calculated for $p < 0.05$; power 80%.
Results: 54 patients were included, 48.1% were male. The majority of subjects had dilated cardiomyopathy (41, 76%) followed by restrictive in 11, hypertrophic in 2. Mean age: 8 years old. Analysis using ROC curve determined the BNP level cut off value of 198.5 pg/ml for predicting future outcomes (specificity: 63.2% and sensitivity: 91.4%).Correlation between BNP level and heart failure (HF) class showed BNP mean level 466.92 pg/ml for HF class I and II and 3004.73 pg/ml for HF class III and IV. ($p = 0.001$). A five- year follow up demonstrated that 48.5% of the patients with HF class I and II were alive and only 3.8% of the cases have had HF class III and IV were free of events.
Conclusions: B-type natriuretic peptide (BNP) could be an additional biomarker and predictor of adverse events in children with heart failure.

P2583 - CARDIAC RESSINCRONIZATION THERAPY FOR TREATMENT OF PEDIATRIC HEART FAILURE AFTER CONGENITAL HEART DISEASE CORRECTION SURGERY

Ana Paula Damiano, Fernando Mello Porto, Raquel Paiuta, Tatiane De Lima Fuentes Andrades, Jorge Luis Da Silva, Fernando Antoniali
Pontifical Catholic University of Campinas, Pediatric Cardiology, Valinhos-Brazil

Cardiac resynchronization therapy (CRT) is a therapeutic option for treatment of severe heart failure (HF) in adults. However, in pediatric patient there's no established consensus. We describe the case of 2 children submitted to CRT for postoperative HF treatment. Patients: ICAB, male, at 18 m, diagnosis of severe dilated cardiomyopathy (LVEF 22%) due to ALCAPA. He has corrective surgery and pacemaker implantation in the 2nd postoperative due to total atrioventricular block, epicardial DDD in LA and LV, but maintained LVEF 20%, QRS > 200 ms and signs of HF (grade IV) with optimized drug therapy. After 1 year, CRT (endocardial electrode implant in RV) was chosen. After 3 months, the patient evolved to grade I HF and maintained good thresholds, QRS <150ms and LVEF 40%. Patient GFG, 5 y, large ASD corrected in 1st year and implantation of pacemaker by TAVB in immediate postoperative period (epicardial VVIR). It evolved with clinical worsening, grade IV HF even with optimized drug therapy ,LVEF 28%, LVBB and QRS > 200ms. Scintigraphy was negative for myocarditis and opted for CRT with multisite electrode on the RA and endocardial RV and new epicardial electrode in LV by lateral thoracotomy, after determination of the best site by strain echocardiogram. After 14 months, he was grade I HF, QRS <150 ms and LVEF 48%. Comments: Therapy of severe HF in the child with CHD has peculiar aspects compared to adults, branch block is common due to extensive surgical scar, as well as associated RV dysfunction. An impairment of ventricular depolarization can lead to mechanical contraction asynchrony, depression of myocardial function and inadequate remodeling. Resynchronization allows simultaneous maximal contraction of both ventricles and improvement of cardiac output. Conclusion: CRT should be considered in cases of postoperative AVB with severe HF, extended QRS and unsatisfactory drug response.

P2597 - CLINICAL OUTCOME OF CARDIOMYOPATHIES DIAGNOSED DURING FETAL LIFE

Takako Toda, Yousuke Kouno, Hiroaki Kise, Keiichi Koizumi, Kanji Sugita, Minako Hoshiai
Yamanashi University, Department of Pediatrics, Chuo-Japan

Background: There have been a few reports of fetal cardiomyopaties (CMs). However, there is a paucity of information about its assessment, treatment, and outcome.
Methods: We retrospectively reviewed our experience with CMs diagnosed in fetal life from 2008 to 2016. Fetal echocardiographic findings, postnatal laboratory findings, acute phase treatment course, and clinical outcome were investigated.
Results: Five cases (4 male, 1 female) were diagnosed as CMs at mean gestational age of 32 ± 3 weeks. All patients were diagnosed as dilated cardiomyopathy. Left ventricular non-compaction (LVNC) was noted in 4 patients. All patients required mechanical ventilation and continuous catecholamine infusion in the neonatal period. All of them improved clinically to some extent after the acute treatment, though 3 cases died of heart failure at the age of 5, 6, and 9 months. Two patients were discharged home. Both were alive at 6 years' and 15 months' follow-up. Cardiovascular profile scores (CVPS) in fetal echocardiography were 7.5 ± 0.7 points in survivors, and 5.3 ± 1.1 points in non-survivors ($p = 0.04$). Median BNP levels at birth were 210 pg/mL (42-378 pg/mL) in survivors, and 2055 pg/mL (1231-3620 pg/mL) in non-survivors. Mean LV EF was higher in survivors than non-survivors ($33 \pm 4\%$ vs $20 \pm 3\%$, $p < 0.05$). Mean neonatal ventilation period and catecholamine requirement appeared shorter in survivors than non-survivors: 5 ± 3 days vs 29 ± 14 days ($p = 0.04$), 9 ± 2 days vs 35 ± 20 days ($p = 0.07$), respectively.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: The prognosis of fetal CMs was deemed to be poor, as more than half of our cases died in infancy. However, our limited experience suggests the patients with higher CVPS, higher LV EF, and lower BNP have better chance of survival after intensive care in the neonatal period.

P2615 - TREATMENT OF VIRAL MYOCARDITIS

Ferran Gran[1], Maria Martinez-villar[2], Jaume Izquierdo[3], Joan Balcells[3], Anna Sabaté, Ferran Rosés[1], Queralt Ferrer[1], Gemma Giralt[1], Pedro Betrián[1], Dimpna C. Albert[1]
Hospital Vall D'hebron, Pediatric Cardiology Department, Barcelona-Spain[1]; Hospital Vega Baja, Pediatric Cardiology Department, Orihuela-Spain[2]; Hospital Vall D'hebron, Pediatric Critical Care Department, Barcelona-Spain[3]

Aims: Viral myocarditis (VM) is a life treatening disease. Viral and immunohistological mechanism has been implicate in disease progression but etiologic treatment strategies has not demostrated to be effective. Since February 2015 a new protocol has been implemented in our institution wich adds immunosupression or antiviral therapy based on the results of endomyocardial biopsy (EMB). The aim of this study is to describe our experience with the implementation of the new protocol.
Material and Methods: pediatric patients (0-16 years old) admitted in our institution from July 2008 to August 2016 with the diagnosis of VM, were included. We compare the outcome of patients diagnosed before (group A; n = 21) versus after (group B; n = 12) the new protocol. The diagnosis was based upon the presentation of clinical symptoms and the presence of a typical pattern on cardiac magnetic ressonance (CRM) or immunohistological confirmation with EMB. This was only performed in patients with severe disease or without improvement after two weeks of clinical presentation.
Results: median age was 16 months (0 months to 14 years) in group A and 26 months (9 months to 16 years) in group B. Seventeen (81%) versus 8 patients (67%, p = 0,42) needed inotropic support. Mechanical support was needed in 4 (19%) and 3 patients (25%, p = 0,68) in each group. The initial ejection fraction was 35% versus 38% (p 0,42). In group A, 6 patients (28,3%) died or needed heart transplantation. In the group B, the only patient who died (8,3%) suffered a cardiac arrest in another institution and mechanical support was stopped because of neurological damage. Complete recovery was present in nine of eleven patients (81%) in group B.
Conclusions: Immunosupression and antiviral therapy could be useful in VM. This treatment should be based on immunohistological and viral examination of BEM.

P2618 - EXTRACORPOREAL MEMBRANE OXYGENATION IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

Fabiana Nossa[1], Ecryd Elias Abdala[1], Rafaella Gato Calmon[1], Fabiola Muller De Oliveira[1], Larissa Gondim[2], Beatriz Furlanetto[3], Nelson Horigoshi[2], Grace Van Leeuwen Bichara[1]
Sabará Hospital Infantil, Pediatric Cardiology, São Paulo-Brazil[1]; Sabará Hospital Infantil, Pediatric Critical Care, São Paulo-Brazil[2]; Sabará Hospital Infantil, Pediatric Cardiac Surgery, São Paulo-[3]

Background/Hypothesis: Extra Corporeal Membrane Oxygenation (ECMO) is an extreme therapy in critically ill children with respiratory or circulatory failure. Children with Acute Lymphoblastic Leukemia (ALL) have more likely to develop heart failure and respiratory insufficiency, caused by the disease itself or some complication of the treatment. Little is known about the use of ECMO for septic shock or respiratory insufficiency in ALL patients, as this disease can increase the risk of this procedure. There described in the literature only 7 cases of ECMO support for respiratory failure in children with ALL, in two differents centers, in which 5 patients survived until the hospital discharged.
Materials and Methods: We report two cases of ECMO in ALL children.
Results: Case One: A two-year-old female, present with a refractory septic shock due to Moraxella catarrhalis infection and pancytopenia. She was on venoarterial ECMO, and the diagnose of ALL and induction treatment was made during ECMO. The patient was off ECMO after 8 days and is responding well to the ALL treatment as a outpatient. Case two: A two-year-old female, who was newly diagnosed with ALL, had a respiratory failure due to H1N1 influenza and parainfluenza 3 infection after the induction phase of the treatment. She was placed on venovenous (VV) ECMO and received Chemotherapy during ECMO. The patient was of ECMO after 26 days and is recovering from the lung disease progressively and receiving the treatment for ALL. The management of anticoagulation was reviewed because of the bleeding predisposition of ALL. There were no major bleeding.
Conclusions: In our experience, ECMO was feasible and safe in children with ALL. Using very careful monitoring, we can have promising results, bringing hope and life expectancy to theses families and children.

