O1289 - IMPROVING TIMELY DISCHARGE BY USING GOAL ORIENTED ROUNDING AND TEAM BASED COMMUNICATION

Alistair Phillips[1], *Nicole Berndsen*[1], *Courtnay Caufield*[2], *Maureen Davis*[2], *Pooja Nawathe*[3], *Stephen Robert*[3], *Vincent Olshove*[1]
Cedars-Sinai Medical Center, Surgery, Los Angeles-United States[1]; *Cedars-Sinai Medical Center, Nursing, Los Angeles-United States*[2]; *Cedars-Sinai Medical Center, Pediatrics, Los Angeles-United States*[3]

Background: Discharge planning for complex congenital heart patients is challenging for the multi-disciplinary team, especially in a cardiac critical care environment. Delays in discharge are often attributed to poor team planning and communication. Multi-disciplinary collaboration with effective communication ensures a seamless and timely discharge.
Methods: Members of the multi-disciplinary team collaborated to establish a rounding process in the intensive care unit to have patients discharged by noon. The rounding process, implemented in October 2015, had pre-defined goals and involved all members of the team: nursing, physicians, case management and allied health professionals. Patient status, eligibility for discharge and anticipated needs were discussed and planned accordingly by appropriate team members. Rounds were audited for goal completion and efficiency and patient discharge times were tracked.
Results: We identified four crucial multidisciplinary rounds: (1) Operational rounds which are brief overview rounds conducted in a conference room, establishing key goals for the day including preparing for the following days discharges, (2) Work rounds – bedside rounds, (3) 4 pm hand-off rounds – review of key goals days, and reviewing barriers to discharge and (4) Late evening rounds with bedside nurse to make sure goals are on track. Surveys were conducted at 1 month and 3 months after process education and implementation was completed. Responses were from all disciplines. There was an overall increase in process understanding, overall efficiency ($p < 0.1$). Prior to implementation of process, 25% patients were discharged prior to noon. From October 2015-September 2016, 40% of patients were discharged before noon.
Conclusion: Establishing a process for goal-oriented, multi-disciplinary rounding improves team communication and coordination of care in preparation for discharge. Ensuring timely discharge improves patient satisfaction and patient flow within the cardiac critical care unit.

O1660 - A CLINICAL EFFECTIVENESS PROGRAM LEVERAGING AGGREGATE PATIENT DATA AT THE POINT OF CARE IMPROVES VALUE IN PATIENTS UNDERGOING CONGENITAL HEART SURGERY

Andrew Shin, *Ling Loh*, *Joseph Kim*, *Heather Freeman*, *Natalie Pageler*, *Michael-anne Browne*, *Christy Sandborg*, *Paul Sharek*, *Claudia Algaze*
Stanford University, Pediatrics, Palo Alto-United States

Background: Healthcare in the United States is increasingly losing value. Decreasing variation is central to reducing waste and cost. The rapid adoption of information technology is regarded as an important means to promote high value care. We describe a clinical effectiveness program leveraging personalized comparative effectiveness information at the point of care to provide target hospital goals for patients following congenital heart surgery.
Methods: Using an observational pre-post-intervention design, patients undergoing one of the 10 core congenital heart surgeries as defined by the Society of Thoracic Surgeons were included. The setting was a tertiary university-affiliated academic children's hospital between September 6, 2016 and December 19, 2016. Personalized comparative cohorts encompassing 2 years of pre-intervention data were constructed utilizing the electronic health record (EHR). Based on the aggregate data, target hospitalization goals (e.g., target extubation time) were tailored for every patient and made visible peri-operatively for healthcare providers in real-time. Outcome metrics included intensive care unit (ICU), total post-operative length of stay (LOS) and associated cost.
Results: A total of 51 patients were enrolled with 47 (92%) completing the program. Other than the Fontan operation, all surgeries experienced a reduction in LOS. We found an aggregate reduction in LOS and variance for ICU (median 3 [IQR 3-4] vs 5 [IQR 3-7] days, $p < 0.001$; mean $3.6 + 1.9$ vs $6.5 + 6.5$ days, $p = 0.003$), and total postoperative LOS (median 6[IQR 5,8] vs 8[IQR 6,12] days, $p < 0.001$; mean $6.5 + 2.3$ vs $10.9 + 9.9$ days, $p = 0.003$), compared with the pre-intervention period. Mortality, reintubation, ICU and hospital readmission rates were unchanged. The annualized cost savings is estimated to be approximately $2.5 million.

Conclusions: Implementation of a clinical effectiveness program that leverages EHR data for real-time comparative effectiveness information decreased variation and safely reduced length of stay and associated cost.

O1973 - HOW HARD DO CARDIOLOGISTS WORK THE PATIENT ENCOUNTER INDEX (PEI) A NOVEL METHOD TO ASSESS THE CLINICAL WORKLOAD OF A PAEDIATRIC CARDIOLOGY SERVICE

Rik De Decker[1], Oliver Barry[2], Rachel Chater[3], John Lawrenson[4]
Red Cross Children's Hospital, Cardiology, Cape Town-South Africa; Boston Children's Hospital, Cardiology, Boston-United States[2]; Graduate School of Business, Uct, Bertha Centre, Cape Town-South Africa[3]; Tygerberg Children's Hospital, Cardiology, Cape Town-South Africa[4]

Background: Correctly assessing the workload of a clinical service may be difficult, particularly for paediatric cardiac services with many complex patients - when a simple count of patient numbers will be misrepresentative. We conceived a novel patient encounter index (PEI), which simply indexes the total daily encounter time as a ratio of a contractual 8-hour working day. A patient encounter is defined as any activity that may directly influence the clinical outcome of a specific patient.
Methods: Nine medical students observed all the daily clinical duties of four full-time cardiology clinicians over a 2-week period. The duration of each encounter and its nature (clinical, analytical, procedural, or discussive) were recorded. Encounters were recorded on pre-designed time sheets, transferred to Excel spread sheets and analysed using simple summary statistics.
Results: A total of 2014 encounters were recorded over 10 working days. On average, clinicians were involved in 45.3 (45.2-58.5) encounters per day, involving 30.9 (17.7-56.2) patients (some patients were encountered more than once per day). The four clinicians' PEIs ranged from 0.74 to 0.96. All encounters were timed from onset to completion; encounters required an average of 6.6 hours of dedicated time per day. The context and implications of these and other data (e.g. encounter intensity) will be presented.
Conclusions: Clinical duties consumed 74-96% of the working day of the clinicians, leaving little time for other essential duties, e.g. teaching and administration. When one clinician is away on leave, there is an 8% increase of each remaining clinician's clinical workload, resulting in PEIs of 0.82-1.04. These data were included into a motivation to increase clinical staffing of our cardiac services, with success. The PEI is a robust and repeatable tool to objectively assess clinical workload of busy clinicians, and may be effectively implemented to influence decisions in service management.

Patient encounter index per doctor per day.

O2299 - PERFORMANCE OF PEDIATRIC CARDIAC SURGERY CENTERS A NATIONAL EFFORT TO REDUCE THE GAPS OF BURDEN OF CONGENITAL HEART DISEASE IN COLOMBIA

Néstor Fernando Sandoval Reyes[1], Marisol Carreño Jaimes[2], Victor Caicedo[3], Victor Castillo [4], Juan Correa [5], Alejandro Escobar[6], Oscar Fernandez[7], Juan Jaramillo[8], Juan Mantilla[9], Olga Maza[1], Sara Mendoza [4], Rafael Meza[6], Federico Nuñez[3], Martin Oviedo[11], Luis Perez[12], Alejandro Ramirez[8], Jairo Sanchez[7], Jorge Zapata[13]
Fundación Cardioinfantil - Instituto De Cardiología, Congenital Heart Institute, Bogota-Colombia[1]; Fundación Cardioinfantil - Instituto De Cardiología, Cardiac Surgery, Bogota-Colombia[2]; Fundación Clínica Shaio, Cardiac Surgery, Bogota-Colombia[3]; Fundación Cardiovascular De Colombia, Cardiac Surgery, Floridablanca-Colombia[4]; Hospital Universitario San Ignacio, Cardiac Surgery, Bogota-Colombia[5]; Centro Cardiovascular Somer Incare, Cardiac Surgery, Rionegro-Colombia[6]; Instituto Del Corazón De Bucaramanga, Cardiac Surgery, Bucaramanga-Colombia[7]; Clinica El Rosario, Cardiac Surgery, Medellin-Colombia[8]; Hospital Cardiovascular Del Niño, Cardiac Surgery, Soacha-Colombia[9]; Clínica General Del Norte, Cardiology, Barranquilla-Colombia[10]; Clínica General Del Norte, Cardiac Surgery, Barranquilla-Colombia[11]; Hospital Simón Bolivar, Cardiac Surgery, Bogota-Colombia;[12] Cardiovid, Cardiac Surgery, Medellin-Colombia[13]

Background: In Colombia about 4.800 new pediatric cardiac surgeries should be performed per year. Knowledge of the characteristics and results of Pediatric Cardiac Surgery Centers in Colombia allows us to determine: The real number of patients treated and the capacity of our country to meet the needs of patients with congenital heart disease to promote new strategies in this field. The aim of this study was to describe the operational capacity of Pediatric Cardiac Surgery Centers in Colombia for 2015.
Methods: A blind online survey was sent to the centers previous a verbal agreement to the willing of participate. The survey had 25 questions related to 4 domains: volume of procedures, services offered, surgical risk evaluation and databases. A descriptive analysis was done in STATA 14.
Results: 13 Pediatric Cardiac Surgery Centers were identified in Colombia and all answered the survey. 38,5% (5/13) are in Bogota, follow by Bucaramanga and Cali with 2 centers each one of them. All centers had pediatric cath lab, int 2015 a total of 2406 cardiac surgeries were done, a mean of 55.6% of all surgeries were on pump, and centers reported 157 adult congenital heart surgeries. The 46% of the centers had only one dedicated surgeon for these surgeries. In 53.8% (7/13) of the centers, all RACHS-1 category procedures are performed. Same proportion of centers had available ventricular assistance devices. The 61.5% (8/13) centers had own database, only 2 centers are reporting to international audit database.
Conclusions: In order to promote changes in the care of our patients we need information. In developing countries, this is one of the most difficult problems, however with the commitment of the surgeons that lead the institutions in Colombia, we could collect this very important information.

ADULT CONGENITAL HEART DISEASE

O1064 - FACTORS ASSOCIATED WITH LONG TERM MORTALITY AFTER FONTAN PROCEDURES. RISK SCORE CREATIOIN BASED ON SYTEMATIC REVIEW OF 6707 PATIENTS FROM 28 STUDIES

Tarek Alsaied[1], Jouke Bokma[2], Mark Engel[3], Joey Kuijpers[4], Samuel Hanke[1], Liesl Zuhlke [5], Bin Zhang[6], Gruschen Veldtman[1]
Cincinnati Children's Hospital, Pediatric Cardiology, Cincinnati-United States[1]; Academic Medical Center, Department of Cardiology, Amsterdam-Netherlands Antilles[2]; Groote Schuur Hospital, Department

of Medicine, Cape Town-South Africa[3]; Academic Medical Center, Depatment of Cardiology, Amsterdam-Netherlands Antilles[4]; Red Cross War Memorial Children's Hospital And University of Cape Town, Department of Paediatrics, Cape Town-South Africa[5]; Cincinnati Children's Hospital, Department of Statistics, Cincinnati-United States[6]

Background: Despite an aging Fontan population, data on late outcomes is still scarce. Reported outcome measures and determinants vary greatly between studies making comprehensive appraisal of mortality hazard challenging.
Methods: We conducted a systematic review to evaluate causes and factors associated with late mortality in patients with Fontan circulation. Late mortality was defined as mortality beyond the first postoperative year. Studies were included if they had >90 patients or >20 late mortalities and/or transplants. Studies with overlapping patients were rationalized to include only the most recent studies to avoid duplication. The pooled hazard ratios were used to create the initial components and weighting of a clinical score for Fontan patients.
Results: From 28 studies, a total of 6707 patients with an average follow-up time of 8.23 ± 5.42years were identified. There were 1000 deaths. Causes of late death were reported in 697 cases. The five most common causes were heart/Fontan failure (22%), arrhythmia (16%), respiratory failure (15%), renal disease (12%), and thrombosis/bleeding (10%). Factors associated with late mortality were evaluated and classified into 9 categories and their relative hazards were used to derive the initial components of a weighted, practical and clinically based Fontan risk score (ranging from 0-100). Nine risk factors including anatomic risk factors, elevated preoperative pulmonary artery pressure, age >7 at the time of the operation, atriopulmonary Fontan, heart failure symptoms, arrhythmia, moderate/ severe ventricular dysfunction or atrioventricular valve regurgitation, protein losing enteropathy and end organ disease (cirrhosis or renal insufficiency) were identified as the most significant.
Conclusion: Factors associated with late mortality after the Fontan operation are summarized in this study, and the components of a new mortality risk score, that is weighted, and potentially usable in an outpatient setting are presented. Prospective validation and refinement of this risk score will be undertaken.

O1148 - PHYSICAL ACTIVITY ASSESSMENT IN PATIENTS WITH CONGENITAL HEART DISEASE AND ASSOCIATIONS TO EXERCISE CAPACITY AND HEALTH RELATED QUALITY OF LIFE

Jan Müller[1], Tamara Amberger[1], Anika Berg[1], Daniel Goeder[1], Julia Remmele[1], Renate Oberhoffer[1], Peter Ewert[2], Alfred Hager[2]
Institute of Preventive Pediatrics, Technische Universität München, Munich-Germany[1]; Department of Pediatric Cardiology And Congenital Heart Disease, Deutsches Herzzentrum München, Munich-Germany[2]

Objective: Improved survival leads to growing importance of functional outcome measures in patients with congenital heart disease (CHD). This study applied the International Physical Activity Questionnaire (IPAQ) to assess self-reported physical activity in patients with CHD and their association to exercise capacity and health-related quality of life (HrQoL).
Patients and Methods: Prior to cardiopulmonary exercise testing (CPET), 786 consecutive patients (335 female, 31.1 ± 11.6 years) with CHD filled in the short form of the IPAQ and the HrQoL questionnaire SF-36.
Results: In total, 393 (50.0%) patients reported health enhancing physical activity (HEPA), 237 (30.2%) minimal activity and 156 (19.8%) inactivity. In comparison to the HEPA group the inactive group had significant lower peak oxygen uptake (74.2% ± 20.7% vs. 86.8% ± 22.3%; $p < .001$) as well as lower physical (91.0% ± 16.9% vs. 97.4% ± 13.6%; $p < .001$) and mental (97.1% ± 22.2% vs. 104.1% ± 15.6%; $p < .001$) HrQoL. Independent for severity class, surgery, age, beta blocker, pacemaker and oxygen saturation, the HEPA group showed in comparison to the inactive group significant less probability for impairments in mental (OR: 0.21 CI: 0.10–0.46; $p < .001$) and physical (OR: 0.49 CI: 0.25–0.97; $p = .039$) HrQoL and exercise capacity (OR: 0.38 CI: 0.24–0.61; $p < .001$).
Conclusions: Categorization of CHD patients with the IPAQ provides clinical information since HEPA patients have a less probability for impaired HrQoL and reduced exercise capacity. Nevertheless, the IPAQ cannot substitute an accelerometer based assessment for physical activity, nor a CPET for exercise capacity.

O1309 - CONGENITAL HEART DISEASE AND RISK OF INFECTIONS IN THE CENTRAL NERVOUS SYSTEM

Carina Bagge[1], Jesper Smit[1], Nicolas Madsen[2], Morten Olsen[1]
Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus-Denmark[1]; Cincinnati Children's Hospital Medical Center, University of Cincinnati Department of Pediatrics, Cincinnati-United States[2]

Background: Central nervous system (CNS) infections are associated with substantial morbidity and mortality. Neurologic complications are prevalent in the congenital heart disease (CHD) population, however the risk for CNS infection is unknown. We aimed to compare the risk of CNS infection in the CHD population with the general population.
Materials and Methods: In this population-based cohort study, we used medical registries covering all Danish hospitals to identify subjects with CHD diagnosed before the age of 5 years, born between 1958 and 2000. Subjects were followed until first-time hospital-diagnosis of any CNS infection, death, emigration, or end of study (December 2012). For each CHD subject, we identified 10 individuals from the general population utilizing the Danish Civil Registration System, matched on sex and birth year. We computed cumulative incidences with death as a competing risk and hazard ratios (HRs) with corresponding 95% confidence intervals (CIs) adjusted for birth year and sex.
Results: The CHD cohort consisted of 10,046 individuals (51% male). Among subjects with CHD, cumulative incidence of any CNS infection by age 30 years was 1.0% and 2.5% for endocarditis, a known risk factor of CNS infection. The overall HR of CNS infection was 2.7 (95% CI: 2.1-3.4) among CHD subjects compared to the general population cohort. The HR for mild CHD was 2.1 (95% CI: 1.4-3.3), moderate CHD 1.5 (95% CI: 0.8-2.6), and severe CHD, including univentricular physiology, 3.9 (95% CI: 2.7-5.6). Lesions with a cyanotic history demonstrated a HR of 4.2 (95% CI: 2.5-7.2). Among CHD subjects without documented record of endocarditis, the risk of CNS infection remained elevated (HR: 2.6; 95% CI: 2.1-3.3). HRs specific to meningitis and cerebral abscesses were 2.5 (95% CI: 1.8-3.5) and 5.0 (95% CI: 3.3-7.4), respectively.
Conclusions: Subjects with CHD experienced an increased risk of CNS infection compared with the general population.

O1339 - ABNORMAL PLASMA LIPID PROFILE IS ASSOCIATED WITH POOR PROGNOSIS IN FONTAN PATIENTS

Hideo Ohuchi, Mitsuhiro Fujino, Hikari Miike, Midori Fukuyama, Jun Negishi, Toru Iwasa, Aya Miyazaki, Isao Shiraishi
National Cerebral and Cardiovascular Center, Pediatric Cardiology, Suita-Japan

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Low plasma levels of total cholesterol (TC), low and high density lipoprotein cholesterols (LDL, HDL) characterize lipid profile in patients after Fontan operation. However, the clinical significance of this abnormality remains unknown.
Purpose: This study was conducted to clarify associations of the abnormal lipid profile with Fontan pathophysiology.
Method and Results: We measured plasma levels of those cholesterols and calculated arteriosclerosis index (AI) in 340 Fontan patients and 28 controls and compared the results with the clinical profiles, including hemodynamics and prognosis. Fontan patients showed lower TC, LDL, HDL ($p < 0.0001$) and similar AI when compared with those in controls. Male gender, low body mass index (BMI), presence of protein losing enteropathy (PLE), and high central venous pressure independently predicted lower LDL ($p < 0.05$-0.001), whereas PLE was the only independent predictor of lower HDL ($p = 0.03$). BMI, PLE, and HbA1c levels independently predicted higher AI ($p < 0.05$-0.0001). During the follow-up, 108 (22 deaths) clinical events occurred. Low HDL and High AI predicted morbidity ($p < 0.05$-0.0001). Furthermore, bivariate model with these variables with brain natriuretic peptide (BNP) or peak oxygen uptake (VO2) revealed that the prognostic value of high AI was independent of these two established prognostic variables ($p < 0.05$ for both models).
Conclusions: Fontan patients showed low TC, LDL, and HDL and high AI, especially low HDL and high AI in PLE patients. Increased AI and low HDL had significant prognostic power regardless of the hemodynamics.

O1351 - SURGICAL STRATEGIES OF PULMONARY VALVE REPLACEMENT AS RE DO PROCEDURE IN PATIENTS WITH CONGENITAL HEART DISEASE

Sabrina Lueck[1], Katarzyna Januszewska[1], Edward Malec[1], Sven Martens[2], Andreas Rukosujew[2]
Division of Pediatric Cardiac Surgery, Dept. of Cardiothoracic Surgery, Muenster-Germany[1]; Division of Cardiac Surgery, Dept. of Cardiothoracic Surgery, Muenster-Germany[2]

Objectives: Many patients with congenital heart disease (CHD) undergo surgical pulmonary valve replacement (S-PVR) due to pulmonary regurgitation after right ventricular outflow tract (RVOT) repair. We compared beating and arrested heart techniques for PVR.
Methods: Data of 57 patients who underwent S-PVR between 2012 and 2016 was analyzed retrospectively.
Results: S-PVR was performed at mean age of 23.6 ± 18.6 years, 21.2 ± 13.5 years after initial surgery for CHD. Indications for re-operation were pulmonary insufficiency in patients with TOF ($n = 39$), congenital pulmonary stenosis/atresia ($n = 11$), TGA ($n = 4$), truncus arteriosus ($n = 1$), previous Ross procedure ($n = 1$) and RVOT reconstruction ($n = 1$). Three different bioprostheses were implanted: Carpentier-Edwards Perimount ($n = 32$), St. Jude Trifecta™ ($n = 23$) and BioIntegral Surgical Bioconduit™ ($n = 1$) measuring 19-27mm. Tricuspid valve annuloplasty was necessary in 11 patients (20%). Surgery was either performed with beating ($n = 28$, Group_A) or arrested heart ($n = 29$, Group_B) technique. Especially in Group_B right ventricular (RV) function was impaired (69%). Cardiopulmonary bypass (CPB) duration differed significantly between the groups who exclusively received S-PVR with aortic cross-clamping (134 ± 75 minutes) and with beating heart (76 ± 38 minutes, $p < 0.05$). 68% of Group_A patients received St. Jude Trifecta™ bioprosthesis and 83% of Group_B patients Carpentier-Edwards Perimount bioprostheses. Median time to extubation was shorter in Group_A (6 hours), compared to Group_B (12 hours, $p = 0.22$) while median ICU-stay was comparable in both groups (Group_A: 2 days; Group_B: 3 days). Patients were discharged after an average in-hospital stay of 11 days (Group_A) and 15 days (Group_B), respectively ($p < 0.05$). 30-day-mortality was the same in both groups (Group_A: 3.6%; Group_B: 3.4%).
Conclusion: S-PVR is common in patients with CHD. Beating heart technique has favorable effects on duration of intubation, ICU and in-hospital stay. Extrathoracic cannulation before sternotomy was used in Group_B and thus CPB duration was significantly longer. Beating heart technique should be used whenever possible, despite impaired RV function.

O1393 - SERUM CARBOHYDRATE ANTIGEN 125 LEVEL PREDICTS FUTURE CARDIOVASCULAR EVENTS IN PATIENTS WITH FONTAN CIRCULATION

Tatsunori Takahashi[1], Kei Inai[2], Hiroki Mori[1], In-Sam Park[1]
Tokyo Women's Medical University, Department of Pediatric Cardiology, Tokyo-Japan[1]; Tokyo Women's Medical University, Division of Adult Congenital Heart Disease Pathophysiology and Life-long Care, Tokyo-Japan[2]

Background: Plasma carbohydrate antigen-125 (CA-125) level has emerged as a biomarker and predictive factor for acute heart failure with normal-structure heart disease. However, the clinical significance of plasma CA-125 level in Fontan circulation remains unclear.
Materials and Methods: We prospectively enrolled 73 consecutive patients older than 15 years with Fontan circulation who were hospitalized between February 2015 and December 2016. Plasma CA-125 level and other biochemical markers were routinely tested within 24 hours of hospitalization. Patients were followed up until the following cardiovascular events occurred: acute or exacerbation of chronic heart failure, clinically significant arrhythmia, or thromboembolism.
Results: The median serum CA-125 level was 25 U/mL (range: 6-678), and was significantly higher in patients with higher New York Heart Association class (NYHA I/II: 21.5 vs. NYHA III: 131, $p = 0.0008$), and those with pretibial edema, pleural effusion, and ascites (160.5 vs. 19.5, $p < 0.0001$/141 vs. 21, $p = 0.0002$/85.5 vs. 19, $p < 0.0001$, respectively). During the follow-up period (9.4 ± 5.0 months), 18 cardiovascular events occurred (10 acute exacerbations of heart failure, 7 arrhythmias, and 1 cerebral thromboembolism). Univariate Cox regression analysis identified 8 clinical predictors ($p < 0.005$): history of protein-losing enteropathy (hazard ratio [HR]: 16.9), CA-125 > 36 U/mL (HR 11.5), aldosterone >298 pg/mL (HR 5.09), dopamine >7 ng/mL (HR 6.11), albumin <3.7 g/dL (HR 7.54), troponin T > 0.006 ng/mL (HR 7.97), sodium <139 mEq/L (HR 4.79), and administration of loop diuretics (HR 4.28). The clinical cut-off points were determined from the receiver operating characteristic curve. Multivariate analysis showed that CA-125 > 36 U/mL ($p < 0.0001$) and aldosterone >298 pg/mL (p 0.025) were independent predictive factors.
Conclusion: In patients with Fontan circulation, the CA-125 level correlates with fluid retention and predicts future cardiovascular events.

O1502 - EXPECTATIONS FOR SURVIVAL AND COMPLICATIONS FOR FONTAN PATIENTS WHO TRANSITION TO ADULT CHD CARE

Mark Dennis[1], Diana Zannino[2], Karin Du Plessis[2], Rachael Cordina[1], Yves D'udekem[2], David Celermajer[1]
Royal Prince Alfred Hospital, Cardiology, Sydney-Australia[1]; The Royal Children's Hospital, Murdoch Childrens Research Institute, Melbourne-Australia[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Long term outcomes of Fontan patients who survive to age 16 years have not been well characterised. The Australia and New Zealand Fontan Registry (ANZFR) follows all Fontan patients in ANZ from childhood and provides a unique opportunity to understand survival and complication rates in Fontan patients who reach 16 years of age and beyond.
Methods and Results: Follow up of all 683 survivors aged 16 years and older who underwent a Fontan procedure in ANZ was analysed. Mortality status was confirmed from a National Death Registry. Mean age of the cohort was 26 8 years; There were 201 atriopulmonary connections (APC), 249 lateral tunnels (LT) and 233 extracardiac conduits (ECC). For those surviving to at least age 16 years, survival at 20 years of age was 96% (95% CI, 95%-98%), 90% (95% CI 87%-93%) at 30 years and 81% (95% CI 76%-87%) at 40 years of age. Survival was significantly worse for the APC patients compared to either type of TCPC; at 30 years of age 87% for APC versus 93% for TCPC; at 40 years, 78% for APC versus 86% for TCPC ($p < 0.01$). At 50 years of age, survival in the APC group was 61% (95% CI, 46-81%); insufficient TCPC patients had survived to that age to allow meaningful survival statistics. At latest follow up, only 53% were in NYHA Class I. After the age of 16 years, 136 (20%) had experienced at least one new arrhythmia, 41 (6%) required a permanent pacemaker, 10 (2%) experienced protein losing enteropathy, 45(7%) had a thromboembolic event and 131 (21%) required a surgical re-intervention.
Conclusions: Increasing numbers of patients with Fontan procedures are entering adulthood. This comprehensively followed shows that a variety of morbid complications is common in Fontan adults, and that there is progressive attrition, particularly in the APC subjects.

O1543 - VORTEX FLOW IN THE RIGHT ATRIUM SURROGATES SUPRAVENTRICULAR ARRHYTHMIA AND THROMBUS AFTER ATRIO PULMONARY CONNECTION TYPE FONTAN OPERATION A NOVEL METHOD OF VORTEX FLOW ANALYSIS USING CONVENTIONAL CINE MAGNETIC RESONANCE IMAGING

Yumi Shiina[1], Kei Inai[2], Tatsunori Takahashi[3], Park In-sam [4], Koichiro Niwa [5], Michinobu Nagao[6]
St.luke's Internspational Hospital, Cardiovascular Center, Tokyo-Japan[1]; Tokyo Women's Medica University, Pediatric Cardiology, Tokyo-Japan[2]; Tokyo Women's Medical University, Pediatric Cardiology, Tokyo-Japan[3]; Medica University, Pediatric Cardiology, Tokyo-Japan[4]; Internspational Hospital, Cardiovascular Center, Tokyo-Japan[5]; Medica University, Diagnostic Imaging & Nuclear Medicine, Tokyo-Japan[6]

Background: We developed a novel imaging technique, named vortex flow (VF) mapping, which demonstrates vortex flow visually on conventional two-dimensional (2D) cine MRI. We assessed circumferential VF patterns and the influences on RA thrombus and supraventricular tachycardia (SVT) in AP connection type Fontan circulation.
Method: Retrospectively, we enrolled 27 consecutive patients (25.1 +/- 9.2 years) and 7 age-matched controls who underwent cardiac MRI. Conventional cine images acquired on 1.5-tesla scanner were scanned for axial and coronal cross-section of the RA. We developed a "vortex flow mapping" which can demonstrate the ratio of the circumferential voxel movement at each phase to the total movement throughout a cardiac cycle towards the center of the RA. The maximum ratio was used as a magnitude of vortex flow (MVF %) in the RA cine imaging. We also measured a percentage of strong and weak VF areas (VFA %).
Results: 15 patients had cardiovascular complications (Group A) and 12 patients did not (Group B). On a transaxial image, strong VFA % in Group A was significantly smaller than that in Group B and controls. On a coronal view, strong VFA % was also smaller, and weak VFA % was larger in Group A compared to them in Group B and controls ($P < 0.05$, and $P < 0.05$). Maximum MVF % in Group A was significantly smaller than other groups ($P < 0.001$). On univariate logistic analyses, weak VFA % on a coronal image, and serum total bilirubin level were important factors of cardiovascular complications (Odds ratio 1.14 and 66.1. 95%CI 1.004-1.30 and 1.59-2755.6. P value <0.05 and <0.05, respectively).
Conclusions: Circumferentially weak VFA % on a coronal image could be one of the surrogate makers of SVT and thrombus in AP connection type Fontan circulation. This VF assessment is simple and clinically useful to detect blood stagnation.

O1571 - MYOCARDIAL PERFUSION ABNORMALITY BY SPECT IMAGING CORRELATES WITH VENTRICULAR MECHANO ELECTRICAL PROPERTY IN ADULT WITH CONGENITAL HEART DISEASE

Mitsuhiro Fujino, Hideo Ohuchi, Yosuke Hayama, Tohru Iwasa, Jun Negishi, Aya Miyazaki, Etsuko Tsuda, Isao Shiraishi
National Cerebral and Cardiovascular Center, Pediatric Cardiology, Osaka-Japan

Background: Myocardial perfusion imaging (MPI) by single-photo emission computed tomography (SPECT) is an established modality to cardiac performance related with myocardial ischemia and/or infarction. However, the clinical role of MPI remains unclear in patients with adult congenital heart disease (ACHD).
Purpose: This study was to clarify the clinical significance of MPI by SPECT for evaluating the mechanical function and electrical property of the systemic ventricle (SV) in ACHD patients.
Methods and Results: Between August 2014 and February 2016, Resting SPECT MPI was performed in 95 ACHD patients (age: 31 ± 10 years, biventricular physiology in 69 and Fontan physiology in 26). We developed MPI defect score (%D: %) as an index of severity of the SV myocardial perfusion abnormality and compared the index with plasma levels of high-sensitive troponin T (hsTnT), brain natriuretic peptide (BNP), end-diastolic volume index and ejection fraction of the SV (EF), QRS duration, and peak oxygen uptake (ml/kg/min). In all ACHD patients, %D was 8.7 ± 8.4, ranged from 0 to 33.8. %D was independently correlated with positively with QRS duration ($p < 0.05$) and negatively with EF ($p < 0.001$) and inversely correlated with PVO2 ($p < 0.05$), whereas %D was not correlated with hsTnT or BNP. These associations remained significant in both ACHD patients with biventricular ($p < 0.05$-0.001) and those with Fontan physiologies ($p < 0.05$), except for an association of %D with EF in Fontan physiology.
Conclusion: SV myocardial perfusion abnormality was common in ACHD patients regardless of the hemodynamic pathophysiology. SPECT-PMI has a significant role for providing us a vital information on SV myocardial perfusion abnormality which is closely associated with SV mechano-electrial property in ACHD patients.

O1578 - ATTENTION DEFICIT HYPERACTIVITY DISORDER IN LARGE ASIA CONGENITAL HEART DISEASE COHORT

Chia-Ching Wang[1], Shuenn-Nan Chiu[2], Mei-Hwan Wu[2], Jou-Kou Wang[2], Chun-Wei Lu[2], Ming-Tai Lin[2], Chun-An Chen[2]
Far Eastern Memorial Hospital, Pediatrics, New Taipei City-Taiwan[1]; National Taiwan Universiry Hospital, Pediatrics, Taipei-Taiwan[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Incidence of late neurodevelopmental disorders as attention deficit hyperactivity disorder (ADHD) was reported to be higher in certain congenital heart disease (CHD) diseases. However, no large scales studies and no relevant studies in Asian population were reported before. We try to define the incidence and risk factors of ADHD in CHD patients.
Methods: From Jun 2015 to May 2016, all CHD patients, aged between 6-15 years, who visited the out-patient clinics in National Taiwan University Hospital were enrolled. We used Swanson, Nolan, and Pelham rating scale (SNAP-IV) Chinese version, which was validated effective, to analyze the three dimensions (inattention, hyperactivity, impulsivity) of ADHD and correlated with previous medical records.
Results: Totally 695 CHD patients (M/F: 372/323) were enrolled in our study with mean age 10.2 ± 2.43 years old. Cyanotic heart disease accounted for 217 patients (31.3%), inclusive of single ventricle 38 patients (5.5%). The incidence of inattention, hyperactivity, and impulsivity were 9.8%, 8.6% and 7.6%, respectively, which showed no significant difference with normal age-matched population. However, the incidence of inattention dimension in cyanotic CHD is 13.8%, which was significant higher than acyanotic CHD (7.9%, $p = 0.019$), especially in single ventricle group (incidence 23.7%, $p = 0.008$). For the hyperactivity and impulsivity dimension, the incidence showed no difference. The risk factors of inattention dimension of ADHD includes post-operative seizure, single ventricle, prolonged cyanosis, multiple operations and cardiopulmonary bypass, and postoperative extracorporeal membrane oxygenation (ECMO) support. Using multivariate regression analysis, post-operative seizure, single ventricle disease and postoperative ECMO support were important risk factors of late inattention disorder.
Conclusion: The overall incidence of ADHD is similar between CHD patients and normal population, but the incidence of inattention dimension is higher in single ventricle CHD and cyanotic CHD. The important risk factors of inattention disorder include post-operative seizure, single ventricle CHD and post-operative ECMO support.

O1582 - FAMILIAL CO OCCURRENCE OF CONGENITAL HEART DEFECTS FOLLOWS DISTINCT PATTERNS

Sabrina Gade Ellesøe[1], Christopher Workman[2], Patrice Bouvagnet[3], Christpher Loffredo[4], Kim L. Mcbride[5], Robert B. Hinton[6], Klaartje Van Engelen[7], Emma C. Gertsen[7], Barbara Jm Mulder[8], Alex V. Postma[7], Robert H. Anderson[9], Vibeke E. Hjortdal[10], Søren Brunak[11], Lars Allan Larsen[12]
Rigshospitalet/university of Copenhagen, Dept. of Cardiothoracic Surgery/novo Nordisk Foundation Center For Protein Research, Copenhagen-Denmark[1]; Technical University of Denmark, Center For Biological Sequence Analysis, Lyngby-Denmark[2]; Groupe Hospitalier Est, Laboratoire Cardiogénétique Hospices Civils De Lyon, Bron-France[3]; Georgetown University, Dept Of Oncology, Lombardi Cancer Center, Washington-United States[4]; Nationwide Children's Hospital, Center For Cardiovascular and Pulmonary Research, Ohio-United States[5]; Cincinnati Children's Hospital Medical Center, Division of Cardiology, The Heart Institute, Cincinnati-United States[6]; Academic Medical Center, Dept. of Clinical Genetics, Amsterdam-Netherlands Antilles[7]; Academic Medical Center, Dept. of Cardiology, Amsterdam-Netherlands Antilles[8]; Newcastle University, Institute Of Genetic Medicin, London-United Kingdom[9]; Aarhus University Hospital, Dept. of Cardiothoracic Surgery, Skejby-Denmark[10]; University of Copenhagen, Novo Nordisk Foundation Center For Protein Research, Copenhagen-Denmark[11]; University of Copenhagen, Wilhelm Johannsen Center For Functional Genome Research, Copenhagen-Denmark[12]

Aims: Congenital heart defects (CHD) affect almost 1% of all live born children and the number of adults with CHD is increasing. In families where CHD has occurred previously, estimates of recurrence risk, and the type of recurring malformation are important for counseling and clinical decision making, but the recurrence patterns in families are poorly understood. We aimed to determine recurrence patterns, by investigating the co-occurrences of congenital heart defects in 1,163 families with 3,080 individuals who had a clinically confirmed diagnosis.
Methods and Results: We calculated rates of concordance and discordance for 41 specific types of malformations, observing a high variability in the rates of concordance and discordance. By calculating Odds Ratios for each of 1,640 pairs of discordant lesions observed between affected family members, we were able to identify 178 pairs of malformations that co-occurred significantly more or less often than expected in families. The data show that distinct groups of cardiac malformations co-occur in families, suggesting influence from underlying developmental mechanisms. Analysis of human and mouse susceptibility genes showed that they were shared in 19% and 20% of pairs of co-occurring discordant malformations, respectively, but none of malformations that rarely co-occur, suggesting that a significant proportion of co-occurring lesions in families is caused by overlapping susceptibility genes.
Conclusion: Familial congenital heart defects follow specific patterns of recurrence, suggesting a strong influence from genetically regulated developmental mechanisms. Co-occurrence of malformations in families is caused by shared susceptibility genes.

O1595 - ARRHYTHMIAS AND SPECIAL ELECTROPHYSIOLOGICAL CHARACTERISTICS IN CONGENITALLY CORRECTED TRANSPOSITION OF THE GREAT ARTERIES

Wei-Chieh Tseng[1], Shuenn-Nan Chiu[2], Mei-Hwan Wu[2], Chun-Wei Lu[2], Jou-Kou Wang[2], Ming-Tai Lin[2], Chun-An Chen[2]
National Taiwan University Hospital/national Taiwan University Children, Department of Emergency Medicine, Taipei-Taiwan[1]; National Taiwan University Children, Department of Pediatrics, Taipei-Taiwan[2]

Introduction: Congenitally corrected transposition of the great arteries (ccTGA) is a rare congenital heart defect. It may associate with complete atrioventricular block (cAVB) and a variety of arrhythmias but the exact mechanisms are still not well-elucidated.
Methods: We reviewed medical records of patients diagnosed with ccTGA and follow-up in our institution from 1998 to 2016. Supraventricular tachycardia (SVT) in our study is defined as paroxysmal SVT (atrioventricular reentrant tachycardia, atrioventricular nodal reentrant tachycardia AVNRT, and twin AVNRT) and atrial arrhythmias.
Results: Ninety-two patients (37 female; 55 male) were enrolled in our study. The 40-year transplant free survival was 78.7% after 1922 patient-years of follow-up: mortality rate was 13% and 4.3% of patients received heart transplant. The 20-year and 40-year SVT free survival rate were 70.4% and 50.5%, respectively. The 20-year and 40-year cAVB free survival rates were 92.2% and 76.8%, respectively. For 31 patients (33.7%) with SVT, paroxysmal SVT accounts for 15 (16.3%) and atrial arrhythmia accounts for 18 (19.6%) with 2 (2.2%) had concomitant both kinds of SVT. Seven patients (7.6%) developed cAVB during follow-up. Neither cardiac operation history nor anatomical features were significantly associated with development of SVT or cAVB. Twenty-two patients received a total of 31 electrophysiological studies for SVT. The mechanisms of SVT include atrial arrhythmia in

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

6 (33.3%) and paroxysmal SVT in 10 (45.5%). The mechanisms of paroxysmal SVT include concealed right-side accessory pathways in 3 (25%), manifest left-side Kent pathways in 2 (16.7%), twin AVNRT in 3 (25%), and AVNRT in 4 (33.3%). Catheter ablation successfully eliminated these paroxysmal SVT in 6 (60%) patients.
Conclusions: Arrhythmia burden, including paroxysmal SVT, atrial arrhythmia, and cAVB, in patients with ccTGA is high and increases over time. The mechanisms of SVT are complicated especially for paroxysmal SVT and can be controlled in some by catheter ablation.

O1596 - THE LYMPHATIC MORPHOLOGY AND FUNCTION IN FONTAN OPERATED PATIENTS

Sheyanth Mohanakumar[1], Niklas Telinius[1], Michael Pedersen[2], Vibeke Hjortdal[1]
Aarhus University Hospital, Department of Cardiothoracic and Vascular Surgery, Aarhus N-Denmark[1]; Aarhus University Hospital, Comparative Medicine Lab, Aarhus N-Denmark[2]

Background: The lymphatics regulate the interstitial fluid by removing excessive fluid. It represents an extremely important step in the prevention of edema. The Fontan procedure has revolutionized the treatment of univentricular hearts. However, it is associated with severe complications such as protein-losing enteropathy (PLE) and peripheral edema that may involve the lymphatic circulation.
Hypothesis: Patients with a univentricular circulation have a reduced functionality of the lymphatic vasculature, which predisposes them to developing complications such as edema and PLE.
Material and Methods: The functional state of lymphatics is investigated using near infrared fluorescence imaging, NIRF. The anatomy is described using non-contrast MRI and the capillary filtration rate is measured using plethysmography. The study population is patients with Fontan circulation operated at Aarhus University hospital. Exclusion criteria is BMI > 30 and age (years) < 18. The Fontan group will be compared with an age, gender and weight matched control group of healthy volunteers.

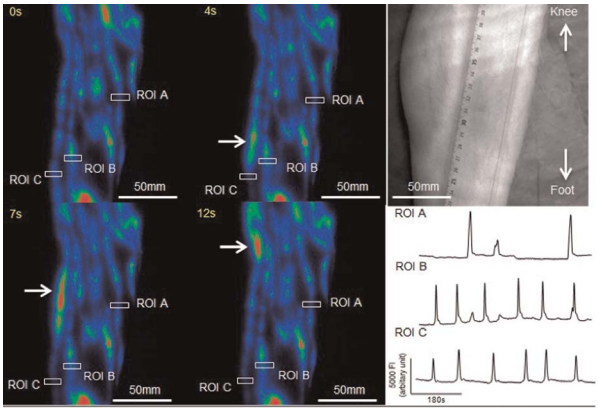

Figure 1.
Near infrared fluorescence imaging with indocyanine green enables lymphatic contractile function to be measured in vivo. *The image series depicts a network of lymphatic vessels on the lower leg. An example of a packet of lymph moving cranially is marked with a white arrow. Top right is a photograph of the same area. Bottom right shows an intensity plot over a longer time course for ROI A, B and C. Pulsatile changes in fluorescence intensity (FI) can be seen, reflecting lymphatic contractions. Images are pseudocoloured rainbowscale with blue and red indicating the least respectively most intense signal.*

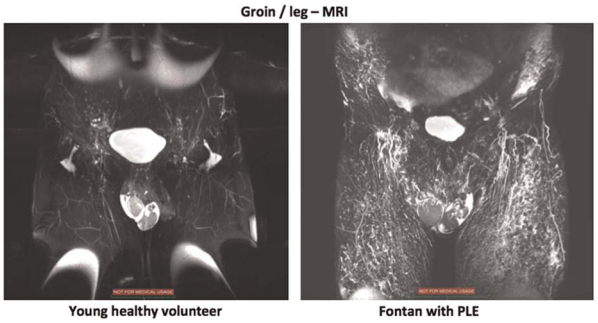

Figure 2.
MRI of lymphatic vessels in the groin area of a healthy control (left) and a Fotan patient (right). The two images depicts the lymphatic vessels in the groin area visualized by MRI. It is clear that the Fontan patient has a massive amount of lymphatic vessels and a abnormal collaterization compared to the healthy volunteer.

Results: The results (Fontan n = 7, Control n = 7) show that Fontan patients with clinical edema have a vast abnormal network of lymphatic collaterization. We also find a dilated thoracic duct with an abnormal course compared to normal. Baseline values found in the control group using NIRF, show that the lymphatic vessels have a contraction frequency: 0.6(0.2) min-1, propulsion velocity: 1.8(0.2) cm/s and are able to generate a pumping pressure: 57(3.2) mmHg. These values correlates with values found in in-vitro experiments. In comparison lymphatic function in the Fontan group using NIRF, shows a contraction frequency: 0.9 (0.2) min-1, propulsion velocity: 2,2(0.4) cm/s and a pumping pressure: 53(3.7) mmHg. No significant difference is seen for these parameters between Fontan patients and controls, $p > 0.05$.
Conclusion: The results indicate that lymphatics in some Fontan patients are abnormal with respect to morphology while function seems not to be altered.

O1751 - MANAGEMENT ERRORS IN ADULTS WITH CONGENITAL HEART DISEASE – PREVALENCE SOURCES AND CONSEQUENCES

Rachael Cordina[1], Gry Eveborn[1], Joshua Jacob[2], Subha Nasir Ahmad[3], John Deanfield [4], David Celermajer[1]
Royal Prince Alfred Hospital, Adult Congenital Heart Disease Service, Sydney-Australia[1]; Royal Prince Alfred Hospital, Department of Medicine, Sydney-Australia[2]; University of Sydney, Sydney Medical School, Sydney-Australia[3]; Great Ormond Street Hospital, Paediatric Cardiology, London-United States[4]

Background: Improved survival has resulted in increasing number and complexity of adults with congenital heart disease (ACHD). Guidelines recommend specialised care but many are still not managed at dedicated ACHD centres.
Methods: We analysed referral sources and appropriateness of management for patients referred to our tertiary-based ACHD Centre over the past 3 years (30 ± 13 years, 44% male). Only new patients ≥16 years with CHD, seen by another cardiologist within 3 years, were included. We compared differences in care between paediatric/ACHD-trained versus general adult cardiology referrals, according to Compliance (C) or Non-Compliance (NC) with published guidelines. Patients referred directly when CHD was identified were classified as C. NC cases were graded according to adverse outcome or risk of adverse outcome; Catastrophic (death/near-death/permanent disability); Major (permanent loss of function/recommendation for unnecessary intervention/failure to

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

recommend necessary intervention exposing patient to unnecessary risk of death); Moderate (less serious loss of function/risk) or minor (failure to meet guidelines concerning diagnosis/treatment).
Results: Of 229 patients included, 128 (56%) were general cardiology referrals (58% with complex CHD) and 101 (44%) were paediatric/ACHD referrals (67% with complex CHD). Forty-seven (37%) general cardiology referrals were NC; 18 (14%) had catastrophic or major issues (n = 2,16 respectively), 17 (13%) moderate and 12 (9%) minor. Twelve (12%) paediatric/ACHD referrals were NC but none were catastrophic, 2 were major, 1 moderate and 9 minor. Deviations from guidelines were far more common in referrals from general compared to CHD-trained ($p < 0.0001$) as were catastrophic/major complications ($p = 0.002$). All catastrophic and 56% of major issues occurred in complex CHD. The most common catastrophic/major issue was mismanaged severe pulmonary regurgitation.
Conclusions: Over half referrals to a specialised ACHD Centre were from general cardiologists, 37% were NC with guidelines, often with catastrophic or major consequences. Adequate access to specialised service provision for this growing population is essential.

O1944 - THE IMPACT OF POST OPERATIVE ACUTE KIDNEY INJURY FOLLOWING FONTAN CONVERSION SURGERY

Sheetal R. Patel[1], John M. Costello[1], Adin-cristian Andrei[2], Carl L. Backer[3], Catherine D. Krawczeski [4], Menghan Liu[2], Barbara J. Deal[1], Craig B. Langman [5], Bradley S. Marino[1]
Ann & Robert H Lurie Children, Pediatric Cardiology, Chicago-United States[1]; Northwestern University Feinberg School of Medicine, Biostatistics, Chicago-United States[2]; Ann & Robert H Lurie Children, Cardiovascular-Thoracic Surgery, Chicago-United States[3]; Stanford University Medical Center, Pediatric Cardiology, Palo Alto-United States[4]; Ann & Robert H Lurie Children, Kidney Diseases, Chicago-United States[5]

Background: Fontan conversion (FC) is a useful option for "failing Fontan" physiology. Acute Kidney Injury (AKI) is associated with worse outcomes after cardiac surgery. We evaluated the incidence, predictors of, and prognostic value of AKI following FC.
Methods: This single-center retrospective cohort study included FC patients from 1994-2016. AKI was classified using KDIGO criteria: AKI 1 = 1.5-2, AKI 2 = 2-3, AKI 3 = > 3 fold increase in serum-creatinine (sCr) within 7-days post-op. Multivariable logistic regression was created to identify risk factors for AKI ≥ 2. Associations between AKI ≥ 2 and post-operative outcomes were evaluated using t-tests. Heart-transplant-free survival among AKI groups was compared using Kaplan-Meier curves and log-rank test.
Results: Included were 139 FC patients: mean age at FC 25 ± 9 years; 81% atrio-pulmonary; 86% left-ventricular morphology; median follow-up after FC 8 (0.02-21) years. Pre-op sCr was normal for all patients. After FC, 63 patients (45%) developed AKI, including AKI 1 in 37(27%), AKI 2 in 10(7%), and AKI 3 in 16 (11%). Renal function recovered (sCr <1.5 times compared to pre-op) by hospital discharge in 86%, 80%, and 19% of patients with AKI 1, 2, and 3, respectively. Independent risk factors for AKI ≥ 2 included higher number of prior sternotomies (OR = 1.97; 95% CI = 1.05-3.68); higher right atrial pressure (OR = 1.18; 95% CI = 1.02-1.37), and prior ablation procedure (OR = 3.45; 95% CI = 1.17-10.18). AKI ≥ 2 was associated with longer postoperative hospital length-of-stay [median 18(8-135) vs. 10(6-58) days; $p < 0.001$]; more chest tube days [9 (5-57) vs. 7(3-28) days; $p = 0.01$]; longer intubation time [median 2(1-117) vs.1(1-6) days; $p = 0.01$], and greater need for dialysis (31% vs. 0%; $p < 0.001$). Greater severity of AKI was associated with worse intermediate-term heart-transplant free survival (Figure 1) and overall survival (figure 2).
Conclusion: Nearly half of patients develop Acute Kidney Injury following Fontan Conversion. AKI ≥ 2 is associated with worse outcomes and reduced survival following FC surgery. Knowledge of AKI predictors may allow for improved FC risk stratification, patient selection, and perioperative management.

Overall survival by AKI severity.