P2620 - MALNUTRITION AS A RISK FACTOR FOR SHORT TERM OUTCOMES AFTER HEART TRANSPLANTATION IN PEDIATRIC PATIENTS AND ADULTS WITH CONGENITAL HEART DISEASE A RETROSPECTIVE ANALYSIS

Carolina Vieira De Campos, Adailson Wagner Da Silva Siqueira, Nana Miura, Marcelo Biscegli Jatene, Estela Azeka
HCFMUSP, Incor, Sao Paulo-Brazil

Heart failure is an important risk factor for malnutrition, due to cardiac cachexia and high metabolic demand. The outcomes for malnourished adults who have undergone heart transplantation (HTx) have been widely studied, however there are few data on pediatric patients and adults with congenital heart disease. The goal of our study was to analyse the nutritional status of such patients and the impact of malnutrition on the short-term outcomes after HTx. A retrospective review of all children and adults with congenital heart disease submitted to HTx between 2012 and 2015 at our institution was performed. Seventy-four charts were reviewed, with 39 females (52%). The average age was 10 ± 7 years. World Health Organization (WHO) growth-charts were used to analyse the anthropometric data. The average height Z-Score was -1,36 ± 1,97 cm, the average weight Z-Score was -1,83 ± 1,78 and the average body mass index (BMI) Z-Score was -1,17 ± 1,64; Twenty-six patients were diagnosed as malnourished, according to the WHO definition of thinness (BMI Zscore < -2 or < 18 for adults); When comparing the malnourished patients short-term outcomes data with the eutrophic ones, descriptive analysis showed, for the malnourished group, a longer time of orotracheal intubation (6,9 ± 20,4 days versus 2,4 ± 2,8), higher incidence of bacterial infection (19,2% versus 10,4%) and rejection diagnosed by endomyocardial biopsy (57,7% versus 52,1%). The use of renal replacement therapy, the incidence of cytomegalovirus infection and the readmission after first hospital discharge were similar between the groups. Although there are several limitations to our retrospective study, the data above ought to inspire better nutritional evaluation and interventions in the patients awaiting HTx.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

P2625 - PEDIATRIC HEART TRANSPLANTATION IN CHILDREN AND ADULTS WITH CONGENITAL HEART DISEASE STENT IN GRAFT VASCULAR DISEASE – 25 YEARS OF SINGLE CENTER EXPERIENCE

Raul Arrieta[1], Marcelo Jatene[2], Adailson Siqueira[1], Germana Coimbra[1], Luiz Kajita[1], Nana Miura[1], Estela Azeka[1]
Heart Institute (Incor) University of Sao Paulo, Pediatric Cardiology, Sao Paulo-Brazil[1]; Heart Institute (Incor) University of Sao Paulo, Cardiac Surgery, Sao Paulo-Brazil[2]

Background: Heart Transplantation is an option for refractory heart failure and intractable congenital heart disease. Graft vascular disease is one of the most important limitations for long term survival. The aim of this study is to report the use of stent in this situation and the clinical outcome.
Patients and methods: it is a retrospective observacional study in a cohort of children and adults with congenital heart disease submitted for heart transplantation from October 1992 to January 2017 at Heart Institute (InCor) University of Sao Paulo Medical School. The angiogram is routinely performed after transplantation. The demographics and outcome of these patients were evaluated.
Results: 8 of 190 (4.2%) patients could be submitted to stent procedure after transplantation. Mean period between the transplant and the stent procedure was 7.7 years. 4 of them (50%) died. Mean follow-up period of 1.7 years. 3 were re-listed for transplantation.
Conclusions: Stent after heart transplantation is feasible for GVD. However another strategies for treatment of allograft vasculopathy need to be considered such as relisting for transplant.

P2637 - BRIDGING CHILDREN TO HEART TRANSPLANT WITH LEVOSIMEDAN CASE SERIES

Carolina Vieira De Campos, Samia Medeiros Barbar, Adailson Wagner Da Silva Siqueira, Paula Vieira Vincenzi Gaiolla, Christiane Kawano, Estela Azeka, Marcelo Biscegli Jatene, Nana Miura, Gustavo Foronda
HCFMUSP, Incor, Sao Paulo-Brazil

The management of children in the waiting list for Heart Transplant (HTx) is difficult and mortality is high. Once the waiting time may be long, clinical deterioration and cardiogenic shock is a possible outcome. Mechanical circulatory support (MCS) is an alternative to spare time in a scenario where organ availability is scarce, although it's not widely available. Alternatively, levosimendan (LVD) is a vasoactive drug that improves myocardial function. Our goal was to analyse the outcomes of children submitted to HTx after being bridged with LVD. We performed a retrospective review of those children admitted at our institution between 2012-2015.The LVD use consisted of an attack dose of 6-10 mcg/kg/min for 10 minutes, followed by a continuous infusion of 0,1-02 mcg/kg/min for a 24-48 hour period. Eighteen patients were bridged to HTx with LVD during the period. Four patients received both LVD and MCS and were excluded from the analysis. The group bridged exclusively with LVD received a total of 41 cycles. There were 7 females (50%) and the average age was 93,1 ± 68,4 months. Sixty-four percent (9 patients) had acquired heart disease. The average BNP pre-LVD was 2073 ± 2633 and post-LVD was 638 ± 512 mg/dl. The average BNP pre-HTx was 874 ± 781 mg/dl. Regarding the short-term outcomes after HTx the average length-of-stay in the intensive care unit was 51,4 ± 75,2 days and the average duration of mechanical ventilation 2,7 ± 2,9 days. One patient (7%) needed renal replacement therapy, five patients (36%) had seizures after HTx and four patients (28,6%) had infection diagnosed as positive cultures with clinical correspondence. There were no short-term deaths and only one patient died within a 1-year period, due to acute rejection. Although it is an expensive drug, it should be seen as a possibility for effectively bridging children for HTx in a scenario where MCS is not widely available.

P2642 - SPECTRUM OF PERICARDIAL DISEASES IN PEDIATRIC POPULATION PRESENTING TO A TERTIARY CARE CENTRE IN INDIA

Vijay Bohra, Anita Saxena, Saurabh Kumar Gupta, Shyam Sunder Kothari
AIIMS, Cardiology, New Delhi-India

Background: There is a paucity of data on pericardial diseases in pediatric population.
Aim: of the study was to define the spectrum and profile of pericardial diseases in Indian pediatric population presenting to a tertiary care centre. It was an observational study. Children ≤15 yrs who presented to a tertiary care centre were studied from Jan 2010 to Dec 2016. A total of 44 patients were enrolled in the study. The most common pericardial disease entities in descending order were chronic constrictive pericarditis (CCP) 13 (29.5%), pericardial effusion (PE) 13(29.5%), pyopericardium 11(25%), effusive constrictive pericarditis 5 (11.4%) and acute viral pericarditis 2 (4.5%). Tuberculosis was the etiology in 18(40.9%) patients. The spectrum of disease appears to have shifted slightly from chronic constrictive pericarditis to pericardial effusion. Comparison of the etiologies of pericardial effusion (PE) showed a slight increase in frequency of malignancy associated and other causes of PE such as hypothyroidism. The incidence of pericardial calcification is much lesser in pediatric age group one subject in each group (11.1%) as seen in our study. Despite receiving the full course of antitubercular treatment patients with tubercular pleural effusion developed constriction in 60% cases. Patients with purulent pericarditis also progressed to constrictive physiology despite adequate parenteral antibiotics in 45% cases.
Conclusion: In our country Tuberculosis still remains as the most common cause of acquired pericardial disease, despite ATT there is progression to Constrictive physiology in most of the cases.

P2648 - PEDIATRIC HEART TRANSPLANTATION AND OPPORTUNISTIC INFECTION ON NON TYPICAL EPIDEMIOLOGICAL SCENARIOS AWARENESS IS KEY TO SUCCESS

Barbara Neiva Tanaka, Carolina Vieira De Campos, Tania Strabelli, Adailson Wagner Da Silva Siqueira, Marcelo Biscegli Jatene, Estela Azeka
HCFMUSP, Incor, Sao Paulo-Brazil

Background: Hystoplasmosis is the most prevalent mycosis in the United States and its agent is found worldwide, although it is an unusual pathogen in Brazil. Most infections are self-limited, but immunosuppressed patients may develop life-threatening presentations.
Case Report: 15 year-old boy status post-Heart Transplant in 2009 (dilated cardiomyopathy), living in the north region of Brazil, presented to the emergency room in respiratory distress with a history of fever, loss of weight and astenia for 1 month. He had already been treated for pneumonia and cytomegalovirus infection in his hometown, without improvement of the symptoms. His clinical status deteriorated quickly, and he was placed on non-invasive ventilation, broad-spectrum antibiotics (including tuberculosis treatment) and vasoactive drugs whilst investigation was held. Laboratory samples showed bycitopenia (leucopenia and low platelets), Chest X-ray showed diffuse bilateral infiltrate and chest CT revealed bilateral centrilobular nodules. Bone marrow biopsy was negative for infectious pathogens. The Histoplasmosis diagnosis was then carried out through a bronchoalveolar lavage. A 30-

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

day course of amphotericin was initiated, with clinical improvement. He was discharged after that period with oral itraconazole.
Conclusion: With the increase in heart transplanted patients, awareness for opportunistic infections should be raised, even if epidemiologically improbable, once targeted treatment is a key for therapeutic success.