O1962 - SURGICAL OUTCOME FOR COMPLICATIONS AFTER REPAIR IN ADULT CONGENITAL HEART DISEASE

Kosuke Yoshizawa[1], Keiichi Fujiwara[1], Nobuhisa Ono[1], Hisanori Sakazaki[2]
Hyogo Prefectural Amagasaki General Medical Center, Cardiovascular Surgery, Amagasaki-Japan[1]; Hyogo Prefectural Amagasaki General Medical Center, Pediatric Cardiology, Amagasaki-Japan[2]

Background: Surgeries for adult congenital heart disease (ACHD) are mainly divided into two groups, repair surgeries in adulthood or surgeries for late complications after repair.
Objectives: To investigate our surgical outcome in ACHD patients with complications after repair (definitive repair or Fontan type operation).
Methods: ACHD patients (age ≥ 18) who underwent major cardiovascular operations between 1991 and 2016 were studied (n = 216, mean age: 35.6 years old, mean follow up: 8.2 years). We identified 82 surgical cases for complications after previous repair

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(Group1). Main surgical indications include RVOT related (n = 39, with Bentall's operation n = 3), TCPC conversion (n = 10), aneurysm after CoA repair (n = 4), and cardiac resynchronization therapy (CRT) (n = 11). Other 134 cases underwent the repair operation in adulthood (Group 2).
Results: Hospital deaths (within 30 days) were found in 3.7% (Group 1) and 2.3% (Group 2) respectively. Group1 had lower late survival rate than Group 2 (log-rank, p = 0.02) and preoperative NYHA class III or IV was detected as a risk factor for overall mortality (p = 0.01).
Conclusion: Our overall surgical outcome in ACHD patients was feasible, although surgeries for complications after repair are still complex. Surgeries of patients with preoperative severe heart failure are challenging.

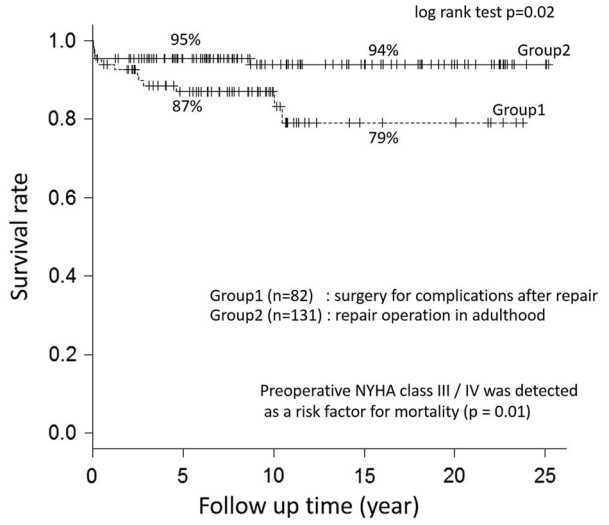

Figure.

O2043 - BURDEN OF AND RISK FACTORS FOR ACUTE KIDNEY INJURY IN ADULTS WITH CONGENITAL HEART DISEASE UNDERGOING CARDIAC SURGERY

Rohit Loomba[1], Christopher Learn[1], Lisa Dipietro[1], Stuart Goldstein[2], David Cooper[1]
Cincinnati Children's Hospital, Cardiology, Cincinnati-United States[1]; Cincinnati Children's Hospital, Renal, Cincinnati-United States[2]

Background: Postoperative acute kidney injury (AKI) in adults with congenital heart disease (ACHD) undergoing cardiac surgery (CS) has not been well characterized. This study used data from the National Inpatient Sample (NIS) to characterize AKI in this population and determine risk factors for postoperative AKI.
Materials and Methods: ACHD patients having undergone CS were identified in the NIS from 2005 to 2012. The presence of AKI was defined by ICD-9 codes during the included admission was then identified. Regression analysis was done to determine factors associated with AKI and determine if AKI impacts length of stay and cost of stay.
Results: 178,191 admissions were analyzed, 25,079 (14.1%) were documented as having AKI. AKI was associated with increased length of stay (21.6 vs 9.7 days, p < 0.001), cost of stay ($312,912 vs. 149,614, p < 0.001), and increased inpatient mortality (15.8% vs. 2.6%, p < 0.001). Surgeries associated with increased AKI frequency were heart transplant (OR 5.531, 95% CI 5.004 to 6.112), septal defect repair (2.103, 1.910 to 2.315), valvuloplasty with (2.017, 1.901 to 2.140) or without valve replacement (1.630, 1.544 to 1.720). Other factors associated with increased frequency of AKI by regression analysis included African American race, heart failure, and tachyarrhythmia.
Conclusion: AKI in those with ACHD occurs in at least 14.1% of admissions with CS based on coding in an administrative database. Specific interventions and risk factors are associated with increased risk of AKI. AKI increases length and cost of stay, and inpatient mortality. Understanding these findings may help improve surveillance and target interventions for AKI in those with ACHD undergoing CS.

O2215 - INCIDENCE AND 30 DAY MORTALITY OF PNEUMONIA RELATED HOSPITALIZATION IN CONGENITAL HEART DISEASE ADULTS COMPARED WITH THE GENERAL POPULATION A NATIONWIDE COHORT STUDY

Nicolas Madsen[1], Søren Paaske Johnsen[2], Henning Bækgaard Laursen[2], Morten Olsen[2]
Cincinnati Children's Hospital, Pediatrics, Cincinnati-United States[1]; Aarhus University, Clinical Epidemiology, Aarhus-Denmark[2]

Background/Hypothesis: The aging adult congenital heart disease (CHD) population may be vulnerable to pulmonary morbidity. We aim to study if adults with CHD are at increased risk for pneumonia (PNA) related hospitalization compared to the general population, and if this risk impacts the subsequent 30-day mortality.
Materials/Methods: This cohort study utilized nationwide population-based medical databases to identify individuals diagnosed with CHD in Denmark between 1963-1996. CHD subtype was divided by complexity: mild, moderate, severe, and univentricular. Adults, alive at age 15 years, were followed between 1977-2013 for the primary outcome (first hospital-based diagnosis of PNA) using the Danish National Registry of Patients (hospital discharge registry covering all Danish hospitals). For each CHD subject, we identified 10 controls from the general population, matched by sex and birth year. A unique personal identifier assigned at birth enabled virtually complete follow-up for migration, death or primary outcome. We computed cumulative incidences and hazard ratios (HR) of PNA-related hospitalization with stratification by CHD complexity. We compared the 30-day mortality associated with these PNA-related hospitalizations.
Results: We identified 13,997 CHD subjects. By 70 years of age, the cumulative incidence of first PNA-related hospitalization in CHD adults was 27%. The overall HR of PNA among CHD subjects compared with controls was 2.6 (95% CI: 2.4-2.8) [mild and moderate CHD: 2.3 (95% CI: 2.1-2.5), severe and univentricular CHD: 3.3 (95% CI: 2.9-3.8)]. Among CHD adults, the 30-day mortality for first PNA-related hospitalization was 9% (n = 1115). The corresponding birthyear and sex adjusted HR comparing 30-day mortality between CHD adults and controls was 1.2 (95% CI: 0.9-1.5) for subjects above 60 years of age, and 1.6 (95% CI: 1.1-2.3) for those under 60 years of age at time of PNA.
Conclusion: The incidence of PNA-related hospitalization, and 30-day mortality, were increased in CHD adults compared with the general population.

O2285 - SOLID NEOPLASMS IN FONTAN PATIENTS REPORT OF TEN CASES IN A SINGLE CENTER

Mi Kyoung Song[1], Chung Il Noh[1], Gi Beom Kim[1], Eun Jung Bae[1], Choong Ho Shin[1], Jae-Kyoung Won[2]
Seoul National University Children, Department of Pediatrics, Seoul-Korea, South[1]; Seoul National University Children, Department of Pathology, Seoul-Korea, South[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Fontan has a unique circulation without subpulmonic ventricle. Chronic elevation of central venous pressure, low cardiac output and mild cyanosis is characteristic feature. Hepatocelluar carcinoma (HCC) and pheochromocytoma (PHEO)/paraganglioma (PG) has been reported recently in this population, but clinical data for solid tumor is scarce.
Method: We conducted a retrospective study on solid tumor developed in Fontan patients at Seoul National University Children's Hospital.
Results: Ten Fontan patients were diagnosed as solid tumor. Six patients (5 males and 1 female) were diagnosed as PHEO/PG and 5 patients (2 males and 3 females) as HCC. One patient had dual primary neoplasms, HCC and PHEO. Median age at diagnosis was 21.2 years (range, 13.7-35.4) in PC/PG and 27.0 years (range, 16.9-37.6) in HCC. Follow-up period after Fontan operation until development of tumor was 18.3 years (range 8.8-27.6) and 21 years (range 15.1-28.8), respectively. Clinical presentation to diagnosis of PHEO/PGL was hypertension in 2 patients and another 4 patients were incidentally detected by CT scan taken for other reasons. HCC was detected on routine screening abdominal sonography or CT in all patients. There were 2 mortalities in these patient group. One patient with malignant PHEO had multiple bone metastasis and died 5 years after the diagnosis due to heart failure and severe cyanosis. One patient with HCC had multiple lung metastasis at diagnosis and died from massive esophageal variceal bleeding in 2 months.
Conclusion: Solid tumor is another late complication after Fontan operation and it can become highly malignant. We have to be alarmed for the malignancy and check regularly for early detection and treatment of the tumor in Fontan patient group.

O2459 - INDICATIONS AND MIDTERM OUTCOMES OF GERIATRIC CONGENITAL CARDIAC SURGERY A MULTICENTER STUDY

Amine Mazine[1], Charles Laurin[1], Murielle Han Yee Yu[2], Xavier Iriart[2], Paul Khairy[3], François Roubertie[2], Nancy Poirier[1]
Montreal Heart Institute, Cardiac Surgery, Toronto-Canada[1]; Centre Hospitalier Universitaire De Bordeaux, Cardiology, Bordeaux-France[2]; Montreal Heart Institute, Cardiology, Montreal-Canada[3]

Background: There is a paucity of data regarding surgical treatment of congenital heart defects in patients aged 60 years and older. The purpose of this study was to examine the surgical indications and midterm outcomes in this patient population.
Methods: Clinical and echocardiographic data were retrospectively gathered from a surgical database of adult congenital heart disease (ACHD) in two tertiary academic centers. Patients with isolated congenital aortic valve disease were excluded from this analysis. The median follow-up was 26 months (interquartile range 3-55 months).
Result: Between 2000 and 2015, 91 consecutive patients (mean 67 ± 5 years; range 60–82 years) underwent surgery for a congenital cardiac defect. Thirty-seven patients (41%) were in NYHA class $\geq$ III/IV. The mean preoperative EuroSCORE II was $4.1 \pm 6.1\%$. Nineteen patients (21%) had undergone previous cardiac surgery. Cardiac diagnoses included sinus venosus atrial septal defect (ASD) in 24 patients, secundum ASD in 23, atrioventricular septal defect in 13, pulmonary stenosis/Tetralogy of Fallot in 12, Ebstein anomaly in 7, coarctation in 2, coronary anomalies in 2, and miscellaneous defects in 8. Preoperative echocardiography revealed moderate tricuspid regurgitation (TR) in 30 patients (33%), and severe TR in 20 (22%), with a mean systolic pulmonary artery pressure (sPAP) of 44 ± 15 mmHg. Operative mortality occurred in 3 patients (4%). The median ICU stay was 2 days (interquartile range 1–4 days). Perioperative morbidity is depicted in Figure 1. At last follow-up, only 2 patients were in NYHA functional class $\geq$ III/IV. Follow-up echocardiography showed residual moderate TR in 11 patients, severe TR in 3, with a mean sPAP of 35 ± 13 mmHg.
Conclusions: The majority of our geriatric ACHD patients underwent surgery for either shunt lesions or right heart valve lesions. Our data demonstrate that surgery can be performed safely in this patient population. Surgical therapy led to improvement in functional status, sPAP and TR at intermediate follow-up.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Grown-up patients with congenital heart disease (GUCH) often present difficult and challenging problems. In developing countries, a lot of children with congenital heart disease (CHD) reach adulthood without correction, due to delay in detection, limited resources, lack of knowledge and financial supports.
Objectives: This study was performed to evaluate the pattern of cyanotic CHD among Indonesian adults in Indonesia.
Methods: Retrospective study was conducted at National Cardiovascular Center Harapan Kita Hospital, Jakarta, as the tertiary cardiovascular center in Indonesia. Data was retrieved from the hospital database from 2007 to 2012.
Results: Among 817 GUCH, there were 104(12.7%) patients diagnosed as cyanotic CHD with median age of 20.9(17.0-66.3) years, 58(55.8%) female and 46(44.2%) male. Tetralogy of Fallot was found in 50(48.1%) patients, Ebstein's anomaly in 9(8.7%) patients, pulmonary atresia with ventricular septal defect in 9(8.7%) patients, complete atrio-ventricular septal defect in 7(6.7%) patients, double outlet right ventricle in 6(5.8%) patients, congenitally corrected transposition of the great arteries in 4(3.8%) patients, total anomalous pulmonary venous drainage in 4(3.8%) patients, transposition of the great arteries with ventricular septal defect in 2(1.9%) patients, and tricuspid atresia in 2(1.9%) patients. There were 5(4.8%) cases admitted with infective endocarditis, where 2 complicated with cerebral abcess and 1 with ischemic stroke. Arrythmia found in 4(3.8%), ventricular dysfunction in 7(6.7%), hematological disorders in 11(10,6%), renal dysfunction in 2(1.9%), and neurological complications in 3(2.9%) patients. Surgical management was performed in 52(50%) patients, whilst conservative treatment in 52(50%) patients. Blalock–Taussig shunt performed in 9(8.7%), tetralogy of Fallot repair in 32(30.8%), bidirectional cavopulmonary shunt in 4 (3.8%) and fenestrated Fontan in 4(3.8%) patients. Overall hospital mortalities were 3(2.9%) patients.
Conclusions: Cyanotic GUCH remains a complicated and unresolved health problem in Indonesia. Early detection and management during childhood is important to reduce the complications of this disease.

O2521 - CHALLENGES IN SURGICAL CORRECTION OF ADULT TETRALOGY OF FALLOT OUTCOMES WITH TARGETED CARE

Kuntal Roy Chowdhuri[1], Nilanjan Dutta[1], Sumir Girotra[2], Sushil Azad[3], Sitaraman Radhakrishnan[3], Savitri Srivastava[3], Parvathi U. Iyer[4], Krishna S. Iyer[1]
Fortis Escorts Heart Institute, Paediatric Cardiac Surgery, New Delhi-India[1]; Fortis Escorts Heart Institute, Paediatric Cardiac Anesthesia, New Delhi-India[2]; Fortis Escorts Heart Institute, Paediatric Cardiology, New Delhi-India[3]; Fortis Escorts Heart Institute, Pediatric Cardiac Intensive Care, New Delhi-India[4]

Background and Aims: Unrepaired adult Tetralogy of Fallot (TOF) is not uncommon in developing countries. Published literature reports discharge mortality of 5 - 15%. Our discharge mortality from 1995- 2005 was 2/81 (2.5%). Risk factors for death were - severe polycythemia, RV dysfunction and collaterals. Subsequently, following strategies were instituted : 1) Aggressive search and preoperative intervention for collaterals 2) staging BT shunt for persistent severe thrombocytopenia 3) Multiple preoperative phlebotomies 4) preoperative neuroimaging to detect infarcts and bleeds 5) Controlled RVOT resection 6) Preemptive management of RV dysfunction. Our aim is to assess whether these strategies resulted in improved outcomes.
Patients and Methods: From 2006 to 2016, total 103 patients (Median age 21 years, range 16 - 50) with diagnosis of TOF (n = 94), DORV [TOF type] (n = 5), TOF with Absent Pulmonary valve (n = 4) were operated . Preoperative MAPCA coiling was required in 21 and 28 received multiple preoperative phlebotomies. 52 patients received transannular patch,5 required pulmonary valve replacement, 2 tricuspid valve repair, 1 aortic and 1 mitral valve replacement . 4 underwent a staging BT shunt for persistent severe thrombocytopenia. Median preoperative hematocrit value was 55% (range 34-78).
Results: In hospital mortality was 0/103 with no late deaths. Median duration of ventilation, ICU and hospital stay was 17 hours (range 4-192), 42 hours (range 8-258) and 8 days(range 4-25) respectively. 5/103 underwent reexploration for bleeding and one required multiple craniotomies for recurrent subdural hematoma. 2 underwent subsequent pulmonary valve replacement after 5 and 8 years.
Conclusions: Early outcomes after surgery for adult TOF can be greatly improved with highly individualized management despite multiple perioperative challenges.

O2525 - ARTERIAL SWITCH OPERATION FOR PATIENTS WITH TRANSPOSITION OF THE GREAT ARTERIES A SINGLE CENTRE TWENTY EIGHT YEAR EXPERIENCE

Vladimiro Vida[1], Lorenza Zanotto[1], Lucia Zanotto[2], Paola Veronese[2], Chiara Tessari[1], Massimo Padalino[1], Biagio Castaldi[3], Ornella Milanesi[3], Giovanni Stellin[1]
University of Padua, Paediatric and Congenital Cardiac Surgery Unit, Department of Cardiac, Thoracic and Vascular Sciences, Padua-Italy[1]; University of Padua, Department of Statistical Sciences, Padua-Italy[2]; University of Padua, Pediatric Cardiology Unit, Department of Child And Woman's Health, Padua-Italy[3]

Background: Complete transposition of the great arteries (D-TGA) is a life-threatening malformation in neonates which requires immediate management. We sought to evaluate our long-term results with arterial switch operation (ASO) for D-TGA during the last 30 years.
Methods: We collected data on 260 patients with D-TGA who underwent arterial switch operation (ASO) between January 1987 and December 2016. Outcome included survival, need for late re-operations/re-intervention and clinical status.
Results: Original diagnoses included: simple D-TGA (n = 177, 68%) and complex D-TGA (n = 83, 32%). The percentage of cases of D-TGA diagnosed prenatally has increased during the last 10 years ($p < 0.0001$). Median age at ASO was 8 days (IQR 6-12 days). Fifteen patients (5.8%) died in hospital (6/177 simple D-TGA, 3.3% and 9/83, complex D-TGA, 10.8%). Sixty-eight patients (26%) presented post-operative complications including: low output syndrome (n = 20, 7.7%), respiratory complications (n = 20, 7.7%) and arrhythmias (n = 18, 6.9%). Median follow-up time after ASO was 10 years (IQR 3.7-17.2 years). There were 2 (2/245 survivors, 0.8%) late deaths. Qverall survival probability at 10 and 20 years after ASO was 93.4% and 92.4%, respectevely. Thirty-five patients (14%) required re-operations/re-interventions, mainly for right ventricular outflow tract obstruction (n = 28). Freedom from re-operation/re-intervention at 10 and 20 years after ASO was 87.2% and 77.8%, respectevely. Prenatal detection of D-TGA reduced the probability of early and late mortality ($p = 0.04$ and $p = 0.04$) and of post-operative complications ($p = 0.04$).
Conclusions: The ASO for D-TGA can performed with low early and late mortality. The prenatal detection of D-TGA reduces significantly postoperative mortality and morbidity.

O2766 - QUALITY OF LIFE AND EXERCISE CAPACITY IN CONGENITAL HEART DISEASE PATIENTS WITH PROSTHETIC HEART VALVES

Hanna Pragt[1], Joost Van Melle[2], Ymkje Van Slooten[1], Arie Van Dijk[3], Gertjan Sieswerda[4], Berto Bouma[5], Pertonella Pieper[2], Tjark Ebels[1]
University Medical Center Groningen, Thoracic Surgery, Groningen-The Netherlands[1]; University Medical Center Groningen, Cardiology, Groningen-The Netherlands[2]; University Medical Center Nijmegen St. Radboud, Cardiology, Nijmegen-The Netherlands[3]; University Medical Center Utrecht, Cardiology, Utrecht-The Netherlands[4]; Academic Medical Centre, University of Amsterda, Cardiology, Amsterdam-The Netherlands[5]

Introduction: Most studies concerning prosthetic valve replacement in congenital heart disease have a focus on the functionality of the prosthesis and mortality. The increased life expectancy of this congenital population shifts the focus to their quality of life, which becomes more and more important. The aim of this study was to find predictors of quality of life and exercise capacity.
Materials and Methods: In a multi-center cross sectional observational study of adults with congenital valve disease, patients with a pulmonary valve replacement (n = 142) were compared with those with an aortic valve replacement (n = 153) and patients with both aortic and pulmonary valve replacement (n = 54). To compare quality of life the Dutch version of the Rand-36 questionnaire was used. Exercise capacity was tested using a treadmill or bicycle ergometer.
Results: Patients receiving a pulmonary valve had significantly lower bodily pain scores than those receiving an aortic valve 82.0 ± 23.2 vs 89.9 ± 16.3 (p = 0.03). On all other categories, patients receiving a pulmonary valve also scored higher, although not significantly when corrected for age and gender. Exercise capacity was a significant predictor for physical functioning ($p < 0.001$), physical role functioning ($p = 0.018$), bodily pain ($p = 0.001$), general health ($p = 0.004$) and social functioning ($p = 0.04$), of the quality of life questionnaire. Patients with pulmonary valve prosthesis had significant lower exercise capacity than those receiving an aortic prosthesis 77.4 ± 2.1 vs 87.7 ± 2.3 ($p < 0.001$). Being employed and playing sports are both predictors for exercise capacity (p-0.002, p = < 0.001).
Conclusion: Even though the patients receiving a pulmonary valve replacement had significantly lower scores on exercise capacity testing compared to patients with aortic and double valve replacement, paradoxically they scored equally or better on the quality of life questionnaires.

O2845 - PERI OPERATIVE MANAGEMENT OF HEART TRANSPLANTATION IN ADULT FAILING FONTAN PATIENTS

Andras Kelecsenyi[1], Louise Coats[2], Jonathan Hayden Smith[1], Asif Hasan[3], Bari Murtuza[3], John O'sullivan[4], David Crossland[4], Anthony Hermuzi[4], Simon Haynes[1], Alan Mccheyne[1], Teresa Chila'[1], Shabana Anwar[5]
Freeman Hospitals, Newcastle Upon Tyne Hospitals Nhs Foundation Trust, Paediatric Cardiothoracic Anaesthesia, Newcastle Upon Tyne-United Kingdom[1]; Freeman Hospitals, Newcastle Upon Tyne Hospitals Nhs Foundation Trust, Congenital Cardiology, Newcastle Upon Tyne-United Kingdom[2]; Freeman Hospitals, Newcastle Upon Tyne Hospitals Nhs Foundation Trust, Paediatric Cardiothoracic Surgery, Newcastle Upon Tyne-United Kingdom[3]; Freeman Hospitals, Newcastle Upon Tyne Hospitals Nhs Foundation Trust, Paediatric Cardiology, Newcastle Upon Tyne-United Kingdom[4]; Freeman Hospitals, Newcastle Upon Tyne Hospitals Nhs Foundation Trust, Cardiothoracic Anaesthesia, Newcastle Upon Tyne-United Kingdom[5]

Background: Heart transplantation for late failure of the Fontan circulation is high risk. Anaesthetic challenges relate to anatomic complexity, previous cardiac surgery and unique physiology.
Objective: We describe the perioperative management of adult failing Fontan patients undergoing heart transplantation and identify strategies that may improve outcome.
Methods: A retrospective case-note analysis of adult Fontan heart transplants at Freeman Hospital, Newcastle upon Tyne, UK between 2009 and 2016 was performed.
Results: 22 patients (26 (17-43) years, 60.1 ± 9.4 kg) underwent isolated heart transplant for failing Fontan. 16 remained in hospital for optimisation including milrinone infusion in 14. Surgical strategy involved pulmonary artery and bicaval anastamosis reconstruction. Knife-to-skin to cardiopulmonary bypass (CPB) was 116.7 ± 51.2 minutes. CPB time was 275 ± 169.1 minutes and organ ischaemic time 156 ± 58.5 minutes. CPB strategy included supranormal flows, maintained haematocrit of 0.30, mannitol and colistin in the prime (n = 14) and fresh frozen plasma (n = 18). Separation from CPB was with epinephrine, milrinone, vasopressin and isoprenaline with 15 requiring inhaled nitric oxide and 18 pacing. All received platelets, 21 had continuous aprotinin and seven cryoprecipitate. Extubation was at 4 (0-56) days. Three required tracheostomy. ICU stay was 11 (2-77) days. 18 required renal replacement therapy for 16.5(4-132) days. One required late renal transplant. Mortality was 31.8%: peri-operative bleeding and multi-organ failure (4), bowel and lower limb ischaemia (2) and sudden cardiac arrest at 132 days (1). ECMO was used post-operatively in five: failure to wean from CPB (1), early graft failure (3), sudden late collapse (1). Two survived with major complications (bilateral above knee amputation, kidney failure, intracranial haemorrhage). There was no allograft rejection.
Conclusion: Heart transplantation for failing Fontan remains a high-risk procedure. Successful management requires meticulous surgical technique, novel bypass management and strategy for coagulopathy. A multidisciplinary team approach is key.

O2924 - SYSTOLIC BLOOD PRESSURE RESPONSE AND ARRHYTHMIA DURING EXERCISE PREDICT PREGNANCY OUTCOME IN WOMEN WITH CONGENITAL HEART DISEASE.

Midori Fukuyama[1], Hideo Ohuchi[1], Chizuko Kamiya[2], Jun Negishi[1], Yosuke Hayama[1], Jun Yoshimatsu[2], Isao Shiraishi[1]
NCVC, Pediatric Cardiology, Osaka-Japan[1]; NCVC, Perinatology and Gynecology, Osaka-Japan[2]

Background: Low New York Heart Association functional class (NYHA) is associated with poor outcome of pregnancy in women with congenital heart disease (WCHD). However, there have been no established criteria for the safer pregnancy in WCHD.
Purpose: To identify major risk factors and determine referral cardiovascular variables during cardiopulmonary exercise testing (CPX) in WCHD.
Method and Results: We retrospectively reviewed 68 WCHDs who had undergone cardiopulmonary exercise testing (CPX) within 5 years before their delivery and the pregnancy outcomes were compared with NYHA, CPX-derived variables (heart rate, oxygen uptake, systolic blood pressure (mmHg) at peak exercise [P-HR, P-VO2, and P-SBP, respectively]) and clinically relevant arrhythmia during CPX (Ex-Arr). Seventeen maternal cardiac and 26 neonatal events occurred. All variables, were associated with maternal cardiac and neonatal events ($p < 0.05$-0.001). Of these, P-SBP and Ex-Arr were the independent determinants of the maternal (odds ratio [OR]:0.96, 95% confidence interval [CI]: 0.92-0.99, $p < 0.05$ for P-SBP) and neonatal events (OR: 0.95,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

95% CI: 0.91-0.99, p < 0.01 for P-SBP, and OR: 21.2, 95% CI: 2.1-559, p < 0.01 for Ex-Arr), except for Ex-Arr for maternal events. The cutoff value of SBP for maternal and neonatal events was 150 and 154, respectively.
Conclusion: All major CPX-derived variables, especially, P-SBP and Ex-Arr, can predict adverse outcome during pregnancy in WCHD. P-SBP ≥ 150 (mmHg) without Ex-Arr could be a reliable reference value for safer pregnancy outcome in WCHD.

AMBULATORY

O1101 - COMPARISON OF INITIAL THERAPY OF INTRAVENOUS IMMUNOGLOBULIN VERSUS INTRAVENOUS IMMUNOGLOBULIN PLUS INFLIXIMAB IN KAWASAKI DISEASE PATIENTS PRESENTING WITH CORONARY ARTERY LESIONS

Pei-Ni Jone[1], Matthew Mulvahill[2], Marsha Anderson[3], Heather Heizer[3], Mary Glode[3], Samuel Dominguez[3]
Children, Pediatric Cardiology, Aurora-United States[1]; Colorado School of Public Health, University of Colorado, Biostatistics and Informatics, Aurora-United States[2]; Children, Pediatric Infectious Disease, Aurora-United States[3]

Background: 80% of Kawasaki Disease (KD) children who develop coronary artery lesions (CAL) have them present at time of diagnosis. These children represent a high risk group that may benefit from more aggressive initial therapy. Infliximab has been shown to decrease inflammation in KD patients when added to standard therapy. Therefore, we compared intravenous immunoglobulin (IVIG) alone with IVIG plus infliximab as an initial treatment in KD patients with CAL to reduce IVIG resistance and to evaluate coronary artery changes between groups.
Methods: KD patients were retrospectively reviewed from 2009-2016. CALs were defined as left anterior descending artery and right coronary artery z-scores > 2.5. KD patients with CALs on initial echocardiogram who were treated with IVIG were compared with those treated with IVIG + infliximab. Clinical characteristics, length of stay, and additional therapy were compared using chi-squared and Fischer's exact tests. Effect of treatment on CALs between groups was assessed using linear mixed models at three time points: baseline, 2 weeks, and 6 weeks post treatment.
Results: 34 KD patients with CALs were treated with IVIG and 35 KD patients with CALs were treated with IVIG + infliximab. There were no differences in clinical and laboratory characteristics between the two groups (Table 1). 50% (17/34) of KD patients treated with IVIG required additional second therapy compared to 17% (6/35) of KD patients treated with IVIG + infliximab (p < 0.008). There was a non-statistically significant trend towards shorter length of stay in the IVIG + infliximab group. There were no significant differences between treatment groups for resolution of CALs or fall in CRP.
Conclusions: IVIG + infliximab should be considered as initial therapy in KD patients who present with CALs as both reduce the need for additional therapy.

Table 1. Patient Clinical and Laboratory Characteristics.

	IVIG (n = 34)	IVIG + Infliximab (n = 35)	p-value
Gender (male/female)	28/6	26/9	0.60
Ag ≥ 1 yearold	28 (82%)	22 (63%)	0.06
Age < 1 year old	6 (18%)	13 (37%)	0.11
Complete Symptoms (≥4)	21 (62%)	19 (55%)	0.59
Day of illness treated	8.09 ± 4.26	9.29 ± 6.69	0.37
Admit to PICU	(15%)	6 (17%)	1.00
CRP	12.52 ± 8.81	13.43 ± 11.23	0.71

GGT	78.12 ± 66.00	116.31 ± 89.13	0.33
Urine WBC ≥10	3 (9.68%)	4 (12.90%)	1.00
Length of stay Mean ± SD	5.94 ± 6.33	3.86 ± 2.16	0.07

O1228 - INFLUENCE OF CARDIAC INTERVENTION ON NEURODEVELOPMENT IN YOUNG CHILDREN WITH CONGENITAL HEART DISEASE IN CENTRAL SOUTH AFRICA THREE MONTH AND SIX MONTH OUTCOMES

Robyn Smith[1], Joanne Potterton[1], Veronica Ntsiea[1], Stephen Brown[2]
University of The Witwatersrand, Physiotherapy, Johannesburg-South Africa[1]; University of The Free State, Paediatrics and Child Health, Bloemfontein-South Africa[2]

Background: Congenital heart disease (CHD) survivors are at risk of neurodevelopmental morbidity. The neurodevelopmental outcomes of children with CHD in South Africa are largely unknown. The aim was to determine the neurodevelopmental outcome of young children with CHD following a cardiac intervention.
Materials and Methods: Forty-eight children, 30 months and younger, were recruited into this observational descriptive study. Children who had previous or emergency cardiac surgery were excluded. Development was assessed using the Bayley Scales of Infant and Toddler Development, Third Edition (BSID-III) before, at three-month and six-month post-cardiac intervention. Developmental outcomes were compared over time, and variables associated with developmental performance determined.
Results: Baseline data was collected for 40 children. The majority of children (n = 26) underwent open-heart surgery in infancy with cardiopulmonary bypass. Most children (n = 30) had moderate disease severity, with 20% (n = 8) having cyanotic lesions. A quarter of the children (n = 10) had Down syndrome (DS). Motor delays were prevalent (27.5%) prior cardiac intervention. Motor performance improved, but language and cognitive performance declined post-cardiac intervention, with age and increasing skill complexity. Hypotonia presented in 45% of children prior to cardiac intervention, resolving post-cardiac intervention in all children without DS. Fifty-nine percent of the children were at-risk of, or presented with developmental delays; 42.5% requiring occupational therapy, 55% physiotherapy and 59% speech therapy services. There was no significant change in the developmental outcome over time. BSID-III subscale scores remained below the test mean of 100. The presence of DS (p < 0.001), disease severity (p = 0.02), maternal age (p < 0.001), age at first surgery (p <0.01), and growth prior to cardiac intervention (p = 0.04) were significantly associated with developmental performance. Social disadvantage negatively impacted developmental performance.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: Neurodevelopmental delays prior to, and post cardiac intervention were prevalent in this study sample. The majority of the children were at risk, or had developmental delays requiring early referral to therapeutic services.

O1319 - IMPROVING PATIENT ACCESS AND SATISFACTION WITH INDEPENDENT PEDIATRIC NURSE PRACTITIONER CARDIOLOGY CLINICS

Julianne Evangelista[1], Jeanne Connor[1], Teresa Saia[1], David Fulton[1], Patricia Hickey[2]
Boston Children, Cardiology, Boston-United States[1]; Boston Children's, Cardiology, Boston-United States[2]

Background: In 2008, wait times for 3rd to next available appointment exceeded 40 days in the cardiovascular outpatient department at a children's hospital. To address the gap in available appointments, Independent Pediatric Nurse Practitioner Cardiology Clinics were implemented as a strategic solution to improve patient access to urgent and non urgent appointments.
Methods: A sample of 128 patients who presented concurrently in physician or pediatric nurse practitioner cardiology clinics from December 2009 through February 2010 was recruited for participation. The hospital's ambulatory patient satisfaction survey was utilized to measure level of patient satisfaction. Survey responses were evaluated using Fisher's exact test. Appointment wait times were compared pre and post implementation of pediatric nurse practitioner clinics.
Results: There was no statistically significant difference in patient satisfaction outcomes between physician or nurse practitioner clinic type. Appointment wait time decreased from 46 to 4 days. Pediatric nurse practitioner clinics included a statistically higher percentage of urgent appointments compared to physician clinics.
Conclusions: This innovative health care delivery model helped reduce appointment wait times while earning high levels of patient satisfaction. Independent Pediatric Nurse Practitioner clinics exemplify the Institute of Medicine's goals for advanced practice nursing and epitomizes what contemporary nursing practice can achieve in a Quaternary care and academic center of excellence. Cardiovascular Nurse Practitioners support the mission and vision of Heart Center to provide timely, patient-centered, cost effective, expert cardiovascular care.

O1638 - EXTENDING PAEDIATRIC CARDIOVASCULAR CARE TO GULU REGIONAL REFERRAL HOSPITAL IN UGANDA CHALLENGES AND OPPORTUNITIES IN A FOUR YEAR EXPERIENCE

Twalib Aliku[1], Andrea Beaton[2], Amy Scheel[2], Alyssa Dewyer[2], Emmy Okello[3], Chris T. Longnecker[4], Sulaiman Lubega[5], Craig Sable[2], Peter Luabi[5]
Gulu University, Paediatrics and Child Health, Gulu-Uganda[1]; Children, Paediatric Cardiology, Washington Dc-United States[2]; Uganda Heart Institute, Adult Cardiology, Kampala-Uganda[3]; Case Western Reserve University School of Medicine, Adult Cardiology, Cleveland, Ohio-Uganda[4]; Uganda Heart Institute, Paediatric Cardiology, Kampala-Uganda[5]

Background: Pediatric cardiac services in resource limited countries are often found only in big cities. Because of these inequalities in access, many more rural children with heart disease suffer death or disability compared to those living near cities. We describe the start a satellite cardiac clinic at Gulu Regional referral Hospital (GRRH) in Gulu, a northern Uganda City 335 km from the capital Kampala.
Methods: A pediatric cardiologist was trained at the Uganda Heart Institute (UHI) in Kampala from September 2010 to August 2013. Initial challenges included lack of functional diagnostic equipment. A RHD primary school screening program in Gulu began in October 2013 through a Collaboration between the UHI and Children's National Health System, USA which provided a portable echo machine. A satellite cardiac clinic, staffed by a Paediatric cardiologist, two research nurses, and administrative support was established at GRRH with support from RHD Action Uganda to provide care for RHD and other cardiac patients (children and adults) from the entire northern region.
Results: Total outpatient visits increased from 20 in 2013 to over 1400 in 2016. Total echoes performed over the period for children age <18 years were 728 (Normal = 263; CHD = 217; Acquired heart disease = 248, majority being 214 RHD drawn from both school screening and symptomatic cases). Twenty children have been linked to surgical or catheter-based care at UHI (n = 15) or abroad (n = 5). Monthly outreach visits are also conducted at Lira Regional Referral Hospital. Local and international partnerships have evolved for care delivery and research in Gulu. Linkage of more patients for definitive care is most challenging for patients who cannot afford transport to UHI.
Conclusions: Extending pediatric cardiac care to regional hospitals in Uganda leads to improved care delivery. However, more resources are needed to improve access to tertiary care that is only available in Kampala.

O1679 - PROMOTING PHYSICAL ACTIVITY TO CHILDREN WITH CONGENITAL HEART DEFECTS IDENTIFYING IMPORTANT KNOWLEDGE TRANSLATION GAPS

Patricia Longmuir[1], Lynne Lynch[2], Li-ann Yap[3], Lorene Bodiam[4], Archie Allison[5], Brian Mccrindle[3], Derek Wong[2]
Cheo Research Institute, Halo Research Group, Ottawa-Canada[1]; Children's Hospital of Eastern Ontario, Cardiology, Ottawa-Canada[2]; The Hospital For Sick Children, Cardiovascular Clinical Research Unit, Toronto-Canada[3]; City of Toronto, Inclusive Services, Toronto-Canada[4]; Variety Village, Program, Toronto-Canada[5]

Background/Hypothesis: Physical activity (PA) counselling during clinical encounters is recommended because children with congenital heart defects (CHD) lead sedentary lives, decreasing quality of life and increasing morbidity risk. Clinicians encourage active lifestyles but families remain uncertain about PA. This study sought to identify PA knowledge translation needs, hypothesizing they would differ between CHD children, parents, and recreation/healthcare clinicians.
Materials and Methods: Interviews/focus groups with 13 CHD patients (6 female), 22 parents (18 female), 14 recreation professionals (9 female), and 24 paediatric cardiology healthcare specialists (18 female). Audio-recorded discussions were transcribed verbatim for inductive qualitative analysis within pre-defined coding frames: a) activity barriers/facilitators, and b) practice recommendations.
Results: All study participants identified a need for written PA resources from a recognized source. "I wish there was something that answered all of the basic, common questions", using specific, easy-to-understand language. "The word cardiac scares people" was also a shared perspective, but the attributed sources of fear and perceived impacts differed. Parents reported instructors being fearful of their children. Recreation leaders felt parents and doctors feared their cardiac PA expertise was limited. Healthcare specialists reported parent fears override their PA recommendations.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Perceptions of successful PA differed between study groups. Children, parents and recreation leaders emphasized fun, engaging activities with family/friends, practical advice on how to make PA happen and novel activity ideas that suit cardiac limitations. Encouraging lots of PA experience/practice and consistently providing/repeating information was recommended. Healthcare providers felt PA adaptations for each child's abilities "may be a dream", encouraging alternate roles (e.g., referee) if needed.
Conclusions: All participants agreed cardiac fear is a major PA barrier, but differed regarding fear sources and impacts. Revising healthcare practice to focus on encouraging PA participation, via practical suggestions and clear information from credible sources, and enhancing awareness of recreation options and expertise are recommended.

O1788 - ANALYSING CURRENT PRACTICE IN THE ASSESSMENT OF PAEDIATRIC CHEST PAIN

Sarah Gummer[1], Tara Barucha [2]
Faculty of Medicine, University of Southampton, Southampton-United Kingdom[1]; University Hospital Southampton, Paediatric Cardiology, Southampton-United Kingdom[2]

Background: Chest pain is a common presenting complaint to General Practitioners, Paediatricians and the Emergency Department, often resulting in paediatric cardiology referral. However, unlike adult chest pain, paediatric chest pain rarely has a cardiac aetiology, often resulting in high levels of unnecessary testing and associated anxiety. Currently there is no UK guidance for paediatric chest pain assessment, which may be a contributory factor for variation in clinical practice.
Aims: To assess the outcome of referrals to a paediatric cardiology department with primary symptom of chest pain.
Methods: A cross-sectional observational study of paediatric patients aged 4-18 years referred to the paediatric cardiology department of a regional tertiary referral centre, with the primary symptom of chest pain. Prospective and retrospective data was gathered in paediatric cardiology clinics and from patient notes between October-December 2016. Data was collected regarding presenting symptoms, history, examination, diagnostic testing and eventual diagnoses.
Results: 42 patients were included in the study (26 retrospective, 16 prospective). 25 patients were female and 17 male, with an average age of 11.47 years (+/- 3.48). Chest pain aetiologies included: 55% (23) idiopathic, 31% (13) musculoskeletal, 7% (3) gastrointestinal, 2% (1) anxiety. 2 patients were still undergoing testing, but their chest pain was not attributed to a cardiac pathology. No patients were found to have cardiac chest pain. All patients had an electrocardiogram (ECG) and echocardiogram and each had an average of 2.9 diagnostic tests. Additional tests included exercise stress tests and ambulatory ECG monitoring.
Conclusions: Paediatric chest pain rarely has a cardiac aetiology. Practice variation and unnecessary resource use are a concern, and a standardised approach to assessment could improve patient care by limiting unfruitful cardiac testing and associated anxiety. A detailed history, physical examination and ECG are usually sufficient for diagnosis of the cause of paediatric chest pain.

O1881 - MATERNAL OPIOID AGONIST THERAPY AND RISK OF CONGENITAL HEART DISEASE IN THE FETUS

Sharon E. Obrien[1], Da Geng[2], Kelly Saia[3], Hira Shresthra [4], Elisha M. Wachman[1]
Boston Medical Center, Boston University School of Medicine, Pediatrics, Boston-United States[1]; Boston University School of Public Health, Biostatistics, Boston-United States[2] Boston Medical Center, Boston University, Ob/gyn, Boston-United States[3] Boston University School of Medicine, Pediatrics, Boston-United States [4]

Background: Maternal opioid use disorder (OUD) during pregnancy has increased over the past decade; current standard of care is treatment with methadone (MTD) or buprenorphine (BPH). Frequently there is concurrent use of psychiatric medications, illicit drugs or cigarettes. Maternal analgesic opioid use early in gestation has been associated with congenital heart disease (CHD). Little data exists about the association of opioid agonist therapy (OAT) with MTD or BPH during pregnancy and risk for CHD.
Objective: Assess impact of opioid agonists for OUD during pregnancy on incidence of CHD.
Methods: Retrospective cohort study of 744 mother-infant dyads at Boston Medical Center between 2006-2015. Inclusion criteria were infants >36 weeks gestational age (GA) and mothers on MTD or BPH at delivery. Outcomes included diagnosis of CHD as per the electronic medical record. Maternal and infant demographics, and pregnancy co-exposures were analyzed. Analysis performed included chi- square test for categorical and dichotomous variables and simple logistic regression for continuous variables.
Results: Of 744 infants, 454 (61.0%) were MTD and 290 (39.0%) BPH exposed. OAT was associated with an increased incidence of CHD (Table) of 2.54% as compared to 0.8% in the general population. There was no difference in CHD based on MTD vs BPH exposure. Earlier first prenatal visit and GA at delivery, or older maternal age trended toward increased risk of CHD, but did not meet significance. Use of psychiatric medications and smoking did not increase risk of CHD. Illicit drug use during the third trimester (n = 61, 8.2%) was associated with increased CHD ($p = 0.01$). In a subgroup analysis excluding those with illicit drug exposure, the incidence of CHD remained higher than the general population at 2.01%.
Conclusion: Prenatal use of opioid agonists for treatment of OUD is associated with increased risk of CHD, with no differences in risk between MTD and BPH.

O1931 - EFFECTS OF US STATE NEWBORN CRITICAL CONGENITAL HEART DISEASE SCREENING POLICIES ON INFANT CARDIAC DEATHS

Rahi Abouk[1], Scott Grosse[2], Elizabeth Ailes[2], Matthew Oster[3]
William Paterson University, Cotsakos College of Business, Wayne, Nj-United States[1]; CDC, National Center on Birth Defects and Developmental Disabilities, Atlanta, Ga-United States[2]; CDC, Children's Healthcare of Atlanta, Cardiology, Atlanta, Ga-United States[3]

Background: With the goal of reducing preventable deaths among infants with critical congenital heart disease (CCHD), screening for CCHD using pulse oximetry has been recommended in the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

United States since 2011. Incorporating this recommendation as part of mandated newborn screening policy, however, is up to each individual state. This study aimed to estimate the effects of state CCHD newborn screening policies on infant cardiac deaths from congenital heart disease (CHD) in the United States.
Methods: Using 2007-2013 period linked birth and infant death data, we utilized a difference-in-differences strategy to estimate the impact of state CCHD screening policies on early infant (24 hour– < 6 months of age) mortality rates for CCHD or other/unspecified CHD. We adjusted for state trends and state-period-specific variables and projected avoidable deaths at the national level.
Results: Between August 31, 2011 and June 1, 2013, nine states implemented mandatory CCHD screening policies. In these states, adjusted rates of early infant mortality from CCHD decreased by 36.8% (95% CI: 12.5%–54.4%) for births during months after implementation of mandatory CCHD screening compared to prior periods and states without CCHD screening policies. Other/unspecified CHD adjusted mortality rates decreased by 17.6% (95% CI: 1.6%–30.9%). We projected that universal CCHD screening in the United States could reduce deaths due to recognized CCHD by 42-180 per year, relative to not screening for CCHD, not including potential reduction in infant cardiac deaths with non-critical or unspecified CHD codes, some of which may reflect undiagnosed CCHD.
Conclusions: These results suggest that mandatory CCHD screening policy achieves the goal of reducing preventable deaths and is an effective public health intervention for the prevention of infant cardiac deaths. These results have important implications for jurisdictions considering CCHD screening policies.

O2038 - EFFECTIVENESS AND SAFETY OF STATIN THERAPY IN CHILDEN A REAL WORLD CLINICAL PRACTICE EXPERIENCE

Rae-Ellen Kavey[1], Cedric Manhliot[2], Kyle Runeckles[2], Samuel Gidding[3], Matthew Demczko[3], Sarah Clauss[4], Ashraf Harahsheh[4], Michele Mietus-snyder[4], Nicolas Madsen[5], Brian Mccrindle[2]
University of Rochester, Pediatrics, Rochester-United States[1]; Hospital For Sick Children, Toronto-Canada[2]; Dupont Children, Wilmington-United States[3]; Children, Washington-United States[4] Cincinnati Children, Cincinnati-United States[5]

Background: Existing evidence of statin use in children is predominantly limited to short-term research trials. To evaluate effectiveness and safety of longer-term statin use in clinical practice, we reviewed results of all children treated for >6 months (m) from 5 Pediatric Lipid Clinics.
Results: There were 334 patients who had 2197 clinical assessments. In 84%of patients, the diagnosis was familial hypercholesterolemia; 16% had combined hyperlipidemia. Mean age at statin initiation was 12.9 ± 3.0 years. Mean duration of therapy was 3.2 years (IQR: 1.6-4.6) with 46% over 3 years. Initial prescribed statin varied over time but 65% were started on atorvastatin and 78% remained on the first statin prescribed. Mean compliance was clinically assessed at 92% and 330 patients(99%) remained on statin therapy at review end. The table displays results for regression analyses adjusted for repeated measures over time for two intervals: baseline(B/L) to 6 m post statin initiation, and 6 +/-3m post initiation to last follow-up(F/U). Statin treatment was initially associated with significant reductions in TC, LDL-C and non-HDL-C with no significant change in fasting TG, HDL-C or safety labs. There were further significant reductions in TC and LDL-C with longer treatment. Only 6 patients complained of any symptoms, none attributed to treatment. While 11% of patients had transient AST or ALT > 3xULN or CK > 10xULN during follow-up, none required discontinuation of statins for persistent elevation. Mean fasting glucose was unchanged throughout F/U and no patient developed diabetes mellitus. Longer duration of statin therapy was not associated with increased odds of lab abnormalities.
Conclusion: These findings in a large series of pediatric patients from real-world clinical practice show that statin therapy for hypercholesterolemia is safe and effectively lowers LDL-C on longer-term follow-up. Side effects are rare and discontinuation of treatment is uncommon.

O2084 - RIGHT VENTRICULAR DYSFUNCTION AND EXERCISE INTOLERANCE IN PATIENTS WITH MODERATE OR SEVERE PULMONARY REGURGITATION IN PATIENTS WITHOUT TETRALOGY OF FALLOT. ARE THEY THE SAME AS TETRALOGY OF FALLOT

Guillermo Larios, Deane Yim, Luc Mertens, Andreea Dragulescu, Lars Grosse-wortmann, Mark Friedberg
The Hospital For Sick Children, Division of Cardiology, Toronto-Canada

Background: Right ventricular (RV) remodeling and dysfunction secondary to pulmonary valve regurgitation (PR) are common after intervention(s) for congenital pulmonary stenosis (PS) or atresia and intact ventricular septum (PA/IVS). Pulmonary valve replacement has largely been evaluated in patients after repair of tetralogy of Fallot (TOF), but it is unknown whether PR has similar effects in on RV function in non-TOF patients. The objective of this study was to compare exercise tolerance and RV function in non-TOF versus TOF children with similar PR and RV dilation.
Methods: Thirty PS or PA/IVS children after intervention(s) with moderate or severe PR (non-TOF group) and 30 patients after surgical TOF repair (TOF group), matched for age and RV end-diastolic volume index (RVEDVi), measured by cardiac magnetic

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

resonance (CMR) were retrospectively studied. Patients with residual PS (>25 mmHg) were excluded. Clinical data, ECG, exercise capacity, echocardiography and CMR were compared between groups.

Results: The groups were well matched for age, RVEDVi, gender distribution and CMR PR fraction (Table). All TOF patients had surgical repair of the RV outflow tract and had a right bundle branch block, versus 13% and 57% of non-TOF, respectively. QRS was wider in TOF patients. Parameters of RV function and exercise capacity were similarly reduced in both groups. The mean RV ejection fraction (RV-EF) and peak oxygen consumption (% predicted) in non-TOF versus TOF were: 48.7 ± 6.4% versus 48.5 ± 7.2%, p = 0.93; and 82.5 ± 17.7% versus 75.6 ± 20.4%, p = 0.24, respectively. Negative correlation was found in both groups between RVEDVi and RV-EF (non-TOF: r = -0.39, p = 0.04, TOF: r = -0.40, p = 0.03).

Conclusions: RV function and exercise capacity are similarly reduced in non-TOF and TOF patients with clinically significant PR matched by RV volume. These data suggest that RV dilatation, rather than the intrinsic disease, drives RV dysfunction. This implies that criteria for pulmonary valve replacement should be applicable to both groups.

Table. Demographic, clinical, ECG, exercise test, echocardiogram and CMR data in non-TOF versus TOF patients.

O2102 - STATE OF THE ART CLINICAL CARE OF THE FONTAN CIRCULATION A MULTI INSTITUTIONAL SURVEY OF PRACTICE VARIABILITY IN IDENTIFIED FONTAN PROGRAMS ACROSS THE UNITED STATES

Adel Younoszai, Michael Dimaria
University of Colorado School of Medicine, Pediatric Cardiology, Aurora-United States

Background: Significantly more children with single ventricle physiology are surviving past Fontan surgery. This unnatural circulation imposes pervasive effects on growth and development and has unique modes of failure. Programs specifically designed to follow children after Fontan are emerging. We hypothesized that significant variability in surveillance testing strategy exists across centers in the United States.

Methods: Eleven academic institutions with established Fontan Care Programs performing a combined, estimated population of 1500-2000 Fontan patients(300 Fontan surgeries/year)were surveyed regarding surveillance testing and basic practice philosophies. Responses were entered into RedCap.

Results: Few practice patterns were identified (table). Neurodevelopmental outcomes were routinely screened in 6 institutions; the rest assessed "as needed". All centers prescribed anticoagulation - most used aspirin alone and none used Coumadin primarily. Only two centers routinely prescribed other medications; one an ACE inhibitor and another a beta-blocker. None routinely used pulmonary vasodilators (including two

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

centers at altitude), though when prescribed a PDE-5 inhibitor was most common. Most sites recommended self-limitation of activity and encouraged exercise; 2 allowed participation in competitive athletics; one prescribed specific exercise plans. Eight programs referred adult Fontans to an adult congenital heart disease (ACHD) program while 3 utilized a combination of ACHD and pediatric cardiologists.
Conclusions: Among large academic centers there is a diversity of surveillance strategy after Fontan. However, there are similarities relative to cardiac and secondary organ screening, consultations, and the lack of routine medication use. While most centers proactively involve hepatology, less than half perform liver biopsy routinely. Decreasing practice variability improves quality outcomes. With a rapidly increasing survivial there is urgent need for re-definition of quality outcomes, collaborative practice patterns to decrease variability and innovative research to better understand the complex adaptations of the body to the unique and challenging Fontan physiology.

O2312 - IMPACT OF CONGENITAL HEART SURGERY ON QUALITY OF LIFE IN INFANTS (1 24 MONTHS) A PROSPECTIVE STUDY

Bhavik Champaneri[1], *Abish Sudhakar*[1], *Manu Raj*[2], *Rinku Roy*[1]
Amrita Institute of Medical Sciences and Research Centre, Pediatric Cardiology, Cochin-India;[1] *Amrita Institute of Medical Sciences and Research Centre, Public Health, Cochin-India*[2]

Background: Few studies have prospectively sought to systematically examine the quality of life (QOL) before and after congenital heart surgery. This is especially true of the low resource environments of low and middle-income countries.
Objectives: To determine the impact of heart surgery on the QOL in a cohort of infants with congenital heart disease.
Material and Methods: This was a prospective study from a tertiary care pediatric cardiac center in Southern India. Consecutive infants (1-24 months), admitted for elective congenital heart surgery were included. Validated local language translations of standard QOL infant questionnaires (1-12 and 13-24 months) reported by parents were used (The PedsQL^{TM} Measurement Model for the Pediatric QOL inventory) and 5 standard domains of QOL- physical functioning, physical symptoms, emotional, social, cognitive functioning were tested. Data was collected at preoperative admission and 6 months after surgery.
Results: Over 18-months, 423 infants (1-12 months: 360, 13-24 months: 63) were included. Follow-up data was available for 361 (85.3%) at 6 months. QOL significantly improved from baseline to 6 months after surgery in all domains except cognitive functioning in 1-12 months group; only physical functioning significantly improved in 13-24 months group (see table). Corrective surgery was associated with greater improvements in QOL in all domains except psychosocial health in the 1-12 m group. Lower surgical risk category (RACHS 1-2) was associated with greater improvements in QOL in all the domains in the 1-12 months group.
Conclusion: Congenital heart surgery is associated with improved physical health in all infants while psychosocial health is unchanged in those older than 12 months. Corrective surgery (as against palliative surgery) and lower surgical risk category are associated with better physical and psychosocial improvement.

O2314 - PRIMARY CONGENITAL ANOMALIES OF CORONARY ARTERIES IN CHILDREN AND ADOLESCENTS

Dimpna C Albert[1], *Idoia Grange*[1], *Anna Sabate-Rotes*[1], *Pedro Betrian*[1], *Ferran Gran*[1], *Ferran Roses*[1], *Joaquin Fernandez-Doblas*[2], *Joaquin Perez-Andreu*[2], *Gemma Giralt*[1], *Raul Abella*[2]
University Vall De Hebron Hospital, Pediatric Cardiology, Barcelona-Spain[1]; *University Vall De Hebron Hospital, Pediatric Cardiac Surgery, Barcelona-Spain*[2]

Background/Objectives: Coronary artery anomalies (CAA) are rare and have the potential to cause present serious myocardial damage, ischemic cardiomyopathy, and sudden cardiac death, but the majority are discovered incidentally. In the present study, children with primary CAA were analyzed to determine the clinical relevance, types of coronary artery anomalies, diagnostic and treatment.
Methods: Retrospective, observational study. Data of our patients below 18 years with CAA in our center until December 2015.
Results: Anomalous coronary arteries were detected in 48 but only in 26 children were isolated (not associated any other cardiovascular disease anomalies or acquired disease). We included 16 anomalous of origin (10 left coronary from pulmonary artery-ALCAPA; 6 anomalous origins from opposite sinus: 5 of right coronary and 1 left coronary); 2 anomalous course; 6 anomalous connections and 2 anomalous number (see Table 1). Mean age at diagnosis was 11,8 years (6m-18y). Murmur was the first symptom, but heart failure was present in 90% of ALCAPA (see Figure). The diagnosis was carried out by echocardiography (ECHO) in 22 cases (84,6%), other imaging modalities (coronary CT, coronary

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

angiography or MRI) were used in 15,4% for the diagnosis and to corroborate anatomy in 38% of cases. The treatment was surgical in 11 children (10 ALCAPA, 1 left coronary artery origin from right sinus), 1 interventional catheterization and 4 with medical treatment. After a mean time of follow-up of 4,4 years, one patient died for complications related to diaphragmatic hernia and the rest of patients are stable on clinical observation.
Conclusions: The most frequent anomaly observed in the present study was related to the ALCAPA. The recognition and diagnosis of these anomalies is important and requires specialization in ECHO (main technique for suspicion and diagnosis), coronary angiographic techniques and other imaging modalities.

Table. Summary of primary congenital anomalies of coronary arteries in children

Coronary arteries anomalies	N 26	Group (N)	Clinical main characteristics	Mean age at diagnosis	% ECHO diagnosis	Other diagnostic techniques	Surgical or interventional treatment (%)
Anomalous origins of coronary artery	16	ALCAPA (10)	Cardiogenic Shock/HF (90%)	7,7 m (3 d–3,9 y)	89%	CA (20%)	(100% Surgical)

O2465 - NEWBORN WELLNESS SCREEN MODIFIED NEWBORN PULSE OXIMETRY SCREENING FOR OUT OF HOSPITAL BIRTHS

Devyani Chowdhury[1], *Katie Williams*[2]
Cardiology Care For Children, Pediatric Cardiology, Lancaster-United States[1]; *Clinic For Special Children, Pediatrics, Lancaster-United States*[2]

Background: Newborn pulse oximetry screening at 24-48 hours of life is recommended to detect critical congenital heart disease (CCHD), but cyanosis can also be due to pulmonary pathology and neonatal infections. Infants born out of hospital often lack a prenatal assessment with ultrasound, have variable rates of maternal GBS testing, and are typically observed only for a few hours after delivery, necessitating a modified pulse oximetry screening protocol.
Methods: Infants had pulse oximetry screening at 1-3 hours of life ("early screen") and again at 24-48 hours ("standard screen") by trained midwives. Midwives were provided training and reliable pulse oximeters (Massimo) to perform the screening. The current AAP-endorsed algorithm for interpreting results was used at both screenings. Midwives followed infants for at least 6 weeks to identify any missed cardiopulmonary pathology or infectious illnesses.
Results: 1212 term infants (50%% male) were screened following parental consent. Prenatal ultrasound was completed for 45% of infants with no CHD identified. 72% of mothers were tested for GBS colonization. Early and standard screens were performed and interpreted correctly for 1077 (89%) infants . At 6 week follow up 1 patient had a small muscular VSD and one was a heterotaxy (unable to obtain saturations); no infections were detected in the cohort.
Conclusion: Preliminary data suggest a combined early and standard newborn pulse oximetry screen can be implemented to detect cyanosis in out of hospital births with a low false positive rate. The early screen is both sensitive and specific with a PPV of 20%. No true positive were identified in the late screen. Of 3 TP 2 had respiratory disease and 1 had complex syndromic cardiopulmonary disease (not CCHD).

Table.

	Early Screen	Late Screen
True positive	3	0
False positive	12	2
True negative	1062	1103
False negative	0	2
Sensitivity	100%	
Specificity	99%	99.8%
NPV	100%	99%
PPV	20%	

O2497 - CORRELATION OF N TERMINAL PRO BRAIN NATRIURETIC PEPTIDE WITH MYOCARDIAL FUNCTION AND ELECTROCARDIOGRAPHIC PARAMETERS IN KAWASAKI DISEASE

Laurent Desjardins[1], *Audrey Dionne*[2], *Leamarie Meloche-dumas*[3], *Anne Fournier*[3], *Nagib Dahdah*[3]
Chul Du Chu De Québec, Université Laval, Pediatrics, Quebec City-Canada[1]; *Boston Children, Pediatric Cardiology, Boston-United States*[2]; *Chu Mère-Enfant Ste-justine, Université De Montréal, Pediatric Cardiology, Montreal-Canada*[3]

Introduction: Pathologic series documented immune myocarditis in nearly all cases of Kawasaki disease (KD), irrespective of coronary complications. N-Terminal Pro-Brain Natriuretic Peptide (NT-proBNP) is useful in the diagnosis of acute KD, but this biomarker has seldom been studied for its relation to myocardial parameters. This study aimed to correlate myocardial response with serum level of NT-proBNP at diagnosis.
Material and Methods: Serum levels of NT-proBNP at diagnosis were retrospectively correlated with echocardiographic

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

parameters of myocardial function and electrocardiogram measurements in the acute (1st week), sub-acute (2-3 months) and chronic (6 months to 1 year) phases of KD.

Results: A total of 127 patients with KD were included in this study from 2010 to 2015, among whom 13 (10%) had coronary aneurysms. NT-proBNP (mean 2029 ± 4433 pg/mL) was elevated in 68 patients (61.4%, mean z-score 2.6 ± 1.6, upper quartile 4.67 ± 0.87), with no correlation with the occurrence of coronary aneurysms (p = 0.2). Basic characteristics were comparable among NT-proBNP quartiles. A lower shortening fraction and higher left ventricular mass index (SF z-score -2.8 ± 4.6 and 56.5 ± 13.1 g/m^2, for the upper quartile) were associated with higher NT-proBNP levels (figure 1). Slower mitral deceleration time, lower E/A ratio and higher E/e' ratio also correlated with higher NT-proBNP, reflecting reduced left ventricle compliance. Moreover, higher NT-proBNP was associated with longer QTc duration, wider QT dispersion and longer PR interval (figure 2). The correlations with elevated NT-proBNP persisted at 3 months but disappeared at 1 year follow-up, with the exception of QTc which maintained a trend towards longer duration.

Conclusion: Acutely elevated NT-proBNP in KD is associated with systolic, diastolic and electrical disturbances, during the acute and sub-acute phases of the disease. These findings suggest myocardial involvement in KD, even in the absence of coronary aneurysm. Therefore, long-term follow-up in patients with elevated NT-proBNP at diagnosis should be seriously considered.

O2657 - RELATIONSHIP OF AMBULATORY BLOOD PRESSURE WITH LEFT VENTRICULAR GLOBAL LONGITUDINAL STRAIN

Carles Bautista
Hospital Sant Joan De Deu, Paediatric Cardiology, Barcelona-Spain

Background: Left ventricular (LV) global longitudinal strain (GLS) is an early indicator of subclinical cardiac dysfunction, even when LV ejection fraction (LVEF) is normal, and is an independent predictor of cardiovascular events. Ambulatory blood pressure (BP) is a good predictor of cardiovascular events, including heart failure. We investigated the association of ambulatory BP measurements with subclinical LV systolic dysfunction in a paediatric community-based cohort with normal LVEF.

Methods: Two-dimensional speckle-tracking echocardiography and 24-hour ambulatory BP monitoring were performed in 49 children (mean age 11 ± 2 years; 56% men) with LVEF ≥55%. All children were sent for cardiac evaluation because of 3-high-BP-values (> p97 according to height) were reported by their paediatricians. Univariable and multivariable linear regression analyses were used to assess the associations of BP measures with GLS.

Results: Higher ambulatory BP values were consistently associated with impaired GLS. After adjustment for pertinent covariates (age, sex, race/ethnicity, body mass index), ambulatory systolic and diastolic BPs was independently associated with GLS (P ≤0.001 for all ambulatory BPs).

Conclusions: Ambulatory BP values are significantly associated with impaired GLS. Office BP is a strong surrogate for ambulatory BP

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

and GLS. Ambulatory BP monitoring might have a role in the risk stratification of hypertensive children for early LV dysfunction.

O2725 - CARDIAC DISEASE IN PEDIATRIC PATIENTS PRESENTING TO CARDIOLOGY DEPARTMENT WITH CHEST PAIN

Tayfun Ucar[1], Meral Demir[2], Melih Dogan[1], Mehmet Ramoglu[1], Ercan Tutar[1], Semra Atalay[1]
Ankara University Medical School, Pediatric Cardiology, Ankara-Turkey[1]; Ankara University Medical School, Pediatrics, Ankara-Turkey[2]

Background: Chest pain in children and adolescents is one of the most common complaint for referral to pediatric cardiologists. In this study, it is aimed to determine the proportion of children referred to pediatric cardiology clinic for chest pain diagnosed with a cardiac cause of chest pain.
Methods: We reviewed 635 (325 male, 310 female and 6-18 years) patients who presented with a chief complaint of chest pain and no history of cardiovascular disease prospectively. Eligible patients were evaluated with regard to demographic and chest pain characteristics, past medical history, family history, findings on physical examination, electrocardiogram and chest radiography. If necessary, futher cardiac evaluation were performed.
Results: 635 patients reported with chest pain during the study period. Only 24 (3.7%) of all patients were determined to have chest pain of cardiac origin. Those with cardiac- related chest pain had been consisted of 10 myopericarditis, 10 mitral valve prolapse, 2 myocardial bridge, 1 coroner vasospasm and 1 hypertrofic cardiomyopathy. All patients had an electrocardiogram. Thirty-eight percent of the cardiac related chest pain had abnormal electrocardiogram compared to those without cardiac related chest pain at 4.3% ($p < 0.001$). Furthermore, when compared these groups, for high risk chest pain characteristics, medical or family history and abnormal cardiovascular exam findings, in cardiac group, these pathologies were significantly high ($p < 0.001$).
Conclusion: Cardiac related chest pain is rare but potentially serious. Although a pediatric cardiology referral may provide reassurance to the primary care and emergency physicians, our results reveal that cardiac pathology for pediatric chest pain are rare. An electrocardiogram in addition to detailed history and careful physical examination is appropriate approach to optimize testing and referral patterns while maintaining a high detection rate for relatively uncommon but significant cardiac disease.

O2999 - CHILDREN WITH CONGENITAL HEART DISEASE (CHD) ARE THEY SAFE TO FLY

Nitha Naqvi[1], Victoria Doughty[1], Simon Ward[2], Ian Balfour-lynn[3], Piers Daubeney[1]
Royal Brompton Hospital, Paediatric Cardiology, London-United Kingdom[1]; Royal Brompton Hospital, Respiratory Physiology, London-United Kingdom[2]; Royal Brompton Hospital, Paediatrics, London-United Kingdom[3]

Background: Healthy children de-saturate by approximately 4% during air flight as cabin pressurisation (5-8000 feet equivalent) results in a reduced fraction of inspired oxygen to the equivalent of 0.15. Little is known about the effect of in flight hypoxia on children with CHD.
Aim: To measure oxygen saturations of children with CHD during a hypoxic challenge /'fitness to fly' test to guide recommendations for supplementary oxygen.
Method: Observational study including children with CHD between 0-≤16 years. Exclusion criteria were pulmonary hypertension; pre-existing oxygen requirement; significant respiratory disease; and baseline SpO2 of ≤74%. A wide spectrum of cardiac diagnoses, including post-operative children, were studied. During testing the child sits inside a plethysmograph (body box) in which oxygen level is reduced to 15% over 5 minutes. Supplemental oxygen was given if saturations fell by more than 15% or to below 70% indicating test failure.
Results: See table & graphs – Figure 1 (69 participants).
Conclusions: Children with CHD having baseline cyanosis (75-94%) or normal saturations (95-100%) with potential for right to left (Rt-Lt) shunting, may desaturate by >15% during hypoxic challenge flight simulation. Hence we recommend children with CHD, with either cyanosis or potential for Rt-Lt shunting, undergo a fitness to fly simulation test prior to real flight, to identify those who should be given oxygen during flight to prevent significant desaturation.

Groups	Baseline SpO_2% (median)	Lowest SpO_2% (median)	Number of Participants Failing Test (%)
Group A (n=37)	95 - 100 (98.3%)	84 – 95 (89.8%)	4 (11%)
Group B (n=32)	75 - 94 (84.8%)	65 - 84 (76.6%)	5 (16%)

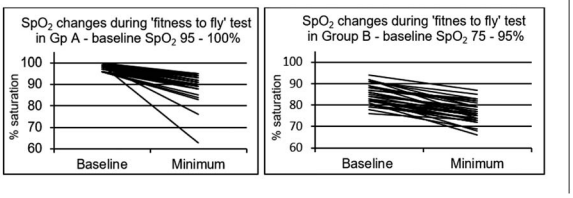

Figure.

ANESTHESIA

O1110 - PREOPERATIVE NUTRITIONAL DEFICITS WORSEN OUTCOMES FOLLOWING PEDIATRIC CARDIAC SURGERY

Faith Ross[1], Gregory Latham[1], Radman Monique[2]
Seattle Children, Anesthesiology and Pain Medicine, Seattle-United States[1]; Seattle Children, Critical Care, Seattle-United States[2]

Introduction: Children with congenital heart disease are at increased risk of acute and chronic malnutrition due to increased metabolic demands and diminished energy intake. In this study, we evaluated the impact of nutritional status on outcomes after pediatric cardiac surgery in a large cohort of children.
Methods: We conducted a retrospective analysis of patients from age 0 to 5 years undergoing cardiac surgery at Seattle Children's Hospital from 2006 to 2015. Anthropometric indices, including height-for-age, weight-for-age, and weight-for-height z-scores (HAZ, WAZ, WHZ), were calculated for each patient using WHO standards. We used multivariate regression modeling controlling for age and surgical complexity to examine the impact of nutritional status on surgical outcomes including 30-day mortality, cardiac arrest, infection, duration of mechanical ventilation, ICU LOS, and hospital LOS.
Results: Nutritional deficits, indicated by low HAZ and low WAZ were associated with increased mortality. This relationship was nonlinear; nutritional status has little impact on mortality until deficits become severe with HAZ or WAZ ≤-2. In this range, each additional unit decrease in HAZ or WAZ is associated with a 2.87% or 2.14% increased risk of mortality respectively. Low HAZ and WAZ were also associated with increased risk of cardiac arrest, infection and longer mechanical ventilation and ICU and hospital LOS.
Conclusion: Nutritional deficits increase the risk of mortality and other adverse outcomes after pediatric cardiac surgery. From our data, HAZ has the strongest relationship with mortality; thus,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

HAZ should serve as a useful screening index for patients at risk for complications related to malnutrition. The dramatic increase in mortality with HAZ and WAZ ≤ -2 indicates that nutritional optimization efforts should be focused on this population. Given the association between nutritional deficits and longer mechanical ventilation and hospital and ICU LOS, focused nutritional optimization has the potential for significant cost savings.

Table. Risk of outcomes based on nutritional status

	30-day Mortality	Cardiac Arrest	Infection
HAZ	Nonlinear*	-0.012* (-0.018,-0.006)	-0.011* (-0.017,-0.004)
HAZ <= -2	-0.029* (-0.050, -0.007)		
WAZ	Nonlinear*	−0.007* (-0.013, -0.002)	-0.008* (-0.014, -0.002)
WAZ <= -2	-0.021* (-0.042, -0.001)		
WHZ	-0.003 (-0.008, 0.002)	0.004 (-0.002, 0.010)	0.002 (-0.006, 0.010)
	Mech. Vent. (days)	ICU LOS (days)	Hospital LOS (days)
HAZ	-0.07* (-0.10, -0.04)	-0.25* (-0.34, -0.15)	-0.57* (-0.74, -0.39)
WAZ	-0.08* (-0.11, -0.05)	-0.22* (-0.33, -0.12)	Nonlinear*
WHZ	Nonlinear*	-0.01 (-0.11, 0.10)	Nonlinear*

For categorical variables, each outcome probability is reported based on a unit change in the z score. For non-categorical variables, the value in the table represents B from robust linear regression model, or the coefficient of the linear relationship between the independent and dependent variables. The values in parentheses represent 95% confidence intervals. *Statistically significant results are starred.

O1863 - OUTCOMES OF CHILDREN WITH CONGENITAL HEART DISEASE UNDERGOING BYPASS SURGERY BY ROUTE OF TRACHEAL INTUBATION IN THE UNITED STATES AN ANALYSIS OF THE SOCIETY OF THORACIC SURGEONS CONGENITAL HEART SURGERY DATABASE

Nathaniel Greene[1], Dylan Thibault[2], Eileen Raynor[3], Alice Wang [4], David Vener [5], Roland Matsouaka[2], Marshall Jacobs[6], Jeffrey Jacobs[7], Kevin Hill[8], Warwick Ames[1]

Duke University, Anesthesiology, Durham, Nc-United States[1]; Duke University, Biostatistics, Durham, Nc-United States[2]; Duke University, Otolaryngology, Durham, Nc-United States[3]; Duke University, Surgery, Durham, Nc-United States[4]; Baylor College of Medicine, Anesthesiology, Houston, Tx-United States[5]; Johns Hopkins University, Surgery, Baltimore, Md-United States[6]; Johns Hopkins All Children, Surgery, Saint Petersburg, Fl-United States[7]; Duke University, Pediatric Cardiology, Durham, Nc-United States[8]

Introduction: In children undergoing cardiopulmonary bypass (CPB) surgery, nasal intubation is more common than in adults, and sometimes preferred due to perceived benefits of less post-operative sedation and a lower risk for accidental extubation. This study sought to describe the practice of nasal intubation in the pediatric population undergoing CPB surgery and assess the risks/benefits of a nasal route against an oral one.
Methods: Patients <18 years of age in the STS Congenital Heart Surgery Database (01/2010–12/2015) were included. Multivariable modeling was used to assess the association between route of tracheal intubation and a composite measure of infection risk. Covariates were included to adjust for important patient characteristics, case complexity, and center effects. Secondary outcomes included length of intubation, hospital length of stay, and airway complications including accidental extubations.
Results: Unadjusted analysis of the entire cohort of 26,788 operations from 50 centers showed nasal intubation to be associated with a higher composite infection rate ($p = 0.004$), longer intubation length ($p < 0.0001$), longer post-operative length of stay ($p < 0.0001$), and a similar rate of accidental extubation ($p = 0.82$). Multivariable analysis in infants and neonates showed the nasal route of intubation was not associated with the infection composite, but was associated with a shorter length of stay, and a shorter length of intubation. Restricting to centers with at least 100 cases per year showed a significant interaction between age and intubation route with a risk change occurring at approximately 6 months of age ($p = 0.003$, Figure 1).
Discussion: While older children undergoing nasal intubation trend similar to the adult population with an increased risk of infection, nasal intubation in children <6 months may confer some protection. This may be related to the timing of maxillary/ethmoid sinus development and/or development of adenoid tissue, acting as a source of bacteria for nasal endotracheal tubes.

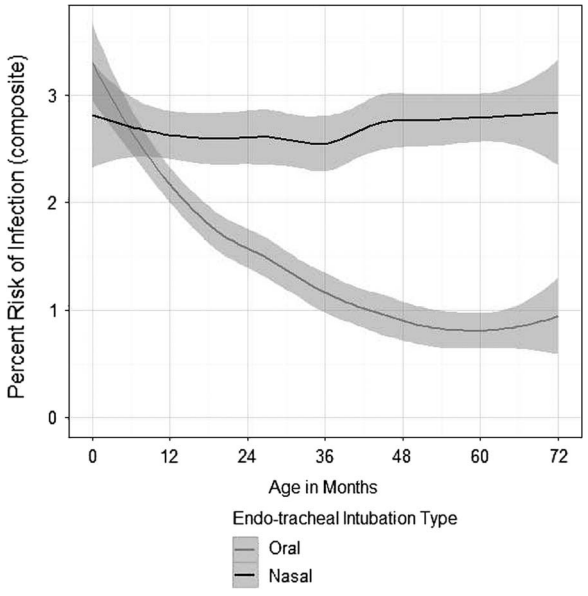

Figure 1.
Risk of Infection for Oral vs Nasal Intubation by Age (72 months and under) with Smoothed line.

O1999 - BASELINE MA FF FLEV AND FIBRINOGEN LEVELS IN NEONATES INFANTS AND CHILDREN WITH CONGENITAL HEART DEFECTS

Michelle Dacosta[1], Thomas Austin[1], Silvia Bunting[2], Nina Guzzetta[1], Bruce Miller[1]

Emory University School of Medicine, Anesthesiology, Atlanta-United States[1]; Emory University School of Medicine, Pathology, Atlanta-United States[2]

Introduction: In children undergoing cardiac surgery, fibrinogen restoration is important in correcting coagulopathies after cardiopulmonary bypass (CPB) (1). However, determining the clinically appropriate measure of fibrinogen for this correction is less than clear. Clauss-method measurement of fibrinogen levels is time consuming and is performed on plasma samples activated with excess thrombin. Thromboelastographic (TEG®; Haemonetics) measurement of "functional fibrinogen" is quicker and is performed on whole blood (WB) samples using a GpIIb/IIIa receptor blocker to inhibit platelets and thus isolate the contribution of fibrinogen to clot strength. Haemonetics has developed a proprietary measure of this functional fibrinogen ("FLEV") derived

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

from the maximum amplitude of these modified TEGs (MA-FF). However, MA-FF and FLEV reference ranges have not been determined for young children. The primary goal of this study was to establish these ranges. A secondary goal was to seek correlation between MA-FF or FLEV values and fibrinogen levels measured by the standard laboratory Clauss method.
Methods: In this prospective observational study, we selected 15 consecutive patients from 5 age groups (<30 days, 1-3 months, 3-6 months, 6-12 months, 12-24 months) and 30 patients >24 months. Patients with bleeding issues or on drugs affecting coagulation were excluded. Samples were collected after induction of anesthesia and prior to surgical incision. MA-FF, FLEV, Clauss derived fibrinogen levels, and platelet counts were measured by our hospital laboratory and values were compared among age groups using ANOVA with post-hoc Tukey-Kramer analyses. Correlation between MA-FF or FLEV and fibrinogen levels was sought using Spearman's correlation with Bonferroni correction.
Results: Results are displayed in the Table. Statistically higher MA-FF and FLEV values were found in infants 1-3 months compared to children 12-24 or >24 months. There were no differences among fibrinogen levels in any of the age groups. Platelet counts were higher in infants 1-3 months compared to children >24 months. MA-FF and FLEV values correlated with Clauss measured fibrinogen levels only after 6 months ($r \geq 0.7$; $p < 0.001$ in all groups >6 months).

Table 1. Comparison of TEG values and laboratory tests.

	MAFF	FLEV (TEG)	Fibrinogen Level (Clauss)	Platelet count	Hematocrit
<30 days	22.2 ± 5.3	406 ± 97	258 ± 82	328 ± 81	43.6 ± 8.2^
1-3 months	26.3 ± 5.7⋆	479 ± 104⋆	283 ± 70	395 ± 103#	37.2 ± 7.1
3-6 months	24.0 ± 3.8	437 ± 70	258 ± 65	336 ± 113	36.3 ± 6.2
6-12 months	22.1 ± 4.3	404 ± 78	271 ± 67	328 ± 150	36.9 ± 5.4
12-24 months	19.8 ± 5.8	361 ± 106	255 ± 76	321 ± 92	39.0 ± 5.2
>24 months	21.2 ± 4.0	378 ± 79	268 ± 53	278 ± 65	39.2 ± 5.0

⋆p <0.05 versus 12-24 months and >24 months for MA-FF and FLEV values.
#p <0.05 versus >24 months for Platelet Count.
^p <0.05 versus 3-6 months and 6-12 months for Hematocrit.

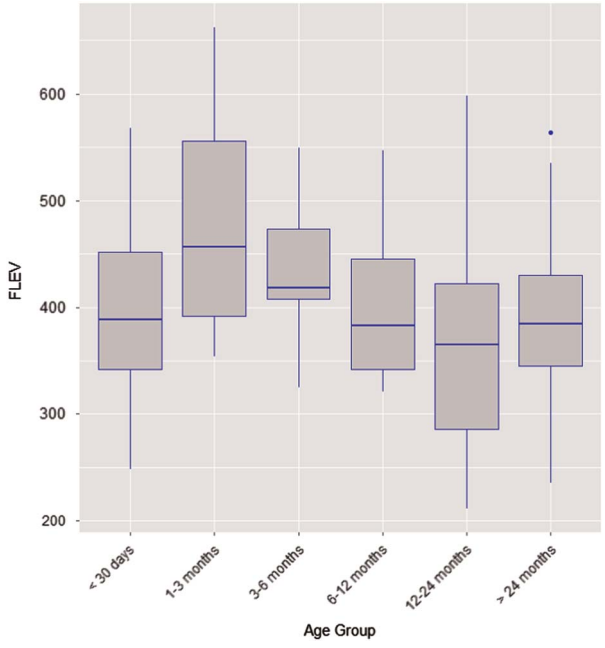

Figure 1.
FLEV values per age Group.

Discussion: This preliminary study establishes reference ranges for MA-FF and FLEV values in 6 age groups of children. These ranges are necessary to guide TEG-directed fibrinogen replacement after CPB. In neonates and infants <6 months WB-derived MA-FF or FLEV values were higher and did not correlate with plasma-derived Clauss fibrinogen levels. This may reflect TEG's ability to assess collective interactions of multiple pro- and anti-coagulant deficiencies (2) or molecular and structural differences in fibrinogen observed in these young infants (3). TEG values may be more useful when making clinical decision in young infants.

Fibrinogen Levels per age Group.

O2207 - ANESTHETIC MANAGEMENT OF ABO INCOMPATIBLE PEDIATRIC ORTHOTOPIC HEART TRANSPLANT A CASE SERIES

Theodora Wingert, Christine Trieu
University of California Los Angeles, Anesthesiology and Perioperative Medicine, Los Angeles-United States

Background: Mounting data have accumulated demonstrating equivalent outcomes and reduced waiting list mortality for pediatric patients receiving ABO-incompatible (ABOi) orthotopic heart transplant (OHT). We present a case series of patients undergoing ABOi OHT and discuss the unique perioperative challenges that arise, including a previously undescribed hemodynamic pattern observed.
Case Series Presentation: There were a total of seven patients undergoing ABOi OHT at our institution from October 2011 to October 2016. Average age was 6.7 months. Five patients' etiology of heart failure was idiopathic dilated cardiomyopathy (DCM), one was due to familial DCM and one was due to hypertrophic CM. Five were on inotropes or vasopressors

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

preoperatively. Five received 3x blood volume exchange transfusion (ET), one received 5x and one received 1x blood volume ET. All were supported with epinephrine and milrinone infusions post-CPB. Of note, during the post-CPB period four patients required near maximal milrinone at 0.8-1 mcg/kg/min, two patients required nitroglycerine boluses, and one required vasodilator infusion for hypertensive urgency.

Perioperative Management: At our institution, ET is undertaken according to a protocol based on patient and donor ABO group, as well as isohemagglutinin titer levels. The CPB circuit is primed with recipient-compatible pRBCs and donor-compatible plasma and platelets. Our protocol entails 3x blood volume ET if isohemagglutinin titers are less than 1:2, and 5x blood volume ET if titers are greater than 1:2. ET produces vasodilatory and hypovolemic hypotension lasting about 3-5 minutes. This can be a challenge in patients with already-failing hearts, thus anticipatory management and close communication with perfusionists is critical. Separation from CPB and the post-CPB period during OHT is typically characterized by vasoplegia, as well as donor organ dysfunction due to ischemia and denervation. However, in our cohort several patients demonstrated unexpected clinically significant hypertension during the immediate post-CPB period requiring antihypertensive treatment.

O2401 - DOUBLE BLIND RANDOMIZED PLACEBO CONTROLLED TRIAL COMPARING THE EFFECTS OF ANTI THROMBIN VS PLACEBO ON THE COAGULATION SYSTEM IN INFANTS WITH ANTI THROMBIN DEFICIENCY UNDERGOING CONGENITAL CARDIAC SURGERY

Rebecca Scholl[1], Claudia Benkwitz[2], Manuel L. Fontes[3], Nirmish Shah[4], Robert D.B. Jaquiss [5], Andrew J. Lodge [5], Warwick A. Ames[1], Mayumi Homi[1], Kelly A. Machovec[1], Edmund H. Jooste[1]

Duke University Hospital, Pediatric Anesthesiology, Durham-United States[1]; Vanderbilt University, Pediatric Anesthesiology, Nashville-United States[2]; Yale, Pediatric Anesthesiology, New Haven-United States[3]; Duke University Hospital, Medicine, Durham-United States[4]; Duke University Hospital, Congenital Cardiac Surgery, Durham-United States [5]

Introduction: Anti-thrombin (AT) is crucial for heparin to be effective and for the prevention of thrombosis. We tested the hypothesis that pre cardiopulmonary bypass (CPB) normalization of AT levels to 100% would improve anticoagulation during CPB, attenuate activation of the coagulation cascade, as measured by fibrin degradation products- D-Dimers, and mitigate microthrombosis in the post-operative period.

Methods: This is a randomized, double blinded, placebo controlled study in infants with AT levels less than 70% undergoing CPB at 2 academic centers. Half were given AT (Thrombate®) to normalize to 100% functional assay and the other half received placebo. We recorded demographics, laboratory values, hemostatic agents, blood products administered, operating room times, 24-hour chest tube output, and occurrence of post-operative thrombosis. Summary statistics, pooled T-test, Fisher exact test and Wilcoxon Rank-Sum test were performed.

Results: Over 24 month period 223 patients were screened, 68 met inclusion criteria, 40 were randomized, and 1 (in Placebo group) was withdrawn during the study due to ECMO initiation in the operating room. Thirty percent of screened patients had AT levels <70%. Table 1 shows demographic and peri-operative variables. Notable differences were observed between the two groups including higher first post-heparin activated clotting time (ACT) and AT levels in the treatment group. Table 2 shows Laboratory results. Significantly, 24 hours post-operative chest tube output, overall blood product transfusions and D-Dimer production were all lower in the AT group. No difference in major adverse events was noted.

Conclusion: Replacement of AT improves anticoagulation during CPB without increased rates of bleeding or adverse events. Furthermore our results suggest extension of these beneficial effects into the postoperative period, reflected by significantly less postoperative bleeding and transfusions, and generation of D-Dimers. We conclude that treatment of low AT levels with exogenous AT is helpful in infants undergoing cardiac surgery.

Table 1. Demographics and perioperative variables.

	AT Group (n = 20)	Placebo group (n = 19)	p value

ELECTROPHYSIOLOGY

O1105 - PERMANENT CARDIAC PACING IN CHILDREN IN A SUB-SAHARAN TERTIAIRY CENTRE

Tantchou Tchoumi Jacques Cabral
Cardiac Centre Shisong Electrophysiology Kumbo-Cameroon

Background: Pacing in children is mainly performed in the setting of congenital or post-surgical complete heart block and less frequently in some surgical patients with sinus node dysfunction. Few data are available concerning Africa. The goal of the study was to investigate the indication, prevalence of permanent cardiac pacing in children and follow -up in St. Elizabeth Catholic General Hospital Shisong, Cardiac centre.
Patients and Methods: From the 10th November 2010 till 10th November 2016, out of 156 patients who underwent a device implantation in the Cardiac Centre Shisong, 9 (5,7%) were children. Data extracted from the records of implanted patients were demographics, clinical indications for device implantation, the electrocardiogram, the echocardiogram.
Results: In the Cardiac Centre Shisong, for bradypacing were implanted 156 pace makers. 10 patients having atrial fibrillation with low ventricular response benefited from a single chambered pace maker. Sick sinus node was diagnosed in 46 patients; 40 cases benefited from a dual chambered pace maker and 6 from a single chambered pace maker. 100 cases had complete atrio-ventricular block and were implanted 5 – patients single chambered and 95 dual chambered pace makers. The pediatric population consisted of 9 children, 7 teenagers suffering from sick sinus node with syncopal attacks, and two children with post surgical complete atrioventricular block in whom was surgically corrected a ventricular septal defect. All patients were above 15 kg and benefited from endovenous pacing, the conventional approach with left subclavian vein puncture being the one used. No complications were seen postoperatively and during the longterm follow-up was registered a death due to severe malaria.
Conclusion: In the Cardiac centre Shisong, permanent pacing in adult and children is of actuality with good results. The main indications are sick sinus node and complete postsurgical block.

O1126 - ALIVECOR FOR LIFE A DIFFERENT APPROACH TO CARDIAC EVENT MONITORING IN CHILDREN

Mairi Macinnes, Helen Morton, Nicholas Martin, Karen Mcleod
Royal Hospital For Children, Cardiology, Glasgow-United Kingdom

Background: The AliveCor heart monitor (Kardia) attaches to a mobile device running the Alive ECG app and has proved successful in diagnosing arrhythmias in adults but there are little data of its use in children. The aim of our study was to evaluate the effectiveness of issuing an AliveCor for Life in children with palpitations.
Methods: Children were eligible for the AliveCor monitor if they were >2 years old, had symptoms of palpitations less frequently than once a week and if they or their parents had a device compatible with the AliveCor monitor. An NHS email account was set up exclusively for receiving ECG recordings emailed via the AliveCor App. The email account was checked twice daily by an experienced cardiac physiologist. The children were given the AliveCor monitor to keep. The number of ECG recordings received, number of arrhythmias documented, quality of ECG recordings, annual costs and patient satisfaction were evaluated.
Results: AliveCor monitors were issued to 50 patients, aged 4 years to 17 years (mean 11 years). 565 ECG recordings were obtained from the AliveCor monitors of which 80 showed arrhythmia (14.2% yield). 523(93%)of the ECG recordings were considered acceptable for analysis and 42 uninterpretable. The AliveCor monitors cost £4,000 for 50. There were no maintenance or retrieval costs and in three patients the AliveCor for Life gave an alternative to an implantable loop recorder (saving a cost of £6,000 for 3 implants) There was high patient satisfaction especially in the teenage group. On comparison with our established methods for non invasive cardiac event monitoring for palpitations, the AliveCor outperformed with respect to ECG recordings, diagnostic yield, annual costs and patient satisfaction.
Conclusions: An AliveCor for Life allows effective, simple and affordable longterm ECG event monitoring in children that is highly acceptable to the patient and parent.

O1194 - VENTRICULAR TACHYCARDIA IN PEDIATRIC POPULATION

Shuenn-Nan Chiu[1], Jou-Kou Wang[1], Chun-Wei Lu[1], Wei-Lun Wu[1], Wei-Chieh Tseng[1], Kun-Lang Wu[2], Mei-Hwan Wu[1]
National Taiwan University Children Hospital, Pediatrics, Taipei-Taiwan[1]; Changhua Christian Hospital, Pediatrics, Changhua-Taiwan[2]

Objective: To delineate the outcome for ventricular tachycardia (VT) in pediatric population.
Methods: From 1991 to 2015, patients who developed sustained VT at the age of 0 to 18 years in a referral center were enrolled.
Results: A total of 116 patients (67 male/49 female) had documented VT, and 62 (53.4%) patients had associated heart disease, namely cardiomyopathy in 21 (18.1%), structural heart disease in 23 (19.8%), channelopathy in 14 (12.1%), and arrhythmogenic right ventricular cardiomyopathy in 6 (5.2%), and some of them with two types of associated heart disease. Idiopathic VT (65 patients) was the most common types of VT; 72.6% with right bundle branch block (RBBB) morphology and 27.4% with left bundle branch block morphology. Forty-one patients received catheter ablation with a success rate of 90.4%, a recurrence rate of 14.3%. None of the patients died during 5.8 + -5.9 years follow-up. Cardiomyopathy with VT exhibited the highest mortality rate (47.6%), especially for those with hypertrophic and restrictive cardiomyopathy. Among 16 patients with coexisting VT and dilated cardiomyopathy, 7 exhibited improved heart function after VT controlled, and could be predicted by onset symptoms, monomorphic QRS morphology, and duration between diagnosis of cardiomyopathy and VT. VT associated with structural heart disesase carries a high risk of mortality, but this risk has decreased after aggressive intervention in recent 15 years. VT with channelopathy can often be controlled by medication , but those with fetal onset has specially high mortality rate and aggressive intervention may be necessary in these patients.
Conclusions: VT in pediatric population, although may carry high mortality when associated with structural anomaly or cardiomyopathy, often has favorable outcome after prompt intervention. The course and clinical outcome is highly dependent on its etiology and age of onset.

O1553 - LEFT VENTRICULAR APICAL PACING IN CHILDREN – FEASIBILITY AND LONG–TERM EFFECT ON VENTRICULAR FUNCTION

Jan Kovanda, Jan Janousek, Miroslav Lozek, Peter Kubus
2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital Children Prague-Czech Republic

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Left ventricular (LV) pacing has been reported to preserve LV function in chronically paced children with atrioventricular (AV) block. We sought to evaluate long-term results of LV apical pacing (LVAP) in patients with both structurally normal heart and congenital heart disease.
Patients and methods: 36 patients with complete spontaneous (N = 22, group A) and surgical AV block (N = 14, group B, systemic LV in all) received an epicardial VVIR (N = 19) or DDDR (N = 17) pacemaker at the median age of 1.69 (IQR 0.04-4.39) years. Bipolar ventricular pacing leads (Medtronic 4968) were placed at the LV apex using a subxiphoid approach (N = 18) or sternotomy (N = 18). After median followup of 2.9 (IQR 1.9-6.2) years echocardiography and exercise stress testing was performed. Data were compared to age-matched normal controls (N = 25, group C).
Results: Pacemaker implantation was uneventful, there was no death and all patients were on LVAP at the end of follow-up. Probability (3 and 6 years after implantation) of absence of pacemaker-related surgical revision (elective generator replacement excluded) was 89.0 and 89.0%, resp. Probability of freedom from battery depletion was 91.4% and 77.8%, resp. Ventricular thresholds at given pulse duration did not change between discharge and last follow-up. There was no significant difference in LV end-diastolic volume index (LVEDVi) and ejection fraction (LVEF) between groups A, B and C at last follow-up. Interventricular and intra-LV synchrony was preserved in groups A and B. Maximum oxygen uptake was, however, lower in group A = mean 33.5 (SD 5.8) and B = 33.9 (6.1) ml/kg/min as compared to group C = 40.8 (6.6) ml/kg/min, p = 0.009.
Conclusions: LVAP carries complete preservation of LV function and synchrony. Pacing-related complications are rare and probability of continued LVAP is excellent despite patient growth.
(Supported by Ministry of Health CZ DRO, University Hospital Motol, Prague, Czech Republic 00064203).

O1783 - A NEW HOLTER TECHNIQUE TO DIAGNOSE AND RISK STRATIFY CHILDREN WITH LONG QT SYNDROME

Kathryn Waddell-smith[1], Halina Hinds[2], Morag Maddon[2], Jackie Crawford[2], Jon Skinner[1]
Starship Children's Hospital, Paediatric and Congenital Cardiac Services, Auckland-New Zealand[1]; Auckland City Hospital, Cardiology, Auckland-New Zealand[2]

Background/Hypothesis: Diagnosing long QT syndrome (LQTS) and predicting risk of cardiac events currently relies on the manifestation of a prolonged QTc or life-threatening event. At least 30% of LQTS subjects have a normal QTc on 12-lead ECG. We hypothesized assessment of repolarisation duration from a single Holter recording may identify disease status and correlate with risk of cardiac events.
Materials and Methods: 145 Holter recordings were analysed. LifeCard CF monitors and DelMar Impressario software were used to calculate mean-QTc and mean-RTPc (R-wave-peak T-wave). Only heart-rates 40-120BPM were included. A single experienced cardiac technician used the semi-automated measurement technique. End-QT was defined by zero crossing point. Bazett heart-rate correction was used. Normative data were taken from 56 controls (0-16years). The highest mean control value was taken as the upper limit of normal (ULN; QTc = 450ms, RTPc = 312ms). Of 89 children assessed for possible LQTS (0-16years); 68 ulitmately were diagnosed with LQTS (44 KCNQ1-positive, 18 KCNH2-positive, 6 gene-unknown (Schwartz scores 4)) and 21 were cascade gene-negative relatives. Results were evaluated against lifetime cardiac events over 987patient-years.
Results: Mean-QTc (48339ms) and mean-RTPc (34534ms) were longer in LQTS individuals than gene-negative relatives and controls combined (Mean QTc 427 + /-20ms;mean RTPc 291 + /-18ms $p < 0.0001$). The mean-RTPc was the same in Gene-negative children and controls, but mean-QTc was 13ms longer ($p = 0.008$). All children with CA (n = 4) were ≥20ms over ULN. 17/18 syncopal patients were ≥5ms above QTc-ULN or ≥15ms above RTPc-ULN. RTPc specificity was superior to QTc. Sensitivity/Specificity (%) of mean-RTPc > 312ms was 90/94 for diagnosis (vs gene-negatives and controls), 100/70 for CA vs all other LQTS and 93/88 for all symptomatic vs asymptomatic LQTS.
Conclusions: Mean Holter RTPc measured with this method is superior to the 12-lead ECG in diagnosis of LQTS and also identifies those at risk of symptoms and cardiac arrest.

O1807 - ANXIETY AND DEPRESSION IN CHILDREN WITH PACEMAKERS (PM) AND IMPLANTABLE CARDIOVERTER DEFIBRILLATORS (ICD)

Victoria Herbsleb[1], Annette Klein[2], Mirko Döhnert[2], Tina Matuschek[2], Stephanie Stadelmann[2], Ingo Dähnert[1], Roman Gebauer[1]
Herzzentrum Leipzig, Klinik Für Kinderkardiologie, Leipzig-Germany[1]; Universitätsklinikum Leipzig, Klinik Für Psychiatrie, Psychotherapie Und Psychosomatik Des Kindes/jugendalters, Leipzig-Germany[2]

Background: The implantation of a PM or an ICD during childhood may reduce quality of life and lead to depression and anxiety disorders. The aim of this study was to evaluate the incidence of depression and anxiety symptoms in patients with implanted cardiac rhythm devices.
Methods: We analysed data from 86 pts. (63 pts. with PM, 23 with ICD) aged 6-19 (mean 12.88 ± 3.96 years), 42 female and 44 male pts. Depression was assessed by using the 20-item Center for Epidemiological Studies Depression Scale for Children (CES-DC). Anxiety disorders were analysed with the 41-item Screen for child anxiety related emotional disorders (SCARED). Both instruments were used as self- and proxy-report. The results were compared to age-matched control groups.
Results: Adolescent patients with implanted cardiac rhythm devices show higher prevalence of anxiety compared to the healthy controls (26.8% vs. 9.9%). Especially adolescent girls with PM or ICD have a higher risk to develop an anxiety disorder in comparison to the normal population (35.3% vs. 11.3%). The self- and the proxy reports did not show a difference in the incidence of depressive symptoms between children with a PM or ICD compared to the control groups. There was no statistical significant difference in the prevalence of anxiety and depression between children with implanted PM or ICD respectively.
Conclusions: Children with implanted cardiac rhythm devices have an increased risk to develop psychological diseases especially anxiety disorders. However also a quarter of the patients showed evidence of depression. Therefore in line with the regular check-ups patients and their parents should be advised and supported in terms of psychological disorders. Screening tests on the basis of standardised questionnaires should be an important part of complex care of these young patients. If necessary further diagnostics and psychotherapy should be taken into consideration.

O1978 - COGNITIVE REQUIREMENTS FOR AUTOMATIC EXTERNAL DEFIBRILLATOR USE. ARE WE STARTING TOO YOUNG

Christopher Snyder[1], Howard Hall[2]
Congenital Heart Collaborative, Pediatrics, Cleveland-United States[1]; Rainbow Babies and Children's Hospital, Pediatrics, Cleveland-United States[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

The purpose is to assess pediatric patients' cognitive ability to appropriately perform CPR and utilize an AED on a human during cardiac arrest.
Methods: A search for data regarding pediatric use (<18 years) of AED's and cognitive ability to perform similar emergent tasks was performed. Data were assimilated and discussed by pediatric electrophysiologist and psychologist. Comparisons were made between emergent duties (exit row seating on plane) and AED use with regard to cognitive and societal beliefs as to when children are prepared to perform these tasks.
Results: The psychological impact of performing CPR and appropriate use of AED requires high levels of cognitive processing. The three cognitive decisions that a child must make to perform these tasks on a human being include: recognizing cardiac arrest, training in CPR and AED and ability to appropriately performing CPR and utilize the AED. Studies of executive function of the developing brain reveal that younger cohorts (7-12) have single factor modeling (1 task) while older cohorts (13-15 years) have fully developed three factor model (3 tasks) consistent with higher level of executive function development.
Conclusion: The cognitive requirements necessary to appropriately perform CPR and utilize an AED on a human being includes the executive function of the brain to perform well in a three factor model, (recognize cardiac arrest, be trained in and appropriately use both CPR and AED). The group recommends that prior to teaching this necessary skill that one must be cognizant of the child's cognitive developmental status and should wait until the child is at least 13 years of age.