P2679 - IS HEART TRANSPLANT FEASIBLE IN CHILDREN WITH RESTRICTIVE CARDIOMYOPATHY WITHOUT PRE TRANSPLANT VENTRICULAR ASSIST DEVICE

Nuria Gil[1], Reyes Alvarez[2], Esther Panadero[2], Ana Pita[3], Irene Hidalgo[4], Manuela Camino[2]
Hgu Gregorio Marañon, Pediatric Cardiology, Madrid-Spain[1] Gregorio Marañon, Pediatric Cardiology, Madrid-Spain[2] Gregorio Marañon, Cc Surgery, Madrid-Spain[3] Gregorio Marañon, Anesthesia, Madrid-Spain[4]

Background: Heart transplant (HTX) in Restrictive Cardiomyopathy (RCM) is a challenge due to the presence of elevated pulmonary resistance. Use of ventricular assist device (VAD) pre-transplant in order to diminish pulmonary resistance is not always possible and increases morbility.
Objective: To describe our experience in HTX with RCM without previous VAD.
Materials and Methods: Retrospective study of our children with RCM receiving HTX from 2006 to 2016. Clinical characteristics, hemodynamic variables pre-post transplant, ischemia time, ECMO need, vasodilator treatment and outcome are described.
Results: From 2006, 89 pediatric HTX were peformed. RCM was Indication in 6 patients (6.7%) with median age of 10 years (4-13) and mean weight: 29.6 Kg (12-66). Etiology: genetic (2), fibroelastosis associated with aortic stenosis (1), Shone syndrome (1) and unknown (2). Hemodynamix variables are shown in the table. All patients had PHT on diagnosis; 4 patients presented PVRI ≥6 Uw/m2, considered high risk patients for HTX. Pulmonary vasodilator medicaments were administered pre transplant. Mean time from diagnosis to listing was 10 months. Waiting list mean time was 2.9 months. Mean ischemia time was 239.5 min (123-310). Pulmonary vasodilator treatment post-transplant: nitric oxid (6), iv sildenafil (1), bosentan (5), oral sildenafil (5) and iloprost (2). All haemodinamic values were normal 1 month after trasplant except in 1 patient whom values are normal after 1 year. 1 patient died in the immediate post-transplant due to cerebral hemmorhage in ECMO. Short term mortality occured in 1 patient because of humoral rejection.
Conclusion: HTX in RCM was possible without previous VAD. Use of pulmonary vasodilators allows listing for HtX with PHT. Decrease in pressure and pulmonary resistance occurs soon after transplant. Choosing a donor with ischemia time ≤240 min to prevent primary graft dysfunction may be a valid strategy to decrease morbimortality.

Table.

Background: Cardiomyopathy remains a leading cause of morbidity and mortality in children worldwide. Although we see 40 – 50 incident cases annually in Cape Town, the characteristics of childhood cardiomyopathies in African children have not been systematically described. IMHOTEP is the first prospective, open-ended registry of prevalent and incident cases of heart muscle disease in children and adults in Africa. It will expand from pilot sites in Cape Town to other centres in South Africa and subsequently have representation from all 56 countries in Africa to accurately characterize cardiomyopathies on the African continent.
Methods: Commencing August 2016, all incident cases of cardiomyopathy or myocarditis presenting to two referral paediatric cardiac centres were enrolled into a dedicated OpenClinica registry (IMHOTEP African Cardiomyopathy Registry). Details captured include demographics, history, physical examination findings, blood investigation results, genetic screening, chest X-ray, ECG,

Table 1. Patient Demographics

Patient no.	Age at first presentation (months)	Sex	Primary caregiver education	HIV status
1	10	F	High school	NE
2	1.5	M	High school	NE
3	6	F	Primary school	E/neg
4	113	M	Postgraduate	NE
5	2.5	M	Unknown	E/neg
6	32	M	High school	NE

15	0.3	M	High school	E/neg
16	47	F	Tertiary	NE

NE – perinatally non-exposed, E – perinatally exposed, neg – HIV PCR negative

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

echocardiogram features and outcome measures (adverse events, hospitalizations, death). Human Research Ethics Committee approvals were obtained prior to implementation of the registry.
Results: Baseline demographic characteristics, modes of initial presentation, echocardiographic parameters and adverse events/outcomes are depicted in Tables 1–4. The majority of patients are infants (11/16, 69%). Four of the 16 patients (25%) are perinatally HIV exposed, but all four tested negative by PCR. The predominant cardiomyopathy phenotype is dilated cardiomyopathy (8/16, 50%) followed by myocarditis (biopsy-proven or clinically suspected, 4/16, 25%). Morbidity and mortality to date has been substantial – two deaths (mortality 13%), average hospitalizations 3/patient, average ICU admissions 1.4/patient, and mean number of days in hospital 30.2 (SD 18).
Conclusions: Already in these early stages, we see the full range of phenotypes represented in African children with cardiomyopathy and a significant mortality and morbidity. The paediatric limb of the IMHOTEP African Cardiomyopathy Registry promises to be a powerful tool to characterize childhood cardiomyopathy in Africa.

Table 2. Mode of initial presentation

Patient no.	Diagnostic category	Modified Ross class	Highest level of care	Days in ICU	Days in hospital
1	Myocarditis	IV	ICU	4	10
2	DCM	III	High care	0	4

P2701 - HAEMODYNAMIC IMPACT OF PULMONARY VASODILATORS ON FONTAN CIRCULATION

Biagio Castaldi[1], Giulia Bordin[1], Massimo Padalino[2], Maddalena Padrini[1], Emiliana Campagnano[1], Giovanni Stellin[2], Ornella Milanesi[1]
University of Padova, Pediatrics, Padova-Italy[1]; University of Padova, Cardio-Thoracic Sciences, Padova-Italy[2]

Aim: The Fontan procedure is the palliative procedure for single ventricle physiology. Pulmonary resistance plays a key role in the success of this operation. There are conflicting data concerning the impact of pulmonary vasodilators on survival and functional capacity among Fontan patients. The aim of this retrospective, single-centre, non-randomised study was to investigate the potential effect of pulmonary vasodilators on pulmonary vasculature in Fontan patients.
Method: Twenty-eight patients with single ventricle physiology were enrolled in the study. Eighteen patients were treated with pulmonary vasodilators: nine patients after Glenn procedure (GroupA) and nine patients after Fontan completion (GroupB). Ten patients with single ventricle after Glenn procedure were enrolled as a control group (GroupC). The primary end point was

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

to assess changes in haemodynamic profile and the diameter of the pulmonary branches after two right heart catheterisations. Adverse events were recorded.
Results: Mean age ± SD was 3.2 ± 1.5 years (Group A), 26.8 ± 12.7 years (Group B), and 3.0 ± 1.0 years (GroupC). Patients included in Group A had smaller pulmonary arteries (Nakata index: 158 ± 50 vs 212 ± 68 mm2/m2; p = 0.047) and reduced arterial compliance (34.3 ± 15.4 vs 56.3 ± 25.6 mm2/[m2*mmHg]; p = 0.03) at baseline compared with Group C. After treatment, Nakata index and pulmonary compliance increased in patients treated with pulmonary vasodilators (Group A), while remaining stable in the control group (Nakata index: +23 ± 21% vs −7 ± 16%, p = 0.003; pulmonary compliance +80 ± 49% vs −8 ± 34%, p = 0.001). Similar results were found in Group B (Nakata index: pre-168.6 ± 70.7 mm2/m2; post-204.9 ± 97.5 mm2/m2; p = 0.026).
Conclusions: Pulmonary vasodilators reduce pulmonary artery resistance and increase vascular compliance, pulmonary artery diameter and cardiac output in Fontan patients. Therefore, pulmonary vasodilators may be used before the Fontan procedure in patients who are at high risk of Fontan procedure failure.

P2718 - BETA 1 ADRENERGIC RECEPTOR ANTIBODIES IN DILATED CARDIOMYOPATHY IN CHILDREN AND THEIR RESPONSE TO AN IMMUNOADSORPTION THERAPY

Manuela Camino[1], Nuria Gil[1], Olalla Alvarez[2], Ana Belen Martinez[2], Esther Panadero[1], Dolores Morales[2], Esther Cervantes[2]
Hospital Gregorio Marañon, Pediatric Cardiology, Madrid-Spain[1]; Hospital Gregorio Marañon, Pediatric Nephrology, Madrid-Spain[2]

Background: β1-adrenergic autoantibodies have been reported in sera from adult patients with dilated cardiomyopathy (DCM). Their removal have demonstrated a hemodynamic benefit.
Hypothesis: Determine the presence of β1-adrenergic autoantibodies in children with DCM and the potential hemodynamic benefit upon their removal by immunoadsorption (IA).
Material and Methods: We tested β1-adrenergic autoantibodies in 17 children The etiology of DCM was : genetics (4), myocarditis (3), mother lupus-associated congenital heart block (3), and idiopathic (7). All patients evidenced ejection fraction (EF) lower than 45%. Immunoadsorption cycle (4 sessions per cycle) therapy was conducted in patients with positive β1-adrenergic autoantibodies. BNP was determinated before and after IA cycle.
Results: Antibody testing resulted to be positive in 7 patients.IA therapy was performed in all of them. The technique was well tolerated. BNP concentration was lowered after each IA cycle in all patients. 3 patients with highest levels of autoantibodies showed the poorest clinical outcome and were transplanted. 2 patients remained negative after 1 cycle of IA and they recovered their heart function completely. 1 patient improved after several cyles of IA (BNP decrease and FE from 30% to 45%) but levels of antibodies remained positive. He died due to sepsis 15 months later. 1 patient with recurrent myocarditis due to parvovirus with an increase in levels of antibodies in each episode was treated with immunoglobulin and IA. Currently, after 5 years.