O2053- CLINICAL AND HEMODYNAMIC ASSOCIATIONS IN INFANTS, TODDLERS AND PRESCHOOL CHILDREN

Liliya Svintsova[1], Irina Plotnikova[1], Olga Dzhaffarova[1], Igor Kovalev[2], Sergey Popov[1]
Cardiology Reserach Institute Pediatric Cardiology Department Tomsk-Russia[1]; Research and Clinical Institute for Pediatrics Pediatric Cardiology Department Moscow-Russia[2]

Aim: To disclose the peculiarities of formation of tachycardia-induced cardiomyopathy syndrome in children of different ages with the help of clinical and hemodynamic data.
Materials and Methods: A total of 158 children with idiopathic arrhythmias aged 0 to 7 years were examined. Nosological groups of arrhythmias included WPW syndrome (n = 82), atrial ectopic tachycardias (n = 44), atrial flutter (n = 11), AV reentry junctional tachycardias (n = 7), and ventricular tachycardias (n = 13). Age groups comprised infants (n = 73), 1–3-year-old children (n = 43), and 3–7-year-old children (n = 98).
Results: The predominant types of arrhythmias were paroxysmal tachycardias in 3–7-year-old children ($\chi = 11.077$, $p = 0.001$) and incessant tachycardias in infants ($\chi = 13.030$, $p < 0.001$). The frequency of paroxysmal tachycardia episodes was higher in infants compared with 1–3-year-old ($p = 0.028$) and 3–7-year-old children ($p < 0.001$). Based on the echocardiography findings, signs of tachycardia-induced cardiomyopathy found more often in older children compared with the younger patients ($\chi^2 = 12.312$, $p = 0.002$). On the contrary, the presence of heart failure was more typical for infants than for 1- to 7-year-old patients ($F = 44.117$; $p = < 0.001$).
Conclusions: Arrhythmogenic heart remodeling occurred more frequently in children aged 3 to 7 years. Clinical signs of heart failure in infants with arrhythmias preceded structural changes and functional abnormalities in the intracardiac hemodynamics indices. The preservation of normal sizes of cardiac chambers in the presence of high heart rates probably resulted in the diastolic dysfunction in infants. The factors leading to these hemodynamic changes were the high average daily heart rate, tendency of tachycardia to permanent and continuously recurring course, and high frequency of paroxysmal tachycardia episodes in infants.

O2120 - THE CLINICAL COURSE AND PROGNOSIS OF MULTIFOCAL ATRIAL TACHYCARDIA IN CHILDREN

Seung Min Baek, Mi Kyoung Song, Eun Jung Bae, Gi Beom Kim, Chung Il Noh
Seoul National University Children's Hospital, Pediatrics, Seoul-Korea, South

Background: Multifocal atrial tachycardia (MAT) is known to have favorable outcome. However pediatric clinical data is insufficient. We report 33 patients with MAT at our institution to ascertain clinical course of MAT and verify possible prognostic factor.
Materials and methods: Medical records of 33 patients diagnosed with MAT from 1997 to 2015 were reviewed. Demographic information, underlying diseases, echocardiographic data were evaluated. Unfavorable outcome defined as mortality and arrhythmia duration greater than 1year and arrhythmia control rate were assessed as outcome.
Results: In 33 patients (19 boys and 14 girls), median age at diagnosis was 1.7 months (range, 0 day to 14.2 years). Twenty seven patients (81.8%) were diagnosed in infancy or neonatal period. Fourteen patients (42.4%) had structural heart disease, including five with hypertrophic cardiomyopathy. Eight had lung disease and six had syndrome all belongs to RASopathy. Two patients developed polymorphic ventricular tachycardia several years later with RyR2 gene mutation confirmed. Median kinds of anti-arrhythmics administered per a patient were 2.4. Direct-current cardioversion or adenosine was tried in eight and nine patients, but was never effective. MAT in 26 patients (83.9%) had been controlled within average 1.2 years. Four mortality cases were reported (3 cardiopulmonary and 1 non-cardiopulmonary mortality). Control rate was higher in infantile group (84.6%) than non-infantile group (66.7%), but was not statistically significant. Accompanying comorbidities was associated with lower control rate without statistical significance. However idiopathic infantile patients had significantly lower rate of adverse outcome than the others ($p = 0.03$).
Conclusions: MAT mostly affects infants and usually has favorable prognosis especially in idiopathic infantile cases. However patients with underlying comorbidities or older than one-year of age at diagnosis have varying clinical course. Long-term follow-up for further arrhythmia and thorough survey for underlying conditions are needed in these patients.

O2386 - CLINICAL OUTCOMES OF LEFT CARDIAC SYMPATHETIC DENERVATION A MULTI CENTRIC STUDY

Ferran Rosés-Noguer[1], Simon Jordan[2], Jim Mcguigan[2], Jan Till[2]
Vall D'hebron Hospital and Royal Brompton Hospital, Paediatric Cardiology, Vic-Spain[1]; Royal Brompton Hospital, Paediatric Cardiology, London-United Kingdom[2]

Background: Left cardiac sympathetic denervation (LCSD) has been used for many years in treating refractory ventricular arrhythmias. We report a multicentre experience in performing LCSD.
Materials and methods: 29 consecutive patients were included, who underwent LCSD since Nov-2011 until Nov-2016.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Syncope, aborted cardiac arrest (ACA) and appropriate ICD discharge, were classified as cardiac events (CE).
Results: Median age was 11,8 years (range 1.0-52.1), weight was 30.0 kg (range 7.8-100), 16(55,2%) were male. Diagnoses included 15(51,7%) patients with LQTS (9 (31,1%) with JLN), 9(31,1%) with CPVT, 1(3,4%) with histiocytoid cardiomyopathy, 1(3,4%) with Emery-Deifuss, and 3(10,3%) with IVF. Prior to LCSD, 14(48,3%) had experienced ≥10 CE, 9(31%) had 5-to-9 CE, and 5(17,2%) had 1-to-4 CE, and 1(3,4%) had no-CE, with an overall median of 11,5(0-87) CE. All patient had tried maximal dose of beta-blockers (BB) before LCSD, 6 were on BB-flecainide, 1 on BB-mexilitine and 1 had tried BB, amiodarone, sotalol and lignocaine. 20(69%) had an ICD before LCSD, all for secondary prevention. Video assisted thorachoscopic approach (VATS) could be performed in 28(96,6%) patients. Only the smallest patient (7,8 kg) underwent a postero-lateral thoracotomy approach as the subpleural ICD coil interfered with VATS ports incisions. Intraoperative complications included 1 VF episode. Long-term side effects included 2 patients with a transient Horner's syndrome (HS) and 1 with permanent HS. Over a median follow up of 42 months (range 1,7-57,5), 21(72,4%) patients had no breakthrough of CE, 5(17,2%) had 1-4 BCE, 2(6,9%) had 5-to-9 BCE and 1(3,4%) had >10 BCE. Overall, there was a significant reduction of CE after LCSD (11.5 (0-87) to 0(0-7); p:0.001) Figure1.
Conclusions: LCSD is a safe and effective technique with few complications in drug refractory ventricular arrhythmias due to channelopathies and other cardiomyopathies. VATS approach is a safe and feasible procedure but may be difficult in very small patients. A significant reduction of BCE has been seen in the majority of patients.

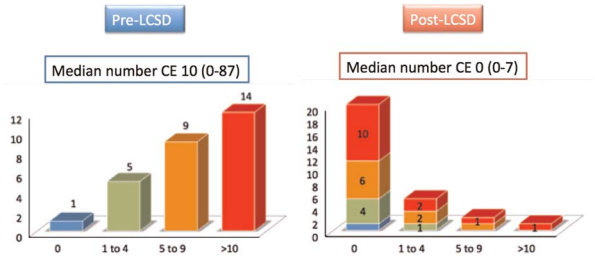

Figure 1.
21(72,4%) patients had no breakthrough of CE, 5 (17,2%) had 1-4bce, 2 (6,9%) had 5-to-9 and 1(3,4%) had >10 BCE. There is a significant reduction of EC after LCSD: Median (11.5(0-87) to 0 (0-7); p:0.001).

O2406 - RISK STRATIFICATION FOR ARRHYTHMIAS IN PEDIATRIC HYPERTROPHIC CARDIOMYOPATHY

Emanuel Kaltenecker, Christian Meierhofer, Naira Mkrtchyan, Nerejda Shehu, Alfred Hager, Peter Ewert, Gabi Hessling, Cordula Wolf
Deutsches Herzzentrum Munich, Technical University Munich, Pediatric Cardiology, Munich-Germany

Background/Hypothesis: Risk stratification for sudden arrhythmic death in pediatric hypertrophic cardiomyopathy (HCM) remains challenging and guidelines for adult HCM are not validated in children.
Objective: To evaluate clinical predictors for arrhythmias in patients with pediatric onset HCM.
Materials and Methods: 40 patients with a diagnosis of HCM between 0 and 18 years of age underwent a detailed clinical evaluation including genetic testing, electrocardiogram, 24-hour Holter recording, cardiopulmonary exercise testing, transthoracic echocardiography (TTE), and magnetic resonance imaging (MRI) with contrast at a follow-up time of 11 ± 6 years. Arrhythmic events were defined as non-sustained or sustained supraventricular or ventricular tachycardia or appropriate implantable cardioverter defibrillator discharge. Clinical characteristics of patients with and without arrhythmic events were compared.
Results: Data are depicted in the Table. Genetic diagnosis was Noonan syndrome or mutations in the sarcomere. Patients with arrhythmias had disease onset earlier in age, significant thicker left ventricular wall thickness on TTE, higher extracellular volume fraction on MRI T1-map as an estimate for interstitial fibrosis, and were more likely to carry a mutation in the troponin T (TNNT) gene. There was no significant difference between groups with regards to genetic diagnosis, the presence of late gadolinium on MRI as an estimate for focal fibrosis, history of syncope, family history of sudden cardiac death, left ventricular outflow tract obstruction and enlarged left atrium.
Conclusion: Risk factors for arrhythmias included early disease onset, magnitude of myocardial hypertrophy and interstitial fibrosis, and the presence of TNNT mutations. This underlines the importance of a thorough clinical evaluation including MRI imaging with contrast and genetic testing in patients with pediatric onset HCM.

Table.

	No arrhythmias	Arrhythmias	p-value
Patients (N)	34	6	NS
Noonan HCM/sarcomere HCM)	12/22	1/5	
Gender (male/female)	19/15	4/2	NS
Sarcomere HCM pts	13/9	3/2	
Age at diagnosis (years)	5.6 ± 6.5	1.8 ± 2.9	0.034
Sarcomere HCM pts	7.6 ± 6.7	2.2 ± 3	0.016
LVWT (z-score)	5.0 ± 1.8	7.0 ± 1.0	0.009
Sarcomere HCM pts	5.3 ± 2.0	6.8 ± 0.8	0.015
ECV (%)	29 ± 4	35 ± 2	0.037
Sarcomere HCM pts	29 ± 5	35	NS
LGE positive	15/27 (56%)	1/3 (33%)	NS
Sarcomere HCM pts	8/18 (44%)	1/2 (50%)	NS
TNNT positive	NA	NA	NA
Sarcomere HCM pts	1/22 (5%)	2/5 (40%)	0.08
LVOTO	20/34 (59%)	3/6 (50%)	NS
Sarcomere HCM pts	11/22 (50%)	2/5 (40%)	NS

Background and Hypotheses: Families of children with a rare inherited arrhythmia condition (IAC) face challenges associated with exposure to traumatic events, complex genetic testing options, activity restrictions, lifelong clinical surveillance, and an increased risk of sudden death. These challenges can bear heavily on children and families, yet parents often struggle to find appropriate psychological support. This prospective cohort study assesses the prevalence and predictors of psychological morbidity in families of children with an IAC.
Materials and Methods: Prior to attending a multidisciplinary IAC clinic in Sydney, Australia, parents complete measures assessing their child's quality of life (QOL) and their own symptoms of post-traumatic stress, anxiety and depression. Family functioning, social support, health literacy and unmet needs are also assessed. Follow-up assessments are completed 1-, 6- and 12-months post-clinic.
Results: Sixty-one parents from 36 families have enrolled in the study (response rate: 62%). Diagnoses include Long QT Syndrome (62%), Catecholaminergic Polymorphic Ventricular Tachycardia (29%), and Brugada Syndrome (9%). Twenty-nine percent of children have had an out-of-hospital cardiac arrest. Prior to clinic, 1 in 5 parents reported symptoms of post-traumatic stress warranting clinical intervention. Fifty-five percent of mothers and 38% of fathers perceived their child's emotional health to be at-risk. Using linear regression with generalised estimating equations to account for familial clustering, and controlling for marital status and parent age, poorer child QOL was associated with lower perceived social support (Beta = 0.85, $p < 0.01$) and greater parental psychological stress (Beta = -7.87, $p < 0.005$). Determinants of poorer family functioning were lower perceived social support (Beta = -0.03, $p < 0.0001$), greater unmet information and support needs (Beta = 0.01, $p < 0.001$), greater parental age (Beta = 0.03, $p < 0.0001$), and being a single parent (Beta = 0.60, $p < 0.0001$).
Conclusions: Children with an IAC and their parents are at increased risk of psychological difficulties. Psychological care should form part of best practice recommendations for families of children with an IAC.

O2456 - CARDIAC RHYTHM DISTURBANCES IN HETEROTAXY SYNDROME

Yui Nishikawa, Hiroko Asakai, Kazuhiro Shiraga, Takahiro Shindo, Yoichiro Hirata, Ryo Inuzuka, Akira Oka
The University of Tokyo Hospital, Pediatrics, Tokyo-Japan

Background: Heterotaxy syndrome is associated with complex cardiac malformations and cardiac conduction system abnormalities. Those with right atrial isomerism (RAI) have dual sinus nodes and dual atrioventricular nodes predisposing them to supraventricular tachycardia (SVT). Those with left atrial isomerism (LAI) lack a normal sins node and are at risk of sinus node dysfunction (SND) and atrioventricular block (AVB). We report the prevalence and risk factors associated with arrhythmias in heterotaxy syndrome.
Methods: A retrospective review of all heterotaxy syndrome patients born and treated at our institution between 2000 and 2014 was performed. Patient demographics, electrocardiograms, echocardiograms and operative records were reviewed. Arrhythmia diagnosis, timing, and prevalence were noted. Atrial situs, gender, univentricular physiology, ventricular dysfunction, presence of significant atrioventricular valve regurgitation, and surgical details such as history of multiple surgeries, TAPVC repair, atrioventricular valve surgery were assessed for potential risk factors of arrhythmia development.
Results: A total of 42 heterotaxy patients were identified; 18/42 (43%) with LAI and 24/42(57%) with RAI. There were 13 deaths [LAI 4/18(10%), RAI 9/24(21%); $p = 0.33$], one of which was due to ventricular fibrillation. The median follow-up period was 5.2 ± 5.3 years. Twenty-two patients had arrhythmias during follow-up; 13/18(72%) in LAI and 9/24(31%) in RAI ($p < 0.05$). In LAI, 10/13 had SND, and 3/10 had AVB. In RAI, 5/9 had SVT, 2/9 had atrial ectopic tachycardia, and 1/9 had junctional tachycardia. Freedom from arrhythmia at 1,3,5 years of age were 23.0%, 53.3%, 68.9% in LAI, and 17.4%, 23.3%, 31.0% in RAI respectively. No risk factors for arrhythmia were identified.
Conclusions: Arrhythmias were commonly seen in heterotaxy syndrome particularly in LAI with more than 50% having arrhythmias at 3 years of age. Clear risk factors were not identified and detailed assessment of new onset arrhythmias and close follow-up are warranted in these high-risk patients.

O2658 - ELECTRO MECHANICAL DYSFUNCTION IN TUBEROUS SCLEROSIS COMPLEX ROLE FOR ARRHYTHMOGENIC RISK PREDICTION AND TREATMENT OPTIONS

Carles Bautista
Hospital Sant Joan De Deu, Paediatric Cardiology, Barcelona-Spain

Objective: Tuberous sclerosis complex (TSC) is an inherited neurocutaneous disorder related to cardiac rhabdomyomas. Rhabdomyomas are typically multifocal and can cause flow and electrical abnormalities. Our aim was to evaluate left ventricular (LV) mechanics by using speckle tracking echocardiography (STE) and ECG features in patients with TSC and rhabdomyomas before and after a course of Everolimus (mTOR inhibitors).
Methods: We studied 16 patients with TSC (median age 1.2 years, range 0-3 years, LVEF >50%). All underwent standard echocardiographic evaluation and STE. ECG and 24 h tape date were also obtained.
Results: Diastolic parameters were significantly abnormal in our patients before and after everolimus (E/e' average: 10.9 ± 5.7 vs. 5.6 ± 3.2, $p = 0.0016$). Global LV longitudinal strain was significantly lower before everolimus ($-16.6 \pm 3.6\%$ vs. $-23.2 \pm 3.1\%$, $p < 0.0001$). LV torsion ($9.1 \pm 4.9°$ vs. $11.9 \pm 3.3°$, $p = 0.046$) was significantly impaired before everolimus. All patients had impaired cardiac repolarization (long QT) and prolonged time to diastolic peak before everolimus course.
Conclusions: Diastolic function, LV longitudinal deformation and LV torsion in patients with TSC improved after a course of everolimus. m-TOR inhibitors have a positive effect on electromechanical cardiac function. Treatment decreases cardiac dysfunction and risk for ventricular arrhythmia. This indicates the potential added value of the assessment of mechanical dysfunction in future risk stratification of TSC patients.

O2730 - COMPARATIVE ANALYSIS BETWEEN ELECTRO AND ECHOCARDIOGRAPHIC FINDINGS OF POOR PROGNOSIS AFTER TOTAL CORRECTION FOR TETRALOGY OF FALLOT

Camilla Ferreira[1], Raimundo Amorim Junior [1], Cybelle Costa[2], Ana Jacome[1], Felipe Mourato[3], Sandra Mattos [4]
Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[1]; Círculo Do Coração De Pernambuco, Caduceus, Recife-Brazil[2]; Círculo

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Do Coração De Pernambuco, Científico, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Geral, Recife-Brazil [4]

Background: Common complications after total correction of tetralogy of Fallot (T4F), include pulmonary insufficiency and right and/or left ventricular dysfunction. They are related to ventricular arrhythmias at early ages and to sudden death. Electrocardiographic (ECG) parameters, such as QRS enlargement above 180 ms, echocardiographic (ECHO) and nuclear magnetic resonance (MRI) parameters have been identified as predictors of these events. This study aims to describe the ECG profile of patients after total correction of T4F and to compare the prevalence of ECG findings of poor prognosis with ECHO findings of residual lesions and ventricular dysfunction, in these patients.

Material and Methods: Retrospective analysis of a database from a Paediatric Cardiology Reference Service of the state of Pernambuco. Among 169 T4F echocardiographic diagnoses, 30 met all the inclusion criteria for analysis of the electrocardiographic profile. Statistical analysis was performed, with $p < 0.05$ being considered significant.

Results: ECG and ECHO were performed on average 4.5 years after corrective surgery. Only one patient presented QRS > 180 ms and six had QRS > 160 ms. The mean QRS duration in the sample was 116 ms. Among patients with RV dysfunction, 66% had QRS > 160 ms, against 15% of those without RV dysfunction ($p = 0.03$). Among the patients with RV dysfunction on ECHO, 66% had a U wave on the ECG ($p < 0,01$).

Conclusion: A lower mean QRS duration was found in the studied sample in comparison to other large series of the literature. This may reflect the repair technique, which did not use a transannular patch. A statistically significant relationship was found between the enlarged QRS interval and ventricular dysfunction. The presence of a U wave was related to right ventricular dysfunction. ECG and ECHO can provide important parameters for the follow-up of patients after total correction of T4F, especially in centers with less technological resources.

O2740 - OUTCOME OF TRANSVENOUS LEAD EXTRACTION IN CHILDREN A SIXTEEN YEAR PAEDIATRIC CASE SERIES.

Andrianos Kontogeorgis[1], Luke Starling[1], Leonie Wong[1], Sian Chivers[1], Ferran Rosés-noguer[2], Jan Till[1], Jonathan Clague[1]

Royal Brompton Hospital, Paediatric Cardiology, London-United Kingdom[1]; Royal Brompton Hospital, London and Vall D'hebron University Hospital Barcelona, Paediatric Cardiology, Barcelona-Spain[2]

Background: Lead extraction is increasingly required to revise chronic transvenous (TV) pacemakers (PM) and defibrillators (ICD). Children pose a particular challenge, as they are implanted at a young age, will require system revisions and have increased related lead failures. Leaving faulty leads in situ avoids all risk but increases the risk of venous obstruction. We report our multicenter experience over 16 years.

Materials and Methods: Retrospective study of outcomes in children ≤16 years of age requiring TV lead extractions between Jan-2000 and Dec-2016.

Results: There were 30 procedures in 28 patients. 14 males(50%). Mean age at time-of-device-implant: 7.5 years(IQR 4.8-11.1), mean age at time-of-lead-extraction: 11.6 years(IQR 9.8-13.9) and a total of 39 leads were extracted. The indication for device implant included CCHB 15, LQTS 6, CPVT 3, BrS 1, TAPVD 1, sick sinus syndrome (SSS) and repaired muscular VSD 1 and JET 1. A total of 20 pacemakers included 14 VVI, 4 DDD, 1 CRT-P, and 1 AAI and 9 ICDs, comprising 6 single and 3 dual chamber. The types of leads and age-at-time-of-extraction comprised 9 atrial leads (mean lead-age 25.3 months; IQR 6.5-36.8), 21 pace/sense leads (mean lead-age 63.8 months; IQR 21-105) and 9 defibrillator leads (mean lead-age 20.1 months; IQR 10.3-33.9). The reason for extraction was lead failure in 18 patients (61%), upgrades/system in 6 cases(21%) and 6 extractions(18%) were due to infection. Complete procedural success was achieved in 27 cases(89%), partial success in 1(4%) and failure in 2 cases(7%). Advanced Laser or mechanical rotor was required in 15(52%) cases and combined locking stylets with manual traction in 14(48%). No major complication or 30 day mortality occurred.

Discussion: Lead extraction can be successfully achieved in 90% of children without complications or 30 day mortality. However, it should be reserved for specialist congenital cardiac centers with careful case selection in the very young.

HUMANITARIAN

O1227 - THE HUMANITARIAN FOOTPRINT CONTRIBUTIONS OF GLOBAL PEDIATRIC CARDIAC SURGERY TO THE HUMAN DEVELOPMENT INDEX OF LOW AND MIDDLE INCOME COUNTRIES

Marcelo Cardarelli[1], Sumeet Vaikunth[2], Frank Molloy[3], Thomas Disessa[3], Elizabeth Sauter[3], Karen Bowtell[3], Roslyn Rivera[3], Katie Mills[4], William Novick[5]

Inova Children Hospital, Surgery, Falls Church-United States[1]; Stanford University, Pediatrics, Stanford-United States[2]; Novick Cardiac Alliance, Surgery, Memphis-United States[3]; Johns Hopkins Ach, Pediatrics, Tampa-United States[4]; University of Tennessee - Novick Cardiac Alliance, Surgery, Memphis-United States[5]

Background: International health organizations endorse global campaigns for humanitarian interventions such as vaccinations and water sanitation due to their proven cost-effectiveness, but remain reluctant to support seemingly expensive global interventions in surgery. We measured the footprint of humanitarian pediatric cardiac surgery in low-middle income countries (LMIC) by gains in the main components of the Human Development Index (HDI): Life Expectancy (LE), Median Years of Schooling (MYS) and Gross National Income per capita (GNIpc). We hypothesized that humanitarian pediatric cardiac surgery would lead to gains in HDI and be categorized as a cost effective intervention.

Material and Methods: After assessing total administrative, logistical and clinical costs incurred by our organization during 2015 and obtaining current HDI indicators for each country visited, independent reviewers calculated the potential incremental difference in these indicators after our intervention. A cost per surgery in USD$ was ascribed to these differences in HDI and a cost effectiveness ratio in disability adjusted life years (DALY) averted was determined for each patient.

Results: During 2015, 444 patients underwent 470 operations in 10 LMIC (mortality 7.8%) at a cost per patient operated of $7,362. After excluding deceased (n = 35), adult (n = 13) and non-cardiac (n = 6) patients, incremental differences in HDI indicators were estimated for the remaining 390 patients. Our global interventions resulted in 17,258.97 DALY averted of LE; 2,308 extra years of schooling and USD$225,639,139 at purchasing power parity of GNIpc gained, representing an average of 44.25 DALY averted of

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

LE; 5.9 extra years of schooling and $578,561 of GNIpc gained per patient at a cost of $166 per DALY averted.
Conclusions: Humanitarian pediatric cardiac surgery in LMIC improves human development indices and is as cost-effective as other subsidized humanitarian interventions. Global health organizations should encourage and support sustainable approaches to humanitarian pediatric cardiac surgery.

O1500 - GLOBAL BURDEN OF CONGENITAL HEART DISEASE

Meghan Zimmerman[1], Alison Smith[2], Craig Sable[1], Theo Vos[3], Christopher Murray[3], Bistra Zheleva[4], Gerard Martin[1], Kathy Jenkins[5], Liesl Zuhlke[6], Nicholas Kassebaum[7]
Childrens National Health System, George Washington University, Pediatric Cardiology, Washington-United States[1]; Institute For Health Metrics and Evaluation, University of Washington, Seattle-United States[2]; Institute For Health Metrics and Evaluation, University of Washington, Global Health, Seattle-United States[3]; Childrens Heartlink, , Minneapolis-United States[4]; Boston Childrens Hospital, Harvard University, Pediatric Cardiology, Boston-United States[5]; Red Cross War Memorial Childrens Hospital, University of Cape Town, Pediatric Cardiology, Cape Town-South Africa[6]; Institute For Health Metrics and Evaluation, University of Washington, Anesthesiology and Pain Medicine, Seattle-United States[7]

Background: There is a large knowledge gap in understanding the global burden of congenital heart disease (CHD). The Institute for Health Metrics and Evaluation (IHME) has collected data worldwide and estimated mortality and morbidity of CHD from 1990 to 2015.
Methods: All available data sources on fatal and non-fatal CHD from 195 countries and territories were systematically reviewed for inclusion in epidemiologic models. Cause of Death Ensemble modeling and DisMod-MR 2.0 were used to produce consistent estimates of mortality and prevalence, respectively, including corresponding uncertainty. Using the publically-available Global Burden of Disease (GBD)-Compare visualization tool (http://vizhub.healthdata.org/gbd-compare), we evaluated CHD burden by seven GBD super-regions. Mortality estimates are available for aggregate CHD; non-fatal estimates are further divided into: critical, severe, and less severe CHD.
Results: Annual mortality (Table-1) from CHD worldwide is estimated to be 303,282 (95% CI 268,772-335,386); 24% of deaths occur in sub-Saharan Africa. Mortality rate in sub-Saharan and North Africa is 7-8 per 100,000 compared to 1 per 100,000 in high-income countries. The mortality rate due to CHD in infants decreased significantly from 1990 to 2015 only in high and middle-income countries. The global prevalence of CHD (Table-2) is 48.9 million (95% CI 34.3-72.8 million). Prevalence, expressed as a percent, is lower in low-income countries (0.2-0.6%) compared to high-income countries (0.9%), suggesting a greater percent of deaths from other causes. The global prevalence of critical, severe and less severe CHD for all ages is 0.002% (0.001%-0.003%), 0.05% (0.04%-0.08%), and 0.59% (0.39%-0.91%), respectively. The prevalence for critical and severe CHD drops below 0.01% and 0.1%, respectively, in all regions except high-income countries by one year of age. Uncertainty estimates are highest in low-income countries.
Conclusions: The novel IHME GBD Compare Tool facilitates visualization of best estimates of GBD data, which improves our understanding of global CHD burden. It provides critical information to help address global inequalities.

Table 1. Congenital heart Disease mortality

Location	< 1 year		All Ages	
	Percent of Deaths	Rate of Death (per 100,000)	Percent of Deaths	Rate of Death (per 100,000)
1990				
Global	3.16% (2.27-4.47)	4047 (2962-5009)	0.81% (0.60-1.13)	7.32 (5.37-10.29)

O1739 - HUMANITARIAN MODEL TO RESCUE THE INVISIBLE CHILD FREE CARDIAC CARE FOR CONGENITAL HEART DISEASE IN INDIA

Ashish Kateva[1], Balaswaroop Sahu[2], Yogesh Sathe[3], Cynthia R. Rovnaghi[4], K. J. S. Anand[4], Nisith Bargava[5], Shreeharsha Satpathy[6]
Sri Sathya Sai Sanjeevani Hospital, Department of Paediatric Cardiac Surgery, Naya Raipur-India[1]; Sri Sathya Sai Sanjeevani Hospital, Department of Paediatric Cardiac Anaesthesiology, Naya Raipur-India[2]; Sri Sathya Sai Sanjeevani Hospital, Department Of Paediatric Cardiology, Naya Raipur-India[3]; Stanford University School of Medicine, Department of Paediatrics, Stanford, Ca-United States[4]; Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiac Surgery, Naya Raipur-India[5]; Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiac Anaesthesiology, Naya Raipur-India[6]

Background: Overall, global childhood mortality decreased by 50% but death and disability from congenital heart disease (CHD) increased progressively in low-/middle-income countries (LMICs) over the past 2 decades. Of the 1·35 million children born each year with CHD, 90% do not have access to diagnostics or adequate care. Communicable diseases dominate the healthcare budget of LMICs, whereas most children with CHD remain undiagnosed and untreated. We present a unique model of preventive, palliative, and curative cardiac care wherein screening, diagnostic, medical & surgical services are provided free of charge.
Materials and Methods: Programmatic and clinical outcomes at Sri Sathya Sai Sanjeevani Hospital (SSSSH) in Naya Raipur were analyzed for 2015 & 2016. All medical, surgical, consultative and ancillary services are rendered totally free of cost to all those who arrive at SSSH.
Results: A total of 8530 children with CHD were evaluated in the out patient department from Jan 2015 to Dec 2016, out of which 2188 were operated. The 30- day mortality for year 2015 was 2.5%, which dropped to 1.3% in year 2016. The STS-EACTS distribution and corresponding mortality for the years 2015 and 2016 are presented in the table (Table 1). The average cost per

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

surgery was INR 67,000 (USD 1000). Many innovative measures are used to keep the cost of treatment low, one of which is training parents to assist the medical team in taking care of their children in the postoperative period.
Conclusions: Three hundred thousand children with congenital heart disease are born each year in India. A tiny fraction of these are treated at present. SSSSH is making a small but significant contribution by addressing the national burden of congenital heart disease.

O2273 - SUCCESSFUL MODEL OF A SUSTAINABLE PROGRAM FOR LOW INCOME PEDIATRIC CHILDREN WITH CONGENITAL HEART DISEASES IN DEVELOPING COUNTRIES

Néstor Fernando Sandoval Reyes[1], Marisol Carreño Jaimes[2], Albert Franz Guerrero Becerra[1], Carlos Eduardo Obando López[1], Jaime Camacho Mackenzie[2], Sonia Emilsen Morales Echavarria[1], Juan Pablo Umaña Mallarino[2]
Fundación Cardioinfantil - Instituto De Cardiología, Congenital Heart Institute, Bogota-Colombia[1]; Fundación Cardioinfantil - Instituto De Cardiología, Cardiac Surgery, Bogota-Colombia[2]

Background: Social Program Give a Life is sustainable program in pediatric cardiac care, for the most needed children in Colombia. Eleven cities are visited every year, looking for children without health insurance who need cardiac care. 2148 children were treated in 13 years of work. 3500 children per year receive free evaluation. The program is supported by local donations and the institution philosophy. Free surgical treatment, transportation and housing is provided to all children and part of their relatives, and medical follow up after the discharge is provided by local allies. The aim is to describe the outcomes of these children undergone to surgery to repair of congenital heart disease compare with all ensured ones matched by RACHS-1 categories 1-3.
Methods: Cohort of patients who belong to the Social Program, from January 2010 to October 2016 who were treated by surgery. Standard statistical methods were used to describe the patient´s characteristics, operative variables, and post operative outcomes.
Results: In this study period 3046 patients were operated by the surgical group, the 15.7% (478/3046) belongs to social program. The 89% (425/478) were between 1 to 18 years old. Procedures in RACHS-1 risk 2, 39.7%, follow by risk 1, 26.4%, and risk 3, 24.7%. Median ICU stay 2 days, median in hospital stay 2 days. Global mortality 1%. Survival at 30 days 99%. In table one are describe the results compare with the rest of the cohort.
Conclusions: Referral centers can develop sustainable program and achieve the same results and guarantee medical follow up for noninsurance patients in developing countries as part of their mission, with no differences in the clinical outcomes. This Initiatives could be reproduced in other countries or centers to help the most needed.

Table 1. Differences between Social Patients and Insurance Patients.

Variable	Social Program n = 434	Not Social Program N = 2022	P Value
Male %	49.1	52.2	0.001
Premature %	12,9	19.7	0.004

Cardiac %	16,1	18.6	0,22
Mortality %	1%	1%	0.89

IMAGING

O1052 - QUANTIFICATION OF BLOOD FLOW BY AUTOMATED THREE DIMENSIONAL REAL TIME VOLUME COLOUR FLOW DOPPLER ECHOCARDIOGRAPHY IN PEDIATRIC ATRIAL SEPTAL DEFECTS

Atsuko Kato[1], Juan Pablo Sandoval-jones[1], Dariusz Mroczek[1], Helene Houle[2], Bogdan Georgescu[3],Rajiv Chaturvedi[1], Kyong-jin Lee[1]
The Hospital For Sick Children, Department of Pediatrics, Division of Cardiology, The Labatt Family Heart Centre, Toronto-Canada[1]; Siemens Ultrasound, Advanced Technology, Mountain View-United States[2]; Siemens Medical Solutions Usa, Inc, Medical Imaging Technologies, Princeton-United States[3]

Objective: Quantification of mitral and aortic valve flows and left ventricular volumes has been validated in adult hearts using real-time three-dimensional (3-D RT-VCFD) echocardiography. In this study, we sought to validate the accuracy of this novel technology in smaller pediatric hearts, across mitral (MV), aortic (AV), pulmonary (PV) and tricuspid (TV) valves and for right (RV) and left (LV) ventricles during percutaneous atrial septal defect (ASD) device closure.
Methods: 45 studies were prospectively performed in 25 children while under general anesthesia and breath-holding technique. 3-D colour flow Doppler across each valve and full volume of both ventricles with ECG-gating were acquired using the Acuson SC2000 (Siemens, CA) machine for 3 beats before and after ASD closure. The 3-beat averaged flows and volumes were measured using a dedicated offline 3-D Flow computational program. Qp/Qs was calculated by the Fick method.
Results: The mean body weight was 30.3 ± 15.4 kg and height 129.6 ± 22.0 cm. The mean Qp/Qs was 1.7 ± 0.5 before closure. Valve flow correlation was high between the PV and TV ($R = 0.96$, $p < 0.001$) and between the AV and MV ($R = 0.91$, $p < 0.001$). There was good correlation between the RV stroke volume and flow across the TV ($R = 0.95$, $p < 0.001$) and PV ($R = 0.88$, $p < 0.001$). The correlation was moderate between the LV stroke volume and the AV ($R = 0.70$, $p < 0.001$) and MV ($R = 0.81$, $p < 0.001$). Qp/Qs correlated with PV:AV flows ($R = 0.82$, $p < 0.001$) and TV:MV flows ($R = 0.84$, $p < 0.001$). There was moderate correlation between Qp/Qs and RV:LV volumes ($R = 0.62$, $p < 0.01$).
Conclusion: Flow measurement using 3-D RT-VCFD echocardiography is feasible and reliable in children in the left and right

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

sides of the heart. The highest correlation was between valves and ventricular volumes within the same side of the heart. This technique provides a non-invasive alternative to historically invasively acquired hemodynamic data.

O1217 - MONITORING THE DEVELOPMENT OF RIGHT VENTRICULAR HEART FAILURE USING HYPERPOLARISED 13C MAGNETIC RESONANCE IMAGING

Peter Agger[1], Janus Adler Hyldebrandt[2], Esben Søvsø Szocska Hansen[3], Farhad Waziri[4], Camilla Omann[4], Nikolaj Bøgh[4], Christoffer Laustsen[3]
Aarhus University Hospital, Dept. of Pediatrics, Aarhus-Denmark[1]; Aarhus University Hospital, Dept. of Clinical Medicine, Aarhus-Denmark[2]; Aarhus University Hospital, Mr Research Center, Aarhus-Denmark[3]; Aarhus University Hospital, Dept. of Cardiothoracic And Vascular Surgery, Aarhus-Denmark[4]

Background: Right heart failure is common in patients with congenital heart disease, but the evaluation of right ventricular function is complicated and inaccurate and the correct timing of intervention is a matter of continuous dispute. Current diagnostics focus on alterations in anatomical and physiological parameters. Magnetic resonance hyperpolarisation, using pyruvate as an active metabolic tracer, is a novel technique that can image the metabolism in tissues non-invasively in real-time. We hypothesised that the metabolic alterations known to occur in heart failure can be assessed and monitored with this technique making it a potential powerful tool in heart failure diagnostics.
Materials and Methods: At baseline five female 5 kg piglets were subjected to banding of the pulmonary trunk. Thereby, progressive heart failure was induced by natural growth. At baseline and every four weeks for 16 weeks the animals were assessed with hyperpolarised pyruvate, conventional MR imaging, 4D echocardiography and blood sampling. Finally, at week 16 cardiac physiology was invasively assessed with conductance catheter technique. End-point data was compared to a weight matched control group.
Results: At 16 weeks right ventricular end systolic pressure-volume relationship, dP/dt_max and preload recruitable stroke work were increased ($p < 0.05$), while the left ventricle exhibited significant diastolic impairment. The myocardial lactate/bicarbonate ratio, depicting the balance between anaerobic and aerobic metabolism, increased from 0.036 to 0.10 ($p = 0.004$). No changes were found in the functional echo-derived right ventricular parameters such as TAPSE, FAC and strain.
Conclusions: At 16 weeks, the animals had developed compensated right heart failure accompanied by a significant impairment of left ventricular diastolic function. Heart failure at this level was not detectable by neither conventional MR imaging nor echocardiography whereas hyperpolarisation data showed an increase in lactate/bicarbonate ratio indicating a shift towards anaerobic metabolism. In this study hyperpolarisation was capable of detecting developing right heart failure prior to conventional imaging modalities.

O1230 - DEVELOPMENT OF SYSTOLIC VENTRICULAR FUNCTION AFTER THE FONTAN OPERATION

Thomas Möller[1], Deane Yim[1], Wei Hui[1], Cheryl Fackoury[1], Edward J. Hickey[2], Luc Mertens[1]
The Hospital For Sick Children, Division of Cardiology, Oslo-Norway[1]; The Hospital For Sick Children, Division of Cardiovascular Surgery, Toronto-Canada[2]

Background/Hypothesis: The aim of our study was to investigate the development of systolic ventricular function in a single center Fontan cohort from preoperatively until five to ten years after the Fontan operation. Our secondary aim was to investigate the functional impact of AV valve and semilunar valve regurgitation, ventricular morphology and mechanical dyssynchrony.
Materials and Methods: We analyzed digitally stored echocardiography studies from three time points in 49 eligible patients: shortly before Fontan completion, postoperatively and five to ten years after. Systolic function was measured preoperatively and late post-Fontan by visual assessment, by fractional area change (FAC), by global longitudinal strain (GLS), and by non-septal longitudinal strain (LSans).
Results: Visually assessed ventricular function was declining by 0.08 ± 0.08 grades per year (Chi square $p < 0.001$). In contrast, FAC, GLS and LSans were unchanged from pre-Fontan until late post-Fontan for the entire group and independently of left or right ventricular morphology. Pre-operative valve incompetency did not change preoperative FAC, GLS or LSans. Linear regression analysis did not show significant influence of either ventricular morphology, gender, age at Fontan operation or post-operative valve incompetency on yearly change of FAC, GLS or LSans. Mechanical dyssynchrony was present in an equally small subgroup of patients before and late after Fontan completion.
Conclusion: Systolic ventricular function in the single ventricle circulation show remarkable stability through the first five to ten years after the Fontan operation. Neither ventricular morphology nor valve incompetency did induce significant functional deterioration. We did not find indications of substantial mechanical dyssynchrony before or late after Fontan completion.

O1331 - INCREASED WAVE REFLECTION INDICES IN YOUNG ADULTS FOLLOWING END TO END COARCTATION REPAIR COMPARED WITH SUBCLAVIAN FLAP REPAIR

Remi Kowalski[1], Jonathan Mynard[2], Joseph Smolich[2], Yves D'udekem[3], Michael Cheung[1]
The Royal Children's Hospital, Cardiology, Parkville-Australia[1]; Murdoch Children's Research Institute, Heart Research, Melbourne-Australia[2]; The Royal Children's Hospital, Cardiac Surgery, Melbourne-Australia[3]

Introduction: The risk of hypertension in adulthood following aortic coarctation (CoA) repair remains high, with controversy on whether resection/end-end anastomosis (E-E) or subclavian flap repair (SFA) constitutes the best surgical approach. Routine echo measures do not identify subjects at risk of hypertension.
Hypothesis: We hypothesised that the novel technique of Wave Intensity Analysis (WIA) would reveal increased wave reflection indices in the E-E group.
Methods: Routine echo assessment of LV function and arch anatomy was performed in 37 patients with repaired CoA (20 SFA, 17 E-E). In addition, WIA was undertaken at the level of the proximal transverse arch using Doppler velocity measures and the aortic distention waveform calibrated to brachial blood pressure, with determination of the intensities of main forward and backward (i.e. reflected) compression waves (FCW and BCW), their pressure effects and the local reflection coefficient (BCW:FCW pressure change ratio).
Results: Patient demographics were similar between groups, but SFA patients had a greater age at follow-up (27 ± 5 vs 19 ± 6yrs, $p < 0.001$), a higher incidence of transverse arch hypoplasia at time of surgery (20 ± 40 vs 0%, $p < 0.04$), and a higher distal transverse arch z-score at follow-up (0.7 ± 1.3 vs -0.1 ± 0.9, $p = 0.04$).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

No differences were evident between SFA and E-E groups in LV dimensions, calculated LV mass, LV systolic function or systolic blood pressure (133 ± 13 vs 130 ± 11 mmHg, p = 0.5). However, while FCW intensities were not different between groups, E-E patients had a higher BCW intensity (p = 0.02), a greater BCW-related pressure increase (16 ± 6 vs 11 ± 5 mmHg, p = 0.02) and higher reflection coefficient (0.41 ± 0.14 vs 0.28 ± 0.11, p = 0.02).
Conclusions: Young adults following E-E repair of CoA have elevated wave reflection indices in the proximal transverse arch, and smaller distal arch z-scores compared with those repaired with SFA. These finding have important implications for development of hypertension in later life.

Introduction: We previously demonstrated that myocardial remodelling at the time of tetralogy of Fallot (TF) repair influences right ventricular (RV) function in the intermediate postoperative period. Its impact on the late postoperative RV function is unknown.
Objective: To re-evaluate previously studied patients and analyse RV function by echocardiography, correlated with the area of myocardial fibrosis at the time of repair.
Methods: 18 patients in the late follow-up (LFU) of TF repair (mean = 95 months, 13 males, age 12-80 months at repair and mean age at LFU = 126,6 months) were enrolled. Tissue-Doppler systolic and diastolic myocardial velocities (S', e', a') were determined: before surgery, 3 days postoperatively, between the 30th-90th PO days, at LFU (mean = 96.6months). Tricuspid annular plane systolic excursion (TAPSE) and RV peak longitudinal systolic global and regional strain (Strain) were analysed at LFU.
Results: The a' myocardial velocity on the RV lateral wall decreased significantly after surgery and persisted abnormal at LFU (RM ANOVA, p < 0.001). There was a significant negative correlation between e' velocity at LFU and myocardial fibrosis (p = 0.02; r = -0.54) and a positive correlation between fibrosis and E/e' ratio (r = 0.787; p = 0.0002). TAPSE was lower than the lower limit for normality in 16 patients. Global longitudinal RV systolic strain was decreased at LFU (<2std) in 14 patients and differed regionally in the mid septal segment (<2std, 5 patients) and in the mid segment of the lateral wall (<2std, 1 patient). There was negative correlation between myocardial fibrosis and systolic Strain in the mid septal segment (p = 0.0376; r = -0.493) but not with overall myocardial deformation index.
Conclusion: Myocardial fibrosis evaluated at the time of repair associated with late alterations in RV diastolic function and deformation index in the mid septal segment. Regional differences may correspond to adaptation of the RV components in the LFU and to the loading conditions. Fibrosis does not influence late systolic function.

O1526 - CONGENITAL HEART DEFECTS IN NIGERIAN CHILDREN PRELIMINARY DATA FROM THE NATIONAL PAEDIATRIC CARDIAC REGISTER

Background/Hypothesis: Congenital heart defects (CHD) are the commonest birth defects and leading cause of birth defect related deaths. Incidence of significant CHD at birth is about 1% worldwide. However, there may be regional differences in pattern, even within countries. There has been no previous original study of regional patterns of CHD in Nigeria. Objective of the study is to compare current regional patterns of CHD and access to treatment in Nigerian children.
Materials and Methods: Seventeen centres nation-wide (6 from the north) participated in the pilot run of a National Paediatric Cardiac Register from January to December 2014. All children confirmed by echocardiography to have CHD were enrolled. Basic patient data from the Northern and Southern regions, such as biodata, echocardiographic diagnosis and details of any intervention

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

received were compared with respect to pattern of disease and access to corrective surgery.
Results: A total of 1318 children including 701 (53.2%) males with CHD were enrolled during the one year pilot and 26.1% were from the North. Half of the patients were neonates and infants while almost one quarter had cyanotic defects. Median age at enrollment was 0.9 years (range 2 days to 18 years). Patients in the North were significantly older at enrollment (3.0 ± 3.7 years versus 2.3 ± 3.5years) – $p = 0.003$. Ventricular septal defects (VSD) were significantly more prevalent in the North (36.0% versus 20.6%) – $p < 0.0001$. Although 1265 (96%) of enrolled patients required surgical intervention, only 210 (16.6%) received the necessary surgery. Furthermore, only 43 (20.5%) of the surgeries done were in-country. More patients in the South (18.8%) received such intervention, compared with 10.5% in the North ($p < 0.0001$).
Conclusion: Over 80% of Nigerian children with CHD have no access to corrective surgery. There are significant differences in access to paediatric cardiology and cardiac surgical services between North and South of Nigeria.

O1860 - ECHOCARDIOGRAPHIC ACCURACY DETECTION OF CORONARY PATTERN IN D TRANSPOSITION OF THE GREAT ARTERIES A NEVER DESCRIBED NEW PATTERN IN OUR 10 YEARS' SINGLE CENTER EXPERIENCE

Alessia Del Pasqua, Carmen Privitera, Valeria Terranova, Carolina D'anna, Marcello Chinali, Claudia Esposito, Maria Iacomino, Paolo Ciliberti, Adriano Carotti, Fabrizio Drago, Fiore Salvatore Iorio, Gabriele Rinelli
Bambino Gesù Pediatric Hospital, Pediatric Cardiology and Cardiovascular Surgery, Rome-Italy

Background: Assessment of coronary artery (CA) anatomy in transposition of the great arteries (TGA) is crucial for planning surgical technique. Echocardiography is still the main diagnostic tool for preoperative CA evaluation.
Aim: To review our last 10 years' TGA experience, and evaluate echocardiographic diagnostic accuracy in detection of CA pattern. Collaterally to determine coronary patterns prognostic implications.
Methods: We retrospectively reviewed echocardiographic and surgical records of TGA cases underwent primary repair in our institution from January 2004 to January 2014, comparing echocardiographic CA description to surgical findings.
Results: We collected 181 cases: 111 were TGA with intact ventricular septum (61%) and 70 TGA associated with ventricular septal defect (39%). Median age and weight at repair were 24 days (range 3-356 days) and 3,380 Kg (range 2,300-7,600 Kg) respectively. Coronary pattern were "usual" in 111 cases (61%) and were confirmed to be such in 95% (106/111). Abnormal coronary patterns were described in 70 patients (39%) and were confirmed in 87% of cases (61/70). Failure to detect coronary pattern was observed in 14 cases as described in the Table. Diagnostic accuracy for intramural CA was 75% but reached 100% in the last 6 years. We correctly identified by echocardiogram one never described coronary pattern: from right coronary ostium arose the right CA, the circumflex CA with posterior loop and an accessory anterior descending artery with anterior loop. From the left ostium arose the anterior descending artery. Global intra operative mortality was 0%; late mortality 1%.
Conclusion: Echocardiography is a very reliable tool in detecting CA in TGA even in complex patterns. Over the last 2 years intramural course detection improved, and we found a new, never described previously, CA pattern.

Table.

UNUSUAL CORONARY PATTERN	ECHOCARDIOGRAPHIC DIAGNOSIS	INTRAOPERATIVE DIAGNOSIS	N. cases	False Positive	False Negative
Circumflex artery	Cx from the RCA	Usual	4	4	2
	Usual	CX from the RCA	2		
Intramural arteries	Normal	Intramural LAD	1	1	1
	Intramural LAD	Normal	1		
Single coronary artery	Single coronary artery from right sinus	Usual	2	2	1
	Usual	Single coronary artery from left sinus	1		
Other	Single coronary artery arising from the left sinus	Inverted origin of the coronary arteries with anterior double loop of RCA and posterior loop of LAD	1	1	
	Usual	Separate origin of Cx and LAD	1		
	Single coronary artery from the left sinus	RCA arise from left sinus with anterior loop and Cx from right sinus with posterior loop	1		

LAD: left anterior descending coronary artery; RCA: right coronary artery; Cx: circumflex coronary artery

O1867 - ROUTINE CORONARY CT ANGIOGRAPHY IN YOUNG ADULTS WITH TRANSPOSITION OF THE GREAT ARTERIES AFTER THE ARTERIAL SWITCH OPERATION – IS THIS AN OPTION OR SHOULD IT BE MANDATORY

Krzysztof Michalak[1], Konrad Szymczyk[2], Katarzyna Sobczak-budlewska[1], Maciej Moll[3], Marek Kopala[3], Pawel Dryżek[1], Jacek Moll[3], Jadwiga Moll[1]
Polish Mother's Memorial Hospital, Department of Pediatric Cardiology, Lodz-Poland[1]; Polish Mother's Memorial Hospital, Department of Diagnostic Imaging, Lodz-Poland[2]; Polish Mother's Memorial Hospital, Department of Cardiac Surgery, Lodz-Poland[3]

Background: Coronary transplantation is the crucial part of successful arterial switch operation especially in the presence of the coronary anomalies. Coronary complications are relatively rare, but from the all postoperative adverse events they are potentially most dangerous. In the late follow-up those patients are frequently completely asymptomatic until a serious coronary event occurs. The Aim of This Study was to present the initial results of our routinely performed coronary CT angiographies (CCTA) in asymptomatic young adults with TGA after ASO.
Methods: This prospective study involves initial series of patients invited for the routine CCTA performed in asymptomatic young adults with TGA after ASO. In each of the case the evaluation of coronary arteries (CAs) included:
- the spatial setup of the great vessels,
- position and angulation of the coronary ostia with the aortic wall
- dimensions of the ostial and narrowest part of CAs,
- volume rendering 3D and curved, multiplanar reconstructions
Results: Among our group of patients with TGA after ASO (currently 715 patients) between September 2015 and October 2016 we performed 30 routine coronary CT angiographies (mean age at examination: 19.3 years). In the majority of the cases aorta was situated rightward and in front of the pulmonary trunk with median angle of great vessels to the sagittal plane of 220 (range: 3-48). The mean position angle for RCA was 460 (clockwise) and for LCA 400(counterclockwise). 12 patients had the acute coronary angulation (<300) of at least one coronary artery. The median height to width ratio for RCA ostium was 1.1; for LCA 1.2; however 2 patients had LCA H:W ratio which exceeds 2. In one patient we detected ostial narrowing caused by surrounding structures (pulmonary trunk), one patient had intramuscular

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

course of LAD, and in two cases muscular band in segment 7 of LAD was present.