P2721 - INITIAL EXPERIENCE IN CHILDREN WITH THE USE OF MACITENTAN IN PULMONARY ARTERIAL HYPERTENSION

Marta Flores, Ana T. Caro, Alberto Mendoza, Belén Toral, Leticia Albert, Elena Corella, Marta Yagüe, Miguel A. Granados, Dolores Herrera, María Arroyas
12 Octubre Hospital, Pediatric Cardiology, Madrid-Spain

Background: Macitentan is an orally active and dual endothelin receptor antagonist (ERA) whose efficacy was assessed in pulmonary arterial hypertension (PAH) on adult patients.It has a slow receptor dissociation kinetic and more affinity with lipophilic membranes compared to other ERA, reducing the risk of hepatoxicity.
Materials: We report our initial experience of its use in two pediatric patients with PAH.
Results: CASE 1: A 2-year-old child who was diagnosed with severe PAH with coincidental atrial septal defect and patent ductus arteriosus. At cardiac catheterization, the mean pulmonary arterial pressure (PAPm) was 70 mmHg, pulmonary arterial wegde pressure (PAWP) 5 mmHg, and pulmonary vascular resistance (PVR) 22.5 UW·m2. She was treated first combining sildenafil with bosentan, and then with ambrisentan, but both had to be discontinued as a result of a significant increase of liver enzyme levels. At the age of 6 years, weighting 23 kg, treatment with macitentan was associated to sildenafil, at a dose of 5 mg/day, without side effects.
CASE 2: A 15-month-old premature infant who was diagnosed after birth with severe valvular aortic stenosis and borderline left ventricle. A Norwood-Sano procedure was perfomed at 6-month-old. The postoperative period was complicated with persistent hypoxemia, and haemodynamic criteria for PAH was diagnosed (PAPm 31 mmHg, PAWP 10 mmHg, PVR 4 UW·m2). He was treated with sildenafil and bosentan, but bosentan had to be discontinued because of hepatoxicity. At the age of 15 months, weighting 7,7 kg, he started treatment with macitentan, at a dose of 2,5 mg/day, without side effects. After 6 months, a second palliative step (Glenn procedure) was performed, without postoperative complications.
Conclusions: macitentan is a promising drug in PAH treatment in the pediatric population because of its low risk of hepatoxicity. Multicentric studies are necessary to determine safety, effectiveness and dosage in children.

P2736 - OXIDATIVE STRESS IN HIGH ALTITUDE IN PATIENTS WITH TRISOMY 21 IS REVERSIBLE BY VITAMIN C

Hutter Damian[1], Rimoldi Stefano[2], Rexhaj Emrush[3], Sartori Claudio[4], Scherrer Urs[5]
Staff Pediatric Cardiology, Cardiology, Bern-Switzerland[1] Staff Adult Cardiology, Cardiology, Bern-Switzerland[2]; Fellow Adult Cardiology, Cardiology, Bern-Switzerland[3]; Staff General Medicine, General Medicine, Lausanne-Switzerland[4]; Head Research Adult Cardiology, Cardiology, Bern-Switzerland[5]

Introduction: Due to the underlying genetic disposition patients with Trisomy 21 are prone for increased oxidative stress. This becomes a significant problem when environmental hypoxemia is present (i.e. congenital cardiac surgery respiratory tract infections, high altitude exposure).
Methods: To evaluate the influence of high altitude hypoxemia we investigated children with Trisomy 21 without congenital heart disease who are living permanently in high altitude in La Paz, Bolivia (3800-4100 m above sea level) and compared them with age and sex matched control. In a second step we treated both groups with Vitamin C.
Results: 33 children with Trisomy 21 (TR21) and 58 controls, age 7.5 ± 5.4years vs. 7.6 ± 4.8years (Tr21 vs. controls), saturation in room air 88.5 ± 3.8% vs. 88.9 ± 2.8% (TR21 vs. controls). RV/RA gradients have been higher in TR 21 patients at baseline (33.5 ± 10.1 vs. 20.2 ± 6, p <0.00001) as did Hb (15.2 ± 2.2 vs. 14.1 ± 1.1, P <0.01). After treatment with Vitamin C for 1 months RV/PA gradient significantly decreased in the TR21

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

group (31.7 ± 5.5 to 27.5 ± 6.9 mm Hg, P < 0.01) while in controls no effect could be observed (23 ± 4.8 vs. 25.5 ± 4.3). Oxygen saturation remained unchanged.
Conclusion: Exaggerated hypoxic pulmonary hypertension in Trisomy 21 patients without congenital heart defect appears to be triggered by oxidative stress since one month administration of oral Vitamin C could induce a significant decrease in RV/PA gradients while healthy control did not show any positive effect under Vitamin C treatment. This beneficial effect was not related to any improvement of arterial oxygen saturation.

P2744 - RECURRENT HYPERCAPNIA AND HYPOXEMIA IN CONGENITAL CENTRAL HYPOVENTILATION SYNDROME (UNDINE SYNDROME) LIKELY ACTS AS ENDOTHELIAL PRECONDITIONING

Luzia Rovina[1], Stefano Rimoldi[2], Emrush Rexhaj[3], Jean-pierre Pfammatter[4], Urs Scherrer[5], Damian Hutter[6]
Fellow Pediatric Cardiology, Cardiology, Bern-Switzerland[1] Staff Adult Cardiology, Cardiology, Bern-Switzerland[2] Fellow Adult Cardiology, Cardiology, Bern-Switzerland[3] Head Pediatric Cardiology, Cardiology, Bern-Switzerland[4] Head Research Cardiology, Cardiology, Bern-Switzerland[5] Staff Pediatric Cardiology, Cardiology, Bern-Switzerland[6]

Introduction: Undine syndrome (US) is a rare disease with severely impaired central autonomic control of breathing and dysfunction of the autonomous nervous system. The incidence is estimated to be at 1 of 200,000 livebirths. Due to reccurent hypercapnia and hypoxia we hypothesized that these patients have higher risk for pulmonary arterial hypertension (PHT) and longterm systemic vascular dysfunction. We examined 7 patients with US at baseline and high altitude in regards to pulmonary artery pressure and systemic vascular disease and compared them with 6 age and sex matched subjects.
Methods: 14 patients with US (18.6 ± 4.1 y) and 15 age and sex matched healthy controls (17.9 ± 1.5 y) were examined at 550 m and at 3883 m above sea level with echocardiography (to measure pulmonary artery pressure). Vascular function was assessed by pulse wave velocity (PWV) and carotid intima-media thickness (IMT).
Results: US patients had mildly elevated RV/PA gradients at 550 m above sea level while no relevant RV/PA gradient was found in the controls (25.8 ± 8.0 vs. 20 ± 4.3 mmHg, P = 0.03). In 3883 m above sea level all US subjects showed only mild increase in RV/PA gradients similar to the controls (33.5 ± 17.8 mmHg vs.29 ± 21 mmHg). Systemic vascular function was impaired in US subjects as shown by an increased PWV (8.0 ± 1.2 vs. 7.0 ± 0.9 m/s, P = 0.02, US vs. control) and IMT (418.4 ± 34.2 vs. 367.7 ± 50.6 μm, P < 0.01, US vs. control).
Conclusion: US patients show impaired systemic vascular function. Despite this findings Undine patients do not show evidence for marked pulmonary hypertension during rapid ascent to high altitude. We speculate that endothelial preconditioning due to intermittent hypoxemia might have a protective effect.

P2797 - RISK OF CELLULAR OR ANTIBODIES MEDIATED REJECTION POST HEART TRANSPLANT IN CHILDREN EFFECT OF ECMO OR VAD USE

Dimpna C Albert[1], Lucas Degano[1], Ferran Gran[1], Joan Balcells[2], Ferran Roses[1], Joaquim Fernandez-Doblas[3], Joaquin Perez-Andreu[3], Paola Dolader[1], Raul Abella[3]
University Vall De Hebron Hospital, Pediatric Cardiology, Barcelona-Spain[1] University Vall De Hebron Hospital, Intensive Care Unit, Barcelona-Spain[2] University Vall De Hebron Hospital, Pediatric Cardiac Surgery,Barcelona-Spain[3]

Background: Studies suggest ventricular assistance device (VAD) or ECMO may increase HLA sensitization in children with heart transplantation (HT) but it is difficult because of confounding factors. We have studied the episodes of cellular rejection or antibodies mediated rejection (AMR) attributable to ECMO or VAD use.
Methods and Materials: We reviewed retrospectively the data of all children <18 years of age transplanted in our center between December-2008 and January-2017. Patients on cardiac support (CS) prior and after the transplant were compared to children never on CS.
Results: A total of 37 children were transplanted, 14 (37,8%) on CS prior at HT, 8(21,6%) after HT (2 with CS preHT). Mean age was 7.35 years (5 m -17,5y); twelve children (32%) had congenital heart disease (previous surgeries). Types of CS were: ECMO in 7 patients (35%), ECMO and Berlin Heart(BH) in 8(40%), VAD or BH 4 and 1 VAD + BH. Mean time of cardiac support was 53,2 days (8 hr- 330 d). Similar immunosuppression protocol was used, except induction: Basiliximab in 17(46%) and thymoglobulin in 20(54%). Basiliximab was related with more cellular rejection (p = 0,049). Cross match was negative in all cases. Only 1 patient had PRA > 10% prior at HT. Episodes of cellular rejection or AMR in patients with/without CS were similar (0 = 0,330/0,693). There was not statistical association with type or durability of CS, diagnosis or previous surgeries. Only one patient died at 11 days related with AMR episode (PRA +). Median time of follow-up was 3,5 year. Overall actuarial survival after cardiac transplantation was 94,5% at 1 month, 89% at 1 year, and 86% at 5 years. Freedom from rejection and survival was similar in our patients with or without CS.
Conclusions: The use of VAD or ECMO in our patients prior or after the HT is not associated with a higher incidence of rejection post-transplant. Overall survival was similar in our patients with/withour CS.

P2820 - PERICARDITIS IN CHILDREN A SINGLE CENTER EXPERIENCE

Catarina Perez-brandão, Conceição Trigo, Fátima F. Pinto
Santa Marta Hospital, Pediatric Cardiology, Lisbon-Portugal

Background: Pericarditis is an inflammation of the pericardium and often occurs with effusion. It may be infectious or noninfectious, secondary to a systemic disease. The aim of this study was to analyze the clinical findings, course and treatment of pericarditis in children treated at our center.
Material and Methods: Retrospective analysis of all children admitted in a pediatric cardiology unit with pericarditis between 2003 and 2015. Patient characteristics were summarized using frequencies and percentages for categorical variables and medians with percentiles for continuous variables.
Results: Fifty patients were analyzed. The median age was 14 years (interquartile range 9 to 15 years) and 40 patients (80%) were male. The most common presentation form was acute pericarditis (80%). Thirty-five patients (70%) presented with chest pain and 26% reported fever. Cardiomegaly was identified in 11 patients' (22%) chest x-ray, sixty percent had an abnormal ECG and 44 patients (80%) had transthoracic echocardiogram changes, namely pericardial effusion. In 17 cases (34%) there was myocardial involvement with raised cardiac biomarkers. Forty-eight percent of patients presented with infectious pericarditis and the pathologic agent was identified in half of these cases, however no seasonal

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

pattern was noticed. Postpericardiotomy syndrome diagnosis was made in 5 cases. The first-line therapy was acetylsalicylic acid in half of patients. Pericardiocentesis was performed in 12 patients. The median length of stay was 9 days (interquartile range 3 to 11 days). There was symptom recurrence in 7 children.
Conclusions: Pediatric pericarditis is a rare condition with scarce epidemiological data available. In this study, infectious acute pericarditis was the most common presentation and about one third of patients had also myocarditis. The symptom recurrence rate is not negligible and is probably related with the type of therapy employed. Recent proposed guideline changes may potentially improve this incidence.

P2824 - MICROFLUIDIC CHIP BASED QUANTIFICATION OF CIRCULATING ENDOTHELIAL CELLS IN PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION

Hannes Sallmon[1], Adam Hatch[2], Brian D. Plouffe[2], Shashi K. Murthy[2], Georg Hansmann[3]
Charité University Medical Center, Neonatology, Berlin-Germany[1]; Northeastern University, Chemical Engineering, Boston-United States[2]; Hannover Medical School, Pediatric Cardiology and Critical Care, Hannover-Germany[3]

Background: Circulating endothelial cells (CECs) have been discussed as potential biomarkers in patients with pulmonary arterial hypertension (PAH). Current protocols for isolation and quantification of these cells are laborious and time-consuming. The aim of this study was to develop and apply a microfluidic chip capable of enumerating CECs (CD146 +) from human whole blood in patients with PAH and age matched controls.
Methods: EDTA blood was collected and injected into polymeric microfluidic chips containing microcolumns pre-coated with anti-CD146 antibody. Captured cells were immunofluorescently stained for additional stem and endothelial cell markers.
Results: The CEC capture chip was first validated against conventional flow cytometry ($r = 0.89$). In a cohort of 66 patients with three forms of PAH (idiopathic/heritable, drug-induced, and connective tissue disease), CEC numbers were significantly increased by 3-5-fold in PAH subjects vs. matched controls. CEC numbers were comparable across PAH sub-classes and were not related to age, postmenopausal status, or body mass index.
Discussion: The CEC capture chip requires 400 μL of whole blood and may serve as bedside test for the screening and monitoring of patients with PAH and other diseases related to vascular injury.

P2832 - IMPACT OF HEART FAILURE CLINIC IN PEDIATRIC AGE

Rachele Adorisio, Nicoletta Cantarutti, Antonella Santilli, Anwar Baban, Fiore Iorio, Fabrizio Drago
Bambino Gesù Hospital, Pediatric Cardiology and Cardiac Surgery, Rome-Vatican City

Objectives: It has been reported that heart failure clinic (HFC) can improve the outcome of adult heart failure patients, in terms of reduction of rehospitalisation, adherence to therapy and improvement in quality of life. The aim of current study was to determine whether a specific HFC is effective also in a paediatric population.
Methods: Since 2013, a specific HFC including two cardiologists and 1 dedicated nurse has been developed in our Department. A multidisciplinary approach and specific disease protocols have been applied. Children affected by: 1) left ventricular ejection fraction <45% in case of dilated cardiomyopathy or after surgery, 2) restrictive and 3) hypertrophic cardiomyopathy 4) Fontan failure and 5) pulmonary hypertension have been referred to our HFC. To evaluate the impact on mortality, rehospitalisation, analysis of comorbidities and compliance to therapy, we made a comparative analysis on 291 children followed between 2011 and 2015, before and after the specific program.
Results: Our population (11.2 + 5 yrs old; 52% male) was represented by: 45% patients affected by cardiomyopathies, 50% CHD with ventricular dysfunction or Fontan failure. After the introduction of this program, a significant reduction of new urgent rehospitalization was observed (2011 vs 2014 75% vs 33%, $p < 0.001$; 2011 vs 2015 75% vs 12%, $p < 0.001$; 2011 vs 2016 75% vs 14%, $p < 0.001$). Acute HF admissions were significantly reduced over the time (2011 vs 2016 52% vs 13%, $p < 0.001$). No differences in terms of mortality have been observed. Major reasons for rehospitalisation were: respiratory (52%), gastroenterological infection (33%), arrhythmias (12%). Major comorbidities included: nutritional aspects, respiratory disease and orthopaedic problems and 45% of patients had more than two comorbidities.
Conclusions: in our center, HFC allowed to significantly reduce the rehospitalisation rate in a paediatric population.

P2839 - INTRACLASS CORRELATION BETWEEN ECHOCARDIOGRAPHIC FINDINGS AND HEMODYNAMIC DATA IN PATIENTS DIAGNOSED WITH IDIOPATHIC PULMONARY HYPERTENSION IN FUNDACION CARDIOINFANTIL – INSTITUTO DE CARDIOLOGIA IN BOGOTA COLOMBIA

Victor Manuel Huertas Quiñones[1], Claudia Maritza Stapper Ortega[2], Alberto García Torres[3], Miguel Ronderos Dumit[2]
Fundación Cardioinfantil - Instituto De Cardiología, Universidad Nacional De Colombia, Universidad Del Rosario, Pediatric Cardiology, Bogotá-Colombia[1]; Fundación Cardioinfantil - Instituto De Cardiología, Universidad Del Rosario, Pediatric Cardiology, Bogotá-Colombia[2]; Fundación Cardioinfantil - Instituto De Cardiología, Universidad Del Rosario, Pediatric Cardiology, Bogotá-Colombia[3]

Objectives: Pulmonary hypertension (PH) is defined as a mean pulmonary arterial pressure ≥ 25 mmHg. The diagnosis of idiopathic PH is made after a thorough study clinical and paraclinical including complete anatomical and functional assessment. The aim of this study is to describe echocardiographic findings and hemodynamic data obtained by cardiac catheterization and assess their degree of correlation.
Materials and Methods: Descriptive cross-sectional study and analysis of matching variables through the comparison of pulmonary pressure measured by echocardiography and catheterization through Interclase correlation coefficient (ICC) and the Bland Altman. The study population were children aged 0 days to 18 years who presented Fundación Cardioinfantil – Instituto de Cardiología in Bogotá (Colombia) diagnosed with idiopathic PH evaluated between January 2010 and December 2013.
Results: 29 patients diagnosed with idiopathic PH studied with echocardiography and cardiac catheterization were included. The degree of PH documented by echocardiography corresponded to severe in 38% of patients. After cardiac catheterization, the degree of PH was classified as severe in 66% of cases. In 18 patients (62%) pulmonary vascular reactivity test was performed, finding positive response in 7 cases (39%). The concordance analysis of pulmonary pressure measured by echocardiography and catheterization was performed in 20 subjects, with a confidence level of 95%. When

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

comparing the measurement results in both tests is a difference of 15 mmHg which is statistically significant. The tests achieved an ICC of 0.55, with 95% of 0.16 to 0.79, which represents a force of moderate agreement.
Conclusions: In the present study the severity of PH corresponded to severe in most patients evaluated for cardiac catheterization. Performing pulmonary vascular reactivity test for both diagnosis and accurate diagnostic decisions is essential. The concordance analysis of pulmonary pressure measured by echocardiography and catheterization through Intraclase Correlation coefficient and the Bland Altman documents a force of moderate agreement.

P2840 - THREE DECADES OF PEDIATRIC HEART TRANSPLANTATION DATA FROM THE SPANISH HEART TRANSPLANTATION REGISTRY

Sonia Marcos-alonso[1], Francisco Portela[2], Manuela Camino[3], Ruben Greco[4], M Ángeles Tejero[5], Luis García Guereta[6], Alberto Alvarez[7], Dimpna Albert[8]
Hospital Materno Infantil A Coruña, Pediatric Cardiology, A Coruña-Spain[1]; Hospital Materno Infantil A Coruña, Cardiac Surgeon, A Coruña-Spain[2]; Hospital Gregorio Marañón, Pediatric Cardiologist, Madrid-Spain[3]; Hospital Gregorio Marañón, Cardiac Surgeon, Madrid-Spain[4]; Hospital Reina Sofía, Pediatric Cardiologist, Córdoba-Spain[5]; Hospital La Paz, Pediatric Cardiologist, Madrid-Spain[6]; Hospital La Paz, Cardiac Surgeon, Madrid-Spain[7]; Hospital Vall D´hebrón, Pediatric Cardiologist, Barcelona-Spain[8]

Introduction: Heart transplantation (HT) represents the treatment of advanced refractory heart failure in children. The Spanish Heart Transplantation Registry collects clinical data of pediatric HT since May 1984.
Objective: Describe the clinical characteristics and outcome of pediatric CT in our country.
Material and Methods: We analyzed the clinical characteristics of donors and recipients and the short and long-term outcome in children under 16 between 1984 and 2014.
Results: A total of 391 HT were performed, 237 males (60%) with a mean age of 6.9 ± 5 years. 19 patients (15.5%) had some degree of renal dysfunction. The main cause were cardiomyopathy in 214 (57.5%) and congenital heart disease in 145 (39%). 182 (50.7%) children were transplanted in urgent status and 48 (26%) had a circulatory assist device (CAD), 45 were implanted in the last decade. The most common cause of death in donors was traumatic brain injury. The mean follow-up time was 6.3 ± 6.4 years. The most frequent complications were rejection (48%), infections (52%), graft vascular disease (10.7%) and tumors (4.7%). The leading cause of death was graft dysfunction followed by acute rejection and sudden death. Survival at first month was 82.2%, one year 74.1%, 5 years 68%, 10 years 59.2% and 15 years 51.4%.
Conclusions: Short and long term outcomes in Spain are consistent with those reported in the world literature, including a continuing trend towards better survival over the years. At present, 1 in 4 children who are transplanted in urgent status has CAD. It would be necessary to analyze the impact of the increasing use of CAD on perioperative survival and during the first year of transplantation as well as to identify risk factors for complications.