O2026 - RISK OF CARDIAC TACHYARRHYTHMIAS AND SUDDEN CARDIAC DEATH IN PATIENTS WITH REPAIRED TETRALOGY OF FALLOT A CARDIAC MRI BASED STUDY

Niek Beurskens[1], Quint Hagdron[2], Thomas Gorter[3], Rolf Berger[2], Karin Vermeulen[4], Joost Van Melle[3], George Lui[5], Frandics Chan[6], Tineke Willems[1]
University Medical Center Groningen, Radiology, Groningen-The Netherlands[1]; University Medical Center Groningen, Congenital Heart Diseases, Groningen-The Netherlands[2]; University Medical Center Groningen, Cardiology, Groningen-The Netherlands[3]; University Medical Center Groningen, Epidemiology, Groningen-The Netherlands[4]; Stanford University Medical Center, Pediatric Cardiology, Palo Alto-United States[5]; Stanford University Medical Center, Radiology, Palo Alto-United States[6]

Background: Cardiac tachyarrhythmias are the leading cause of sudden cardiac death (SCD) in patients with repaired tetralogy of Fallot (TOF). We evaluated risk factors for SCD or sustained ventricular tachyarrhythmia (VT) and supraventricular tachycardia (SVT) in patients with repaired TOF.
Materials and Methods: Children and adults with repaired TOF who underwent cardiac magnetic resonance (CMR) imaging between 2007 and 2016 at four tertiary centers were retrospectively assessed. Potential risk markers, based on surgical history, CMR, electrocardiography and echocardiography, were analyzed for prediction of the primary composite endpoint of sustained VT/SCD, and for the secondary endpoint of SVT.
Results: A total of 531 cases were included. During a median follow-up of 2.6 (0.9-5.6) years, 29 (6%) reached the primary endpoint of VT/SCD and 51 (10%) the secondary endpoint of SVT. Multivariable cox proportional hazards regression identified right ventricular mass index (RVMi) ≥50 g/m2 (Hazard ratio [HR] 6.95; 95% confidence interval [CI] 3.14-15.4; $p < 0.001$), RV ejection fraction <45% (HR 2.93; 95% CI 1.30-6.60; $p = 0.009$), and QRS-duration ≥164ms (HR 4.81; 95% CI 2.17-10.7; $p < 0.001$) to be independent predictors of VT/SCD. Kaplan-Meier curve showed that in patients with all aforementioned risk factors, 69% experienced VT/SCD after nine years post-CMR [log rank $p < 0.001$]). Body mass index ≥25 kg/m2 (HR 3.33; 95% CI 1.79-6.16; $p < 0.001$) and older age at TOF repair ≥5 years (HR 2.74; 95% CI 1.47-5.12; $p = 0.002$) independently predicted SVT. Kaplan-Meier curve illustrated that in patients with both risk factors, 46% developed SVT within nine years following CMR [log rank $p < 0.001$]).
Conclusions: In patients with repaired TOF, RV hypertrophy, RV systolic dysfunction, and prolonged QRS duration were strong independent predictors of VT/SCD. Obesity and older age at TOF repair were associated with the occurrence of SVT. The present study therefore contributes to the risk stratification for sustained VT/SCD and SVT in patients with repaired TOF.

O2045 - IMPACT OF LOADING CONDITIONS ON VENTRICULAR FUNCTION BEFORE AND AFTER CONE RECONSTRUCTION IN EBSTEIN'S ANOMALY

Elodie Perdreau[1], Victor Tsang[2], Marina Hughes[3], Mohammed Ibrahim[4], Xavier Iriart[5], Sachin Khambadkone[3], Jan Marek[3]
Gosh and University Hospital of Bordeaux, Pediatric and Congenital Cardiology, Limoges-France[1]; Gosh and Bart's Hospital, Pediatric and Congenital Cardiology, London-United Kingdom[2]; Gosh, Pediatric and Congenital Cardiology, London-United Kingdom[3]; Bart's Hospital, Pediatric and Congenital Cardiology, London-UnitedKingdom[4]; University Hospital of Bordeaux, Pediatric and Congenital Cardiology, Bordeaux-France[5]

Background/Hypothesis: The Cone reconstruction in Ebstein's anomaly (EA) aims to reduce tricuspid valve regurgitation (TR) and reposition the valve to the anatomic annulus, but post-operative progress of ventricular function is poorly understood. This study evaluated the ventricular adaptation to the altered loading conditions after Cone reconstruction.
Material and Methods: A retrospective study assessing longitudinal change was conducted from 2009 to 2014. All symptomatic patients with EA and severe TR undergoing surgery were included. Transthoracic advanced echocardiography was performed pre- and postoperatively (at short-term (<30 days) and mid-term). Conventional and longitudinal 2D strain parameters were measured for LV and RV. Paired analyses were compared using Wilcoxon Matched-pairs signed rank test.
Results: The echocardiographic data of 17 patients, aged 15 (1-57 years) at operation could be analysed. Median follow up was 6 months (8 days-54 months). GOSH score was significantly reduced after Cone repair (1.1 ± 0.2 vs 0.3 ± 0.1, $p = 0.020$) as well as TR (4 (3-4) vs 1 (0-3), $p < 0.001$). The TAPSE (26.4 ± 5.8mm vs 8.7 ± 3.2mm, $p < 0.001$), RV FAC ($45.0 \pm 8.1\%$ vs $35.5 \pm 5.8\%$,$p = 0.038$) and LV 2D peak systolic strain were significantly reduced postoperatively (-20.5 ± 2.8 vs -17.7 ± 2.8, $p = 0.041$), but the LV 2D strain tended to recovery in mid-term postoperative period (-20.7 ± 3.1 in pre-op vs 18.8 ± 2.4 in mid-term post-op, $p = 0.247$). There was no evidence of systolic mechanical dyssynchrony.
Conclusions: Although clinical outcome of Cone reconstruction remains excellent, acute post-operative changes in loading conditions leads to reduction of myocardial contractility of both ventricles, with a trend to later recovery for LV.

O2073 - THREE DIMENSIONAL ECHOCARDIOGRAPHY VERSUS CARDIAC MAGNETIC RESONANCE FOR ASSESSMENT OF THE RIGHT VENTRICULAR VOLUMES IN PATIENTS WITH CONGENITAL HEART DISEASE AFTER PERCUTANEOUS PULMONARY VALVE IMPLANTATION

Francesca R Pluchinotta[1], Luciane Piazza[1], Pierpaolo Tarzia[1], Laura Fusini[2], Mauro Pepi[2], Massimo Lombardi[3], Mario Carminati[1], Claudio Bussadori[8]
IRCCS Policlinico San Donato, Pediatric Cardiology and Adult Congenital Heart Disease, Milano-Italy[1]; IRCCS Centro Cardiologico Monzino, Milano-Italy[2]; IRCCS Policlinico San Donato, Multimodality Cardiac Imaging, Milano-Italy[3]

Background: Cardiac MR (CMR) is the gold standard for right ventricular (RV) quantification. In the recent years transthoracic three-dimensional echocardiography (3DE) is becoming increasingly available in the routine clinical practice. The purpose of this study was to investigate the clinical significance and interchangeability of these modalities to evaluate patients with congenital heart disease (CHD) who underwent percutaneous pulmonary valve implantation (PPVI) for RV outflow tract dysfunction.
Materials and Methods: 52 patients who underwent PPVI were evaluated with 3DE and CMR to quantify the RV. RV volumes and ejection fraction (EF) were measured for both imaging techniques with commercially available softwares (Tomtec-Germany for 3DE and Medimatic-Netherlands for CMR data). Paired t test,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Bland-Altman analysis and Pearson's correlation analysis were used as most appropriate.
Results: 80% of the patients had adequate image quality on 3DE and was included in the study. 78% had a primary disease of the RV (tetralogy of Fallot, pulmonary atresia, transposition of the great arteries,…), while 9 patients had a natively normal RV and underwent PPVI after a Ross procedure. No differences were found regarding age, body size and type of valve implanted. Linear regression analysis showed high correlation coefficients between 3DE and CMR ($p < 0.001$). Bland-Altman analysis showed limited bias and narrow limits of agreement (LOA) between the two techniques: End Diastolic Volume index (EDVi): bias -2.1 ml, LOA ±22.8 ml; End Systolic Volume index (ESVi): bias -4.1 ml, LOA ±15 ml; EF: bias 4%, LOA: ±16.3. A non-significant trend towards overestimation of volumes by 3DE was observed. The 3DE measurements were found to be highly reproducible in terms of intra-observer variability (EDVi 0.97, ESVi, 0.87, EF 089, $p < 0.001$).
Conclusions: The present study supports the applicability of 3DE for the assessment of RV volumes and EF in patients with CHD after PPVI.

Table 1. Comparison of RV volumes and EF between 3DE and CMR

	CMR	3DE	P*	r
EDVi (ml/m^2)	82.98 ± 23.52	85.12 ± 22.48	0.001	0.873
ESVi (ml/m^2)	37.33 ± 17.60	41.4 ± 15.60	0.001	0.897
EF (%)	56 ± 10.6	52.04 ± 9.89	0.001	0.675

O2162 - MULTI PARAMETRIC ECHOCARDIOGRAPHIC ASSESSMENT FOR PREOPERATIVE DECISION MAKING IN SURGICAL TREATMENT OF ATRIOVENTRICULAR SEPTAL DEFECT

Anastasia Schleiger[1], Jelena Buracionok[1], Katharina Schmitt[1], Oliver Miera[1], Mustafa Yigitbasi[1], Mi-Young Cho[2], Joachim Photiadis[2], Felix Berger[1], Stanislav Ovroutski[1]
DHZB, Department of Congenital Heart Disease/Pediatric Cardiology, Berlin-Germany[1]; DHZB, Department of Congenital Heart Surgery, Berlin-Germany[2]

Introduction: Surgical management of unbalanced atrioventricular septal defect (AVSD) remains challenging because of a high mortality rate and difficulties in decision making between biventricular repair (BVR) and univentricular palliation (UVP) in borderline cases. In this study we aimed to define echocardiographic criteria for imbalance and prove their predictability for mortality and reoperation rate.
Methods: From 1986 to 2016 671 patients diagnosed with AVSD were identified in our institution. 532 patients received AVSD repair, 2.5% of these patients had unbalanced AVSD but were suitable for biventricular strategy. Of 253 patients pre- and postoperative echocardiographic data were available for retrospective analysis. For echocardiographic assessment modified atrioventricular valve index (mAVVI), ventricular cavity ratio (VCR), left ventricular inflow index (LVII) and right ventricle/ left ventricle inflow angle were measured. Left atrioventricular valve reduction index (LAVRI) was calculated to estimate left atrioventricular valve area after cleft closure. Correlation was proved between echocardiographic indices, surgical strategy, postoperative course, survival and reoperation rate.
Results: mAVVI was the only index to distinguish between balanced and unbalanced AVSD and predict surgical strategy (Jegatheeswaren et al.). Borderline cases (n = 13) received biventricular repair and had no higher mortality or reoperation rate. Inflow angle positively correlated with ventilation time ($p < 0.01$) and predicted early postoperative course. LAVRI <1.0, moderate mitral valve regurgitation and a mean gradient >3 mmHg on discharge were associated with reoperation.
Conclusion: No index correlated with mortality. mAVVI seemed usable for preoperative decisions concerning interventricular balance. Correlation of right ventricle/left ventricle inflow angle with ventilation time may indicate the importance of ventricular septal defect size for postoperative course. LAVRI and residual mitral valve regurgitation/stenosis correlated with reoperation rate. A multi-parametric echocardiographic assessment using indices for ventricular and atrioventricular valve size can facilitate decision making in borderline cases of unbalanced AVSD and surgical management of the atrioventricular valve.

O2224 - ROLES OF PRESSURE AND VOLUME LOAD ON NATURAL PROGRESSION OF RIGHT VENTRICULAR DILATION AND REVERSE REMODELING AFTER PULMONARY VALVE REPLACEMENT IN PATIENTS WITH REPAIRED TETRALOGY OF FALLOT A SERIAL FOLLOW UP CARDIOVASCULAR MAGNETIC RESONANCE STUDY

Chun-An Chen[1], Shyh-Jye Chen[2], Wen-Yih Tseng[3], Yao-Hui Tseng[2], Mao-Yuan Su[2], Mei-Hwan Wu[1], Chun-Wei Lu[1], Ming-Tai Lin[1]
National Taiwan University Children's Hospital, Cardiology, Taipei-Taiwan[1]; National Taiwan University Hospital, Medical Imaging, Taipei-Taiwan[2]; National Taiwan University, Center For Optoelectronic Biomedicine, Taipei-Taiwan[3]

Background: Different patterns of right ventricular (RV) remodeling in response to different types of hemodynamic burden have been observed in patients with repaired tetralogy of Fallot (rTOF). However, little is known about the impact of hemodynamic load on the progression rate of RV dilation, nor on the RV reverse remodeling after pulmonary valve replacement (PVR). We sought to investigate these issues using serial CMR studies.
Methods: We identified 188 rTOF patients who had received at least 2 CMR studies from our institutional database (482 CMR studies). The natural progression rate of the RV end-diastolic volume index (EDVi) (RVEDV PR) was calculated using the change in the RV EDVi over time. Patients with a pulmonary regurgitation (PR) fraction ≥ 25% and peak RV outflow tract gradient of ≤25 mm Hg were classified into RV volume overload group, and all the remaining patients were classified into mixed load group.
Results: Over a median interval of 3.9 years, the median RVEDV PR was 4.6 mL/m2/y (n = 169). Patients with upper-quartile RVEDV PR (>7.5 mL/m2/y) were younger at the time of first CMR study and repair; had a higher baseline PR fraction, larger RV dimensions, and a lower left ventricular ejection fraction; and were more likely to have volume overload as the predominant hemodynamic burden (n = 91) as oppose to mixed load (n = 78). In multivariate analysis, predominant RV volume overload was independently associated with upper-quartile RVEDV PR. Forty-one patients subsequently received PVR, and RV size decreased substantially. However, it was pre-PVR RV size, age at

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

PVR, and post-PVR PR fraction independently associated post-PVR RV size, but not types of hemodynamic burden before PVR.
Conclusions: Patients with predominant RV volume overload are at a higher risk of rapid natural progression of RV dilation. However types of hemodynamic burden before PVR was not related to the extent of RV reverse remodeling after PVR.

O2255 - QUANTIFICATION OF PULMONARY VALVE REGURGITATION IN PATIENTS WITH TETRALOGY OF FALLOT BY A NOVEL ECHOCARDIOGRAPHIC IMAGING OF VECTOR FLOW MAPPING

Satoshi Yasukochi[1], *Junpei Kawamura*[1], *Yusuke Nakano*[2], *Kiyohiro Takigiku*[1], *Kouta Takei*[1], *Sei-ichi Tazawa*[1], *Masashi Utsumi*[1]
Nagano Children's Hospital, Pedaitric Cardiology, Azumino-Japan[1]; *Yokohama City University, Pedaitrics, Yokohama-Japan*[2]

Background: The pulmonary valve regurgitation (PR) is a key to determine a long-term outcome after surgical treatment of Tetralogy of Fallot (TOF) by causing right ventricular (RV) dilatation and dysfunction. Only quantification for PR could be measured by cardiac magnetic resonance (CMR).
Aim: We aim to quantify PR of patients with TOF by a novel imaging modality of echocardiography: Vector Flow Mapping (VFM) and to validate the results of this new imaging by CMR-Flow study.
Method: Thirty-four patients after surgical repair of TOF, mean age at examination of 14.8 years and interval from definitive surgery of 11.9 years, were investigated. The color Doppler images of RV outflow tract including main pulmonary artery was obtained by Prosound F75 (Hitachi-ALOKA ltd) with VFM mode, and calculated the blood volume across the measured line perpendicular to pulmonary valve ring (PV) as a sum of integration of blood flow velocity at multiple sampling gate along a cardiac cycle by off-line analyzing software (Hitachi-Aloka ltd.) The ratio of regurgitation to forward flow at PV measured by VFM (PRF-VFM) was compared to those by CMR which were measured by phase-contrast flow quantification (PRF-CMR).
Results: PRF-VFM was good in agreement with PRF-CMR: (PRF-CMR) = 0.917*(PRF-VFM), $r^2 = 0.63$ as Figure 1. Limitation: The limitation of this technique is the quality of image of RVOT and a color Doppler signals, especially in the presence of turbulent accelerated flow by stenotic RVOT because of aliasing artifacts.
In conclusion, our new imaging modality of VFM is very powerful tool to determine PRF in as accurate quantification as that of CMR when to diagnose the severity of PR in patients with TOF.

O2309 - MYOCARDIAL CONTRACTILE RESERVE AND CORONARY FLOW RESERVE FOLLOWING ARTERIAL SWITCH OPERATION FOR TGA REGRESSED AND PRESERVED LV

Rajat Kalra[1], *Sivasubramanian Ramakrishnan*[2], *Ak Bisoi*[1], *Saurabh Gupta*[2], *Anita Saxena*[2]
Aiims, CTVS, New Delhi-India[1]; *Aiims, Cardiology, New Delhi-India*[2]

Introduction: The functional capability of the 'regressed' left ventricle (LV) with transposition of great arteries (TGA) may be different from those who underwent early arterial switch operation (ASO). The functional reserve and coronary flow reserve may also differ and have never been studied before.
Methods: All patients who underwent an ASO for TGA at least 6 months prior were included in the study. All the patients underwent a detailed echocardiography followed by adenosine stress echocardiography.
Results: We included 40 patients for echocardiography, with 22 patients (mean age 276.45 ± 121 days) undergoing an ASO with a preserved LV and 18 patients (mean age 336.17 ± 115.88 days) with a regressed ventricle at time of surgery. The LV ejection fraction was within normal limits at baseline (63.19 ± 10.95 Vs 60.44 ± 14.24; P value 0.50) and increased with adenosine stress in both the groups (67.31 ± 8.71 Vs 61.58 ± 13.11; P value 0.12), however, the increase was not statistically significant. Similarly, there was no significant difference in the parameters including longitudinal, circumfential and rotational strain between both the groups. The change following adenosine stress was also not significant in both the groups. However, the coronary flow reserve seems to be preserved.
Conclusion: Patient with regressed left ventricle undergoing arterial switch operation adapt well to systemic afterload and perform as well as patients of arterial switch operation with preserved left ventricle at 6 months follow up. The myocardial contractile reserve seems to be reduced in both the groups despite a preserved coronary flow reserve.

O2531 - CARDIAC OUTPUT DISTRIBUTION IN THE FETUS WITH COARCTATION

Max E Godfrey[1], Monika Drogosz[2], Kevin G. Friedman[2], Gerald R. Marx[2], Wayne Tworetzky[2]
Shaare Zedek Medical Center, Pediatric Cardiology, Jerusalem-Israel[1]; Boston Children, Cardiology, Boston-United States[2]

Introduction: Coarctation of the aorta (COA) remains one of the most challenging diagnoses by fetal echo, with false positive diagnosis being quite common. Although relative left-sided anatomic hypoplasia is well described in these fetuses, the physiological aberrations have not been well characterized. In the normal fetus, the left ventricle supplies approximately 40% of the combined ventricular output (CVO) but it is unknown whether this holds true in fetuses with COA. We hypothesized that patients with confirmed neonatal COA would have lower left ventricular (LV) output in utero.
Methods: We included 41 patients who underwent surgery for neonatal COA between 2005 and 2015 and analyzed data from their fetal echos, including aortic and pulmonary valve size (AOV and PV) and ventricular output. Findings were compared to our institutional normal fetal data, matched for gestational age (n = 177).
Results: Median gestational age was identical in both cohorts (24.71, p = 0.8).The AOV z-score was significantly lower in the COA cohort (-2.2 vs -0.155, p < 0.0001), and the PV z-score higher (0.43 vs -0.012, p = 0.0071). The LV component of CVO was lower in COA than in controls (median of 28.9% vs 41.3%, p < 0.0001), as was the total CVO (449 ml/kg/min vs 553 ml/kg/min, p = 0.0012). Both the AOV annulus (p = 0.005) and the AOV Doppler velocity-time integral (VTI) (p < 0.0001) increased less with advancing gestational age in patients with COA than in normal fetuses.
Conclusion: Fetuses with confirmed neonatal COA have significantly reduced LV component of CVO. This is likely due to a smaller AOV as well as reduced VTI. The reduced VTI may in turn be a result of reduced preload from lower amount of right-to-left flow at the foramen ovale. Further work is necessary to elucidate this pathophysiology and evaluate its potential for enhancing prenatal diagnosis of COA.

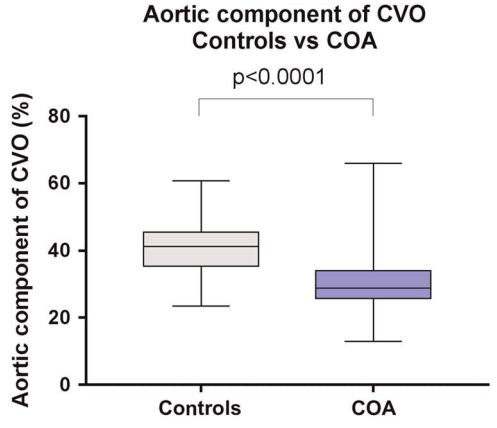

Figure.

O2664 - DIASTOLIC KINETIC ENERGY MEASURED BY 4D FLOW MAGNETIC RESONANCE IMAGING IS RELATED TO RESTRICTIVE RIGHT VENTRICULAR PHYSIOLOGY IN PATIENTS WITH REPAIRED TETRALOGY OF FALLOT

Pia Sjöberg[1], Sebastian Bidhult[1], Jelena Bock[1], Einar Heiberg[1], Håkan Arheden[1], Shahab Nozohoor[2], Ronny Gustafsson[2], Marcus Carlsson[1]
Dept of Clinical Physiology, Lund University, Skane University Hospital, Lund-Sweden[1]; Department of Cardiothoracic Surgery, Lund University, Skane University Hospital, Lund-Sweden[2]

Background: The clinical relevance of restrictive right ventricular (RV) physiology in patients with pulmonary regurgitation (PR) after repair of Tetralogy of Fallot (rToF) is debated. 4D-flow cardiovascular magnetic resonance (CMR) enables quantification of ventricular kinetic energy (KE) which may provide improved understanding of the pathophysiology. The aim of the study was to quantify ventricular KE in patients with PR after rToF and evaluate the impact of restrictive RV physiology.
Materials and Methods: Fifteen patients with rToF and PR (5 females, median age 24 years, range 18-52) underwent CMR including four-dimensional (4D) phase-contrast flow sequence. Thirteen healthy volunteers (2 females, median age 28, range 23-43) were used as controls. Ventricular segmentation was performed in cine SSFP images and imported to 4D-flow dataset. KE in the RV was calculated as $KE = \frac{1}{2}mv^2$ for each time frame. Restrictive physiology was defined as forward flow in the pulmonary artery during atrial contraction measured by 2D-flow CMR. Results are presented as mean ± SD.
Results: No difference was seen in RV peak systolic KE in patients, 10.2 ± 4.2mJ compared to controls, 8.3 ± 2.0 mJ, p = 0.21. RV peak diastolic KE was higher in patients, 8.0 ± 5.1mJ than controls, 3.1 ± 1.3mJ, p = 0.0002, also indexed to stroke volume (SV), 0.06 ± 0.03mJ vs 0.03 ± 0.01mJ, p = 0.0004. Examples are shown in fig 1. Mean peak systolic KE/peak diastolic KE ratio was lower, 1.6 ± 0.9mJ, p = 0.0004, in patients versus controls, 2.9 ± 1.1mJ, fig 2. Patients with a nonrestrictive physiology (n = 5, open circles) had ratio < 1 or in one case just above 1, whereas ratio > 1 was related to restrictive RV (n = 10, filled circles). Cohen's kappa 0.84.
Conclusions: Peak diastolic KE is increased in rTOF with PR, but the flow pattern in restrictive rTOF is more similar to controls and further studies are necessary to evaluate the impact on clinical outcome.

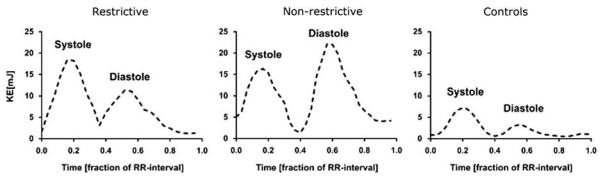

Figure 1.

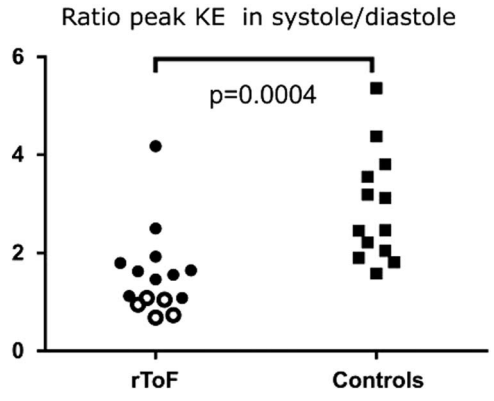

Figure 2.

O2835 - TRICUSPID VALVE ROTATION ANGLE (TVRA) PREDICTS THE SUCCESS OF CONE TYPE RECONSTRUCTION FOR EBSTEIN'S ANOMALY; NOVEL APPROACH USING CARDIAC MRI

Marina Hughes[1], Beatrice Bonello[2], Preeti Choudhary[2], Jan Marek[2], Victor Tsang[3]
Great Ormond Street Hospital, Cardiology Department, London-United Kingdom[1]; Great Ormond Street Hospital, Cardiology Department, London-United Kingdom[2]; Great Ormond Street Hospital, Cardiac Surgery Dept, London-United Kingdom[3]

Aim: To identify critical cardiac MR-derived attributes of the variable Ebsteinoid tricuspid valve (TV) that could preclude effective cone-type surgical reconstruction.
Methods: A retrospective assessment of all adult and pediatric patients with Ebstein's anomaly of TV and pre-operative CMR, undergoing cone-type surgical reconstruction, by a single surgeon, within two surgical centres. CMR-derived geometric measurement of the displacement and rotation of the plane of systolic apposition of the leaflets (TVRA angle), in the RV vertical long axis image, was related to the short-term surgical result of all operated patients. The primary outcome measure was early dehiscence, re-operation or modified surgical plan. Other CMR factors assessed: area ratios of cardiac chambers (from 4-chamber view), BSA-indexed functional RV volume (RVEDVi), and TV regurgitant fraction (TR%). Non-parametric statistical tests compared the groups.
Results: Since the first procedure in 2010, 33 patients (15 male) had pre-op CMR and underwent surgery at a median (25th-75th C) age 16 (3-57) years. 5/33 patients experienced early surgical failure, with even temporal spread between 2010-2016. Significant risk factors for technical failure of repair were increased TVRA (median 73degrees (62-78) vs 49 degrees (39-60), $p < 0.01$), smaller RVEDVi (98 mL/m^2 (66-141) vs 173 mL/m^2 (121-212), $p = 0.02$), decreased TR% (36% (23-53) vs 59% (43-70), $p = 0.046$) and increased age (35 yrs (19-49) vs 15 yrs (8-21), $p = 0.04$. Other CMR indicators of Ebstein disease severity: 'RA area: rest of heart' ratio, 'Right heart:Left heart' area ratio, cardiothoracic ratio or RV ejection fraction did not relate to early surgical failure. The TVRA was measureable even with poor image quality and showed low inter-observer variability.
Conclusions: A measured angle of rotation of the effective plane of closure of the Ebsteinoid TV may be a simple, reliable marker of the technical feasibility of cone-type surgical reconstruction. Though prospective testing is needed, this angle may improve case-selection and therefore surgical outcome.

INTENSIVE CARE

O1145 - RISK STRATIFICATION OF PREMATURE BABIES WITH CONGENITAL CARDIAC DISEASE

Ioana Dumitrascu-Biris[1], Grenville Fox[2], Hammad Khan[2]
Evelina Children Hospital, Paediatric Cardiology, London-United Kingdom[1]; Evelina Children Hospital, Neonatal Unit, London-United Kingdom[2]

Objectives: Describe a risk stratification for prematurity associated with congenital heart disease (CHD).
Methods: 11 years retrospective case control review of a neonatal database "BadgerNet". Outcome measures of 154 premature babies with congenital cardiac disease were compared with pre-term controls (175) without congenital cardiac abnormalities. We enrolled all preterm babies with CHD born before 36 gestation weeks at St Thomas' Hospital. Babies with isolated patent ductus arteriosus were excluded to avoid bias. In order to describe the risk stratification we randomly selected a control group of premature babies without CHD born before 36 gestation weeks. Among the two groups birth weight, gender and gestational age was similar.
Results: Our primary outcome was survival to discharge from neonatal unit. Of 154 live born premature (below 36 weeks gestation) infants between January 2005-December 2015, (12.33%) died in neonatal intensive care compared to controls (4%). The odds ratio(OR) of dying in prematurity with CHD was 3.37(95% confidence interval [CI]: 3-3.74). The incidence of necrotizing enterocolitis (NEC) among our study group was (16.88%) versus controls (7.42%)giving odds ratio of 2.53(95% confidence interval [CI]: 2.16-2.9). We also looked at sepsis and (66.88%) premature babies with CHD were treated for it compared to (55.42%) controls, odds ratio (OR) 1.62(95% CI: 1.32-2.06).The mean length of stay in neonatal unit was also significantly longer: 36.94 days versus 24.25 days for controls. We divided our population into four groups: 23-26 gestation weeks (GW), 27-29 (GW), 30-32 (GW) and 33-36 (GW) and the most common cardiac diagnostic among the 23-26 (GW)premature babies was pulmonary stenosis/atresia (40%) while in the last category (22.05%) had coarctation of the aorta followed by (13.23%) transposition of great arteries and truncus arteriosus.

O1152 - PRE OPERATIVE NUTRITION IN NEONATES UNDERGOING SURGERY FOR CONGENITAL HEART DISEASE AND ITS IMPACT ON POSTOPERATIVE COURSE

Kurt Piggott[1], Anne Liu[2], Jessica Monczka[3], Harun Fakioglu[1], Carlos Blanco[1], Sukumar Suguna Narasimhulu[1], Kamal Pourmoghadam[4], William Decampli[4]
Arnold Palmer Hospital For Children, Pediatric Cardiac Intensive Care, Orlando-United States[1]; University of Central Florida, Pediatrics, Orlando-United States[2]; Arnold Palmer Hospital For Children, Pediatric Nutrition, Orlando-United States[3]; Arnold Palmer Hospital For Children, Pediatric Cardiothoracic Surgery, Orlando-United States[4]

Background: Nutrition is vital in maintaining optimal cellular and organ function, particularly in neonates undergoing congenital heart surgery. Achieving nutritional goals preoperatively is challenging, particularly with fluid restrictions and suboptimal oral intake. We sought to evaluate our ability to achieve pre-operative caloric goal and ascertain its effects postoperatively.
Materials and Methods: We retrospectively reviewed neonates from 2011-2015 who underwent congenital heart surgery at Arnold Palmer Hospital for Children. Multiple nutritional and post-operative variables were collected. Study outcomes included hospital length of stay (HLOS) and duration of mechanical

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

ventilation (DMV). T test, chi-square, and multivariate analysis were used.
Results: 121 neonates were reviewed. 79 (65%) patients did not achieve preoperative caloric goal with a (median age 5 days), while 42 (35%) did (median age 13 days). Of those achieving caloric goal, 35 (83%) achieved it via total parental nutrition (TPN) or a combination of TPN and enteral feeds. 85 patients (70%) achieved their protein goal. Catheterization/reoperation ($p = 0.03$) and high-grade acute kidney injury (AKI) ($p = 0.008$) were more likely to occur in those not achieving caloric goal preoperatively. Those with higher STAT category ($p = 0.01$) were less likely to achieve caloric goal. Those not achieving caloric goal had a longer hospital length of stay (HLOS) ($p = 0.02$). There was no statistically significant difference in the incidence of sternal wound infections. Multivariable analysis with interaction term using AKI as the dependent variable found that failure to achieve caloric goal preoperatively increased the adverse effect of lower protein intake on renal function and was associated with AKI (0.04).
Conclusion: Achieving preoperative nutritional goal in neonates undergoing congenital heart surgery is challenging. Failure to achieve calorie and protein goals may lead to increased risk of high-grade AKI and prolonged HLOS.

O1187 - EFFECT OF GUIDELINES BASED MANAGEMENT ON THE EARLY POST OPERATIVE OUTCOME AFTER BLALOCK TAUSING SHUNT

Sameh Ismail[1], Munira Almaazmi[1], Mahmoud Elbarbary[1], Wedad Almadani[2]
National Guard Hospital, Pediatric Cardiac Intensive Care, Riyadh-Saudi Arabia[1]; National Guard Hospital, Ational and Gulf Center For Evidence Based Health Practice, Riyadh-Saudi Arabia[2]

Background and Aim: Modified Blalock- Tausing shunt (MBTS) is a palliative procedure in cyanotic heart diseases to facilitate blood flow to the lung (1), though it showed significant post-operative mortality and morbidity especially in the neonatal group. to master the post-operative management and minimize complication, mortality and morbidity, we designed and implemented executive guidelines to maintain patients respiratory and hemodynamically stable especially during the critical early post-operative period. Aim of our study to evaluate the patient outcome after implementation of these guideline in our center.
Methods: We conducted a retrospective chart review analysis of all children who underwent MBTS since year 2000 till December 2015, we excluded cases of hypoplastic left heart syndrome. We compared the early outcome of patients operated after the guidelines implementation (March 2013 till December 2015) (group A) with patients operated before implementing the MBTS guidelines (group B). Also we compared the early outcome of patients showing over-circulation (over-shunting) with other patients after implementation of the guidelines.
Results: 197 patients underwent MBTS since year 2000 till December 2015, 25 patients (64% neonates) after the implementation the guidelines (group A), and 172 patients (60% neonates) before the guidelines implementation (group B). there was a significant improvement in the postoperative course and morbidity after guidelines implementation. The ventilation time, reintubation rate, inotropic support duration, and postoperative complications were significantly lower in (group A), there was a trend of higher mortality in group B (15.7% VS 8%) (p 0.5), but it was more obvious in the neonatal patients group (19.41% VS 6.25) (p 0.2).
Conclusion: This study prove that protocol based management of patients after MBTS can improve the postoperative course and outcome.

O1275 - HETEROTAXY SYNDROME AND INTESTINAL ROTATION ABNORMALITIES – A PROSPECTIVE STUDY

Lindsay Ryerson[1], Andrew Mackie[2], Scott Pharis[3], Charissa Pockett[3], Reeni Soni[4], Deborah Fruitman[5], Kristine Guleserian[6], Melissa Nater[7], Stephen Raynor[8], Bryan Dicken[9]
Stollery Children, Pediatric Cardiac Intensive Care Unit, Edmonton-Canada[1]; University of Alberta, Department of Pediatrics, Edmonton-Canada[2]; University of Saskatchewan, Department of Pediatrics, Saskatoon-Canada[3]; University of Manitoba, Department of Pediatrics, Winnipeg-Canada[4]; University of Calgary, Department of Pediatrics, Calgary-Canada[5]; Nicklaus Children, Division of Cardiovascular Surgery, Miami-United States[6]; Advocate Children, Advocate Children, Oak Lawn-United States[7]; University of Nebraska Medical Center, Division of Pediatric Surgery, Omaha-United States[8]; University of Alberta, Department of Surgery, Edmonton-Canada[9]

Background: Infants with heterotaxy syndrome (HS) have an abnormal arrangement of organs along the right-left body axis. Malrotation is the most clinically significant intestinal rotation abnormality (IRA). The objective of this study was to prospectively observe a cohort of infants with HS and determine the incidence and natural history of IRA and volvulus in this population.
Materials and Methods: Prospective observational study; inclusion criteria were a diagnosis of HS and age ≤ six months. HS was defined as any arrangement of organs that was not complete situs solitus or situs inversus with associated congenital heart disease. Screening for IRA was at the discretion of each participating center. IRA was classified as positive, negative, indeterminate or nonrotation.
Results: Subjects were recruited from January 2012 to December 2016. Forty infants from seven institutions across North America were included; 22 subjects had right atrial isomerism and 18 had left atrial isomerism. Median length of follow up was 587 days (range 21-1823). 31/40 infants (78%) were screened, all with upper gastrointestinal imaging. Ten were screened because of symptoms. 23 infants (74%) had IRA; malrotation ($n = 14$), nonrotation ($n = 7$), and indeterminate ($n = 2$). Both patients with indeterminate rotation had duodenal atresia. Of the ten patients screened due to symptoms, nine had IRA and two infants had an emergent Ladd procedure. Of the 30 infants either not screened or screened routinely, two (6.7%) had emergent laparotomy and Ladd procedure for symptoms they developed at 18 and 20 days. Only one infant had a prophylactic Ladd procedure. Of the four symptomatic infants who had an emergent Ladd procedure, none had volvulus. No infant presented later than two months of age with symptoms of IRA.
Conclusions: IRA is common in HS patients, most commonly malrotation. Only 10% of the cohort had an emergent Ladd procedure; volvulus was not observed.

O1311 - RISK FACTORS FOR AND BURDEN OF ACUTE KIDNEY INJURY IN CHILDREN UNDERGOING CARDIAC SURGERY FOR CONGENITAL HEART DISEASE

Rohit Loomba[1], Lisa Dipietro[2], Stuart Goldstein[2], David Cooper[2]
Children's Hospital of Wisconsin/Medical College of Wisconsin, Cardiology, Milwaukee-United States[1]; Cincinnati Children's, Cardiology, Cincinnati-United States[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Acute kidney injury (AKI) is common after pediatric cardiac surgery (CS), which is associated with morbidity and mortality. There are sparse data regarding associations with specific lesions and cost.
Materials and Methods: Pediatric admissions with CS were identified in the Kids Inpatient Database (KIDS). The presence of AKI defined by ICD-9 codes during the included admissions was then identified. Regression analysis was done to determine factors associated with AKI and factors associated with longer length of stay, cost of stay, and greater need for extracorporeal membrane oxygenation (ECMO).
Results: 60,216 admissions were included in this analysis; 1,708 (3%) were documented to have AKI. AKI admissions were associated with: younger patient age (2.0 vs 3.1y, $p < 0.001$), longer stay (50 vs. 13 days, $p < 0.001$), more ECMO (20.6% vs. 1.3%, $p < 0.001$), increased cost ($620,156 vs. $153,596, $p < 0.001$) and increased mortality (31.8% versus 2.1%, $p < 0.001$). Cardiac lesions most associated with AKI were total anomalous pulmonary venous connection (OR 3.1, 2.6-3.7; $p < 0.001$), hypoplastic left heart syndrome (OR 2.4, 2.1-2.7; $p < 0.001$) and common arterial trunk (OR 2.2, 1.8-2.8; $p < 0.001$). CS most associated with AKI were heart transplant (OR 21.6, 19.2-24.2; $p < 0.001$), Fontan (OR 8.4, 6.9-10.2; $p < 0.001$), and complete repair of common arterial trunk (OR 3.2, 2.5-4.1; $p < 0.001$).
Conclusions: While AKI incidence was low compared to published reports, likely due to undercoding, we observed that AKI significantly increases mortality, length, and cost of stay. The postoperative AKI risk observed with underlying cardiac lesion and CS provides potential guidance for increased AKI surveillance and targeted AKI interventions in these populations.

O1359 - DEVELOPMENT AND IMPLEMENTATION OF INPATIENT GOAL DRIVEN CLINICAL PATHWAYS FOR CONGENITAL HEART SURGERY PATIENTS

Amy Donnellan[1], *Holly Desena*[1], *Anne Peach*[1], *Amy Ryan*[2], *Nicolas Madsen*[1], *Jean Storey*[1], *David Nelson*[1]
Cincinnati Children, Heart Institute, Cincinnati-United States[1]; *Cincinnat Children, Heart Institute, Cincinnati-United States*[2]

Background: With advances in the fields of congenital cardiac surgery and cardiac intensive care resulting in improved outcomes and survival, there is increased interest in decreasing morbidity and length of stay to better optimize long-term outcomes. Longer length of stay following cardiac surgery is associated with increased risk of infection, poor neurodevelopmental outcomes, and increased hospital costs. To these ends, development of simplified, "user-friendly" evidence informed, clinical practice pathways is paramount.
Objectives: To design and implement goal driven standardized clinical pathways for cardiology inpatient teams at Cincinnati Children's Hospital Medical Center, in an effort to reduce practice variation and promote evidence-based medicine.
Methods: A multidisciplinary team designed goal driven standardized clinical pathways for nine STS Benchmark postoperative cardiac surgical procedures. The three goals for all clinical pathways were: expedite extubation time, and reduce CICU and hospital length of stay. Each pathway recommends specific interventions to accomplish the goals. The team employed the Improvement Science Model and used Plan-Do-Study-Act cycles to refine each clinical pathway, identify practice variation, and address communication barriers. Balancing and outcome measures were calculated using statistical process control methodology.
Results: In the 20-month period following implementation, 131 patients were enrolled onto a clinical pathway. 120 patients met the recommended duration of mechanical ventilation goal for a 92% success rate. 92 patients met the recommended CICU length of stay goal for a 70% success rate. 83 patients met the recommended hospital length of stay goal for a 63% success rate. The balancing measures of ward to CICU bounce-back rate was low at 4% and the 30 day readmission rate of all cause was only 2%.
Conclusions: Implementation of goal driven clinical pathways revealed key lessons regarding practice variation, communication failures and unexpected patient clinical status. Duration of mechanical ventilation and length of CICU stay has improved.

O1458 - MULTICENTER VALIDATION OF THE VASOACTIVE VENTILATION RENAL SCORE AS A PREDICTOR OF PROLONGED MECHANICAL VENTILATION AFTER NEONATAL CARDIAC SURGERY

Christopher W. Mastropietro[1], *Katherine Cashen*[2], *Lisa M. Grimaldi*[3], *Keshava Murty Narayana Gowda*[4], *Kurt D. Piggott*[5], *Michael Wilhelm*[6], *John M. Costello*[7]
Riley Hospital For Children At Indiana University Health, Pediatrics, Indianapolis, In-United States[1]; *Children, Pediatrics, Detroit, Mi-United States*[2]; *Phoenix Children's Hospital, Pediatrics, Phoenix, Az-United States*[3]; *Cleveland Clinic, Pediatrics, Cleveland, Oh-United States*[4]; *The Heart Center At Arnold Palmer Hospital For Children, Pediatrics, Orlando, Fl-United States*[5]; *University of Wisconsin, Pediatrics, Madison, Wi-United States*[6]; *Ann & Robert H. Lurie Children's Hospital of Chicago, Pediatrics, Chicago, Il-United States*[7]

Objectives: We sought to validate the vasoactive-ventilation-renal score (VVR), a novel disease severity index, as a predictor of prolonged duration of mechanical ventilation (DMV) in a multicenter cohort of neonates who underwent cardiac surgery.
Methods: Neonates less than 30 days old who underwent cardiac surgery at seven institutions within the United States in 2015 were retrospectively reviewed. VVR is calculated as follows: VVR = ventilation index + vasoactive-inotrope score (VIS) + Δ creatinine [change in serum creatinine from baseline*10]. Prolonged DMV was defined as greater than 96 hours (ICD-10-CM procedure code 5A1955Z). Receiver operative characteristic curves were generated and the abilities of the VVR obtained at three time points - ICU admission and 6 and 12 hours postoperatively - and the peak value of these three measurements to correctly classify patients as having prolonged DMV were compared to other predictor variables using area under the curve (AUC) values. Multivariable logistic regression modelling was also performed.
Results: We reviewed 273 neonates. Median age at time of surgery was 7 days (interquartile range: 5-12 days). Eight-six (31%) had single ventricle anatomy. Prolonged DMV occurred in 89 patients (32%). AUC values for the VVR at each time point as predictors of prolonged DMV were significantly greater than values for the corresponding ventilation index, VIS, and lactate (Table). The VVR also outperformed STAT mortality category as a predictor of prolonged DMV (Table). On multivariable regression analysis, after adjustment for potential confounders, VVR measurements at each time point were independent predictors of prolonged DMV (Odds ratio for peak VVR: 1.08, 95% confidence interval: 1.04, 1.12).
Conclusions: In a multicenter cohort of neonates who underwent cardiac surgery, the VVR was a reliable predictor of postoperative DMV and outperformed more traditional measures of illness severity.

Table. Relationship between Predictor Variables and Prolonged Duration of Ventilation.

Predictor Variables	Median(IQR)	Maximum	AUC (95% CI)
STAT Mortality Category	4 (3-5)	5	0.66 (0.59-0.72)
Admission lactate (mg/dL)	3 (1.7-5)	13.1	0.68 (0.61-0.75)
6-hr lactate (mg/dL)	2.7 (1.6-4.1)	13.4	0.68 (0.61-0.75)
12-hr lactate (mg/dL)	2.2 (1.5-3.2)	11.6	0.66 (0.59-0.73)
Peak lactate (mg/dL)	3.7 (2.3-5.3)	13.4	0.69 (0.62-0.76)
Admission VIS	8 (5-11)	30	0.69 (0.62-0.76)
6-hr VIS	8 (5-11)	37	0.68 (0.61-0.75)
12-hr VIS	8 (5-12)	64	0.69 (0.62-0.75)
Peak VIS	10 (6-13)	64	0.70 (0.63-0.77)
Admission ventilation index	19 (15-25)	112	0.72 (0.66-0.79)
6-hr ventilation index	17 (13-22)	96	0.76 (0.70-0.83)
12-hr ventilation index	16 (12-21)	74	0.74 (0.67-0.80)
Peak ventilation index	21 (16-27)	112	0.78 (0.71-0.84)
Admission VVR	28 (22-38)	127	0.78 (0.73-0.84)
6-hr VVR	27 (21-34)	109	0.81 (0.75-0.86)
12-hr VVR	26 (20-33)	92	0.82 (0.76-0.87)
Peak VVR	31 (24-40)	127	0.82 (0.77-0.88)

[a]AUC: Area under the receiver operating characteristic curve; CI: confidence interval; IQR: interquartile range; STAT: Society of Thoracic Surgeons-European Association for Cardio-Thoracic
Surgery Congenital Heart Surgery mortality category; VIS: vasoactive inotrope score; VVR: vasoactive-ventilation-renal score.

[b]Patients extubated between 0 and 6 hours postoperatively (n = 4) were excluded from 6-hour and 12-hour analyses; patients extubated between 0-12 hours postoperatively (n = 8) were excluded from 12-hour analyses.

O1786 - RISK ADJUSTED VARIATION IN CICU PERFORMANCE AFTER PEDIATRIC CARDIAC SURGERY AN ANALYSIS OF THE PEDIATRIC CARDIAC CRITICAL CARE CONSORTIUM

Sarah Tabbutt[1], Janet Donohue[2], Wendy Zhang[2], Mounsumi Banerjee[2], Sara Pasquali[2], Jennifer Schuette[3], Jeffery Alten[4], Jeffery Jacobs[5], Ravi Thiagarajan[6], John Butcher[7], Nancy Ghanayem[8], Michael Gaies[2]

University of California San Francisco, Pediatrics, San Francisco-United States[1]; University of Michigan, Pediatrics, Ann Arbor-United States[2]; Johns Hopkins, Pediatrics, Baltimore-United States[3]; University of Alabama, Pediatrics, Birmingham-United States[4]; Johns Hopkins, Surgery, Tampa-United States[5]; Harvard, Pediatrics, Boston-United States[6]; Cincinnati Children's Hospital, Pediatrics, Cincinnati-United States[7]; University of Texas, Pediatrics, Houston-United States[8]

Background: Risk adjustment for patients undergoing congenital heart surgery is vital for comparative analyses, data transparency and public reporting. Current surgical mortality risk models focus on assessment at the time of surgery. We aimed to develop a mortality risk adjustment model to measure quality of cardiac intensive care unit (CICU) care after cardiovascular surgery, and to describe variation in performance across hospitals within the Pediatric Cardiac Critical Care Consortium (PC4).

Methods: We identified preoperative, intraoperative and variables from the first two CICU postoperative hours, which were felt to be independent of CICU management.

Variables associated with CICU mortality at $p < 0.1$ were included in a multivariable logistic regression with variables retained at $p < 0.05$. Bootstrap resampling (1000 samples) was used to derive bias-corrected confidence 95% intervals (CI) and model validation. A standardized-mortality-ratio (SMR; observed-to-expected mortality) was calculated for each hospital, and bootstrap resampling was performed again to derive the CI around the SMR estimate.

Results: The analytic cohort included 8,543 CICU admissions from 23 PC4 centers. Table 1 shows the results of the PC4 Surgical Risk Model. The model demonstrated good discrimination (C-statistic 0.92) and calibration (Hosmer Lemeshow X2 7.49, $p = 0.48$). Figure 1 demonstrates the SMR derived from the PC4 Surgical Mortality Risk Model organized by hospital CICU volume. There did not appear to be an association between hospital CICU volume and SMR.

Conclusions: The PC4 Surgical Mortality Risk Model is a novel risk-adjustment method that incorporates severity of illness variables inclusive of when care is transferred to the CICU following surgery; thus facilitating comparative analyses of CICU performance. For the first time, we report that variation in CICU performance exists across PC4 participating hospitals, with no apparent association between CICU volume and case mix adjusted survival.

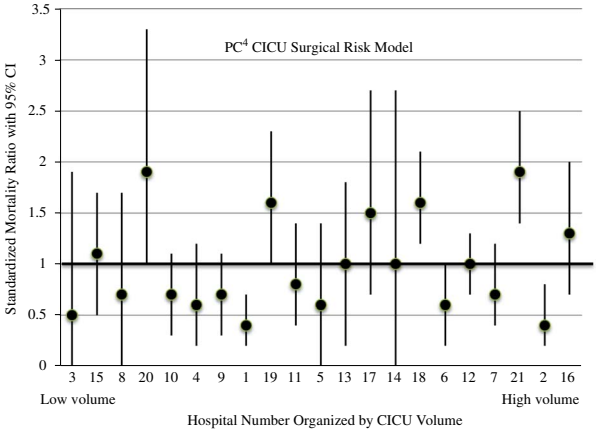

Figure.

Table.