P2862 - REDUCED INFLUENCE OF TGFβ SIGNALING OVER BMP SIGNALING IN THE MCT + AC SHUNT RAT MODEL OF PULMONARY ARTERIAL HYPERTENSION

Lysanne Jorna[1], Jan-renier Moonen[1], Diederik Van Der Feen[1], Quint Hagdorn[1], Beatrijs Bartelds[1], Marco Harmsen[2], Rolf Berger[1]
University Medical Center Groningen, Pediatric Cardiology, Groningen-The Netherlands[1]; University Medical Center Groningen, Pathology and Medical Biology, Groningen-The Netherlands[2]

Background: Pulmonary arterial hypertension (PAH) is a cardiopulmonary disorder in which cellular proliferation in the arterioles is responsible for excessive proliferation of the arteriolar cells obstructs the vasculature, which increases pulmonary arterial pressures. As important regulators, endothelial cells are anticipated to be the major culprits in PAH. Interestingly, the presumed dysbalanced TGFβ/BMP pathway has never been dissected on endothelial level in rat models for PAH.
Aim: To map the expression and regulation of TGFβ and BMP pathway mediators to assess the presence and nature of their dysbalance in rat models for PAH.
Methods: The pathway components Tgfbr1, Bmpr2, Smad2, Smad8, Serpine1 and Id3 were assessed by RT-qPCR, and pSMAD2/3, pSMAD1/5/8, PAI-1 and ID-3 were assessed with IF in three different PAH models, i.e the MCT + AC-shunt, MCT only and AC-shunt only at early (d14) and late (d28) stage.
Results: IF staining of intra-acinar arteries showed no differences in localization or expression of the proteins pSMAD2/3, pSMAD1/5/8, PAI-1 and ID-3. In isolated pulmononary ECs, gene expression of all pathway components in all models except the Flow only model was downregulated in compliance with the PAH progression (table1). The ΔCT value ratio of Tgfbr1:Bmpr2 is 1:2.8 in the Sham group versus 1:1.2 on MCT + Flow day 28. This is mimicked in the MCT only group, where the Tgfbr1:Bmpr2 ratio dropped from 1:2.8 to 1:1 on day 28. The Flow only model shows an initial drop of 1:1.6 on day 14, but corrects to 1:2.3 on day 28.
Conclusion: In isolated endothelial cells of the MCT + Flow and MCT only PAH models, the influence of TGFβ pathway over the BMPR2 pathway gradually decreases. In the Flow only model this aspect ratio normalizes. This suggests that TGFβ inhibiting agents could have no effect in rat models of PAH, and might also not benefit patients with CHD-PAH.

P2869 - LATE "FAILING" FONTAN IN A TERTIARY CENTER IN PORTUGAL 18 YEARS FOLLOW UP

Ana Correia-Costa[1], Paulo Éden Santos[1], Jorge Casanova[2], António Rodrigues Sousa[2], Sofia Granja[1]
Centro Hospitalar S. João, Pediatric Cardiology, Porto-Portugal[1] Centro Hospitalar S. João, Cardiothoracic Surgery, Porto-Portugal[2]

Background: The Fontan procedure represents the final surgical stage of the troublesome univentricular pathway. We aimed to describe some of the factors associated with "Late Failing" Fontan (FF) circulation.
Materials and Methods: Clinical medical records of children/young adult born after 1987 submitted to Fontan procedure and followed up at a tertiary centre in Portugal, were reviewed. Patients with evidence of early FF were excluded. Late FF was defined as: death/

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

transplant, Fontan conversion, heart failure (HF) symptoms, protein-losing enteropathy (PLE) or plastic bronchitis.
Results: Fourty-six patients were included, 25 males (54,3%), with 4-29 yo at present, with complex CHD (table 1). Thirty patients had single LV anatomy, 12 single RV anatomy and four biventricular heart. Total cavopulmonary connection (TCPC) was performed in all patients and the median age was 5,7yo (P25-P75: 4,4-7,6yo). Forty-one patients had an extracardiac conduit (EC) and five a lateral tunnel (LT); 37 were fenestrated Fontan. Eleven patients (23.9%) developed late FF: five PLE, five HF and one death. No patient were submitted to cardiac transplant or Fontan conversion. The only deceased patient was 13yo (5,2yo after surgery) with malignant arrhythmia. The median time of FF presentation was 5.0yo(P25-75: 0.6-9.9)after the Fontan surgery. Comparing with the non-FF, FF patients more frequently had LT Fontan (4/5 vs EC conduit 7/41, $p < 0,001$) and arrhythmias (4/8 vs no arrhythmia 5/30, p 0.049). All patients with ventricular dysfunction (5/46) developed FF ($p < 0,001$). No other significant differences were found between the groups (ventricular morphology, size of pulmonary arteries, presence of fenestration, collateral vessels).
Conclusions: Less than 25% of our patients developed late FF. The lack of associations between some of the studied factors and FF might be due to the small sample. Future studies on the factors predicting the outcome of Fontan procedure are imperative to improve the management of these patients.

Table 1. Baseline Characteristics of all patients, Non-"Failling" Fontan and "Failling' Fontan Patients.

P2910 - TEN YEAR EXPERIENCE OF A PEDIATRIC HEART TRANSPLANT PROGRAM IN BRASILIA BRAZIL

Jorge Afiune[1], Cristina Afiune[2], Manuela Cabral[2], Claudio Cunha[3], Fernando Atik[3]
ICDF, Pediatric Cardilogy, Brasilia-Brazil[1]; ICDF, Pediatric Cardiology, Brasilia-Brazil[2]; ICDF, Cardiac Surgery, Brasilia-Brazil[3]

Introduction: Heart transplantation is the last remaining therapeutic option for children with end-stage heart disease. Building a pediatric heart transplantation program is still challenging in developing countries.
Objectives: To describe the early and midterm results of a pediatric heart transplantation program in Brasilia.
Methods: We included all pediatric patients (≤18 years) who were listed for a heart transplantation in a pediatric cardiac center between 2007 and 2016.Parameters analyzed were obtained prospectively over the years.
Results: 42 children with a mean age of 5.7 years (2 months to 15.5 years) were listed for cardiac transplantation as intention to treat. Cardiomyopathy was present on 35 children(83%) and 23 (55%) were aged ≤5 years. 32 children (76%) were on INTERMACS ≤3, while 21 (50%) were on mechanical ventilation. 17 children (41%) died while on waiting list and 3 children were delisted (clinical improvement). Mortality in the waiting list was higher in children aged <1 year (86% x 36%) and those who were in INTERMACS ≤3 (50% x 10%). Cardiac transplantation was done in 22 children (52%), with a waiting list time of 94 days (2 to 502 days). Mean cold ischemia time was 140 minutes (57 to 270 minutes). ICU stay after transplantation was 18 days (3-48 days) and hospital stay was 43 days (3-84 days). Mean follow-up time was 3.2 years (35 days at 7.2 years), and survival rate at 30 days, 1 and 5 years were 86%, 82% and 82%, respectively. At least one episode of rejection occurred in 63% of the patients, and one child had a lymphoproliferative disease after 2 years of transplantation.
Conclusions: Early and midterm results obtained with this new pediatric cardiac transplantation program in Brasilia were quite satisfactory although mortality rate on waiting list was very high especially in children less than 1 year of age.

P2912 - DESCRIPTIVE STUDY ON ANTHRACYCLINE INDUCED CARDIOTOXICITY IN PAEDIATRIC ONCOLOGY PATIENTS IN SINGAPORE

Nicole Min Chan[1], Wai Lin Ang[2], Soe Nwe Mya[3], Mei Yoke Chan[3], Ching Kit Chen[2]
National University of Singapore, Yong Loo Lin School of Medicine, Singapore-Singapore[1] KK Women's and Children's Hospital, Cardiology Service, Department of Paediatric Subspecialties, Singapore-Singapore[2]; KK Women's and Children's Hospital, Haematology-Oncology Service, Department of Paediatric Subspecialties, Singapore-Singapore[3];

Introduction: Anthracyclines as chemotherapeutic agents are widely used to treat childhood cancers. Cardiotocixity is a known adverse effect of anthracycline treatment; however, its incidence in Singapore is unknown. The aim of this study was to evaluate the epidemiology of paediatric anthracycline-induced cardiotoxicity in Singapore.
Method: This was a single-center, retrospective analysis of 25 paediatric oncology patients who were treated with anthracyclines and subsequently developed cardiotoxicity. Primary data analysed were quantified echocardiographic findings, details of anthracyclines used, onset of cardiotoxicity and treatment, as well as their outcomes. Secondary points included patient profiling and patient follow up.
Results: Doxorubicin was the most commonly used anthracycline, 52% of patients underwent doxorubicin treatment with a mean cumulative dose of 206 mg/m2. Other anthracycline treatments used were daunorubicin, epirubicin and idarubicin with a mean doxorubicin-equivalent cumulative dose of 217 mg/m2. The cohort developed cardiotoxicity at 10.8 years with decreased ventricular function being the most common diagnosis. The entire cohort had their cardiotoxicity diagnosed by imaging (mean fractional shortening: 22%, mean left ventricular end-systolic dimension: 45.5mm, mean left ventricular end-systolic dimension: 36.1mm), with 52% being diagnosed as an inpatient. The cohort's

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

cardiac disease free time was 19.2 months and had a total follow up period of 3.8 years with a 68% survival rate (65% of whom remained in remission). The number of cardiac events was 2.71 and 20% of the cohort developed congestive heart failure. The most common treatment used were angiotensin converting enzyme inhibitors.
Conclusion: This was the first local study of its kind, with the aim to gain a deeper understanding of the local paediatric population's cardiac response to anthracyclines, which would help in future management, monitoring and counselling of such patients, and pave the way for more related studies.

P2975 - CLINICAL DETERMINANTS OF OPTIMAL BETA BLOCKER DOSE IN CHILDHOOD HYPERTROPHIC CARDIOMYOPATHY

Ingegerd Östman-Smith
Sahlgrenska Academy, Gothenburg University, Department of Clinical Specialties, Gothenburg-Sweden

Background: Pharmacokinetic studies of carvedilol have established that infants require 4.3 times higher dose/kg body weight to obtain comparable plasma-levels to adults, and 2-11 year-olds 2.9 times, and 12-15 year olds 1.4 times higher. Propranolol is metabolized by the same enzyme, and accordingly it is to be expected that physiologically equivalent beta-blockade effect would require different propranolol-doses across this age range.
Methods: Consecutively diagnosed patients (age range 0-19 yrs) with hypertrophic cardiomyopathy (HCM), n = 105, between 1983-2000 at the John Radcliffe Hospital, Oxford, UK, and between 2000-2015 at the Queen Silvia Children's Hospital, Gothenburg, Sweden, that were treated with propranolol (or equivalent doses metoprolol or bisoprolol) because of symptoms, outflow-tract obstruction at rest, or progressively worsening hypertrophy. The doses were titrated up to achieve a profound beta-receptor blockade as judged by 24 h Holter and heart-rate response to exercise testing according to standardized protocol (Östman-Smith et al, JACC,199;34:1813-22). Beta-blocker dose required were analyzed in four age-ranges, and correlation analysis with different clinical features was performed.
Results: Beta-blocker dose correlated significantly with age at diagnosis ($p < 0.0001$, correlation coefficient (cc) -0.411), septum-to cavity ratio ($p < 0.0001$; cc = 0.606), Detroit Z-score septum ($p < 0.0001$; cc = 0.540), left-atrium-to-aortic ratio ($p = 0.0007$; cc = 0.351) and left ventricular outflow-obstruction ($p = 0.0004$; cc = 0.390). Propranolol doses/day required for optimal beta-blockade at different age ranges were 0-1.9yrs (n = 35): median 11.6 mg/kg [IQR 7.2-17.4]; 2-6.9yrs (n = 16): 6.5 [5.2-9.4] mg/kg; 7-12.9yrs (n = 20): 7.4 [5.8-10.5] mg/kg; 13-19.9yrs (n = 34): 6.4 [4.6-8.0] mg/kg. In the whole group HCM-related to Noonan-spectrum disorders was significantly correlated to a higher dose, but this was an age-related effect, as correlation did not remain significant when patients were compared within the same age range.
Conclusions: Infants require substantially higher doses/kg body weight for adequate beta-blockade than older children. Above the age of two, degree of hypertrophy, outflow tract obstruction and indicators of diastolic dysfunction also influence dose-requirement significantly.

P2997 - NEUROVASCULAR COMPLICATIONS IN CHILDREN SUPPORTED ON BERLIN HEART EXCOR DEVICE EARLY RISK FACTORS FOR STROKE

Suzan Kakat[1], Troy Dominguez[1], Mary Mathias[2], Ray Hreiche[1], Marios Kaliakatsos[3], W. Kling Chong[4], Matthew Fenton[5], Tain-Yen Hsia[6], Maura O'Callaghan[1], Ann Karimova[1], Aparna Hoskote[1]
Great Ormond Street Hospital for Children Nhs Foundation Trust, Cardiac Intensive Care Unit, London-United Kingdom[1]; Great Ormond Street Hospital for Children NHS Foundation Trust, Haemophilia Comprehensive Care Centre, London-United Kingdom[2]; Great Ormond Street Hospital for Children NHS Foundation Trust, Department of Neurology, London-United Kingdom[3]; Great Ormond Street Hospital for Children NHS Foundation Trust, Department of Radiology, London-United Kingdom[4]; Great Ormond Street Hospital For Children NHS Foundation Trust, Department of Cardiology and Transplantation, London-United Kingdom[5]; Great Ormond Street Hospital For Children NHS Foundation Trust, Department of Cardiothoracic Surgery, London-United Kingdom[6];

Introduction: The incidence of neurovascular complications (NC) after Berlin Heart (BH) EXCOR ventricular assist device (VAD) remains high despite considerable VAD experience and aggressive management of anticoagulation.
Aims: To identify perimplantation risk factors for neurovascular complications after BH VAD implantation.
Methods: Retrospective cohort study of children supported with BH VAD at our institution from November 2004 to May 2015. Pre-, peri-, post-implantation clinical data, neurovascular complications, coagulation profile, platelet function tests and inflammatory markers were analysed. NC were identified by head CT and/or brain MRI performed as clinically indicated.
Results: A total of 75 children were supported with BH VAD for end-stage heart failure at a median age 2.9 years (1.2-8.8 years) and median weight 13 kg (9-26 kg). The most common indication was for end-stage cardiomyopathy (70/75). The median time on VAD support was 39 days (16-102 days). Overall survival to transplant or recovery was 85% (64/75). NC occurred in 21/75 (28%) at a median duration 15 days (8-35 days) after implantation. Of the children with NC, 11 had an ischaemic stroke, 7 had a haemorrhagic stroke, and 3 had subdural haematomas. After NC, 7/21 (33.3%) died due to devastating neurological complication, and out of the remaining 14, 12 were transplanted and 2 recovered. Using multivariable analysis, total blood products given within 24 hours after VAD implantation [HR 1.04 (95% CI 1.02-1.06)], weight (per 10 kg) [HR 0.65 (95% CI 0.56-0.75)], and postop C-reactive protein levels [1.01 (95% CI 1.00-1.01)] were independently associated with NC.
Conclusions: Risk of NC remains high and these events usually occur early after BH VAD implantation. Postoperative blood product requirement and CRP potentially identify modifiable risk factors for stroke.

P3005 - A STUDY SHOWING THE EFFICACY OF NO FOR PULMONARY VASULCAR BED REACTIVITY DELIVERY WITH NOVEL IMPROVISED HOOD

Neeraj Awasthy[1], Anuja Kulkarni[2]
Max Hospital,Saket, Pediatric Cardiology, Delhi-India[1]; Max Hospital, Saket, Cardiac Anesthesia, Delhi-India[2]

Context- Study of delivery of NO for diagnostic cardiac catheterization in paediatric patient BIPAP vs paediatric Hud.
Aims and Objective: Effective delivery of NO with the HUD which is comparable to BIPAP delivery, in pediatric spontaneously breathing patient with the use of NOXBOX machine.
Methods and Material: This is comparative prospective pilot study, to assess effectiveness of delivery of NO via HUD, compared to that of BIPAP mask. Study population is grouped into two based on mode of delivery as BIPAP receiving group and HUD receiving group. Each group contain 5 spontaneously breathing pediatric patient with underlying pulmonary hypertension, and, NO is delivered to assess reversibility of pulmonary vasculature.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Result: data collected as above, in HUD group, we were able to deliver NO effectively in acceptable range in all 5 patients same in BIPAP group.
Conclusion: We found that this system of NO delivery by HUD is a simple delivery system with wide applicability. We have shown that it has similar efficacy as that of BIPAP to deliver NO and O2. Its safety profile appears to be comparable to that of standard, more complicated, delivery systems.

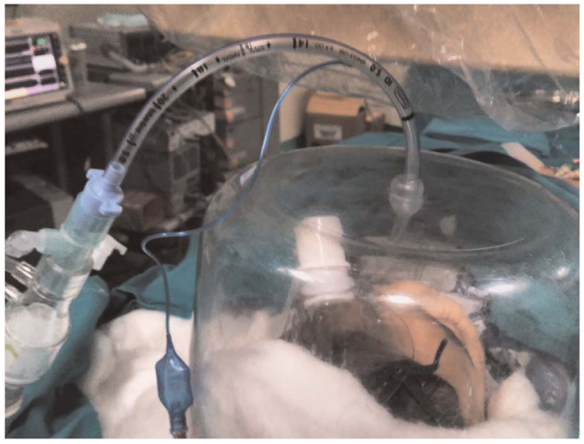

Figure.