PC[4] Surgical Risk Model

Risk Factor	Odds Ratio	p-value	95% bias corrected confidence interval
Age at surgery			
Reference: child			
Preterm neonate	4.62	<0.001	2.2 to 9.8
Term neonate	2.48	0.004	1.3 to 4.6
Infant	1.63	0.086	0.9 to 2.8
Adult	1.78	0.432	0.6 to 3.8
Any chromosomal abnormality or syndrome	1.58	0.013	1.1 to 2.3
Greater than two previous cardiac surgeries	3.05	<0.001	1.7 to 5.5
Any STS preoperative risk factor	2.13	<0.001	1.5 to 3.0
Preoperative ventilation (yes/no)	2.49	<0.001	1.8 to 3.5
STAT score	1.51	<0.001	1.3 to 1.8
On mechanical ventilation at postoperative hour two in the CICU	4.57	0.004	1.6 to 13
Maximum vasoactive index score during first two postoperative hours in CICU	1.02	<0.001	1.01 to 1.03
On ECMO during first hour following surgery in the CICU	15.88	<0.001	9.8 to 25.8

O2333 - EXTUBATION FAILURE IN INFANTS UNDERGOING PEDIATRIC CARDIAC SURGERY RISK FACTORS AND IMPACT ON OUTCOME

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Extubation failure contributes significantly to morbidity costs of care following pediatric cardiac surgery.
Objectives: To identify the risk factors for failure of planned extubation after pediatric cardiac surgery and examine its impact on surgical outcomes.
Methods: Consecutive pediatric (0-18 years) cardiac surgical cases (January 2014 - March 2016) were identified from the institutional database. Failed extubation was defined as reintubation within 72 hours of extubation. A multivariable logistic regression analysis was done to identify preoperative, operative and postoperative risk factors.
Results: Of 1280 children included, 120 (9.4%) had extubation failures. 11%(138) were <30days and 46%(569) were 30days-1year old. Primary causes were cardiovascular (65, 42%) which included systemic ventricular dysfunction(27), systemic valve regurgitation (7), pulmonary hypertension(11), residual lesions(10), tachyarrhythmias(5), and pulmonary edema(5). Respiratory causes (67, 43%) were extra thoracic upper airway obstruction(18), small airway obstruction(11), lung collapse(31), and ventilator associated pneumonia(7). Other causes (23, 14%) were sepsis(10), seizures(4), apnea(18), diaphragm palsy(2), pneumothorax(2), pleural effusion (1) and re-exploration(1). Preoperative variables associated with failed extubation were age <1year, emaciated appearance, < 5th percentile of body mass index for age, oxygen saturation <85%, prematurity, and associated chromosomal anomaly. Postoperative variables were low output state and sepsis. Pulmonary artery banding (27%), Ebstein's anomaly (40%), ALCAPA (22%) and arterial switch with VSD closure and aortic arch repair (33%) had the highest incidence of failed extubation. Length of ICU stay [373 vs. 116 hours, $p < 0.001$] and mortality was 6.7% vs. 2.4%, (p-0.015) was significantly higher in patients with failed extubation.
Conclusion: Failure of planned extubation of infants is not uncommon in pediatric cardiac surgery and is associated with higher mortality and length of ICU stay. The risk is higher in younger, malnourished, premature, hypoxic infants undergoing complex cardiac surgeries.

O2571 - IMPACT OF MALNUTRITION ON THE POSTOPERATIVE OUTCOME FOLLOWING PAEDIATRIC CARDIAC SURGERY

Kanagarajan Natarajan[1], Udaya Murmu[2], Selvakumar Ganesan[2], Giridhar Dhandayuthapani[2], Ravindra Satyanarayana[3], Benjamin Ninan[1]
The Madras Medical Mission, Cardiac Anesthesia, Chennai-India[1]; The Madras Medical Mission, Pediatric Intensive Care, Chennai-India[2]; The Madras Medical Mission, Pediatric Cardiology, Chennai-India[3]

Background: Malnutrition is a common cause of morbidity and mortality in children with CHD. Hypermetabolic state in the peri-operative period may increase the morbidity and mortality. We analysed the impact of malnutrition in 100 children who underwent heart surgery using cardiopulmonary bypass (CPB).
Materials: In a retrospective study, 100 malnourished children, who underwent open heart surgery with CPB included. 292 children were operated between January to October 2016. Patients were divided into two groups: Simple surgery (n = 32) and Complex surgery group (n = 68). Simple group included: ASD and VSD. Complex group included: TOF, dTGA, TAPVC, Truncus arteriosus, BDG shunt, and AV canal defect. Patients were divided into Grade I to IV based on the IAP classification. Simple group: Grade I- 13, Grade II- 09, Grade III-08, and Grade IV-08. Complex group: Grade I-19 , Grade II -18 , Grade III-23 and Grade IV-02. The outcome variables measured were: Duration of CPB time, Aortic cross clamp time, duration of ventilation, length of ICU, hospital stay and in-hospital mortality.
Results: Prevalence of malnutrition in our patient population was 34.24%.The age of the patients was ranging from one month to 5 years. In Simple group 37 children had mild to moderate malnutrition (Grade I&II) and 25 children were severely malnourished (Grade III & IV). In complex group 38 children had mild to moderate malnutrion while 24 children were severely malnourished. In both groups, children with severe malnutrition required longer duration of mechanical ventilation (>72 hours) compared to children with lesser grades of malnutrition (Simple group – 9% Vs 33%, Complex group – 10.8% Vs 28%).The length of ICU and hospital stay was higher in severely malnourished children.
Conclusion: The degree of malnourishment was associated with adverse outcome following pediatric cardiac surgery. Severely malnourished children had longer duration of ventilation, ICU and hospital stay.

O2694 - USE OF NEAR INFRARED SPECTROSCOPY TO PREDICT EXTUBATION OUTCOMES IN NEONATES AFTER CARDIAC SURGERY

Eleanor A. Gradidge[1], Lisa M. Grimaldi[2], Katherine Cashen[3], Kashava Murthy Narayana Gowda[4], Kurt D. Piggott[5], Michael Wilhelm[6], John M. Costello[7], Christopher W. Mastropietro[8]
Phoenix Children, Critical Care, Phoenix-United States[1]; Phoenix Children, Cardiovascular Intensive Care, Phoenix-United States[2]; Children, Critical Care, Detroit-United States[3]; Cleveland Clinic, Pediatric Critical Care, Cleveland-United States[4]; Heart Center At Arnold Palmer Hospital For Children, Pediatric Cardiac Intensive Care, Orlando-United States[5]; University Of Wisconsin, Pediatric Cardiac Intensive Care, Madison-United States[6]; Ann And Robert H. Lurie Children, Cardiology And Critical Care Medicine, Chicago-United States[7]; Riley Hospital For Children, Critical Care, Indianapolis-United States[8]

Background/Hypothesis: Near infrared spectroscopy (NIRS) is used at many centers to monitor tissue perfusion after neonatal cardiac surgery. We hypothesized that an increase in NIRS values would predict extubation success in a multi-center cohort of neonates following cardiac surgery.
Methods: We conducted a secondary analysis of data collected prospectively in a study of neonates (≤ 30 days) who underwent cardiac surgery at seven tertiary care institutions in the United States in 2015. Baseline (i.e., in the operating room before surgery) and pre-extubation cerebral or renal NIRS values were analyzed. Extubation failure was defined as need for reintubation within 72 hours. NIRS measurements in neonates who extubated successfully were compared to neonates who failed extubation using student t-tests, as well as multivariate logistic regression analysis.
Results: We reviewed 283 neonates, of whom 159 had baseline and pre-extubation NIRS values recorded: 133 had cerebral and renal values, 16 had only cerebral values, and 10 had only renal values. Median age at time of surgery was 6 days (range: 1-29 days); 52 (33%) neonates had single ventricle anatomy. Fifteen (9.4%) neonates failed extubation. Baseline cerebral and renal NIRS values were not statistically different between successfully extubated neonates and neonates who failed extubation. Pre-extubation cerebral and renal NIRS were significantly higher in neonates who extubated successfully compared to those who failed extubation (Table). At the time of extubation, an increase in cerebral NIRS ≥ 5% from baseline had a positive predictive value of 98.6% (95% CI: 91.1%-99.8%) for extubation success. On multivariable analysis, an increase in cerebral NIRS by ≥ 5% was independently associated with extubation success (odds ratio 8.9, 95% CI: 1.1-73.2).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Increase in NIRS values predicts extubation success in neonates following cardiac surgery. NIRS may be a helpful, non-invasive adjunct to extubation readiness assessment. Further study is warranted.

Table. Cerebral and Renal Near Infrared Spectroscopy (NIRS) Measurements.

Cerebral NIRS	Extubation Success (n = 136)	Extubation Failure (n = 13)	*p*-value
Baseline	66 ± 14	67 ± 15	0.72
Pre-extubation	70 ± 13	62 ± 12	**0.04**
Δ NIRS†	4 ± 15	-5 ± 14	**0.04**
Renal NIRS	**Extubation Success (n = 128)**	**Extubation Failure (n = 15)**	***p*-value**
Baseline	63 ± 14	63 ± 14	0.98
Pre-extubation	75 ± 14	66 ± 13	**0.02**
Δ NIRS†	12 ± 18	3 ± 20	0.09

†Δ NIRS: Baseline minus pre-extubation NIRS.

O3008 - RISK FACTORS FOR SEIZURES IN NEONATES FOLLOWING SURGERY WITH CARDIOPULMONARY BYPASS

Maryam Naim[1], J. William Gaynor[2], Rui Xiao[3], Jodi Chen[1], Andrew Costarino[1], Susan Nicolson[1], Stephanie Fuller[2], Christopher Mascio[2], Thomas Spray[2], Stephen Kimmel[4], Daniel Licht[5], Nicholas Abend[5]
Children, Anesthesiology, Critical Care Medicine and Pediatrics, Philadelphia-United States[1]; Children, Surgery, Philadelphia-United States[2]; University of Pennsylvania, Biostatistics and Epidemiology, Philadelphia-United States[3]; The University of Pennsylvania, Medicine, Biostatistic and Epidemiology, Philadelphia-United States[4]; Children, Pediatrics, Philadelphia-United States[5]

Objective: Neonates undergoing surgery with cardiopulmonary bypass (CPB) are at risk for seizures. Following implementation of routine postoperative continuous electroencephalography (CEEG), we reported an 8% seizure incidence of which 85% were exclusively subclinical. Determination of risk factors for post-operative seizures will help target CEEG resources.
Methods: We performed a retrospective chart review study of neonates who underwent surgery from June 2012 to December 2015 to identify electrographic seizure predictors using logistic regression. Receiving operator curve (ROC) characteristics assessed model performance.
Results: 386 of 398 (97%) of postoperative neonates were monitored with CEEG. 31 (8%) had postoperative seizures. Seizures started at a median of 29 hours (IQR 29,37) after return from the operating room (OR). Seizures were EEG-only in 28 (90%), and constituted status epilepticus in 13 (42%). Mortality was higher with (8/31, 26%) than without (22/335, 6%) seizures ($p < 0.0001$). Univariable analyses (Table) identified seizure predictors: gestational age, delayed sternal closure, deep hypothermic circulatory arrest duration, CPB duration, ECMO in the OR and cardiac arrest in the OR. On multivariable analysis (Table), gestational age <38 weeks and CPB duration >60 minutes were significant risk factors for postoperative seizures. The area under the ROC curve for this model was 0.74. If a cut-point determined by optimal model sensitivity and specificity then 291 of 386 (75%) would have been selected to undergo CEEG monitoring, and 3 of 31 (10%) with seizures would not have been identified (sensitivity 90%, specificity 26%). The 8% seizure incidence would yield a positive predictive value of 10% and negative predictive value of 97%.
Conclusion: Postoperative seizures occurred in 8% of neonates following surgery with CPB. Risk factors for seizures were gestational age <38 weeks and CPB duration >60 minutes. However, since the current model only has fair performance, development of a more robust seizure prediction model is warranted.

Table. Eleclrographic seizure predictors.

*A gestational age cutoff of 38 weeks was used in the multivariate analysis.
**Cardiopulmonary bypass duration >60 minutes was used in the multivariate analysis.
***ECMO and cardiac arrest in the OR were used as these events occurred before monitoring was initiated.

INTERVENTIONAL CARDIOLOGY

O1051 - LONG TERM RESULTS AFTER IMPLANTATION OF AN UNRESTRICTIVE BABYSTENT IN THE INFANT POPULATION

Peter Zartner[1], Viktor Hraska[2], Boulos Asfour[2], Martin Schneider[1]
German Paediatric Heart Centre, Cardiology, Sankt Augustin-Germany[1]; German Paediatric Heart Centre, Cardiac Surgery, Sankt Augustin-Germany[2]

Rationale: All conventional stents suited for the implantation in newborns or infants have a maximum dilatable diameter below the expected growth of nearly all vessels in those patients. Either their use has to be avoided or later surgical removal is implicated.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Method: The Babystent (BS) is a premounted, balloon expandable metal stent of 6 mm diameter and 20 mm length. Due to its special design the stent struts will open up along the full length of the stent from a diameter of 10 mm on, so that there is no limiting upper diameter.
Population: Between 2010 and 2014, seventeen BS were implanted in 14 patients (mean age 4 months [1–14 months]. All but one stent were placed into the aortic isthmus for coarctation. One stent was used to enlarge the superior vena cava in a 6 months old after Glenn anastomosis. Redilations were performed in all patients between one and 7 times. One BS was falsely explanted by a surgeon not realising the nature of the BS. Summarized follow-up time is 47.2 patient years ranging from 2 to 6 years.
Results: Sixteen BS are still in place in 13 patients. Circumferential integrity is lost in 5 patients with redilations of minimal 10 mm. Mean BS diameter is 8.8 mm [7–12 mm]. None of the patients has received a different stent in the position where the BS was implanted, no related re-operation was necessary. Instent tissue proliferation was found early in 5 BS, but was considered mild. A small dissection occurred in one patient after redilation.
Conclusion: The BS shows good results in treating coarctations. Despite some intimal proliferation occurred, late proliferation was rare. The loss of the circumferential integrity of the BS does not necessarily lead to collapse of the stented area.

O1081 - SAFETY AND EFFICACY OF TRANSCATHETER CLOSURE OF OUTLET TYPE VENTRICULAR SEPTAL DEFECTS IN CHILDREN AND ADULTS WITH AMPLATZER DUCT OCCLUDERS

Hsin-Chia Lin[1], Ming-Tai Lin[2], Chun-An Chen[2], Jui-Yu Hsu[3], Su-Man Lin[4], Mei-Hwan Wu[2], Jou-Kou Wang[2]
National Taiwan University Hospital Yun-lin Branch, Pediatrics, Taipei City-Taiwan[1]; National Taiwan University Children, Cardiology, Taipei City-Taiwan[2]; Taipei Tzu Chi Hospital, Pediatrics, Taipei City-Taiwan[3]; Taipei Veterans General Hospital, Anesthesiology, Taipei City-Taiwan[4]

Background: The literature regarding transcatheter closure of outlet-type VSDs is scant.
Methods and Results: A retrospective chart review of patients with outlet-type VSD scheduled for transcatheter closure during October 2013 to November 2016 was performed at a children's hospital. Although 25 patients underwent catheterization, the intervention was abandoned in 3 because of moderate-to-severe aortic valve prolapse with aortic regurgitation (AR). Transcatheter closure was attempted in 22 patients and was successful in 20 (90.9%; 12 males and 8 females; mean [± standard deviation] age and body weight: 16.4 (± 16.0) years and 39.2 (± 24.3) kg, respectively). The median VSD diameter was 4.1 mm (range: 1.2–5.5 mm). ADO II (size range: range: 4–6 mm) was placed in 19 patients and ADO I (size: 8 mm) in only 1 patient. Device closure failed because the sheath could not be advanced through a retrograde or antegrade route in 1 patient and because the occluder dislodged in another patient. During a mean follow-up of 11.1 months (range: 1.4–25.7 months), 2 patients showed trivial-to-mild new-onset AR on echocardiography. Preprocedural mild AR disappeared in 4 patients. No heart block, or device failure occurred.
Conclusions: Transcatheter closure of outlet-type VSDs with Amplatzer duct occluders is feasible. Although no significant aggravation of AR was observed in the mid-term follow-up, long-term follow-up is mandatory.

O1123 - RIGHT VENTRICULAR OUTFLOW TRACT STENTING IN TETRALOGY OF FALLOT INFANTS WITH RISK FACTORS FOR EARLY PRIMARY REPAIR

Juan Pablo Sandoval[1], Rajiv Chaturvedi[2], Lee Benson[2], Gareth Morgan[3], Glen Van Arsdell[2], Osami Honjo[2], Cristopher Caldarone[2], Kyong-Jin Lee[2]
National Institute of Cardiology, Pediatric Cardiology, Mexico City-Mexico[1] Hospital For Sick Children, Pediatrics, Toronto-Canada[2] Children's Hospital Colorado, Pediatrics, Denver-United States[3]

Background: Tetralogy of Fallot (TOF) with cyanosis requiring surgical repair in early infancy, reflects poor anatomy, and is associated with more clinical instability and longer hospitalization than those who can be electively repaired later. We bridged symptomatic infants, with risk factors for early primary repair, by right ventricular outflow tract (RVOT)-stenting (Stent).
Methods and Results: Four groups of TOF with confluent central pulmonary arteries were studied: Stent (n = 42), primary repair (<3 months-old) with pulmonary stenosis (early-PS; n = 44) and atresia (early-PA; n = 49) and Surg > 3mo (3-11 months old) (n = 45). Stent patients had the smallest pulmonary arteries with a median [95% credible intervals] Nakata index (mm2 /m2) of 79 [66, 85] compared with the early-PA 139 [129, 154], early-PS 136 [121,153] and Surg > 3mo 167 [153, 200] groups. Only Stent infants required unifocalization of aortopulmonary collaterals (17%). Stent and early-PA infants were younger age and lower weight than earlyPS infants. Stent infants had the most multiple comorbidities. Stenting allowed deferral of complete surgical repair to an age (6 months), weight (6.3 [5.8, 7.0] kg) and Nakata index (147 [132, 165]) similar to the low-risk Surg > 3mo group. The 3 early treatment groups had similar ICU/hospital stays and high re-intervention rates in the first 12 months after repair, compared with the Surg > 3mo group.
Conclusions: RVOT-stenting of symptomatic TOF with poor anatomy (small pulmonary arteries) and adverse factors (multiple comorbidities, low weight) relieves cyanosis and defers surgical repair. This allowed pulmonary arterial and somatic growth with clinical results comparable to early surgical repair in more favourable patients.

O1411 - IMPLANTATION OF A NOVEL ATRIAL FLOW REGULATOR DEVICE IN SEVERE PULMONARY ARTERIAL HYPERTENSION

Sreeja Pavithran, Rajeshkumar Ramasamy, Ramyashri Chandrasekaran, Kothandam Sivakumar
The Madras Medical Mission, Department of Pediatric Cardiology, Chennai,-India

Background: Balloon atrial septostomy and atrial septal stenting are accepted modalities to enhance systemic cardiac output in severe pulmonary arterial hypertension (PAH) though the size of the atrial septal communication is unpredictable. An atrial flow regulator (AFR) device has been designed with varying sizes of fenestrations with the aim to provide a predictable atrial communication.
Materials andMethods: Patients with syncope and or right heart failure due to severe Idiopathic PAH were planned for AFR device implantation with 8 or 10 mm fenestration after transseptal puncture, as part of an investigational trial.
Results: 9 patients (two males) with severe Idiopathic PAH underwent AFR device implantation during June to December 2016. Age ranged from 15 – 39 years (median 30). All patients had history of syncope . All except one was in NYHA Class 3. All were receiving optimal pulmonary vasodilator therapy and were non-responders on vasodilatory testing. Fenestration size was 10 mm in

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

six patients and 8 mm in three. There were no procedural complications. Right to left shunt was demonstrated soon after implantation in all. Arterial oxygen saturation postprocedure ranged from 87 to 92% (mean 90).Mean cardiac output improved from 3.47 to 4.32 L/mt.All patients were maintained on antiplatelet agents. At follow up ranging from 2 days to 6 months, none had recurrence of syncope, right to left shunt was sustained in all. Mean six minute walk distance improved from 375 m to 427 m. All except one had reduction in the N terminal Pro BNP levels.
Conclusion: Atrial flow regulator device implantation is a novel and safe method of creating a predictable interatrial right to left shunt in patients with severe PAH and syncope. Long term follow up is needed to document the patency of the fenestration.

O1417 - PERCUTANEOUS CLOSURE OF PATENT DUCTUS ARTERIOSUS WITH THE NIT OCCLUD® PDA DEVICE IN 268 CONSECUTIVE CASES

Andrii V. Maksymenko[1], Yulia L. Kuzmenko[1], Arkadii A. Dovhaliuk[2], Oleksandra O. Motrechko[1], Nikolaus A. Haas[3], Anja Lehner[3], Illya M Yemets[4]
Ukrainian Children's Cardiac Center, Interventional Cardiology, Kiev-Ukraine[1]; P.l. Shupyk National Medical Academy of Postgraduate Education, Kiev-Ukraine[2]; Ludwig-Maximilians University, Pediatric Cardiology and Intensive Care, Munich-Germany[3]; Ukrainian Children's Cardiac Center, Cardiac Surgery, Kiev-Ukraine[4]

Background: We report our single-center experience with the pfm Nit-Occlud® coils for closure of patent ductus arteriosus (PDA).
Methods: From 08/2008 to 12/2015, 268 consecutive patients were admitted for transcatheter closure of a PDA with the pfm Nit-Occlud® coil. Clinical, echocardiographic and angiographic data were evaluated retrospectively.
Results: Median age at the time of the intervention was 5.2 years (range 5 month to 62 years and median weight was 19.3 kg (range 5.5 to 97 kg). 10 patients (3.7%) had a body weight <10 kg. The most common PDA types were type E and A, according to the Krichenko classification (44.4% and 33.2%). 12 cases were residual PDAs postoperatively (4.5%). Mean diameter at the narrowest point was 1.8 ± 0.8 mm (range 0.4 to 4 mm), mean size of the ampulla was 5.2 ± 2.7 mm (range 1 to 15 mm) and mean length was 9.2 ± 3.3 mm (range 2 to 25 mm). Mean pulmonary artery pressure before closure was 30.7 ± 4.4 mmHg (range 20 mmHg to 47 mmHg). Device implantation could be successfully achieved in all cases. Device sizes applied were 4 × 4 mm (17 pt) and up to 11 × 6 mm (21 pt). The 7 × 6 mm device was most commonly used (37.6%). Mean fluoroscopy time was 9.3 ± 7.3 min; mean stay in hospital was 3.4 ± 1.5 days. In one patient a second coil had to be placed. In a further patient with headache post-interventionally, MRI verified a minor ischemic stroke. Symptoms resolved completely during follow-up with 7 days of low-dose aspirin. No further adverse events occurred. Closure rates documented at 3-10 days, 3 month and 6 month post intervention were 95.1%. 97.6 and 98.4%, respectively.
Conclusion: Closure of PDAs with sizes up to 4x15 × 9 mm (min. diameter/ampulla/length) can be done effectively and safe using the Nit-Occlud® PDA device. 6-month follow-up showed an uneventful outcome and excellent closure rates.

O1433 - TRANSCATHETER CLOSURE OF PATENT DUCTUS ARTERIOSUS UNDER ECHOCARDIOGRAPHIC GUIDANCE

Jassim Abdulhamed[1], Atif Alsahari[2], Mashail Binobaidan[2], Khalaf Alkhalaf[2], Mohammed Al Issa[2]
Prince Sultan Cardiac Centre, Pediatric, Riyadh-Saudi Arabia[1]; Cardiac Centre, Pediatric, Riyadh-Saudi Arabia[2]

Background: Transcatheter closure of patent ductus arteriosus (PDA) is done in the cardiac catheterization laboratory, usually under fluoroscopic and angiographic guidance. The aortogram is used for assessing PDA size and shape pre-device implantation. Additionally, post-device deployment aortograms are applied for the assessment of device position, profile and residual shunt. Angiograms expose patient to radiation and possible untoward effects of contrast media. Recently, transthoracic echocardiography {TTE} has been utilized to guide in PDA closure to avoid radiation exposure, reduce the risk of arterial sheath insertion, as well as contrast material.
Material and Method: Forty six patients {30 Females and 16 Males} underwent TTE guided device closure of PDA between July 2013 and November 2016. Age range 4 months to 8 years and weighing 3.2-23 Kgs . In all the patients the procedure was performed under conscious sedation except one was intubated and ventilated. In 37 patients the procedure was performed transvenously and in 10 retrogradely.
Results: The device was successfuly deployed in all patients except in one the device was embolized to pulmonary artery but successfully retrieved and replaced by a bigger one. Flouroscopy time ranged between 2.2 and 13 minutes.
Conclusion: Transcatheter closure of PDA can safely and effectively be performed under TTE guidance, it can be completed transvenously or retrogradely , we prefer the transvenous approach so that we do not need to pass a sheath through the femoral artery.

O1649 - LONG TERM OUTCOME FOLLOWING PERCUTANEOUS CLOSURE OF ISOLATED SECUNDUM ATRIAL SEPTAL DEFECTS IN CHILDREN A FRENCH NATIONWIDE SERIES OF 1000 CONSECUTIVE PATIENTS

Zakaria Jalal[1], Lucia Mauri[2], Claire Dauphin[3], Celine Gronier[4], Sebastien Hascoet[5], Bruno Lefort[6], Mathias Lachaud[7], Caroline Ovaert[2], Alain Fraisse[2], Jean-benoit Thambo[1], Alban-elouen Baruteau[8]
University Hospital of Bordeaux, Congenital Heart Disease, Pessac-France[1]; University Hospital of Marseille, Congenital Heart Disease, Marseille-France[2]; University Hospital of Clermont Ferrand, Congenital Heart Disease, Clermont-France[3]; Strasbourg, Congenital Heart Disease, Strasbourg-France[4]; Centre Chirurgical Marielannelongue, Congenital Heart Disease, Le Plessis Robinson-France[5]; University Hospital of Tours, Congenital Heart Disease, Tours-France[6]; University Hospital of Nantes, Congenital Heart Disease, Nantes-France[7]; Royal Brompton Hospital, Division of Cardiology, Department of Pediatrics, London-United Kingdom[8]

Introduction: Transcatheter closure has become the preferred treatment strategy in most cases of isolated, secundum atrial septal defect (ASD). Although widely used, data on long-term outcomes in the pediatric population are scarce. We aimed to assess procedural characteristics, early clinical outcome, long-term device-related complications and the electrical remodeling after transcatheter closure of isolated ASD in children.
Methods: A 1998-2014 retrospective multicentre study was performed at 8 French tertiary institutions, including all patients <18 yo who attempted a percutaneous ASD closure with an Amplatzer Septal Occluder.
Results: 1000 children [38% males, median age: 9 yrs (0.7-18.0), median weight: 27 kg (6-92)] were referred for transcatheter ASD closure. They all had a significant left-to-right shunting assessed by right ventricular dilation and/or a 1.5:1 Qp/Qs ratio; Median

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

ASD size was 15 mm in transthoracic echography (TTE). ASD closure was guided by fluoroscopy and transoesophageal echocardiography in 627 cases (62.7%) or TTE in 373 cases (37.3%). Procedural success rate was 94% with a median occluder size of 19-mm (4-40). Device placement was unsuccessful in 60 patients (6%) due to unfavourable anatomy in 38, early device embolization in 12 and other causes in 10 patients. Follow-up data were available for 829 patients. After a mean FU of 53 ± 31 months (range, 5–204), all patients were alive and 96% were asymptomatic. Long-term complications included supraventricular arrhythmias (n = 6) and pulmonary hypertension (n = 2). No cardiac erosion, late ASO dislodgement or stroke occurred.From an electrical standpoint, supraventricular arrhythmias occurred in 6 patients, no late atrioventricular block was observed and there was no significant difference between preprocedural and last follow-up ECG.
Conclusions: Our large-scale pediatric cohort confirms that transcatheter closure of isolated secundum ASDs is a safe procedure in children, with a favourable long-term outcome and no life-threatening delayed complication.

O1759 - FEASIBILITY OF TRANSCATHETER PULMONARY ARTERY BANDING AND LONG TERM OUTCOMES IN COMPARISON TO SURGICAL BANDING IN A SWINE MODEL

Abdul Khan, B. Rush Waller, Kim Allen, Lindsey Bird, Tom Fagan, Shyam Sathanandam
University of Tennessee, Lebonheur Children, Pediatrics, Memphis-United States

Background: There have been attempts to develop a transcatheter pulmonary flow restrictor (PFR) as an alternative to surgical pulmonary artery banding (PAB) without great success. We modified the Microvascular-Plug (MVP) to be used as a PFR. The objectives of this study were to demonstrate feasibility of transcatheter implantation and retrieval of this PFR, and compare long term PA growth whilst using the PFR vs. PAB.
Methods: The PFR was implanted in bilateral PA in 8-newborn piglets weighing 2.12-3.17 kg. A left PAB was placed via thoracotomy in 4 other newborn piglets (2.29-2.84 kg). Transcatheter retrieval of the PFR was performed after 3 weeks (4.6-5.6 kg) in 3-piglets, 6 weeks (9.4-10.6 kg) in 3-piglets and at 12 weeks (19.2-20.4 kg) in 2-piglets. Four piglets were sacrificed following PFR retrieval for histopathology. The rest were followed until 12 weeks to study PA growth. Debanding of PAB was performed at 6 weeks (8.1-11.4 kg). The surgical control piglets were recatheterized at 12 weeks (23.4-26 kg) to compare PA growth.
Results: The median time required for PFR implantation and retrieval were 40 and 90 minutes respectively. Immediately post-PFR implantation, the RV systolic pressure increased from a median of 20 mmHg to 51 mmHg (40-67 mmHg; $p < 0.001$). There was 75% endothelialization of the device by 6weeks. Retrieval of PFR was 100% successful at 3weeks, 75% at 6weeks and 50% at 12weeks. At 12 weeks, the LPA size in the PFR group and the PAB group were similar (median 8.6 vs. 8.4 mm, $p = 0.44$). There was grade-1 vessel injury immediately post-retrieval and none at 12weeks.
Conclusions: It was feasible to use the MVP as a PFR. Transcatheter retrieval of this device is possible before complete endothelialization. PA growth was not affected post-retrieval and is comparable to surgical PAB. This PFR has to be trialed in humans before recommending its routine use.

O1840 - STENT PLACEMENT FOR TREATMENT OF AORTIC COARCTATION IN CHILDREN UNDER 30 KG ACUTE AND LONG TERM OUTCOMES

Marcelo Ribeiro[1], Amanda Vicente[2], Vinícius Destefani[2], Rodrigo Costa[1], Simone Pedra[3], Daniela Kreuzig[3], Virgínia Santana[4], Carlos Pedra[1]
Instituto Dante Pazzanese De Cardiologia, Invasive Cardiology, São Paulo-Brazil[1]; Instituto Dante Pazzanese De Cardiologia,Fellow In Pediatric Cardiology, São Paulo-Brazil[2]; Instituto Dante Pazzanese De Cardiologia, Echocardiography, São Paulo-Brazil[3]; Instituto Dante Pazzanese De Cardiologia, Pediatric Cardiology, São Paulo-Brazil[4]

Introduction: The use of stents for aortic coarctation (CoAo) in children presents some challenges as limitations of vascular access and lack of published data regarding the reintervention. We sought to evaluate the safety, feasibility and effectiveness of these stents in children, with an emphasis on follow-up.
Methods: A retrospective analysis of children under 30 kg who had undergone stent placement for CoA between April/2009 and December/2015 was performed. Stents that can be expanded to larger diameters have been used. Demographic, clinical, hemodynamic and follow-up data were collected. The endpoints evaluated included: severe adverse events (SAE), persistent high blood pressure and need for reintervention.
Results: Thirty-seven patients (27 with native CoAo), with mean age and weight of 5.4 ± 3.4 years and 16.2 ± 7.0 kg were enrolled respectively. Immediately, the peak-peak gradient decreased from 33.7 ± 15.1 to 5.4 ± 5.3 ($p < 0.01$) and the ratio of CoA diameter/Descendent Aorta increased from 0.40 ± 0.16 to 1.0 ± 0.20 ($p < 0.01$). There were no deaths or immediate SAE. Thirty-four patients were followed during a mean period of 43.1 ± 19.4 months, using echocardiography and computed tomography of aorta. Five patients still needed antihypertensive drugs. Seven patients required percutaneous reinterventions (36.1 ± 19.0 months after initial treatment) due to aortic aneurysm (1), residual stenosis above the stent (1) and adjustment to somatic growth (5). One patient required surgery due to residual hypoplasia of aortic arch (15.1 months later). Freedom of all reinterventions was 95%, 78%, 54% and freedom of balloon dilations was 95%, 81%, 81% in 12, 36 and 60 months, respectively. All of reinterventions have been carried out successfully, with no SAE.
Conclusion: Stenting for treatment of CoAo in children was feasible, safe and effective. A significant rate of reintervention was observed mainly due to the anticipated need for stent diameter adjustment to the somatic growth. However, continuous surveillance for arch hypoplasia and aneurysm formation is advisable.

O1852 - PROSPECTIVE STUDY ON PATENT DUCTUS ARTERIOSUS STENTING IN CYANOTIC CONGENITAL HEART DISEASE WITH DUCTUS RELATED BRANCH PULMONARY ARTERY STENOSIS

Marhisham Che Mood, Mazeni Alwi, Hasri Samion, Haifa Abdul Latiff, Anu Ratha Gopal, Putri Yubbu, Johan Aref Jamaluddin
National Heart Institute, PCHC, Kuala Lumpur-Malaysia

Ductus-related branch pulmonary artery (PA) stenosis is common in cyanotic congenital heart disease (CHD). Ductal stenting is not recommended for concerns of jeopardizing growth of the affected branch. This however has not been based on extensive evidence.
Objective: To study PA growth in duct-dependent cyanotic CHD with branch PA stenosis following ductal stenting.
Methods: Prospective, non-randomized study. Inclusion criteria: Patients with duct-dependent pulmonary circulation age

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

<3 month. Pre-procedure CT Angiogram (CTA) was performed for morphologic evaluation of PDA and PA. Ductal stenting was performed in all patients except in those with severely tortuous PDA. PA growth was monitored by CTA at 3 months and cardiac catheterization at 9 months. Affected branch PA (P1) and contralateral PA (P2) were measured. P1/P2 ratio was calculated.
Results: Between February 2014 to May 2015, 34 patients underwent PDA stenting, 16 via transfemoral artery approach (47.1%), axillary artery in 12(35.3%), transvenous in 5(14.7%). 26 (75.5%) had LPA stenosis, 5(14.7%) RPA stenosis. 28 had CTA evaluation at 3 months and 25 had catheterization at 9 months. At presentation, P1 was 3.5 + 3.0mm (Z score -1.48) and P2 4.6 + 3.6mm (Z score -0.31) respectively, P1/P2 ratio 0.7. At 9 months, P1 was 7.3 mm (Z score +1.68) and P2 9.7 mm (Z score +2.84), P1/P2 ratio 0.8. 3 patients required rescue Blalock-Taussig shunt due to compressed stents and 1 stent thrombosis. 2 stents redilated for in-stent stenosis. There were no deaths and no stent migration. 13 underwent corrective surgeries and 6 underwent palliative cavopulmonary shunt.
Conclusions: Ductal stenting in ductus-related branch PA stenosis results in satisfactory growth of PA despite jailing of an affected branch. This is a viable alternative to surgery for the early palliation of duct-dependent cyanotic CHD. However close monitoring is required and further studies are warranted.

O1907 - EVALUATION OF CENTRAL PULMONARY ARTERIES GROWTH FOLLOWING PDA STENTING IN PATIENTS WITH DUCT DEPENDENT PULMONARY CIRCULATION

Hala Elmarsafawy[1], *Fatma Aboalsoud Taha*[2]
Children Hospital, Mansoura University, Pediatric Cardiology, Mansoura-Egypt[1]; *Tanta University, Cardiology, Tanta-Egypt*[2]

Background: If stent is implanted in arterial duct,it may result in better angle between PDA and pulmonary arteries, allowing for improved growth.
Aim of Work: evaluate ability of PDA stenting to promote pulmonary arteries growth in patients with congenital heart diseases-duct dependent pulmonary (CHD-DDP) circulation.
Methods: 58 patients with CHD-DDP who had PDA stenting 2009-2016 in Mansoura and Tanta University children Hospitals underwent evaluation of pulmonary arteries (within 6 -12 months post stenting).
Results: PDA stenting was successful 49/58 (84.5%) patients; 31 males (63.3%) 18 females (36.7%) mean age 13.5 ± 10.4 days, mean weight 2.9 ± 0.5 kg.22 (44.9%) patients had complex CHD-DDP, 14 (28.6%) PA/IVS, 13 (24.5%) PA-VSD. Prestenting, presecond stage measures were compared.oxygen saturation increased 67.1 ± 8.0 to 81.2 ± 8.0 (P <0.001*). RPA increased 0.36 ± 0.05 to 0.60 ± 0.11, P <0.001 *(Z-1.23 ± 0.91 to 0.18 ± 0.81 (P <0.001*) LPA increased 0.34 ± 0.06 to 0.58 ± 0.10, P <0.001* (Z-1.13 ± 0.86 to 0.48 ± 0.97, P <0.001*). Nakata index increased 108.89 ± 33.53 to 183 ± 48 ± 40.58 mm^2/m^2 (P < 0.001*)
Conclusion: PDA stenting is effective in promoting global and individual pulmonary artery growth in CHD with duct dependent pulmonary circulation. It ensures uniform balanced distribution and growth of pulmonary arteries.

O2076 - PERCUTANEOUS CLOSURE OF ATRIAL SEPTAL DEFECT USING NIT–OCCLUD® ASD–R LONGTERM RESULTS

Alexandra Heath[1], *Inge Von Alvensleben*[1], *Joaquin Navarro*[2], *Gabriel Echazu*[2], *Rainer Kozlik-feldmann*[3], *Silvia Ureña*[2], *Franz Freudenthal*[1]
Kardiozentrum, Pediatric Cardiology, La Paz-Bolivia[1]; *Cmqbb, Pediatric Cardiology, Cochabamba-Bolivia*[2]; *Uni Hamburg, Pediatric Cardiology, Hamburg-Germany*[3]

Background: Ancient weaving technique inspired the development of closure devices for congenital heart diseases.
Aim: To assess clinical efficacy and safety of Nit–Occlud® ASD–R in the percutaneous closure of secundum atrial septal defects (ASD). Background: ASD is 2.3 times more frequent at high altitude. Percutaneous ASD closure has been demonstrated to be safe and effective with many potential benefits over surgical closure.
Methods and Results: Retrospective, observational study of patients treated with the Nit–Occlud® ASD–R between May 2007 and March 2011. Fortynine out of 53 patients underwent successful device closure of ASD. The median age at closure was 11 years (range 3–67) and the mean weight was 27,1 kg (range 13–75). Sixtynine per cent of patients were females. The mean fluoroscopy time was 14 minutes (range 5–53). The mean procedure time was 70 minutes (range 45–150). The mean defect size measured by the stop –flow technique was 17,8 mm (range 5.6–31) with, the mean size of the implanted device being 18 mm (range 6–28), 1.0 times the defect size. Patient follow up up to Dezember 2017 ranged from 67 to 113 months, median 87 months. Immediate closure was observed in 71.4% of the cases, with 91.7% closure after 24 hours, 93.7% after 1 month, 95.8% after 3 months and 100% after 6 months. Device embolization occurred in one patient within 24 hours requiring surgical device removal. There were no other major complications including death in the follow up time.
Conclusions: Our experience with the NitOcclud® ASD–R device demonstrates it to be safe and highly effective with very.

O2110 - TRANSCATHETER CLOSURE OF THE PATENT DUCTUS ARTERIOSUS IN PREMATURE INFANTS IS AN EFFECTIVE ALTERNATIVE TO VIDEO ASSISTED THORASCOPIC SURGICAL CLOSURE

John Breinholt[1], Elizabeth Wang[1], Chandra Srinivasan[1], William Douglas[2]
University of Texas Health Science Center at Houston, Pediatrics, Houston-United States[1]; University of Texas Health Science Center at Houston, Pediatric Surgery, Houston-United States[2]

Background: Patent ductus arteriosus (PDA) closure in premature infants has been primarily surgical. Transcatheter closure provides a less invasive alternative. Video-Assisted Thorascopic Surgery (VATS) and transcatheter PDA closure in premature infants are compared.
Methods: Medical records of premature infants under 3 kilograms, with VATS or transcatheter PDA closure from 1/2012 to 1/2017, were reviewed. Procedural details, complications, and short-term outcomes were compared.
Results: Patient data and results are presented in Table 1. Thirty-five infants underwent VATS; Twenty infants underwent transcatheter closure with a Medtronic Microvascular Plug (n = 16) or Amplatzer Vascular Plug II (n = 4), deployed prograde via a 4 F delivery system, without arterial access. Patients of each group were of similar age, but weighed less at time of surgery. Complete PDA closure was achieved in all patients except one VATS patient with a small residual shunt 70 days after surgery. Procedural complications for VATS included: 3 with vocal cord dysfunction; and 1 each with peri-procedural cardiopulmonary resuscitation, chylothorax, and post-operative hypertension. No acute procedural complications occurred in the catheterization group. One transcatheter device embolized 9 days after deployment and was successfully retrieved and another implanted. Fewer complications occurred in the catheterization group. Time to extubation and discontinuation of respiratory support was similar. Tracheostomy was performed in 2 VATS patients and 1 catheterization patient. Surgical patients were more likely to be discharged on home oxygen therapy. There were 3 deaths in the VATS group, with none attributed to the procedure.
Conclusions: Transcatheter device closure of PDAs offers a successful and less invasive alternative to surgery in premature infants with fewer complications. Extubation and freedom from respiratory support were comparable to VATS, nevertheless, fewer patients required home oxygen at discharge. Transcatheter closure warrants further study and development.

Table.

	Catheterization	Surgery	p-value
Gestational age (weeks)	27.3 (23-35.6)	25 (23.4- 36.3)	0.07

O2111 - CHALLENGES OF DEVICE CLOSURE OF PATENT DUCTUS ARTERIOSUS WITH PULMONARY ARTERY HYPERTENSION

Balekundri Vijayalakshmi
Pmssy, Super Speciality Hospital, Bengaluru Medical College and Research Institute, Cardiology, Bengaluru-India

Introduction: Transcatheter Device closure of patent ductus arteriosus (PDA) is treatment of choice. However device closure in presence of severe pulmonary artery hypertension (PAH) is challenging. But there is limited literature on patient selection, technical considerations, and complications of device closure in patients of PDA with severe PAH.
Aim: To know the challenges and evaluate techniques for feasibility, efficacy of device closure of PDA with severe PAH.
Materials and Results: Out of 1,695 cases of device closure of PDA, 296 (17.5%) with PAH formed material for this study. To test the feasibility of device closure by occlude PDA with the appropriate device, instead of balloon for ten minutes without oxygen inhalation. The device was released only if PAH(especially mean pressure) reduced. PAH decreased in all except in 1 patient after closure with muscular ventricular septal occluder (MVSDO), pulmonary artery pressure (PAP) transiently increased (became suprasystemic), without significant reduction in aortic pressure. Device embolized in 10 patients (3.4%). Percutaneous retrieval was done in 5 (by snare in 3 and by fixing the cable to device in 2) and replaced with bigger devices. The surgical removal of the embolized MVSDO and ligation was done in 5 cases. All patients were on oral sildenafil and bosentan until PAP regressed to normal. Follow up was from 6 months to 9 years. No residual shunt in any patient on follow-up. The PAP regressed to normal in all except 5 cases (2.03%) of Down's syndrome with systemic PAP.
Conclusions: Device closure of PDA with PAH is feasible, safe in all age groups. Temporary PDA occlusion with device is effective and time saving for evaluating pulmonary vascular reactivity. Device embolization in aorta is higher with severe PAH. Novel method of retrieval is effective.

O2115 - PERCUTANEOUS TRANSCATHETER CLOSURE OF ATRIAL SEPTAL DEFECT ONLY UNDER THE GUIDANCE OF TRANSESOPHAGEAL ECHOCARDIOGRAPHY IN CHILDREN

Weize Xu, Qiang Shu, Jingjing Ye, Jianhua Li, Jiangen Yu
The Children, The Heart Center, Hangzhou-China

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Objective: To investigate the feasibility, safety and effectiveness of transcatheter closure of atrial septal defect (ASD) under the guidance of transesophageal echocardiography (TEE) in children.
Methods: From Nov.2014 to Aug. 2016, 129 cases of children undergoing percutaneous transcatheter closure of atrial septal defect received the procedure completely guided and monitored by TEE. After 3 month of the operations, patients were followed up by conducting transthoracic echocardiography.
Results: 129 cases were identified by TEE as having atrial septal defect, The diameter of ASD was 3~24mm, the median was 9.52±4.12mm, the diameter of the Amplatzer occluder was 6~ 32mm, the median was 14.19±4.60 mm.Immediate post-operative check by TEE and during the follow-up by TTE, there were no complications such as occluder displacement, valvular injury, peripheral vascular injury and pericardial effusion. Residual shunt about 1.7mm was documented in a 2 holes patient and self-healed after 1 month. Residual shunt about 3 mm in another multiple holes patient existed during follow-up.
Conclusions: Percutaneous transcatheter closure of atrial septal defect completely guided by TEE is safe and effective. The advantages of high success rate, low complication rate and reasonable price make it easy to promote in children.

Figure 1.
Operating in the OR only under the guidance of Echo, no DSA, no X-Ray.

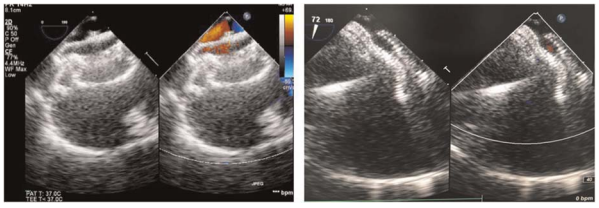

Figure 2.
The interval rim between two holes was 8.3 mm, two Amplatzer occluders were implanted, only under the guidance of Echo.

O2156 - CHEATHAM PLATINUM COVERED STENT IN AORTIC COARCTATION 13 YEARS SINGLE CENTER EXPERIENCE AND FOLLOW UP

Gianfranco Butera[1], Claudio Bonanno[1], Luciane Piazza[1], Massimo Chessa[1], Angelo Micheletti[1], Diana Negura[2], Carmelo Arcidiacono[1], Antonio Saracino[1], Domenica Basile[1], Alessandro Giamberti[3], Giuseppe Pomè, Mario Carminati[1], Alessandro Frigiola[1], Vlasta Fesslova[1]
Policlinico San Donato IRCCS, Congenital Cardiology, San Donato Milanese-Italy[1]; Policlnico San Donato IRCCS, Congenital Cardiology, San Donato Milanese-Italy[2]; Policlinico San Donato IRCCS, Congeital Cardiology, San Donato Milanese-Italy[3]

Background: Stent implantation is an effective therapy for aortic coarctation and recoarctation. Covered stent implantation may provide protection from potential complications. Here we report on our 13 years' experience with the use of covered Cheatham-Platinum (CCP) stents.
Methods: From January 2003 and January 2017, 122 patients with native (80 pts) or post-operative (42 pts) aortic coarctation were treated at our institution. At procedure median age was 16,5 years (range 6-68 years) and median weight was 58 Kgs (range 22-110 kg). The median gradient before the treatment was 40 mmHg (range 12-75 mmHg). Seventy-seven subjects had complex lesions (75.5%) while 25 patients had simple lesions (24.5%).
Results: Success rate was 95% (72,5% with a residual gradient <10 mmHg; 20,5% with a residual gradient between 10 and 20 mmHg). Mean coartaction gradient decreased from 39.7 to 5,7 mmHg ($p < 0.001$). Mean coarctation segment diameter increased from 5.7 to 13.4 mm ($P < 0.0001$). Incidence of early related-procedure adverse events was 8%. (lesion of external iliac artery, transient ischemia of left hand, transient femoral artery spasm, hyponatremia and convulsion). Two cases with aortic rupture after bare stent implantation or redilatation were treated. In both cases, covered stent implantation was used as a rescue option. At a median follow-up of 53 months (range 12-164 months) reintervention occurred in 21 patients (17%). Independent predictors associated with reintervention at follow up included the presence of complex lesions (P 0.0054) and ratio proximal aorta/coartaction (OR 1.06; CI: 1.01 -1.11, P 0.009). Anti-hypertensive medication was needed in 39 subjects (while it was needed in 102 subjects pre-procedure).
Conclusions: Covered stent implantation for aortic coarctation is a safe and efficacious treatment. Covered CP stents are rescue devices in case of aortic rupture.

O2351 - PERCUTANEOUS PULMONARY VALVE IMPLANTATION WITH SAPIEN VALVES IN NATIVE AND LARGE RVOT; EARLY AND MID TERM RESULTS

Ahmet Celebi, Ilker Kemal Yucel, Orhan Bulut, Sevket Balli
Dr Siyami Ersek Hospital For Cardiology, Pediatric Cardiology, Istanbul-Turkey

Introduction: We present early and midterm results of PPVI with Sapien valve in repaired tetralogy of Fallot (TOF) patients with native-large RVOTs.
Method: 62 s/p repaired TOF patients who had native RVOT with with free pulmonary regurgitation, significant dilatation of the RV and without significant RVOT stenosis. Balloon sizing was performed with compliant (34 mm Amplatzer sizing) for interrogation (BI). The size of the balloons that the Andra Stents XXL would be mounted on was decided up to the indentation diameter occurred during BI; as at least 1 mm larger than the indentation diameter.
Results: Mean age and weight of the patients were 17.7 (7-50) years and 42(22-90) kg, respectively. Before presenting mean pressure gradient between RV and MPA was 4.8 (0-10) mmHg. Mean indentation diameter with BI was 26.4(22-32) mm. Mean balloon size used for prestenting was 28.1(24-30) mm. Successful PPVI was achieved in all; 29 mm in 53 and 26 mm in nine. PPVI was performed in same session in seven and 3-12 weeks after prestenting in 55. In addition to RVOT stenting, stent implantation to branch pulmonary artery was performed in 13. There was no significant complication. Valve function was good in all immediate after and at the last follow-up; a median of 14 months (2-29 months). RV volumes decreased and mild paravalvar leakage was observed only in six. No reintervention required yet.
Conclusion: PPVI with Sapien valve, which has larger sizes as 26 and 29 mm, is feasible and safe in patients with native RVOT

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

without stenosis. Prestenting for providing a secure landing zone is the most important part of the procedure. Only Andra XXL stents which has an expansion capacity up to 32 mm can be used for this purpose, currently.

O2359 - TRANSCATHETER CLOSURE OF CORONARY ARTERY FISTULAS; SINGLE CENTER EXPERIENCE IN 9 YEARS PERIOD

Ahmet Celebi, Ilker Kemal Yucel, Orhan Bulut, Sevket Balli, Taliha Oner, Mehmet Kucuk
Dr.Siyami Ersek Hospital For Cardiology and Cardiovascular Surgery, Pediatric Cardiology, Istanbul-Turkey

Introduction: We present our experience with CAF's between 2007 and 2016.
Method: 29 patients aged between 2 months - 67 years (median 7 years) underwent to cardiac catheterization. The procedure was performed preferably with retrograde approaches if it is feasible, otherwise antegrade approach was used by establishment an AV loop.
Results: In 29 patients, angiograms demonstrated 31 fistulas arising from right coronary artery (RCA) (13), left anterior descending artery (8), circumflex artery (CX) (5), left main coronary artery (5). They were opening to right ventricle (14), right atrium (12), pulmonary artery (3), superior vena cava (1) and bronchial artery (1) with single (19) and multiple orifices (12). There were 7 fistulas with multiple feeding arteries. Transcatheter closure was not attempted since they were very small in six. In two patients with two separate fistulae, large one was closed and the other small ones were left untreated. Intervention was successful in all and realized with retrograde and antegrade way in 20 and 3, respectively. Complete occlusion was achieved in all. 8 coils, 14 vascular plugs (1, 2 and 4) and 4 duct occluders were used. A patient suddenly died four days later probably due to thrombosis in huge and slow filling coronary arteries since the reciprocal competitive flow after closure. There were huge dilated RCA and CX artery communicating with each other acting as multiple feeding arteries and opening into the RV. It was closed by a vascular plug just distal to the orifice. Other patients are well without recanalization during the median 41 months of follow-up.
Conclusion: CAF's may present in a great variety in morphology. It is not uncommon to see multiple feeding arteries and especially multiple distal openings. Effective and safe percutaneous transcatheter closure is possible in majority of cases but it is not free of complications.

O2479 - BRANCH PULMONARY ARTERY VALVE IMPLANTATION REDUCES PULMONARY REGURGITATION AND IMPROVES RIGHT VENTRICULAR SIZE FUNCTION IN PATIENTS WITH LARGE RIGHT VENTRICULAR OUTFLOW TRACTS

Athar M. Qureshi[1], Doff B. Mcelhinney[2], Younes Boudjemline[3], Nicola Maschietto[4], Shabana Shahanavaz[5], Richard A. Krasuski[6], Luke J. Lamers[7], Massimo Chessa[8], Bryan H. Goldstein[9], Matthew J. Gillespie[10]
Texas Children's Hospital, Cardiology, Houston, Tx-United States[1]; Lucile Packard Children's Hospital, Stanford, Cardiac Surgery, Palo Alto, Ca-United States[2]; Hospital Necker Enfants Malades, Cardiology, Paris-France[3]; Department of Women and Children's Health, Padova University, Cardiology, Padova-Italy[4]; St. Louis Children's Hospital, Cardiology, St. Louis, Mo-United States[5]; The Cleveland Clinic, Cardiology, Cleveland, Oh-United States[6]; American Family Children's Hospital, Cardiology, Madison, Wi-United States[7]; Irccs-policlinico San Donato - University Hospital, Cardiology, Milan-Italy[8]; Cincinnati Children's Hospital, Cardiology, Cincinnati, OH-United States[9]; The Children's Hospital of Philadelphia, Cardiology, Philadelphia, PA-United States[10]

Background/Hypothesis: Patients with large right ventricular outflow tracts (RVOTs) are excluded from available percutaneous pulmonary valve options using standard techniques. In some of these patients, percutaneous branch pulmonary artery (BPA) valve implantation may be feasible. However, the long term effects of valves in the BPA position is largely unknown.
Materials and Methods: Retrospective data from 10 international centers was collected on patients with significant pulmonary regurgitation in whom a percutaneous BPA valve was attempted.
Results: 22 patients, age 26 (13-58) years, weight 72 (26-147) kg underwent an attempt at percutaneous BPA valve implantation (14 unilateral and 8 bilateral). Melody valve implants were attempted in 18 patients and Edwards Sapien valves (all unilateral) in 4 patients. There were 2 failed attempts, with both patients eventually undergoing successful percutaneous valve implants (1 in a BPA and 1 in the native RVOT). Procedural complications occurred in 2 patients (wire related lung injury in 1 and pulmonary emboli in 1). Follow up echocardiography demonstrated no patient having more than mild regurgitation through the implanted valves with 50% of patients showing a reduction in right ventricular size. MRI data (11 patients) revealed a decrease in RVEDV index from 157 (103-429) to 90 (76-429) ml/m^2 ($p < 0.01$) and a decrease in RVESV index from 80 (41–387) to 47 (41- 347) ml/m2 ($p = 0.015$). At a follow up of 21 (1-91) months, NYHA functional class improved from 2.6 (+/- 0.9) to 1.7 (+/- 0.8), ($p < 0.01$), with 4 late deaths. One valve was surgically explanted due to endocarditis.
Conclusions: Percutaneous BPA valve implantation results in a reduction in RV volume with favorable clinical benefit in the intermediate term. Until percutaneous valves for large RVOT become widely available, this procedure remains an option for select patients.

O2522 - RADIATION IN CONGENITAL CARDIAC INTERVENTIONS ELEVEN YEARS OF EXPERIENCE IN A TERTIARY CENTRE.

Srinivas Ananth Narayan[1], Thomas Krasemann[2], Shakeel Qureshi[3], David Gallacher[4], Reza Razavi[2]
Kings College, Biomedical Engineering, Harrow-United Kingdom[1]; GSTT NHS Trust, Paediatric Cardiology, London-United Kingdom[2]; GSTT NHS Trust, Paediatric Cardiolgy, London-United Kingdom[3]; GSTT NHS Trust, Medical Physics, London-United Kingdom[4]

Background and Aim: Exposure to ionising radiation is one of the important adverse effects of cardiac catheterisation. Children are uniquely more susceptible to the potential carcinogenic effects as their tissues may be more sensitive (as they are actively growing) and they have many more years or life following the exposure for the effect to be seen. This study sought to report patient radiation dose across a range of interventional cases in a tertiary paediatric cardiac centre.
Method: All patients who underwent an interventional procedure in our supra-regional centre between 01/01/2005 to 31/12/2015 were identified from the Departmental electronic databases. Measures of radiation exposure including fluoroscopy (screening) time (minutes), DAP (Dose-area product) in cGy.cm2 (centigray. square centimetre) basic demographic data like patient's procedural age and weight, procedural type and type of interventional procedure were recorded in a custom-designed database.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

The effective dose (in milliSievert; mSv), was calculated using PCXMC software (v2.0, STUK, Helsinki, Finland).

Results: 3165 procedures were performed. Details in Table 1–3. For overall cohort, the median fluoroscopy time was 16 minutes (IQR 5–20 minutes), Median DAP was 203 (IQR 40 – 1100) cGy.cm2. The median Effective dose was 2.24 mSv (IQR 0.8 to 6.1 mSv ICRP 103). Overall, nearly 16% of the cases had DAP of more than 2000 cGy.cm2 of skin exposure. The Kruskal-Wallis test showed that there were statistically significant differences in all measures of radiation (Screening time, DAP and effective radiation dose) exposure across procedure types ($p < 0.0001$). Para valvar leak occlusion cases were associated with the highest median effective dose, followed by fenestration closure in Fontan and VSD occlusion.

Conclusion: This study provides a guide ranges for radiation dose and fluoroscopy time for common procedures. They serve as benchmarking tools and also provide a reference standard for which future dose reduction interventions can be compared.

O2568 - ANDRASTENT XL IMPLANTATION FOR THE TREATMENT OF COARCTATION OF THE AORTA IMMEDIATE AND MIDTERM RESULTS

Ahmet Celebi, Orhan Bulut, Ilker Kemal Yucel, Sevket Balli, Taliha Oner, Gökmen Akgun, Selma Oktay Ergin
Dr Siyami Ersek Hospital For Cardiology and Cardiovascular Surgery, Pediatric Cardiology, Istanbul-Turkey

Introduction: AndraStents are cobalt–chromium balloon expandable, hand mounted stents recently developed for large vessels. We will present our experience on AndraStents implantation for coarctation of aorta (COA).

Methods: Between 2012 and 2016, AndraStent XL were used in 34 patients for COA by hand crimping on BIB, Z-Med or Powerflex balloons.

Results: AndraStents XL were implanted in 34 patients, 23 with native COA and 11 with recurrent coarctation (after balloon angioplasty in seven, and after CP stent implantation in four). Middle aortic syndrome (MAS) was present in two. The median age was 11 years (5–30), and median weight was 38 kg (15–75 kg). Two of them weighed less than 20 kg (15 kg and 17 kg). All procedures were successful (no stent migration, aorta dissection or vessel injury). Two separate stents were implanted for MAS in two and implanted to transvers arc in one. The foreshortening percentages were found to be similar to those claimed by the manufacturer on fluoroscopic images. The vessel diameter was increased from a median 5.4 mm to a median of 12.3 mm, the systolic gradient across the aorta decreased from 35 mmHg before the procedure to 1.5 mmHg after the procedure. In a median 15 months follow up re-dilatation of stents was performed 12 months after only in a patient with MAS.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: AndraStents have several advantages over CP stents: Its material and design allow better tissue penetration and better curve, and a lower crimping profile. It can be used one Fr larger than the balloon shaft in lesions straight ways to reach such as CAO, so it can be used in patients less than 20 kg in weight. A relatively low radial force, tendency to slipping of the stent during the advancing in tortuous way and absence of covered form are disadvantages when compared with CP stents.

O2875 - PERIMEMBRANOUS VENTRICULAR SEPTAL DEFECT DEVICE CLOSURE CHOOSING BETWEEN ADOI AND ADOII

Amal El-Sisi[1], Rodina Sobhy[1], Victor Jacob[2], Hala Hamza[1]
Cairo University, Pediatric Cardiology, Cairo-Egypt[1]; Cairo University, Anaesthesia, Cairo-Egypt[2]

Background: Transcatheter closure of perimembranous ventricular septal defects (pmVSDs) is a well-established procedure. Recently, Amplatzer duct occluders (ADO) I and II have been reported to close large series of pmVSDs successfully. ADOs are economical compared with the standard Amplatzer VSD occluders; a major consideration in developing countries with low budget programs.
Aim of the Work: We report closure of symptomatic, hemodynamically significant pmVSDs using the ADOI and ADOII devices. Although there are no set criteria for choosing between ADOI and ADOII, the former's price tag includes snare and long sheath. Thus, we aim to predetermine device usage based on transthoracic echocardiography (TTE) findings.
Methods: Between March 2013 and November 2014, 30 patients had transcatheter closure of pmVSDs using the ADO devices. The median age was 4 years (range: 1.1-13 years) and median weight was 15 kg (range: 6.5-85 kg). ADOII could not be used in VSDs larger than 6 mm and/or with a large aneurysm. The median VSD size as assessed by echocardiography was 5.5 mm while the mean was 5.5 mm (range: 3-12 mm), while by angiography it was 5 mm & the mean was 4.75 mm (range: 3-9 mm).
Results: The median fluoroscopy time (FT) was 8 minutes (range: 5 -38 min). We inserted ADOI in 13 patients and ADOII in 17 patients (no significant difference between median age and weight in each group). VSD size was significantly larger and FT was longer in ADOI patients; the device type matched what was decided from TTE data in 84% of cases. Follow up ranged from 2-24 months (median12 months). The mean LVEDD z-score of the patients was 1.1 before VSD closure, while it was 0.63, 0.35 and 0.23 at the 1-month, 3-month and last follow up, respectively. Complete closure rates immediately, at 24 hours and

O2897 - SINGLE CENTER EXPERIENCE OF 65 FETAL AORTIC BALLOON VALVULOPLASTY

Joanna Dangel[1], Adam Koleśnik[2], Marzena Dębska[3], Romuald Dębski[3], Agnieszka Grzyb[2], Grażyna Brzezińska-rajszys[2], Monika Kowalczyk[2], Andrzej Kansy[4], Beata Rebizant[3], Bohdan Maruszewski[4]
Warsaw Hospice For Children Foundation, Referral Center For Fetal Cardiology, Warsaw-Poland[1]; Children, Cardiology Department, Warsaw-Poland[2]; The Center of Medical Postgraduate Education, 2nd Department of Obstetrics and Gynecology, Warsaw-Poland[3]; Children, Cardiac Surgery Department, Warsaw-Poland[4]

Background: Fetal cardiac interventions(FCI) have been established for changing the natural history of evolving HLHS or rescue fetuses. The national program for FCI started in June 2011, 88 interventions were performed since then.
Material and Methods: We performed 65 fetal aortic valvuloplasty (fBAV) in 60 fetuses. After 10 procedures under general anesthesia we switched to deep mothers' sedation and local anesthesia. Fentanyl and pancuronium was given into the umbilical vein, since 2013 atropine was added. There were 54 fetuses with evolving HLHS and 6 with severe heart failure, 5 hydropic.
Results: 62 procedures were technically successful (95%). In one fetus the valve was not crossed - it was aortic atresia with visible leaflets. In 5 fetuses the procedure was repeated after 1 to 3 weeks. There were 6(10%) fetal demise related to the procedure, 3 of them were hydropic. One fetus developed severe aortic insufficiency after the procedure and died 5 days later. 53 fetuses were live born, 2 of them very prematurely, related to the procedure. There were 3 late premature deliveries by planned CC occurred in different center. Two of those children died, one is on single ventricle pathway. Out of 48 fetuses delivered at term 14 had biventricular circulation (28% from live-born) and alive. 2 did not require any treatment during first 4 months of age. 4 had mitral stenosis with pulmonary hypertension, which made further steps very difficult. 21 alive after single ventricle pathway. There are 70% survivors from all live-born fetuses. Fetuses with border-line left ventricles were the most difficult group for treatment. Hybrid pathway with BV conversion was successful in 2, and failed in 4 fetuses.
Conclusion: fBAV is technically successful procedure, however still there are some unexpected complication. The result of fBAV is unpredictable. The treatment options in neonates and children after fBAV are difficult and complicated.

O2983 - FIRST MULTICENTER TRANSATLANTIC EXPERIENCE WITH THE NEW ULTRASEPT DEVICE FOR ATRIAL SEPTAL DEFECT PERCUTANEOUS CLOSURE.

Hospital De Santa Marta, CHLC, Serviço De Cardiologia Pediátrica, Área De Coração, Tórax E Vasos, Lisboa-Portugal[1]; Ignacio Chávez National Institute of Cardiology, Cardiology, Mexico-Mexico[2]; Hopitaux Universitaires De Geneve, Cardiology, Genève-Switzerland[3]; Centre Hospitalier Universitaire, Cardiology, Nacy-France[4]; Asklepios Klinik Schealmstadt, Cardiology, Schwalmstadt-Germany[5]; Hospital Papa Giovanni XXIII, Cardiology, Bergamo-Italy[6]; Ignacio Chávez National Institute of Cardiology, Pediatric Cardiology, Mexico-Mexico[7]; Hospital De Santa Marta, CHLC, Pediatric Cardiology, Lisboa-Portugal[8]

Background: The gold standard treatment for ostium secundum atrial septal defects (ASD) is percutaneous closure. Some concerns remain with the most commonly used devices, namely the inability to access trans-septally the left atrium, the risk of cardiac perforation and niquel content. We present the first-in-man multicenter experience with the 5th generation of the Ultrasept Atrial Septal Occluder Device, released in 2016.
Material and Methods: The Ultrasept is a self-centering, fully retrievable double-disk device that consists of a dual circular design nitinol frame covered with polyvinyl alcohol patches and additional central polyester patch. Its most advantageous features include the extremely low profile, the reduced metal mesh, the septal puncture friendly patch and the flexible and adaptable wire frame. We report a series of consecutive patients from six centers, from Europe and South America.
Results: 44 patients were catheterized with a mean age 11.2 ± 12.7years (min 2.6; max 48.6) and a mean weight 32.0 ± 22Kg (min 7.7; max 94.0). Using transesophageal echocardiogram, the maximal ASD diameter was 8.8 ± 3.1mm (min 5.0; max 15.0) and, with balloon-sizing, it measured 11.4 ± 3.5mm (min 6.0; max 19.5). The procedure was successful in all. The immediate residual shunt was trivial in 14/44, mild in 1/44 and none in the remainder 29/44. No patient showed device interference in venous drainage or valve function. In the 1 month follow-up visit, the closure rate was 100%. Patients were maintained with 6 months of antiaggregation therapy. At 6 months follow up, all patients remain asymptomatic, arrhythmia-free and without residual shunt.
Conclusions: Our current study showed that the new Ultrasept device has comparable short-term safety and efficacy to other commonly used devices and present additional favorable characteristics such as a an extremely low profile, atraumatic and soft device that is trans-septal puncture friendly and with low metal content.

NURSING

O1504 - CULTIVATING EXCELLENCE THROUGH NURSE EMPOWERMENT

Mary C. Mclellan[1], Kaitlin Doherty[2], Debra Morrow[1], Beverly Small[1], Annette Imprescia[1], Jason Thornton[1], Dorothy M Beke[1], Kathy Jenkins[1], Patricia Hickey[3]
Boston Children Hospital, The Heart Center, Boston-United States[1]; Boston Children, Iqic, Boston-United States[2]; Boston Children Hospital, The Heart Cente, Boston-United States[3]

Background: Nurse empowerment can improve patient outcomes through increased nurse retention, high levels of work engagement and innovative behaviors. Empowered nurses experience high motivation, less burnout and job strain, increased job satisfaction, more autonomy and greater respect than nurses in traditionally designed organizations [1–4]. In low-middle income countries, educational and cultural barriers preclude nurse empowerment. The International Quality Improvement Collaborative (IQIC) for Congenital Heart Surgery in Developing World Countries was created in 2007 to reduce mortality through: safe peri-operative practice, infection reduction and team-based practice through nurse empowerment [5].
Materials/Methods: There are currently 47 hospitals from 22 different countries enrolled in the IQIC. Sites participated in monthly didactic webinars designed to facilitate participatory learning, provide a collaborative learning experience, and adapted to individual needs of each center. Infection reduction modules introduced evidence-based nursing practice bundles and specific infection reduction components. Team-based practices focused on standardized communication tools and processes to promote nurse empowerment. Physician-nurse teams from each site oversee project management and quality improvement data collection entered into an IQIC database. Reports are provided to each site with their data and comparison aggregate collaborative data for annual benchmarking. Multidisciplinary IQIC teams conducted site visits for hospital tours, data audits, round table discussions and formal presentations to reinforce collaborative goals.
Results: Since 2010, 25 of the 92 webinars presented advanced nursing content at the request of participating sites. Fifteen nurses from various sites delivered presentations across four IQIC-sponsored international learning sessions. Posters at these sessions described seven, nurse based site initiatives. Two sites have effective nurse-lead infection control initiatives. Risk adjusted mortality and infections have significantly improved at participating IQIC sites [5,6].
Conclusions: Nurse empowerment after IQIC enrollment has been demonstrated by development of nursing leadership, autonomy, high levels of work engagement, innovative initiatives, and improved nurse-sensitive patient outcomes at IQIC sites.

O1516 - HEALTH RELATED QUALITY OF LIFE IN POST OPERATIVE CONGENITAL HEART DISEASE PATIENTS SINGLE CENTRE EXPERIENCE FROM PAKISTAN

Laila Akbar Ladak[1], Babar Hasan[2], Janice Gullick[3], Khadija Awais[4], Ahmed Abdullah[4], Robyn Gallagher[1]
Charles Perkins Centre, The University of Sydney, Sydney Nursing School, Sydney-Australia[1]; The Aga Khan University, Pediatrics and Child Health, Karachi-Pakistan[2]; The University of Sydney, Sydney Nursing School, Sydney-Australia[3]; The Aga Khan University, Medical College, Karachi-Pakistan[4]

Introduction: Health related quality of life (HRQOL) issues are common in postoperative Congenital Heart Disease (CHD) patients and often need intervention. There is paucity of data regarding HRQOL in CHD patients from low/middle income countries (LMIC). This mixed methods study conducted in Pakistan aims to provide HRQOL quantitative and qualitative data from CHD patients and their families.
Methods: CHD patients ($n = 140$) and their age matched healthy siblings as controls ($n = 140$), completed the PedsQLTM 4.0 Generic Core and PedsQLTM Cognitive Functioning Scale to determine HRQOL. CHD patients ($n = 22$) and their parents ($n = 20$) were interviewed to explore impact of CHD surgery, challenges and needs after surgery. Matched cohort was compared using t test, predictors were identified utilizing generalized linear model and qualitative data was interpreted through content analysis.
Results: Mean age of CHD patients was 9.98 ± 5.56 years, 68% were male, 50% had a university educated parent and 68% had income below LMIC poverty line. Majority ($n = 98$) had their first

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

CHD surgery at >1 year age and mean follow up time was 4.12 ± 1.92 years. Compared to controls, CHD patients had statistically and clinically significant lower HRQOL in all domains, with the worst HRQOL reported for the emotional domain (Table 1). HRQOL was higher in patients with better income, educated parents and an extended family, and lower in those who had longer cardiopulmonary bypass time, higher cardiac prognostic severity, higher RACHS score, re-operations and on cardiac medications. Patients and families highlighted "physical limitations" as their greatest concern; however, "emotional concerns" including "not being normal", "future uncertainty", "impaired family life" and "life-long care" were prevalent and complex.
Conclusions: HRQOL issues effect post-operative CHD patients in Pakistan, with the most disadvantaged being most effected. Solutions need to address the emotional impact on patients and lifelong concerns of parents.

Table 1. Differences in HRQOL – CHD versus Siblings

Domains	CHD Mean ± SD	Siblings Mean ± SD
*Physical	83.77 ± 19.11	98.86 ± 3.35
*Emotional	73.68 ± 17.59	92.46 ± 11.21
*Social	95.00 ± 10.96	99.07 ± 4.74
*School	86.47 ± 17.75	98.48 ± 4.54
*Psychosocial	84.92 ± 12.28	96.09 ± 5.87
*Total	84.66 ± 12.72	96.55 ± 5.31
*Cognitive	90.51 ± 18.27	96.9 ± 9.50

O1758 - EVALUATION OF CICU ADVANCED PRACTICE PROVIDER EDUCATION AND PRACTICE VARIATION

Lindsey Justice[1], Louise Callow[2], Rohit Loomba[3], Jennifer Harvey[4], David Cooper[1]
Cincinnati Children, CICU, Cincinnati-United States[1]; C.S. Mott Children, CICU, Ann Arbor-United States[2]; Children, Cardiology, Milwaukee-United States[3]; Lucille Packard Children, CICU, Palo Alto-United States[4]

Background: The education, training, and scope of practice of CICU advanced practice providers (APPs) is highly variable. A survey was administered to determine specific variations that leave gaps in competence.
Methods: A list of pediatric cardiothoracic surgery programs was generated from the STS database (N = 112). 8 institutions do not have APPs in the CICU/PICU, thus N = 104. A self-administered, electronic survey was delivered via email to 157 APPs at those institutions. 83 APPs responded (53% response rate), representing 36 institutions (35% of institutions).
Results: 65% of respondents started as new graduates. 93-100% obtain a history and physical, order/interpret labs, develop management plans, order/titrate medications and respiratory support. Ability to perform invasive procedures was highly variable but more likely for those in a dedicated CICU. 77% were oriented by another NP, with a duration of orientation <4 months (66%). 83% of APPs with <1 year of experience were oriented by another NP, but 50% of APPs with 7 or more years of experience were oriented by an attending physician. 50% of APPs had no guidelines in place to guide learning/competency during orientation. 67% were not evaluated in any way on their knowledge or skills during or at the end of orientation. Orientation was rated as poor/fair by the majority of respondents for electrophysiology (58%) and echocardiography (69%). 71% rated orientation as moderately effective or less. Respondents stated they would benefit from more structured didactic education with clear objectives, standardized management guidelines, and more simulation/procedural practice. 85% were very/extremely supportive of a standardized CICU APP curriculum.
Conclusions: Orientation for CICU APPs is highly variable, content depends on the institution/preceptor, and competency is not objectively defined or measured. A standardized curriculum is needed and is currently being developed.

O2100 - USE OF HIGH RISK PRECAUTION PROTOCOL TO REDUCE CARDIAC ARRESTS IN THE CARDIAC INTENSIVE CARE UNIT

Christine Riley[1], Evan Hochberg[2], Melissa Jones[1], John Berger[1], Darren Klugman[1]
Children's National Health System, Cardiac Critical Care, Washington DC-United States[1]; Children's National Health System, Performance Improvement, Washington DC-United States[2]

Background: Cardiac arrests in pediatric cardiac intensive care units (CICU) are associated with a significant increase in morbidity and mortality. A large multi-institutional cohort estimated overall post-operative arrest rate of 2.6%, arrest rates increased with procedural complexity to as high as 12.7% independent of center volume. Extracorporeal membrane oxygenation (ECMO) is often a rescue intervention during cardiac arrest (eCPR). Survival rate after eCPR is reported just over 50%, with only half of survivors having normal neurological status. Given the vulnerability of this patient population and the negative impact cardiac arrest has on morbidity and mortality rates; our primary aim was to assess the use of a bedside tool highlighting particularly vulnerable patients on arrest rates in the CICU.
Materials and methods: High Risk Precautions (HRP), an inter-professional bedside tool for CICU patients at high risk of cardiac arrest, was created to emphasize high patient acuity, create a framework for improved inter-professional communication, and formally limit nonessential cares and noxious stimuli during this vulnerable period. The tool was generated with medical and nursing team input, trialed, and rolled out to all staff. Patients meeting high risk criteria were placed on HRP.
Results: Forty one tools were collected and analyzed. In the 5 months following implementation of the HRP, we experienced a 38.95% reduction in average monthly rate of cardiac arrests in the CICU, and a 9.39% decrease in the average monthly rate of ECMO deployments. No patients arrested while on high risk precautions. These changes were made despite a high level of new nurse onboarding.
Conclusions: Early data suggest our methods were successful in deceasing arrest rates in the CICU by highlighting this subset of high risk patients, optimizing inter-professional communication regarding clinical goals, and formally limiting nonessential cares and noxious stimuli.

RHEUMATIC

O1244 - ECONOMIC LOAD OF PENICILLIN PROPHYLAXIS ON FAMILIES OF RHEUMATIC HEART DISEASE PATIENTS RESULTS FROM A PEDIATRIC RHD REGISTRY IN INDIA

Anita Saxena[1], S Ramakrishnan[1], Anurag Mehta[2], Dhruv Kazi[3]
All India Institute of Medical Sciences, Cardiology, New Delhi-India[1]; Ut Southwestern Medical Centre, Cardiology, Dallas-United States[2];

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Center For Healthcare Value, and Global Health Sciences University of California, Cardiology, San Fransisco-United States[3]

Introduction: Rheumatic heart disease (RHD) continues to be a public health problem in developing countries and cost is a major barrier to medication adherence in these regions. The economic impact of penicillin prophylaxis on families of RHD patients is not known.
Methods: We prospectively collected self reported data from the parents of RHD children recruited in the hospital based AIIMS Pediatric RHD Registry. The data included out of pocket expenses on, a) the drug penicillin, b) transportation to the health facility for injection, and c) the provider, for administering injection. We derived monthly estimates of all three categories of costs by adjusting visit costs for frequency of administration. All costs were reported in Indian Rupee (INR), 100 INR are equal to 1.5 US Dollar.
Results: The cost data was provided by 394 patients. The age of patients ranged from 5-18 years (11.5 ± 2.8), 256 (65%) were boys. Most patients were from rural areas (n = 346, 87.8%) and from lower and lower/upper lower socio-economic strata on the modified Kuppuswami socio-economic scale (n = 287, 72.8%). The total monthly out of pocket cost of penicillin prophylaxis was INR 74.7 ± 105.8. The drug cost represented only 33.2% of the total out of pocket costs (INR 24.8 ± 13.7). The cost of transportation to receive the injection (44.6%, INR 33.3 ± 104.9), and the cost of administration (22.2%, INR 16.6 ± 24.2) comprising the remainder of the total cost. The cost of injection provider and the cost of transportation to the health facility exceeded cost of the drug for 37.6% of the patients.
Conclusions: Two third of the total economic load of penicillin prophylaxis on families of RHD patients is constituted by transportation and provider costs. This can be a major barrier to long-term adherence to secondary prophylaxis. Future efforts must be directed at improving access and lowering total cost of secondary prophylaxis.

O1245 - CHANGING THE RHEUMATIC HEART DISEASE EXPERIENCE FOR CHILDREN IN UGANDA THE IMPACT OF A PEDIATRIC SUPPORT GROUP

Amy Scheel[1], *Andrea Beaton*[1], *Emmy Okello*[2], *Chris Longenecker*[3], *Isaac Otim*[4], *Peter Lwabi*[5], *Craig Sable*[1], *Allison Webel*[6], *Twalib Aliku*[7]
Children, Pediatric Cardiology, Washington DC-United States[1]; *Uganda Heart Institute, Cardiology, Kampala-Uganda*[2]; *Case Western Reserve University, Cardiology, Cleveland-United States*[3]; *Lira Regional Referral Hospital, Nursing, Lira-Uganda*[4]; *Uganda Heart Institute, Pediatric Cardiology, Kampala-Uganda*[5]; *Case Western Reserve University, Nursing, Cleveland-United States*[6]; *Gulu University, Pediatrics, Gulu-Uganda*[7]

Objective: To assess the impact of a peer-support group to improve knowledge, quality of life, and social support for children diagnosed with rheumatic heart disease (RHD).
Methods: Children from Gulu Municipality diagnosed with RHD and receiving monthly injectable penicillin were invited to participate in a monthly support group for 6 months. Pre- and post-intervention assessments included a baseline RHD knowledge assessment, a measure of pediatric health related quality of life (HRQOL) (PedsQLTM4.0), and a measure of pediatric social support (Hawthorne Friendship Scale). Each session incorporated elements of cooperative play and team building, RHD education, emotional support, and a snack. A short evaluation was used at each session to capture participant experiences.
Results: 42 participants returned parental consent, attended >3 support group sessions, and were included in the data analyses. The majority of participants had latent RHD (83%), identified through previous screenings. Attending support group meetings resulted in increased total pediatric HRQOL scores (60.3 v 70.2, $p < 0.001$), as well as the following pediatric HRQOL sub-scores (physical functioning 55.3 v 68.6 ($p < 0.001$), social functioning 64.2 v 75.8 ($p < 0.001$) and school functioning 59.2 v 69.1 ($p = 0.001$)). Additionally, significant increases in Friendship Scale scores (15.4 v 19.7, $p < 0.001$) and RHD Knowledge scores were observed (3.6 v 6.4, $p < 0.001$).
Conclusions: Peer support groups are effective at normalizing decreased HRQOL scores and increasing RHD disease knowledge and social support. Our findings suggest that peer support groups implemented in conjunction with RHD screening and clinical programs can minimize the negative psychosocial effects associated with early RHD detection.

Table.

	RHD Knowledge		Support Component	
Session	***Topics***	***Supporting material / Activity***	***Activity***	***Discussion starter***
1	N/A	Baseline RHD Knowledge Quiz	QOL and Friendship Scale assessment	N/A
2	Bacteria and strep throat: How one gets RHD and how it can be prevented	Group discussion on myths and fears surrounding RHD	Obstacle course in pairs (one partner is blindfolded led by verbal cues from the other)	Trust: How did it feel to trust someone you just met? Does this relate to your diagnosis with RHD?
3	The heart: anatomy, function and importance	Coloring activity: filling in a black and white image of the heart with red and blue crayons to represent blood flow through the heart	Hula Hoop pass: hold hands and then pass a hula hoop around the circle without unclasping partners hand	Challenges: what obstacles or "hoops" have you had to jump through because of your diagnosis with RHD?
4	The heart: How RHD affects anatomy and function. How RHD is diagnosed	1. Children listened to their own heart with stethoscope 2. Viewing of Echo images of affected Mitral and Aortic valves	Paper Plate Face Mask: create a mask that represents the strongest version of yourself	Feelings: How do you feel when others find out you have RHD? Do they treat you differently?
5	Treatment: the importance of monthly penicillin injections and routine follow ups	Group discussion on myths and fears surrounding penicillin injections	Penicillin Adherence key chains: children spelled out name in beads and then received a heart bead for being in the support group. At each penicillin clinic the children get a new bead to add to the chain	Monthly injections: How do you feel when you have to miss school for injections? Do you tell people where you are going?
6	N/A	Post-intervention RHD knowledge quiz	QOL and Friendship Scale assessment	N/A

O1889 - EPIDEMIOLOGY AND RISK FACTORS FOR CORONARY ARTERY LESIONS IN CHILDREN WITH INCOMPLETE KAWASAKI DISEASE IN SHANGHAI FROM 2008 THROUGH 2012

Fang Liu
Children, Cardiovascular Center, Shanghai-China

Objective: To analyses the epidemiological features of incomplete Kawasaki disease (IKD) in Shanghai from 2008 through 2012, and investigate the possible risk factors of coronary artery lesions (CAL) in IKD.
Subjects and Methods: This study used the epidemiological survey database of Kawasaki disease in Shanghai from January 2008 through December 2012. The diagnosis of IKD used the AHA diagnostic criteria for KD issued in 2004.
Results: A total of 2304 KD cases were recorded, of which 816 cases were classified as IKD (35.42%). The ratio between male and female was 1.51:1. IKD patients under 1 year of age accounted for the highest proportion (36.40%), and IKD was seen in a highest percentage of patients under 6 months of age (52.69%).There was no statistical difference between CKD and IKD patients in terms of the number of patients receiving IVIG, timing of initial IVIG, the dosage and administration of IVIG. the incidence of IVIG resistance in IKD patients (2.70%) was lower than that in CKD patients (5.71%) (P = 0.001). CAL were found in 90 IKD cases (13.60%) and 201 CKD cases (14.58%) (P = 0.135). The incidence of CAL in IKD infants under 6 months of age (18.36%) was significantly higher than that in other age group (9.01%, P = 0.002), and in these cases, the incidence of CAL was higher than that in CKD patients under 6 m (11.26%, P = 0.026). Risk factors for CAL in IKD patients include age, No. of principle clinical signs, ESR, ALB.
Conclusions: IKD accounts for as high as 35.42% in Shanghai from 2008 through 2012, especially in infants under 6 months, more than half of KD patients presents as incomplete KD. IKD babies less than 6 month have a significantly higher incidence of CAL either than IKD patients in other age groups or than CKD patients in the same age group.

O2036 - THE DIAGNOSIS OF MILD RHEUMATIC HEART DISEASE THREE REVEIWERS ARE BETTER THAN ONE

Elizabeth Tilton[1], Nicola Culliford-Semmens[1], Ross Nicholson[2], John Stirling[1], Rachel Webb[3], Nigel Wilson[1]
Starship Childrens Hospital, Paediatric Cardiology, Auckland-New Zealand[1]; Kidzfirst Hospital, Paediatrics, Auckland-New Zealand[2]; University of Auckland, Paediatrics, Auckland-New Zealand[3]

Background: The echocardiographic (echo) features of advanced rheumatic heart disease (RHD) are mostly unequivocally diagnostic of RHD. In contrast, echo screening for RHD predominantly detects milder forms of RHD. For logistical reasons, most screening studies have utilised a single echo reviewer to report echocardiograms. In New Zealand, we have used a 3 reviewer reporting system when practical. The aim of this study was to formally compare the rate of reporting agreement between 2 and 3 reviewers.
Methods: 144 de-identified echocardiograms of children from high prevalence RHD settings were classified by WHF 2012 guideline criteria. Cases included: mild RHD, those with mitral or aortic regurgitation at the upper limit of the physiological range, and congenital valvar abnormalities. Each echocardiogram was independently reported by two reviewers. If there was discordance of the diagnostic category between the two reviewers, a third reviewer reported the echocardiogram. If a 2/3 majority was not reached, an open review of the echocardiogram was undertaken by the three reviewers to reach a consensus (Figure).
Results: The final consensus classifications were Definite RHD (n = 18), borderline RHD (50), upper limit physiological regurgitation/normal (61) and congenital mitral or aortic valve anomaly (15). There was a 60% consensus agreement between the 2 reviewers. There was no significant differences of agreement for the different diagnostic categories, Chi-Squared p = 0.8104. Using 3 reviewers, majority agreement increased to 89%. 11% of cases required an open discussion. (Figure)
Conclusions: The potential variance of one or even two reviewers reporting abnormal echocardiograms of mild RHD is revealed by this study. A three reviewer reporting system is preferable if resources allow.

Introduction: Anecdotal evidence suggests a significant burden of Rheumatic Heart Disease (RHD) in Timor-Leste. We conducted the first echocardiography-based screening study to determine the prevalence of RHD in school-aged Timorese children. Additionally, we prospectively tested the utility of an abbreviated echocardiographic screening protocol limited to the parasternal-long-axis-view.
Methods: Students were enrolled from schools in urban and rural districts in Timor-Leste, using opt-out consent that was approved by ethics committees. All students underwent a full screening echocardiogram performed on a Vivid I or Q machine by cardiologists. Following the first parasternal-long-axis-view with 2-D and colour-Doppler, cardiologists were required to log any abnormalities detected prior to proceeding to a full screening study. Those with abnormal screening studies immediately underwent a full congenital echocardiogram. RHD was classified as borderline or definite as per World Heart Federation criteria.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

The prevalence of RHD and the sensitivity and specificity of the abbreviated protocol was calculated.
Results: Total of 1413 children were screened; 739 (52%) female and the median age was 12 years (range 4-24). The point prevalence of definite RHD was 1.8% and borderline 1.6% (total 3.4%). An abnormal parasternal-long-axis-view was documented in 113/1413 (8.0%). No cases of RHD were missed. The sensitivity and the specificity of the abbreviated protocol in detecting RHD was 1.0 and 0.95 (CI 95% 0.94-0.96) respectively. Congenital heart disease was identified in 20 children (1.4%) with 2 needing cardiac surgery. Of these 14 had abnormalities on parasternal-long-axis-view. Only insignificant congenital cardiac defects were missed. All children were linked to care.
Conclusion: This prospective study showed that an abbreviated screening protocol, in school-aged children, limited to a single parasternal-long-axis-view had very high sensitivity and specificity to detect RHD. Only minor congenital defects were missed. Adoption of such screening protocol could make screening more efficacious and practical in regions where RHD remains endemic.

O2425 - ECHOCARIOGRAPHIC SCREENING FOR RHEUMATIC HEART DISEASE IN 4515 SUDANESE SCHOLARS EVIDENCE OF HEALTH INEQUITY.

Sulafa Ali[1], Sara Domi [2], Bahja Abbo[3], Tajuldeen Bushari[2], Rabab Abbas[2], Khalid Al Awad[3], Abdelrahman Elhassan[2]
University of Khartoum, Pediatric Cardiology, Khartoum-Sudan[1]; Sudan Heart Centre, Pediatric Cardiology, Khartoum-Sudan[2]; Niyala Hospital, Pediatrics, Niyala-Sudan[3]

Introduction: Rheumatic heart disease is the commonest cause of acquired heart disease in Sudan with a clinical prevalence of 11 per 1000 in 1992.Introduction of hand held echocardiography (HHE) enabled the detection of subclinical disease which was found to be several folds higher than clinical prevalence in many countries. We carried this study to measure the echo prevalence and to initiate a prevention program.
Methodology: This is a prospective epidemiological study on scholars 10-15 yrs of age.phase 1 was conducted in khartoum (september 2015 - Februray 2016). Phase 2: Conducted in south Darfur, Niyala camps for Displaced people (July- september 2016). Echocardiographic (echo) screening using HHE (V scan-GE) was conducted in khartoum by pediatric cardiology fellows using the World Heart Federation criteria. While in Niyala, a simplified protocol using one echo view performed by trained medical officers was utilized.Suspected cases underwent detailed echo examination using standard echo (SE) machine. Training of health personnel was conducted through lectures & workshops.
Results: In Kartoum a total of 3000 scholars were screened,8 cases were found to be positive for RHD by HHE. Out of them,only 1 case was confirmed by SE. The echo prevalance of RHD was 0.3 per 1000. In Darfur, a total of 1515 cases were screened. By HHE, 59 cases were positove for RHD. Outof these 34 underwent SE; 29 of whom were found to have RHD; 22 had definite and 7 had borderline disease. HHE sensitivity was was 85.2%. The estimated prevalence was 33.3 per 1000. A total of 779 health workers were trained and 50 000 posters and pamphlets were distributed. The striking difference of RHD prevalance in 2 areas is an indication of health sevice inequity and the need to mobilize resources to primary health care in remote areas.

SURGERY

O1078 - COMPARISON OF LEFT VENTRICULAR RE TRAINING IN DEXTRO AND LEVO TRANSPOSITION OF THE GREAT ARTERIES

Richard Mainwaring[1], William Patrick[1], George Lui[2], Frank Hanley[1]
Stanford University School of Medicine, Pediatric Cardiac Surgery, Stanford-United States[1]; Stanford University School of Medicine, Cardiovascular Medicine, Stanford-United States[2]

Background: Patients with both Dextro- and Levo-transposition of the great arteries (D-TGA and L-TGA) are born with the right ventricle (RV) serving as the systemic pump. In both circumstances, the RV may fail as the result of myocardial dysfunction and/or tricuspid regurgitation. Once the RV begins to fail, there are limited medical or surgical options. However, one alternative possibility is to re-train the left ventricle (LV) in preparation for a late arterial switch. The purpose of this study was to evaluate the results of LV re-training in D- and L-TGA.
Methods: This was a retrospective review of 50 patients with D- and L-TGA who were enrolled in an LV re-training program. This included 25 patients with D-TGA, the majority of whom had previously undergone an atrial switch. There were also 25 patients with L-TGA (ie corrected TGA) who did not have a prepared LV due to the absence of a ventricular septal defect or sub-pulmonic stenosis.
Results: The average number of pulmonary artery bands was 1.9 ± 0.4 for D-TGA and 1.5 ± 0.3 for L-TGA ($p < 0.05$). Thirteen of 25 (52%) patients with D-TGA underwent successful LV re-training compared with 24 of 25 (96%) in L-TGA ($p < 0.001$). Ten of 13 (77%) patients with D-TGA underwent successful late arterial switch compared with 18 of 18 (100%) in L-TGA who underwent a double switch procedure ($p < 0.05$).
Conclusions: USIONS: The data demonstrate significant differences in the success of LV re-training and late arterial switch for D- and L-TGA. It is our inference that these differences are related to the condition of the patients at the time of enrollment for LV re-training rather than an inherent difference in LV myocardium.

Table 1. Characteristics of patients enrolled in LV re-training

	D-TGA	L-TGA	p value
Median age (range)	16 years (8 m to 43 y)	11 months (1 m to 24 y)	$p < 0.001$
NYHA class III or IV	23	3	$p < 0.001$
Moderate TR	12	14	p = NS

O1153 - SURGICAL TECHNIQUE FOR ADULT COARTATION REPAIR TWENTY YEARS SINGLE INSTITUTION EXPERIENCE

Mario Fittipaldi[1], Elisabeth Rumball[1], Alan Kerr[1], John Artrip[1], Clare O' Donnell[2], Nigel Wilson[2], Kirsten Finucane[1]
Starship Children, Paediatric Cardiac Surgery, Green Lane Paediatric and Congenital Cardiac Service, Auckland-New Zealand[1]; Starship Children, Paediatric Cardiology, Green Lane Paediatric and Congenital Cardiac Service, Auckland-New Zealand[2]

Paraplegia following coartaction repair in infants and neonates is a devastating complication.The risk is significantly higher in older children, adults and for recurrent coartaction, with an incidence of up to 5%.In our institution in the last 20 years,99 adult congenital

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

patients(>16 years old) were diagnosed with coartation of aorta. All patients were initially considered for an interventional approach and discussed in a multidisciplinary meeting. Sixty-eight adults were treated with either ballooning and/or stenting in the same time period. Thirty-three of them have been treated surgically via median sternotomy or left thoracotomy. Through the surgical approach of left thoracotomy we implemented the use of left heart bypass (LHB) to maintain spinal cord perfusion during repair to provide additional protection and extend the margin of safety and time to execute an accurate repair in more than half cohort. LHB was instituted after full heparinization using centrifugal pump without a reservoir. Blood was returned to the descending aorta distal to the coarctation. The circuit was filled retrogradely with blood from the patient. Femoral blood and left arterial pressure were maintained around a mean of 50 mmHg and 6-9 mmHg. In all our population treated we had only one early mortality, no late mortality and no major neurological/renal complications. There were no abdominal complications. In a mean follow up time of 6.45 years we observed 64% of patients with an improvement of their hypertensive status. In the same follow up time 90% of our patients had at least one MRI scan; only 6% of them showed a mild residual stenosis. In conclusion surgical repair of aortic coartation in adults can be performed safely with excellent early and late results. In addition the use of left heart bypass is an effective technique to augment spinal cord perfusion, and allow careful reconstruction (NB: video would support this presentation).

O1172 - DIAMOND SHAPE ANTERIOR LEAFLET RECONSTRUCTION FOR SEVERE MITRAL REGURGITATION

Juan R. Leon Wyss[1], Vladimiro Vida[2], Ralph E. Delius[3], Ysailis Mariñez[1], Cynthia Del Rosario[4], Fradwikigns Vargas[5], Walid Elias[1], Juan M. Espinosa[1], Janet Toribio[6], Dhamelise Then[6], Rebeca Perez[7], Adabeyda Baez[6]

Cedimat, Pediatric Cardiac Surgery, Santo Domingo-Dominican Republic[1]; Azienda Ospedaliera Di Padova, Pediatric Cardiac Surgery, Padova-Italy[2]; Children's Hospital of Michigan, Pediatric Cardiac Surgery, Detroit-United States[3]; Cedimat, Pediatric Cariology, Santo Domingo-Dominican Republic[4]; Cedimat, Pediatric Perfusion, Santo Domingo-Dominican Republic[5]; Cedimat, Pediatric Cardiology, Santo Domingo-Dominican Republic[6]; Cedimat, Pediatric Cardiiology, Santo Domingo-Dominican Republic[7]

Background: Repair of severe mitral valve regurgitation due to an anterior leaflet cleft, isolated or in combination with atrioventricular cannal defects, present a challenge and the degree of postoperative regurgitation is the principal risk factor for reoperation and long term survival. We present a technique cleft closure that utilizes a diamond shape patch that restores the normal saddle like anatomy and incorporates native subvalvuvar structures.
Material and Methods: Review of all patients with severe preoperative mitral regurgitation secondary to a mitral cleft that underwent mitral valve reconstruction with diamond shape patch for anterior leaflet cleft reconstruction. Repair was performed with CorMatrix or autologous pericardium. Echocardiographic evaluation of mitral regurgitation was quantified through measurements of indexed vena contracta, related jet and proximal isovelocity surface area (PISA).
Results: From March 2014 to November 2016, 30 patients (mean age 11.6 months , range 4 months to 5 years) with severe mitral regurgitation underwent mitral cleft reconstruction with diamond shape patch using either CorMatrix in 23 (76%) or autologous pericardium in 7 (23%). Included were 16 complete, 8 transitional, 5 partial atrioventricular septal defects, 2 patients with tetralogy of Fallot/atrioventricular septal defect and 2 patients with isolated mitral cleft. There were no early or late deaths. Mean follow up was 9.5 months (range 1 to 24 months). One patient (3.3%) with CorMatrix developed severe mitral regurgitation 6 months after surgery and two (6.6%) with autologous pericardium developed moderate mitral regurgitation 1 and 12 months after surgery. The remaining 27 patients (90%) remain with no or mild mitral regurgitation.
Conclusions: Diamond shape patch cleft reconstruction for severe mitral regurgitation is a simple technique to obtain an anatomical competent valve and avoids artificial chordae implantation in children. Initial results are very encouraging and longer follow up controls.

O1247 - MINIMALLY INVASIVE OFF PUMP TRANSTHORACIC DEVICE CLOSURE OF ISOLATED VENTRICULAR SEPTAL DEFECT 10 YEAR EXPERIENCE

Quansheng Xing, Qin Wu
Women and Children, Heart Center, Qingdao-China

Objective: Minimally invasive off-pump transthoracic device closure of VSDs under transesophageal echocardiography (TEE) guidance was initialy performed in China in 2007 and has increasingly been performed in China and out of China. The aim of the study was to analyze the safety, efficacy, and long-term follow-up data associated with this technique.
Methods: From March 2007 to November 2017, 632 cases with VSD size from 3 to 12 cm (5.23 ± 4.51 cm) underwent this procedure in our heart center. All the procedures were performed in the operating room. A 2-4 cm inferior sternotomy or the left third intercostals incision was made. Under TEE guidance, through the chosen right ventricle (RV) free wall puncturing point, the delivery system with occlusion device of appropriate size was introduced into RV cavity, defect and then left ventricular (LV) cavity. Then, the LV disc, waist and the RV disc were deployed in LV, septum and RV respectively. After complete TEE assessing for absence of complications, the device was released. Patients were followed up with a standard protocol.
Results: The procedure was successful in 596 cases (94.3%), and was converted to conventional surgical repair in 36 patients (5.7%). The mean device implanting time (puncture to release) was 19.3 ± 12.9 min (3 to 48 min). The mean device size implanted was 6.32 ± 4.25 mm (4 to 14 mm). 565 patients (94.7%) were followed up. During a mean 48.9 ± 26.6 months (1 to 116 months) follow-up period, no mortality occurred. There was no major complication and 54 minor adverse events being detected during the entire follow-up period.
Conclusions: Minimally invasive off-pump transthoracic device closure of VSDs appeared to be excellent with encouraging long-term outcomes. This technique not only provides a third alternative to open heart surgery and transcatheter closure but also shows more advantages.

O1724 - THE ROSS OPERATION IN CHILDREN A TWENTY YEAR SINGLE INSTITUTION EXPERIENCE IN ARGENTINA

Gladys Salgado[1], María Eugenia Olivetti[1], Guillermo Moreno[2], Analía Martín[1], Pablo García Delucis[3], Jorge Barreta[3], Horacio Capelli[1]

Hospital De Pediatría Dr. JP Garrahan, Pediatric Cardiology, Olivos-Argentina[1] Hospital De Pediatría Dr. JP Garrahan, Pediatric Cardiac Intensive Care, Buenos Aires-Argentina[2] Hospital De Pediatría Dr. JP Garrahan, Cardiac Surgery, Buenos Aires-Argentina[3]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Objective: To analyze the medium and long-term results of the Ross surgery in a young population.
Materials and methods: Between 1995 and 2014, 110 Ross procedures were performed at a median age of 13 years (0.6-19). The aortic valve was incompetent 29.8%, stenotic 10.8% and both lesions were present in 59.4%. A bicuspid aortic valve was documented in 71% of patients (pts). A balloon aortic dilatation was undertaken prior to surgery in 58 pts (64%). The aortic root replacement was the most frequently used surgical technique.
Results: Survival at 5 and 10 years was 94% and 87.5%, respectively. Sixteen reoperations (15%) were needed: autograft replacement 5.4%, RV-PA conduit replacement 5.4% and both 1.3%. The median time between the Ross surgery and the redo was 33.9 months. Free of reoperation at 2 and 5 years was 90% and 78%. The overall mortality rate was 6.3% (7/110). There was a significant decrease in mortality to less than 3% since 2002 and no mortality was registered in the last decade. Incremental risk factors of mortality were: an aorto-pulmonary mismatch >3 mm (n = 4), CPB time >240 minutes (n = 6), ACC time >180 min, age <8 years, weight <20 kg and postoperative arrhythmias (n = 2). From the multivariate analysis, the presence of ventricular dysfunction (n = 6) (OR 7.7 CI95% 0.54-108), postoperative arrhythmias (OR 14.4 CI95% 0.86- 246) were independent predictors of mortality.
Conclusion: The Ross surgery is associated with a good quality of life in the long-term follow-up. A significant aorto-pulmonary mismatch, the presence of postoperative arrhythmias and ventricular dysfunction, as well as a CPB time >240 minutes and ACC time >120 min were associated to higher early mortality. This last one shows a significant decline from 2002 probably associated with the learning curve and the development of ventricular assist devices since 2006.