P3007 - PERCUTANEOUS IMPELLA DEVICE FOR MECHANICAL CIRCULATORY SUPPORT IN CARDIOGENIC SHOCK PEDIATRIC EXPERIENCE

Sebastian Tume[1], Dhaval Parekh[2], William Dreyer[2], Aamir Jeewa[3], Iki Adachi[4], Henri Justiono[2], Athar Quereshi[2]
Baylor College of Medicine/Texas Children, Critical Care Medicine, Houston-United States[1]; Baylor College of Medicine/Texas Children, Cardiology, Houston-United States[2]; The Hospital For Sick Children, Cardiology, Toronto-Canada[3]; Baylor College of Medicine/Texas Children, Congenital Hear Surgery, Houston-United States[4]

Background: Management of acute cardiogenic shock frequently involves use of aggressive pharmacologic support. Patients who fail to respond to standard medical therapies might require mechanical circulatory support. Recently, Impella ventricular assist device has been approved for management of cardiogenic shock in adults. Experience with Impella support in children is limited. We present our experience with Impella device in a pediatric cardiovascular intensive care unit (CVICU) at a freestanding children's hospital.
Methods: All patients treated with Impella device between September 2014 and June 2015 were included in retrospective analysis. Demographic, hemodynamic and laboratory data were reviewed and reported using descriptive statistics. Data was compared using Student's t-test with significance level at $p < 0.05$.
Results: Total of 13 Impella devices were implanted in 10 patients: CP (n = 6), and 5.0 (n = 7). Median patient age was 18 years (13,35), weight of 77 kg (56,124), and BSA of 1.97 m2 (1.61,2.47). Average length of CP support was 4 days (median 3.5 (1,10)) and 5.0 device 19 days (median 12(10,45)). Average flow for CP and 5.0 was 3.0 L/min and 4.2 L/min. There was a significant improvement in PCWP post implantation ($p = 0.03$) and 24 h vasoactive score ($p = 0.03$). Compared to immediate post device implant, the lactate at 24 hours and creatinine at 5 days were significantly lower ($p < 0.05$). Median LDH level was 1813 U/L (791,7264) and plasma hemoglobin <30 mg/dL (<30,86) after 5 days of support. Insertion site bleeding occurred with 6 devices (46%). All patients survived to ICU discharge.
Conclusion: Impella support for acute cardiogenic shock shows hemodynamic benefits with a limited morbidity and no early mortality in pediatric CVICU. This modality could be considered as a support option in management of older children with acute cardiogenic shock to achieve end organ recovery or as a bridge to clinical decision.

P3013 - TWELVE YEARS EXPERIENCE WITH PEDIATRIC CARDIOMYOPATHY IDENTIFYING OUTCOME RISK FACTORS

Zeinab Selim, Sonia El Saiedi, Rasha Ammar, Reem Esmail, Inas Abd El Satar
Cairo University, Pediatric Cardiology, Cairo-Egypt

Back Ground: Pediatric cardiomyopathy (CM) is a rare but serious and often life-threatening condition. In children, cardiomyopathy is often a part of multisystem disorder, which requires the attention of multiple subspecialists.
Objective: The aim of this work is to describe the most common demographic, clinical features and its relationship to the outcomes of children diagnosed with cardiomyopathy in the clinic during that period.
Materials and Methods: This retrospective descriptive study was carried out at the Pediatric cardiomyopathy Clinic, children's Hospital, Cairo University, to review the files of patients diagnosed with cardiomyopathy in the period from 2004 to 2016.
Results: The cases diagnosed with cardiomyopathy during that period were 1282 cases. The patient files included 948 cases with DCM, 260 cases with HCM, 45 cases with RCM, 29 cases with LVNC and one case with RVD. The age of the patients ranged from 10 days to 18 years with a mean age at presentation of 3.2 years. The most common clinical presentation was dyspnea (84.9%) followed by heart failure while chest infection were (50.6%). A family history was positive in (48.5%). Treatment was mainly treatment of heart failure or LVOTO. 142 (11.1%) of our patient died and 396(39.6%) with lost follow up more than 5 years. There were significant risk factors for mortality including reduced shortening fraction, ejection fraction, repeated intensive care unit admission and history of a metabolic disorder. Insignificant risk factors will be also identified and described.
Conclusion: The current study demonstrates that children with CM are at particular risk for death during the initial ICU admission and reduced FS/LVEF may be predictive of outcome, Patients with significant risk factors may benefit from closer outpatient observation and perhaps, earlier consideration for stem cell therapy and cardiac transplantation.

P3024 - THE CORRELATIONS BETWEEN THE GENOTYPE OF FBN1 MUTATION AND PHENOTYPE IN 85 UNRELATED TAIWANESE PATIENTS WITH MARFAN SYNDROME

Hsin-Hui Chiu[1], Mei-Hwan Wu[2], Po-Ting Yeh[3], Yi-lwun Ho[4], Chih-Chieh Yu[4], Chih-Wei Yu[5], Jou-Kou Wang[2]
Taipei Medical University Hospital, Pediatrics, Taipei-Taiwan[1]; National Taiwan University Hospital, Pediatrics, Taipei-Taiwan[2]; National Taiwan University Hospital, Ophthalmology, Taipei-Taiwan[3]; National Taiwan University Hospital, Internal Medicine, Taipei-Taiwan[4]; National Taiwan University Hospital, Radiology And Medical Imaging, Taipei-Taiwan[5]

Objectives: To explore the correlations between FBN1 genotype and phenotype in Taiwanese Marfan syndrome.
Methods: From May 2007 to Sep 2013, a total of 125 patients (mean age: 25.1 ± 14.6 years, 58% male) diagnosed as Marfan syndrome fulfilling the Ghent criteria and confirmed with FBN1

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

gene mutation were enrolled. Mutation was identified by denaturing high-performance liquid chromatography or High-resolution melting analysis.
Results: A total of 85 mutations were identified in 125 proved MFS patients. The mutation comprised 60 missense, 9 nonsense, 15 frame shift, and 1 whole exon deletion. Most mutations located in exon 11-24 (28.2%), then exon 25-40 (22.4%), and in cbEGF like domain (63.5%), then TGFBP domain (18.8%). The distributions of age and young patients number were even in the whole gene without statistical significance. The correlation of genotype and phenotype based on the exonic location showed that mutations in exon 1-24 were associated with major ocular symptoms. Mutations in exon 41-57 were associated with major cardiovascular and skeletal symptoms but less ocular involvement. Mutations in exon 58-65 were associated with minor symptoms in three systems. Based on the classification of domain, mutations in NH2 region were associated with major cardiovascular and ocular symptoms. Mutations in COOH region were associated with minor symptoms. Mutations in hybrid domain were associated with major cardiovascular symptoms. Based on mutation type, nonsense mutations were associated with major cardiovascular symptoms.
Conclusions: Genotype information is essential for diagnosis of Marfan syndrome. The usefulness of predictive genetic testing in FBN1 mutations requires further investigation.

P3028 - THROMBOELASTOGRAPHY PLATELET MAPPING IN CHILDREN SUPPORTED WITH THE BERLIN HEART EXCOR PEDIATRIC WHEN MIGHT IT NOT WORK AND WHAT ARE THE ALTERNATIVES

Jenna Murray, Sharon Chen, John Dykes, David Rosenthal, Christopher Almond
Stanford University, Cardiology, Palo Alto-United States

Background: Pediatric centers rely primarily on Thromboelastography and Platelet Mapping™ (TEG/PM) to dose-adjust platelet inhibitors in children supported with the Berlin Heart EXCOR Pediatric. It is unclear whether TEG/PM™ results are accurate because PM has not been validated in children. We sought to evaluate the agreement between 3 platelet function assays in a Berlin Heart recipient who had a poor PM™ response to high-dose platelet inhibitor therapy.
Methods: Platelet function was measured serially using TEG/PM, standard optical platelet aggregometry (OA) and Multiplate (MP) in a 3 year-old boy supported with a Berlin Heart. For TEG/PM, ASA response was evaluated by % inhibition to Arachadonic Acid (AA) while DPA and clopidogrel response was evaluated by % inhibition to adenosine di-phosphate (ADP). Platelet aggregation for OA was evaluated by % aggregation and for MP by standardized units (out of 100).
Results: Following EXCOR implant, ASA was uptitrated to a target dose of 30 mg/kg/day, DPA to 4 mg/kg/day and clopidogrel to 1 mg/kg/day as per institutional protocol. At target doses, the %AA inhibition from TEG/PM (N = 34) ranged from 0% to 33% and the %ADP inhibition ranged from 0% to 35% consistent with a poor response. By contrast, OA revealed a %AA and %ADP aggregation of of 5-35% and MP revealed ASA and ADP aggregation of <30 U, both consistent with good platelet response.
Conclusion: In selected patients PM has poor agreement with OA raising questions about its validity. By contrast OA has good agreement with PM, which requires a smaller blood sample (<1 cc) suggesting it may have advantages over PM. Further studies are need to determine the optimal method for measuring platelet function in children.

P3035 - SILDENAFIL THERAPY OF PULMONARY HYPERTENSION IN CHILDREN LONG TERM (10 YEARS) SURVIVAL OF PATIENTS

Yuri Belozerov, Olga Groznova
Academician Yu.E.Veltishchev Research Clinical Institute of Pediatrics, N.I.Pirogov Russian National Research Medical University, Cardiology Department, Moscow-Russia

Background: Determination of the efficacy, safety and tolerability of specific drugs for the treatment of pulmonary arterial hypertension in children is a crucial task in pediatrics. Results of a prospective study (2004-2016) estimating long-term (over 5 years) survival of patients received sildenafil monotherapy are interesting for the choice of treatment both by patient and the doctor.
Methods: Clinical examination, cardiopulmonary test (bicycle ergometer), hemodynamic evaluation, chest X-ray, BORG dyspnoea scale, ophthalmologic (including colour vision) evaluation, electrocardiography, ECHO-cardiography, clinical labs, BNP, pro-BNP were performed.
Results: Four patients with primary pulmonary hypertension (WHO class II-III), and 9 patients with pulmonary hypertension associated with congenital heart disease (class II-III) were followed. 5-year survival in primary pulmonary hypertension was 100%, in pulmonary hypertension associated with congenital heart disease - 89%. Three patients with congenital heart disease have underwent successful surgery 3, 8 and 9 years after start of the therapy (previously considered as inoperable). Four patients died: 20 months (ventricular fibrillation), 6 years (sudden cardiac death), 7 years (perforated duodenal ulcer) and 7 years (progression of pulmonary hypertension amid pulmonary infectious diseases) after start of the therapy.
Conclusions: Sildenafil monotherapy in patients with primary pulmonary arterial hypertension and associated with congenital heart disease pulmonary arterial hypertension improves long-term survival.