O1734 - TIMING OF ELECTIVE BIDIRECTIONAL GLENN SHUNT IS EARLY BETTER

Lauren Kane[1], Luis De León[1], Ruth Ackah[2], Rohini Siggreddi[2], Carlos Mery[1], Iki Adachi[1], Jeffrey Heinle[1], E. Dean Mckenzie[1], Charles Fraser, Jr.[1]
Texas Childre's Hospital/Baylor College of Medicine, Congenital Heart Surgery, Houston-United States[1]; Baylor College of Medicine, Congenital Heart Surgery, Houston-United States[2]

Background: The ideal timing to perform the bidirectional Glenn (BDG) procedure remains unclear. The purpose of this study was to compare the early and late outcomes of patients undergoing a BDG before and after 6 months of age.
Materials and Methods: 550 patients undergoing an elective BDG procedure (1995–2016) were divided into 2 groups: <6 months (n = 200) and >6 months (n = 350). Primary outcomes included operative mortality, survival to Fontan, and survival after Fontan. Data were analyzed using Kaplan-Meier method and log-rank tests.
Results: There was an equal distribution of patients with right and left-sided single-ventricle anatomy between groups. There was no statistical difference in operative mortality [4/200 (2%) vs 2/350 (0.3%), p = 0.20]. Younger patients had a longer hospital length of stay [median 8 days vs 6 days, p < 0.001] and reintervention rate [37% vs 27%, p = 0.02]. Five years following BDG, 338 (61%) patients have undergone Fontan (60%) or BV repair (1%), 37 (7%) have required takedown, transplant or have died, and 175 (32%) were alive waiting (31%) or were not candidates for Fontan (1%). The groups had equivalent interstage attrition [14/200 (7%) vs 22/350 (6%)] (Figure) and hospital survival after Fontan [129/130 (99%) vs 245/253 (98%), p = 0.14].
Conclusions: The BDG procedure is feasible and safe in patients as young as two to three months of age. Despite having longer hospitalization and reinterventions in the interstage period, younger patients demonstrate early and late survival comparable to that seen in older patients.

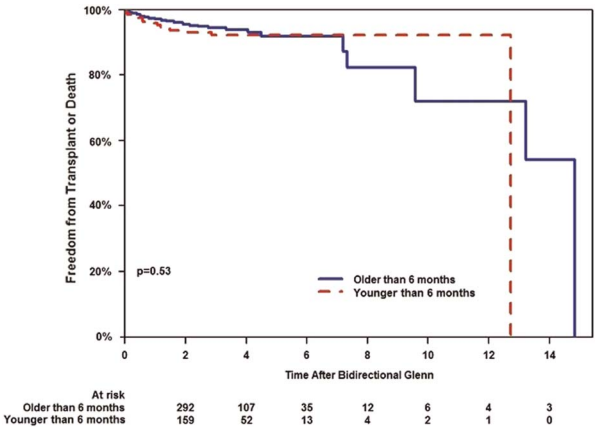

Figure.
Freedom from transplant or death prior to Fontan in patients older and younger than 6 months of age.

O1866 - ISOLATED VS COMPLEX TRANSPOSITION OF THE GREAT ARTERIES – IS THERE STILL A DIFFERENCE IN POSTOPERATIVE PROGNOSIS

Krzysztof Michalak[1], Maciej Moll[2], Katarzyna Sobczak-Budlewska[1], Jadwiga Moll[1], Marek Kopala[2], Tomasz Moszura[1], Paweł Dryżek[1], Jacek Moll[2]
Polish Mother's Memorial Hospital, Department of Pediatric Cardiology, Lodz-Poland[1]; Polish Mother's Memorial Hospital, Department of Cardiac Surgery, Lodz-Poland[2]

Background: Arterial switch operation (ASO) is currently the method of choice for transposition of the great arteries (TGA). The additional defects associated with TGA increasing the complexity of ASOs and may have an impact on postoperative outcomes. The aim of this study was to compare the frequency of the most common and severe postoperative adverse events in patients with isolated TGA in reference to the complex cases.
Methods: In this retrospective review, we consecutively enrolled all patients who underwent an ASO for TGA between the years 1991 and 2015. Patients were divided into two group – first one included only those with isolated TGA, without any additional cardiovascular defects, coronary anomalies, with one stage operation performed between 3rd and 14th day of life; the second group included rest of the patients with complex cases of TGA after ASO. We analyzed the difference between those groups in regards to the early and late postoperative mortality, reinterventions (surgical and catheter based procedures), coronary events, significant neoaortic insufficiency (NeoAR) and supravalvular pulmonary stenosis (SVPS).
Results: A total of 715 patients with isolated and complex TGA were included in this study. The average follow-up was 10.5 years (SD:7.6; completeness of the follow-up: 97.3%). The overall early and late postoperative mortality rates were 7.4% and 2.1% respectively, with the significant difference between two analyzed groups (p = 0.025; log-rank test). Freedom from cumulative

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

reinterventions at 25 years after the ASO was 92.8% for simple and 82% for complex TGA group ($p < 0.001$; log-rank test). Coronary events were more frequent in patients with complex TGA (8.5% vs 4.9%) but this difference didn't reach the statistical significance ($p = 0.054$;log-rank test). The significant SVPS (>25 mmHg) was associated more frequently with complex TGA (16.1% vs 6.3%; $p < 0.001$; chi-square test). Similarly the presence of significant NeoAR (moderate or severe) was also more frequently associated with complex cases (8.3% vs 4.5%; $p = 0.045$; chi-square test).

O1971 - ARTERIAL SWITCH OPERATION FOR TRANSPOSITION OF GREAT ARTERIES WITH INTACT VENTRICULAR SEPTUM RESULTS OF LATE PRIMARY REPAIR

Domenica Paola Basile, Mauro Lo Rito, Angelo Micheletti, Javier Fernandez Sarabia, Antonio Saracino, Giuliano Giusti, Alessandro Giamberti, Giuseppe Pomè, Alessandro Frigiola, Mario Carminati

IRCCS Policlinico San Donato, Department of Paediatric Cardiology and Cardiac Surgery, San Donato Milanese-Italy

Background: Arterial switch operation (ASO) for transposition of great arteries (TGA) with intact ventricular septum has to be performed in the first weeks of life, to achieve good results and avoid left ventricle deconditioning. The aim of our study is to investigate results of ASO performed after 21 days of life compared to "gold standard" repair performed within the first 21 days of life.
Materials and Methods: Retrospective single center study including all infants with TGA and intact ventricular septum who underwent ASO between May 2004 and February 2016. Patients were grouped according to the age at the operation: "early repair" (age < 21 days) and "late repair" (age > 21 days). Differences among groups were addressed in terms of postoperative outcomes: in-hospital mortality, incidence of ECMO and left ventricular dysfunction.
Result: Infants included in the study were 137 (male = 93). 55 cases (40%) were in the "late repair" group. Pre-operative echocardiogram showed "banana shaped" left ventricle in 38 patients; 35 out of 38 belong to the "late repair" group. Yacoub type A (n = 91) and Yacoub type D (n = 31) were the most common coronary patterns detected. Intramural course was found in 10 cases. Overall hospital mortality was 8% (n = 11) with no statistically significant difference between the two groups (late = 5% Vs. early = 10%, $p = 0.364$). ECMO incidence in late group (13%) is almost double compared to early repair group (7.5%) although not statistically significant ($p = 0.295$). 6 patients had post-operative left ventricular dysfunction at discharge with no differences in incidence among groups ($p = 0.536$). Median hospital stay was similar between groups (late = 22 days Vs. early = 20 days, $p = 0.223$).
Conclusions: Primary late ASO has led to similar results compared with early ASO although the need of post-operative ECMO, to support left ventricle recovery, remains higher in this group. Primary ASO can be performed, with low in-hospital mortality, in infants more than 21 days.

Table.

Patient's variables	Total	Early repair (n = 82 pts) N (%)	Late repair (n = 55 pts)	P-value
Sex (male)	93	58 (70%)	35 (68%)	0.383
Coronary pattern				
Type A>	91 (66%)	54 (66%)	37 (67%)	0.634
Type B	4 (2%)	2 (2%)	2 (4%)	
TypeC	7 (5%)	6 (8%)	1 (2%)	
Type D	31 (23%)	18 (22%)	13 (23%)	
TypeE	3 (2%)	2 (2%)	1 (2%)	
Intramural	10 (7%)	8 (10%)	2 (3.6%)	0.177
Banana shape	38 (28%)	3 (4%)	35 (64%)	0.000
Age at surgery - days (median, IQR)	8.5 (7-12)	27 (25-36)	13 (8-27)	0.000
Cardiopulmonary bypass time (min) (median, IQR)	150 (125-175)	145 (122-179)	150 (134-165)	0.7812
Aortic cross clamp time (min) (median, IQR)	90 (75-108)	75 (70-90)	85 (125-175)	0.022
Chest left open (days) (median, IQR)	3 (2-4)	3 (2-3)	3 (3-5.5)	0.0337
ECMO support	13 (10%)	6 (7.5%)	7 (13%)	0.295
Hospital mortality	11 (8%)	8 (10%)	3 (5%)	0.364

O2042 - SUCCESSFUL MANAGEMENT STRATEGIES FOR THE HIGH RISK FONTAN IN THE SETTING OF HYPOPLASTIC LEFT HEART SYNDROME

Ramesh S. Kutty, Phil Botha, Safak Alpat, Dawood K. Mehsood, John Stickley, Natasha E. Khan, Timothy J. Jones, William J. Brawn, David J. Barron

Birmingham Children' Hospital, Cardiac Surgery, Birmingham-United Kingdom

Objective: Patients at high risk for Fontan completion include those with poor haemodynamics and unfavourable anatomy. This a particular concern in Hypoplastic Left Heart Syndrome (HLHS) with pulmonary vascular problems or impaired ventricular function. We identified successful management strategies and risk factors for Fontan completion in patients with HLHS in order to define high risk patient groups and examine outcomes in relation to decision making and preoperative preparation.
Methods: All HLHS patients assessed for Fontan completion in a single centre from 2005-2016. High-risk classified as: (1) Poorly developed pulmonary vasculature; (2) High pulmonary Vascular Resistance (PAP > 15 mmHg + /-TPG > 6 mmHg); (3) ≥ moderately impaired ventricular function and end diastolic pressure > 14 mmHg. Outcomes analysed with focus on early Fontan failure (defined as takedown, prolonged ICU stay/chest drainage, or transplantation/death).
Results: Of 225 HLHS patients assessed, 201 underwent Fontan completion. Thirteen(6%) were declined due to poor pulmonary vasculature/lymphangectasia (n = 3) or severely impaired ventricular function (n = 10). The latter were all referred for transplantation and 4 died. No deaths were reported at 30 days post Fontan, and 4 deaths (2%) between 60 days and 6 years(median follow-up of 5.0 years). Three patients required Fontan takedown and two transplantation. Seventeen (8%) had raised PVR pre-operatively and were treated with sildenafil. Fifteen responded and underwent successful Fontan; 5 patients continuing on sildenafil long term. Two patients with impaired function received preop dobutamine infusion before successful Fontan. Patients who failed Fontan had relatively low mean Nakata Index ($195 \pm 31 mm^2/m^2$). Preop PAP and TPG were not associated with Fontan failure. No other risk factors were identified for prolonged pleural drainage although there was a trend for smaller Nakata Index.
Conclusion: Careful patient selection can deliver good Fontan outcomes in the HLHS group. Interim treatment with sildenafil is a useful adjunct in patients with high PVR. Poorly developed pulmonary vasculature is associated with later Fontan failure.

O2093 - RISK FOR AND OUTCOMES OF PERI OPERATIVE STROKE ASSOCIATED WITH THE FONTAN PROCEDURE

Billie-Jean Martin[1], M. Florencia Ricci[2], Michelle Noga[3], V. Ben Sivarajan[4], Paula Holinski[4], Joseph Atallah[2], Mohammed Al Aklabi[1], David Ross[1], Ivan Rebeyka[1]
University of Alberta, Surgery, Edmonton-Canada[1]; University of Alberta, Pediatrics, Edmonton-Canada[2]; University of Alberta, Radiology, Edmonton-Canada[3]; University of Alberta, Critical Care, Edmonton-Canada[4]

Background: Studies looking at risk of stroke in single ventricle patients have focused on long-term outcomes, with little specific attention paid to the peri-operative period. We aimed to assess predictors of stroke at the time of Fontan operation.
Methods: All children who underwent a Fontan operation between 1996 and 2016 were included. Data including anatomy, surgical technique, and cardiopulmonary bypass details at Fontan were obtained from the surgical database and patient charts. Peri-operative stroke was defined as any clinically evident cerebrovascular event during the Fontan hospitalization. Characteristics were compared between subjects who suffered a stroke and those who did not; the association between stroke and length of stay (LOS) and mortality was also evaluated.
Results: This study included 320 subjects (107 hypoplastic left heart syndrome (HLHS), 135 female), 23 (7.2%) of whom suffered a perioperative stroke. Confirmatory neuroimaging was available for 20 (87%) of the stroke subjects. There were 17 deaths (6 peri-operative) over the course of follow-up; 10-year survival was 95.2%. Median age (3.3 vs 3.3 years) and weight at Fontan (14.2 vs 14.1 kg) did not differ between groups, nor did Fontan type, use of fenestration, or cardiopulmonary bypass times (all $p > 0.05$). However, subjects with HLHS were more likely to suffer a stroke than those without (12.2% vs 4.7%, $p = 0.015$), as were children who had part of their procedure done with fibrillatory arrest (16.7% vs 5.5%, $p = 0.006$); these associations persisted in multivariate analysis. A peri-operative stroke was associated with a longer LOS (median 20 vs 10 days, $p = 0.0001$), but not mortality: one child died post stroke, after having left hospital (HR 1.23, 95% CI 0.29, 5.23).
Conclusions: Peri-operative stroke is not uncommon with the Fontan operation, especially in children with HLHS anatomy. These children do survive but likely face challenges in terms of education and quality of life.

O2109 - AUGMENTATION OF THE PULMONARY ARTERIES IS NOT ASSOCIATED WITH WORSE LONGER TERM OUTCOME A PROPENSITY MATCHED ANALYSIS FROM THE AUSTRALIA AND NEW ZEALAND FONTAN REGISTRY

Lauren Shearer[1], Kim Betts[1], Robert Justo[1], Prem Venugopal[1], David Winlaw[2], Andrew Bullock[3], Terry Robertson[4], Tom Gentles[5], Yves Dudekem[6], Nelson Alphonso[1]
Lady Cilento Childrens Hospital, Queensland Paediatric Cardiac Service, Brisbane-Australia[1]; The Childrens Hospital At Westmead, Heart Center For Children, Sydney-Australia[2]; Princess Margaret Hospital For Children, Childrens Cardiac Centre, Perth-Australia[3]; The Womens and Childrens Hospital, Paediatric Cardiology, Adelaide-Australia[4]; Starship Childrens Hospital, Green Lane Paediatric and Congenital Cardiac Service, Auckland-New Zealand[5]; Royal Childrens Hospital, Cardiac Surgery, Melbourne-Australia[6]

Background: Adequacy of the pulmonary arteries is essential for a durable Fontan circulation. Long-term data following pulmonary artery (PA) augmentation in association with the Fontan is lacking.
Methods: Pre-operative, operative and follow-up data for 1437 patients in the Australia and New Zealand Fontan Registry (1975-2015) was analysed. The primary endpoints were death and death or failure (takedown, transplant, PLE or plastic bronchitis). Cox regression with propensity score matching (1:1 nearest neighbour) was used to determine the risk or benefit conferred due to pulmonary artery augmentation.
Results: 48 (3.3%) patients underwent PA augmentation after a cavo-pulmonary shunt but prior to Fontan (surgical n = 14, balloon dilatation n = 16, stent insertion n = 19). 12 of these patients required further intervention at the time of Fontan (surgical = 7, intraoperative stent = 4, combined = 1). A further 105 (7.6%) patients underwent PA augmentation at the time of Fontan (surgical = 104, stent = 1). Median follow-up was 6.4 years with 10 deaths (6.5%) in the PA augmentation group and 10.5 years with 95 deaths (7.4%) in the non-augmentation group. Tests for frailty showed no significant variance in outcome between surgical centres or different decades. Initial unadjusted Kaplan-Meier log-rank and Cox regression demonstrated no significant difference in both endpoints between the 2 groups (death: HR 1.35, 95% CI 0.70–2.60, $p = 0.366$; death or failure: HR 1.39, 95% CI 0.83–2.34, $p = 0.211$). Propensity score matching yielded a total of 262 matched patients (131 in each group) with adequate balance for all covariates (median residual bias = 0.05). Subsequent Cox regression demonstrated no significant difference in the risks of death (HR 1.30, 95% CI 0.49–3.41, $p = 0.596$) and death or failure (HR 0.92, 95% CI 0.46–1.85, $p = 0.817$)
Conclusion: The requirement for PA augmentation prior to or at Fontan does not confer worse longer-term outcomes. An aggressive approach towards PA augmentation for hypoplastic pulmonary arteries is justified in prospective Fontan patients.

O2145 - CLINICAL OUTCOME OF CONTEMPORARY EXTRACARDIAC CONDUIT TOTAL CAVOPULMONARY CONNECTION A 15 YEAR SINGLE CENTER EXPERIENCE

Qiuming Chen, Shoujun Li, Zhongdong Hua, Keming Yang, Hao Zhang, Lu Rui, Kai Ma, Sen Zhang, Lei Qi
Fuwai Hospital, Pediatric Cardiac Surgery, Beijing-China

Objectives: This study aimed to evaluate the clinical outcome of contemporary extracardiac conduit total cavopulmonary connection and identify risk factors affecting early and late outcomes.
Methods: Between January 2000 and December 2014, 453 patients (median age, 6.7 years, range: 2.1 to 36.6 years) with a wide range of underlying diagnoses underwent ECC with a prior (n = 202) or simultaneous (n = 251) bidirectional cavopulmonary shunt. Thirty six patients (7.9%) showed heterotaxy, and fenestration was created in 247 patients (54.5%). The clinical outcome were retrospectively reviewed from the medical records. The median follow up was 4.5 years with a maximum of 15.5 years. Survival was examined with the Kaplan–Meier method, and risk factors were analyzed in the multivariate hazard domain.
Results: There were 21 early and 8 late deaths. The Kaplan–Meier estimated survival rate was 94.4 ± 1.1% at 5 years and 88.7 ± 3.7% at 10 and 15 years. Late-occurring morbidities included tachyarrhythmia in 10, bradyarrhythmia in 4, protein losing enteropathy in 5 and thromboembolism in 7 patients. Freedom from late occurring morbidities at 15 years was 82.6% ± 5.1. Outcomes were equivalent between fenestrated and nonfenestrated patients. Among survivors, 95.4% were classified in New York Heart Association class I or II at the latest follow-up. Multivariable analysis demonstrated heterotaxy, right ventricular morphology and longer cardiopulmonary bypass time to be independent risk factors for early death. Multivariable Cox regression revealed heterotaxy (odds ratio [OR]: 4.504, p = 0.001) and longer cardiopulmonary bypass time (OR: 1.009, P < 0.001) as risk factors for death, and elevated preoperative pulmonary artery pressures (P = 0.013) as risk factor for Fontan complications.
Conclusions: Contemporary extracardiac conduit total cavopulmonary connection can be performed with low mortality and morbidity rates and achieves excellent long-term outcomes. Heterotaxy and longer cardiopulmonary bypass time was associated with death.

O2153 - MID TERM OUTCOMES OF AORTIC ARCH RECONSTRUCTION IN NEWBORNS AND INFANTS A 5 YEAR EXPERIENCE FROM A START UP CONGENITAL HEART SURGERY PROGRAM

Ismihan Selen Onan[1], Okan Yildiz[1], Behzat Tuzun[1], Aylin Demirel Basgoze[1], Erkut Ozturk[2], Alper Guzeltas[2], Pelin Ayyildiz[2], Sertac Haydin[1]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiovascular Surgery, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[2]

Background: The aim of the study was to present our experience in aortic arch reconstructions in newborns and infants with or without concomitant pathologies.
Materials and Methods: Between October 2011 and December 2016, 96 newborns and infants with hypoplastic aortic arch with or without concomitant pathologies underwent aortic arch reconstruction as primary operation. Patients were retrospectively analyzed using the hospital database. The demographic data, additional procedures and clinical outcomes were reviewed. Risk adjustment analysis was performed using the Aristotle basic scores (ABC), Aristotle comprehensive scores (ACC) and Complexity levels (CL).
Results: Seventy-seven (80%) patients presented with two-ventricle physiology and the others (20%) had single ventricle. All patients (male/female: 58/39) were operated through median sternotomy with cardiopulmonary bypass. Mean age was 72 days (range: 3- 360). Mean weight was 4,1 kg (range: 2,2-9,2). A high correlation was found between the ABC, ACC and CL and mortality ($p < 0.05$), indices of morbidity and technique difficulty (Table1). Fourteen (14.5%) patients needed extra corporeal membrane oxygenation, 4 of them were discharged and followed-up. In hospital mortality developed in 20 cases with significantly higher risk scores and complex additional procedures. No late mortality occurred during mean follow-up time of 477 days (range: 20-1800). During follow-up, 8 (10.5%) of 76 patients need a re-intervention for re-coarctation, which included re-operation (n = 3) and balloon dilatation (n = 5).
Conclusion: In patients who undergo surgery for aortic arch hypoplasia, postoperative morbidity and survival seems to be more dependent on preoperative characteristics and ABC, ACC and CL than the type of surgery.

Table 1. Aristotle risk scores of patients.

	ABC	ACC	CL
Isolated aortic arch surgery[@]	7	7	2
All patients	7.9	10	2.5
Survivors	7.7	9.5	2.4
Non-survivors	8.9	12.2	3.1

Data are presented as the mean values. Note that risk scores of non-survivors are more than survivors ($p < 0.05$).
[@] = expected risk score in isolated arch surgery in Aristotle scoring system. ABOAristotle basic score, ACC = Aristotle comprehensive score, CL = complexity levels.

O2160 - LONG TERM RESULTS AFTER SURGICAL REPAIR OF AVSD OVER A 30 YEARS' PERIOD AT A SINGLE CENTRE INSTITUTION

Anastasia Schleiger[1], Jelena Buracionok[1], Katharina Schmitt[1], Oliver Miera[1], Mi-young Cho[2], Joachim Photiadis[2], Felix Berger[1], Stanislav Ovroitski[1]
DHZB, Department of Congenital Heart Disease/Pediatric Cardiology, Berlin-Germany[1]; DHZB, Department of Congenital Heart Surgery, Berlin-Germany[2]

Background: Despite improved survival after atrioventricular septal defect (AVSD) repair over the last decades patients are still at risk for reoperation especially addressing left atrioventricular valve. We analyzed our 30 years' experience to define risk factors for mortality and reoperation after AVSD repair.
Methods: Between 1986 and 2016 532 patients received AVSD repair. 2.4% of these patients had unbalanced AVSD, but biventricular repair was feasible. Complete AVSD was presented in 72.0%, intermediate AVSD in 21.7% and partial AVSD in 6.3%. Median age was 6.2 months, 50 patients were younger than 3.5 months. Standard AVSD repair was performed using two patch technique (81.5%) and cleft closure (97.3%). 56 patients received previous surgery (72% pulmonary artery banding).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Distribution of trisomy 21 was 59.4%. Results were divided into two surgical eras (1986-1999 and 2000-2016).
Results: Surgical era strongly correlated with mortality: In-hospital mortality decreased from 9.9% in pre-millennium era to 2.6% in post-millennium era ($p < 0.001$). Median follow-up time was 14.3 years. Freedom from reoperation was 79.7%. Main indication for reoperation was left ventricular valve regurgitation. 13.5% received mitral valve repair, 6.2% mitral valve replacement. Previous mitral valve repair was associated with mitral valve replacement. 4.2% received reoperation for left ventricular outflow tract obstruction and 4.3% for tricuspid valve regurgitation. Reoperation rate was significantly lower in patients with trisomy 21 ($p < 0.001$). Age lower than 3.5 months correlated with mortality and reoperation, especially for mitral valve repair ($p < 0.001$). Mortality and reoperation rate did not differ between patients with unbalanced AVSD and balanced AVSD.
Conclusion: AVSD repair can be performed with excellent results and good long term survival. Patients with trisomy 21 demonstrate no difference in survival but lower reoperation rates. Left atrioventricular valve regurgitation is main indication for reoperation.

O2259 - EARLY OUTCOME OF FONTAN OPERATION BASED ON AGE EXPERIENCE OF TERTIARY CARDIOVASCULAR CARE IN INDONESIA

Maha Fitra Nasiruddin[1], Poppy S Roebiono[1], Oktavia Lilyasari[1], Radityo Prakoso[1], Anna Ulfah Rahajoe[1], Indriwanto Sakidjan[1], Yovi Kurniawati[1], Ganesja M. Harimurti[1], Dicky Fakhri[2], Budi Rahmat[2]
Faculty of Medicine Universitas Indonesia - Rsjpd Harapan Kita, Cardiology and Vascular Medicine,Jakarta-Indonesia[1]; Rsjpd Harapan Kita, Pediatric and Congenital Heart Disease Cardiac Surgical Unit, Jakarta-Indonesia[2]

Background: Fontan procedure represents the final stage for the palliation of univentricular heart and early intervention for optimal result is important. In developing countries, patients mostly came late due to many problems and outcomes after Fontan operation is then a matter of concern.
Objective: This study aimed to evaluate the clinical outcome of intra hospital and 1 month after Fontan operation at National Cardiovascular Center Harapan Kita, as the tertiary care in Indonesia.
Method: We reviewed patients underwent Fontan operation between 2006 and 2016. Patients were divided into two groups, group A less than 5 years old ($n = 70$), and group B above 5 years of age ($n = 78$). Pre-operative, operative and post-operative data and 1 month outcomes were assessed.
Results: Total of 148 patients old with median age at operation 6 (3-22) years were included. Hospital mortality was 8 (11.4%) in group A and 7 (9%) in group B ($p = 0.621$). Pleural effusion duration and length of hospital stay were not significantly different between two groups 14.9 ± 2.26 vs $12.36 \pm 10{,}64$ days, $p = 0.39$, and 20.61 ± 13.4 vs. 22.13 ± 17.4 days, $p = 0.657$, respectively). Re-hospitalization within 1 month post-operative course found in 9 (12.9%) patients group A and 15 (19.2%) patients group B ($p = 0.294$). Re-hospitalization which mostly due to recurrent pleural effusion (protein loosing enteropathy) was significantly higher in older group ($p = 0.016$). Re-operation were also not significantly different between both groups (1 (1.4%) vs. 5 (6.4%), $p = 0.125$).
Conclusions: There were no differences in morbidity, mortality, and re-hospitalization between age groups of Fontan operations. Rehospitalization caused by recurrent pleural effusion due to protein loosing enteropathy was more frequent in older group.

O2320 - TOTAL ANOMALOUS PULMONARY VENOUS CONNECTION IMPROVED EARLY OUTCOMES WITH AN ALTERNATE MANAGEMENT STRATEGY

Kuntal Roy Chowdhuri[1], Nilanjan Dutta[1], Sumir Girotra[2], Sushil Azad[3], Sitaraman Radhakrishnan[3], Savitri Srivastava[3], Parvathi U. Iyer[4], Krishna S Iyer[1]
Fortis Escorts Heart Institute, Pediatric Cardiac Surgery, New Delhi-India[1]; Fortis Escorts Heart Institute, Pediatric Cardiac Anesthesia, New Delhi-India[2]; Fortis Escorts Heart Institute, Pediatric Cardiology, New Delhi-India[3]; Fortis Escorts Heart Institute, Pediatric Cardiac Intensive Care, New Delhi-India[4]

Background: Surgical repair of TAPVC has been associated with significant mortality especially in developing countries, largely blamed on post-operative pulmonary hypertensive crises. We believe that altered ventricular dynamics post-operatively are more responsible for mortality and have evolved a management strategy accordingly. The results of this strategy are presented.
Patients and Methods: 283 patients (median age -93 days; median weight -4100 gms) with isolated TAPVC underwent repair between Jan 2001 and Dec 2016. 51% had supracardiac, 27% had cardiac, 10% had infracardiac and 12% had mixed connections. 140 (49.5%) had pulmonary venous obstruction at some level. 17% required emergent surgery, 24% were semi-urgent and the rest were done electively on priority. Operative strategies included 1) normothermic bypass with short cross-clamp duration 2) posterior approach for supra and infra cardiac connections 3) routine ligation of the vertical vein. Post-operative strategies included 1) routine left atrial pressure (LAP) monitoring instead of pulmonary artery pressure monitoring to track left ventricular function 2) aggressive afterload reduction 3) frequent echocardiographic assessment of bi-ventricular dynamics and 4) weaning from ventilator support only when LAP was consistently low.
Results: In-hospital mortality was 5/283 (1.76%). Causes of death were severe sepsis -3, bronchomalacia -1, malignant arrhythmia-1. No patient required mechanical support or inhaled nitric oxide. Median ventilator duration and hospital stay was 52 hours and 11.2 days respectively. All survivors were discharged with documented unobstructed pulmonary venous drainage.
Conclusion: Early outcomes following surgery for TAPVC can be improved by a strategy focused on tracking ventricular function rather than pulmonary artery pressure. Nitric oxide and mechanical support are easily avoidable.

O2499 - LEFT VENTRICLE RETRAINNING OF D TRANSPOSITION OF GREAT ARTERIES IN THE THIRD WORLD. THE BUCARAMANGA EXPERIENCE

Javier Mauricio Castro-monsalve[1], Claudia Ximena Flores-Rodriguez[1], Diego Humberto Marquez-Bohorquez[2], Juan Carlos Gomez-Nuñez[2], Anderson Bermon[3], Sara E. Mendoza[2], Igor Donis[2], María Constanza Basto-Duarte[2]
Fundación Cardiovascular De Colombia, Cardiology, Bucaramanga-Colombia[1]; Fundación Cardiovascular De Colombia, Surgery, Bucaramanga-Colombia[2]; Fundación Cardiovascular De Colombia. Phd Student Ces, Research, Bucaramanga-Colombia[3]

Introduction: A left ventricle (LV) dysfunction is a usual natural development frequently found in our country, regarding to a delayed diagnosis of D-Transposition of Great Arteries (DTGA) in infants. In this scenario Pulmonary Arteries (PA) banding was performed to train the LV for anatomical repair.
Methods: LV retraining was performed in 18 patients with DTGA intact ventricular septum (IVS) from 2006 to 2016,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

when a "Banana Shaped" LV and/or LV mass <35 gr/m2 was diagnosticated.

Results: The mean age for retraining was 60 days ranging from 24 days to 4 years. Mean weight 4,3 kg (3.5-11 kg) (table1). Causes of LV dysfunction were late diagnosis, sepsis, neurologic complications and a patient with LV dysfunction since birth. Pre-training Mean LV mass was 28 gr/m^2 with a gain of 2.5 gr/m^2 in the first 24 hours, 14 gr/m^2 (10days), 30 gr/m^2 pre-switch. Pre-switch LV mass was not related with ECMO post-switch (p 0.84). There was no relation between the patients in the 75 percentile of mass gain and age or weight pre-training. Initially 72% had a grade III deviation of ventricular septum, 28% grade II. Pre-switch 46% grade I, 54% grade II. 39% changed from Grade III to II immediately post banding. Two patients died from cardiac failure, another two from non-cardiac causes. Three patients needed ECMO after arterial switch with 2 survivors. There was no mortality during the LV retraining period. Five patients are pending the arterial switch operation.

There was a 78% post- arterial switch survival.

Conclusions: Although controversial, LV mass and septum morphology still are simple and useful tools in LV dysfunction analysis. LV retraining is a viable option for patients with LV dysfunction planned for an anatomical repair of DTGA with IVS, in patients once considered not suitable for a direct switch procedure in our country.

O2556 - CONTINOUS METABOLIC MONITORING ALLOWS TAPERING OF NORMOTHERMIC AND HYPOTHERMIC CARDIOPULMONARY BYPASS DURING OPEN HEART REPAIR IN INFANCY

Riccardo Giuseppe Abbasciano, Stiljan Hoxha, Salvatore Torre, Elisa Biondani, Silvia Surdo, Luca Barozzi, Tiziano Menon, Giuseppe Faggian, Giovanni Battista Luciani
University of Verona, Division of Cardiac Surgery, Verona-Italy

Backgroound: Traditionally, perfusion parameters for cardiopulmonary bypass (CPB) in infants have been based on body weight, resulting arguably in overestimated nominal flows related with higher morbidity. Aim of the study was to assess safety and efficacy of a CPB strategy that implemented continuous metabolic and hemodynamic monitoring during open-heart repair in infants.

Materials and Methods: 31 patients undergoing surgery using normothermic CPB (mean age: 1.4 ± 1.7 years, mean body weight: 7.8 ± 3.8 kg) and 23 patients using hypothermic (25 °C) CPB were enrolled (mean age: 9.4 ± 24.0 months, mean body weight: 4.8 ± 3.5 kg). The patients were managed according to conventional CPB flows (150 mL/min/kg), except for a 20 minutes test during which CPB was adjusted to the minimum flow to maintain MVO2 >70% and rSO2 >45%. Hemodynamic, metabolic and clinical variables (along with gaseous microemboli (GME) generation in a subgroup of twenty patients) were compared within patient groups. Moreover, in a recent pilot study we evaluated the impact of metabolic guided CPB on renal function assessing splanchnic NIRS and post-operative urine output and creatininemia trend.

Results: The 20 minute test allowed reduction of CPB flows greater than 10% and 20% ($p < 0.05$) respectively in the normothermic and in the hypothermic CPB population, with no impact on pH, blood gas exchange and lactate. There was 1 (1.8%) in-hospital mortality, no neurological morbidity and no need for ECMO support. Moreover, mean GME generation was greatly decreased during the metabolic-guided CPB test, standing at 15% and 45% ($p < 0.05$) of the value recorded during standard CPB, respectively on the arterial and venous line. Preliminary results from the pilot study seem to suggest no major impact on renal function.

Conclusions: The present study shows that a safe individualized strategy of conduction of CPB, which allows significant flow reduction, maintaining normal haemodynamic and metabolic parameters, both in normothermia and moderate hypothermia may be possible.

O2602 - INTRAOPERATIVE REVISION DURING ARTERIAL SWITCH OPERATION IN THE CURRENT ERA

Yuki Nakamura[1], David Kalfa[1], Paul Chai[1], Anjali Chelliah[2], Lindsay Freud[2], Emile Bacha[1], Jan Quaegebeur[1]
Morgan Stanley Children's Hospital, Pediatric Cardiac Surgery, New York-United States[1]; Morgan Stanley Children's Hospital, Pediatric Cardiology, New York-United States[2]

Background: Arterial switch operation is a relatively safe operation nowadays. We hypothesize that intraoperative revision for coronary malperfusion still plays an important role in the current era.

Methods: From January 2005 to December 2016, 255 patients underwent arterial switch operation. Factors related to the need for intraoperative revision were analyzed. Morbidity was compared in patients with/without intraoperative revision. A subanalysis was performed for 134 patients operated on by the most senior surgeon, and the "standard technique" for a simple anatomy

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

and "modified technique" for a more complex anatomy were defined. The factors related to the application of the "modified technique" and the relationship between "modified technique" and intraoperative revision were analyzed.
Results: Seventeen patients (7%) needed intraoperative revision, and factors related to intraoperative revision were body weight at surgery ($p = 0.051$) and eccentric position of the coronary ostium ($p = 0.01$). Discharge mortality was 2% overall: 2/17 with intraoperative revision vs 3/238 without it ($p = 0.04$). Patients who underwent intraoperative revision had longer postoperative hospitalization ($p = 0.003$). Application of the "modified technique" was related to unusual coronary artery origin and branching pattern ($p < 0.001$), major malalignment of the commissures ($p < 0.001$), and eccentric position of the coronary ostium ($p = 0.007$). Application of the "modified technique" did not correlate with intraoperative revision ($p = 0.51$).
Conclusions: The need for intraoperative revision was related to eccentric coronary ostium but not to unusual coronary artery origin and branching pattern. Although the need for intraoperative revision was related to higher mortality and morbidity, it likely also contributed to our excellent results after arterial switch operation.

O2638 - IS BILATERAL GLENN A RISK FACTOR PRIOR TO FONTAN COMPLETION

Alain Serraf, Eitan Keizman, David Mishaly, Joseph Danieli, Sharon Borik, Yelena Skorchin
The Chaim Sheba Medical Center, Congenital Heart Center, Ramat Gan-Israel

Objective: Safe Fontan completion requires normal ventricular function, pulmonary arteries (PA) anatomy and low pulmonary vascular resistances (PVR). Bilateral Glenn (BBDG) is generally associated with PA bifurcation stenosis and presents multiple sources of pulmonary blood flow. We suggest that in BBDG prior to Fontan, PVR are underestimated and ends up with a less optimal outcome.
Methods: From 2008 to 2016, 98 patients with single ventricle anatomy enter a Fontan pathway. 80 had a single superior Vena Cava (SVC): G1 whereas 18 had 2: G2. Both groups were similar in terms of demographic, intra cardiac anatomy, number of previous surgeries and physiologic functional data prior to Fontan procedure. All received extra cardiac Fontan, 53% with fenestration. Uni and multivariate analysis were performed with regard to mortality and failure. A p-value <0.05 was considered as significant.
Results: There were more heterotaxy in G2. BBDG gave better growth of both right and left PA but created a PA bifurcation stenosis. Stormy post operative course with elevated liver enzymes and renal failure, mortality rate (22% vs 3.75%) and Fontan failure rate (21.5% vs 6.5%) were higher in G2. Multivariate analysis showed that heterotaxy ($p = 0.027$) and bigger size of right PA ($p = 0.035$) only were independant risk factors for poor outcome, the latter meaning that pulmonary flow distibution is uneven. Survival and Freedom from Fontan Failure rates were 93.5% and 87% in G1 vs 78% and 72% in G2 (p = ns) at 5 years post operatively.
Conclusions: This study demonstrates that BBDG present multiple sources of pulmonary blood flow with a stenosis in between meaning separate right and left lungs blood flows. Calculation of PVR prior to Fontan, should be performed in accordance with this anatomo physiologic consideration.It also suggests that surgical technique should address this anatomy either early in life or at time of Stage II.

O2762 - AORTIC VALVE RECONSTRUCTION WITH THE OZAKI PROCEDURE IN PEDIATRIC PATIENTS EARLY OUTCOMES IN 21 PATIENTS

Christopher Baird[1], Christian Kreutzer[2], Michele Borisuk[1], Brenda Sefton[1], Gerald Marx[1], Pedro Delnido[1]
Boston Children's Hospital, Harvard University, Cardiac Surgery, Boston-United States[1]; Cardiac Surgery, Buenos Aires-Argentina[2]

Introduction: The Ozaki procedure with complete cusp replacement has shown excellent results in the adult population. Early results with pediatric patients with congenital aortic valve disease are reported here.
Methods: A retrospective analysis of aortic valve reconstruction using the Ozaki procedure was performed on 21 consecutive patients (15 male) with congenital aortic valve disease at a single institution from March 2015 to September 2016. Outcome measures included mortality, surgical or catheter-based re-interventions and echocardiographic measurements.
Results: Eleven patients had AR and 10 patients AS/AR. Seven, 11 and 3 patients had tricuspid, bicuspid and unicusp valves, respectively. Eleven patients had a prior aortic valve repair and one patient had a prior bioprosthetic AVR. Median age at surgery was 10.5 years (IQR 5-14) and weight was 27.4 kg (IQR 18-60). There were 2 infants (1-2 years), 13 children (3-12 years), 4 adolescents (13-17 years) and 2 adults (ages 23 and 24). Pre-operative echocardiography revealed the average annular diameter was 2.07 ± 0.44 mm and peak gradient for AS/AR patients was 57.18 ± 21.14 mmHg. Three leaflets replaced in 15 patients, two in one patient, and one in five patients. Autologous and photofix bovine pericardium were used in 11 and 10 patients. There were no mortalities or conversions to valve replacement. Median hospital and ICU LOS was 5.25 and 1.87 days. Median follow-up was 4 months (range, 1-13). At discharge, no patients had more than mild regurgitation and mean peak gradient was 14.15 ± 8.35 mmHg. At late follow-up (5.2 months) no patients had more than mild stenosis and 20 patients had mild or less regurgitation. None required aortic valve re-operation.
Conclusions: The Ozaki procedure has excellent short-term results and could be considered for aortic valve reconstruction in pediatric patients with congenital aortic valve disease. Longer-tem follow-up is necessary to determine the optimal patch material, valve function and

O2895 - TETRALOGY OF FALLOT INCIDENCE AND TIMING OF PULMONARY VALVE REPLACEMENT AFTER INITIAL REPAIR

Carl Backer[1], Michael Monge[1], Osama Eltayeb[1], Michael Shipp[1], Stuart Berger[2], John Costello[2]
Ann & Robert H. Lurie Children, Cardiovascular-Thoracic Surgery, Chicago-United States[1]; Ann & Robert H. Lurie Children, Cardiology, Chicago-United States[2]

Background: The timing and incidence of pulmonary valve insertion after initial repair of tetralogy of Fallot (TOF) is important for strategic planning and counseling of families and may be influenced by initial surgical technique. We conducted a retrospective chart review of patients who underwent primary repair of TOF at our institution and assessed the timing and incidence of need for pulmonary valve replacement (PVR) after different surgical strategies.
Material and Methods: The surgical records of all patients treated at our institution for TOF from 1990 to 2016 were obtained. Patients were divided into 3 groups based on repair technique: 1) transatrial-transpulmonary, 2) transatrial-transpulmonary with

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

infundibular patch, and 3) transannular patch. Patients were then evaluated for the incidence and timing of PV insertion.
Results: There were 327 patients who underwent TOF repair. Of these 160 (49%) had transatrial-transpulmonary repair, 89 (27%) had transatrial-transpulmonary repair with an infundibular patch, and 78 (24%) had transannular patch repair. A total of 76 (23%) prior shunt operations were performed in 7% (11/160), 25% (22/89), and 55% (43/78) of patients, respectively ($p < 0.001$). Median age at repair was 0.49 years. Nineteen patients (5.8%) underwent PVR following TOF repair (mean age was 13.7 ± 5.2 years). Of these 19 patients, 4 had a prior transatrial-transpulmonary approach, 2 had a transatrial-transpulmonary patch, and 13 had a transannular patch procedure ($p < 0.001$).
Conclusions: The placement of an infundibular patch did not increase the incidence of need for late PV insertion. Patients with a transannular patch were at the highest risk for undergoing a late PV insertion. Patients requiring a preliminary shunt operation have a much higher incidence of need for transannular patch at the time of repair for TOF. Our strategy of emphasizing valve preservation has resulted in only 6% of TOF repair patients undergoing late pulmonary valve insertion.

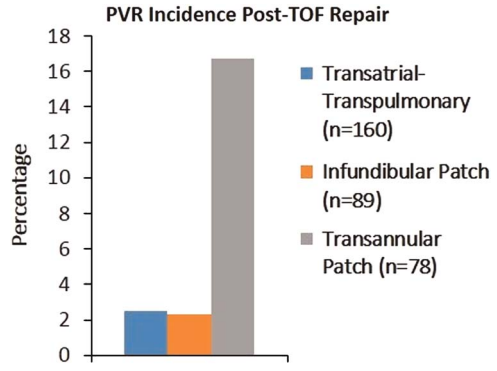

Figure.

O2929 - SURGERY ON DILATED AORTA ASSOCIATED WITH CONNECTIVE TISSUE DISEASE OR INFLAMMATORY VASCULITIS IN CHILDREN AND ADOLESCENT PATIENTS

Jae Gun Kwak, Woong-han Kim, Jeong Ryul Lee, Yong Jin Kim
Seoul National University Children's Hospital, Thoracic and Cardiovascular Surgery, Seoul-Korea, South

Background: We reviewed the patients who underwent surgery for dilated aorta, especially which was associated with connective tissue diseases or inflammatory vasculitis in children and adolescent.
Methods: Medical records of the patients who underwent aortic surgery for dilatation due to connective tissue diseases or inflammatory vasculitis between 2000 and 2016 were retrospectively reviewed. We excluded the cases of post-stenotic dilatation, acquired dilative aortic diseases, or secondary dilative change due to other congenital heart diseases or procedures.
Results: We have 12 patients who underwent surgery for dilated aorta. The median age was 10.2 years (5.4 months ~ 20.7 years), and the median body weight was 28.1 kg (6.8 kg ~ 81.5 kg). Associated diseases were Marfan syndrome (N = 4), Loeys-Dietz syndrome (N = 3), Kawasaki disease (N = 1), Takayasu's arteritis (N = 1), PHACE syndrome (N = 1), and Tuberous sclerosis (N = 1). Remaining 1 patient was supicious of having a connective tissue disease, however, not definitely confirmed. Most commonly involved area were aortic root and ascending aorta, but distal aortic arch was involved in 2 patient (unknown disease and tuberous sclerosis patients). Various surgical techniques were used to reduce dimension of dilated aorta and aortic root or aortic valve regurgitation, from simple aneurysmorrhaphy to David operation. For 79.2 ± 29.4 months of follow-up duration, there were 2 cases of follow-up loss in Marfan syndrome patients, and 5 reoperations in 3 patients. Except 1 patient, functional class and ventricular function were well maintained in all followed-up patients, however, the dimension of aortic root and involved aorta showed progressive dilation by time.
Conclusion: The cases of surgical treatment for the dilated aortopathy associated with connective tissue diseases and inflammatory vasculitis were very rare in children and adolescent. Most of the patients showed tolerable postoperative course, however, they showed progressive dilation of involved aorta by time even after surgical treatment. Close and regular follow-up is mandatory.

O3025 - IS THERE ANY ADVERSE EFFECT AFTER SYSTEMIC –TO PULMONARY ARTERY SHUNT IN PATIENTS WITH BIVENTRICULAR CIRCULATION 24 YEARS' EXPERIENCE AT OKAYAMA UNIVERSITY

Shunji Sano[1], Sachiko Kawada[2], Toshikazu Sano[2], Yasuhiro Kotani[2], Shingo Kasahara[2], Kenji Baba[3]
UCSF, Pediatric Cardiac Surgery, San Francisco-United States[1]; Okayama University, Cardiovascular Surgery, Okayama-Japan[2]; Okayama University, Pediatric Cardiology, Okayama-Japan[3]

Objective: Recent trend of surgical management in complex congenital heart defects is one stage total repair rather than staged palliation. The main reason is the high mortality and morbidity after shunt. From database of STS and EACTS, the mortality after shunt is more than 5% even in patients with biventricular physiology. We report our 24 years' single institution experience of systemic –to-pulmonary artery shunts in patients with biventricular circulation.
Methods: From January 1993 to June 2016, 228 consecutive patients underwent Blalock-Taussig (BT) shunt or central shunt. Morphology included: tetralogy of Fallot (39), pulmonary atresia with ventricular septal defects (VSD) (55), with major aorto-pulmonary collaterals (MAPCAs) (22), pulmonary atresia with intact ventricular defect (20), double outlet right ventricle (23), transposition of the great arteries(TGA) with VSD and pulmonary stenosis (10), congenitally corrected TGA (7) and others (52). Median age was 64 days and median body weight was 4.6 kg (0.9-14 kg). Modified BT shunt was used to 226, original BT in 1 and central shunt in 1 patient. Surgical approach was by thoracotomy in 150 patients and median sternotomy in 78 patients. Most of the shunt in neonates and small infants was done by senior surgeons.
Results: No early mortality and morbidity. There was no in hospital re-intervention or re operation. Before total correction, 1 patient died 4 years after shunt (patient was lost to follow up after shunt). Shunt failure was observed in 1 patient with thrombosis in the shunt due to staphylococcus septicemia 52 days after the shunt.
Conclusions: There was no increased mortality and morbidity after the shunt in patients with biventricular circulation. Therefore, surgical management should be individualized to the patient.

TRANSPLANT/HEART FAILURE/PULMONARY HYPERTENSION

O1262 - MITOCHONDRIAL OXIDANT STRESS AND IRON DYSREGULATION IN DOXORUBICIN INDUCED CARDIOTOXICITY

Lauren Manning[1], Feras Hares[2], John Charpie[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

University of Michigan Medical School, Pediatrics & Communicable Diseases, Ann Arbor-United States[1]; University of Toledo College of Medicine, Toledo-United States[2]

Background/Hypothesis: Doxorubicin (DOX) is an anthracycline-based chemotherapeutic agent used to treat a variety of cancers in both adults and children. The most serious adverse effect of DOX is a cumulative, potentially life-threatening cardiotoxicity associated with myocardial oxidative stress. Recent data suggest that DOX-induced oxidant stress may result from mitochondrial iron dysregulation. The aim of this study was to evaluate the impact of DOX on mitochondrial oxidant stress and iron handling in isolated neonatal cardiomyocytes.
Materials and Methods: Cultured neonatal rat cardiomyocytes (H9c2) were treated with 5 μM DOX ± 1 μM mito-tempo (MT), a specific mitochondrial targeted antioxidant, in complete media for 18 hours (time to maximum apoptotic response based on previous experiments). Control H9c2 cells were cultured in complete media without DOX. Oxidant stress was assessed by measuring thiobarbituric acid reactive substances (TBARS) reflecting lipid peroxidation. Mitochondrial iron transport was assessed by measuring changes in mRNA expression of the mitochondrial specific ATP-binding cassette sub-family B (ABCB) iron transporters using qPCR.
Results: Compared with untreated control cardiomyocytes, oxidant stress was increased 3-fold, and ABCB7 and ABCB8 expression was reduced by greater than 50% in response to DOX. MT treatment attenuated oxidative stress, and improved both ABCB7 and ABCB8 expression during DOX exposure (Table).
Conclusion: DOX treatment increases mitochondrial oxidant stress associated with decreased expression of two important mitochondrial ATP-binding iron transporters. A mitochondrial specific antioxidant partially restores both ABCB7 and ABCB8 expression and attenuates mitochondrial oxidant stress in response to DOX treatment. These results confirm that DOX-induced cardiotoxicity is associated with abnormal mitochondrial iron handling and oxidant stress. Mitochondrial ATP-binding iron transporters are novel potential therapeutic targets for preventing cardiotoxicity in response to DOX treatment.

Table.

	Control	DOX	DOX + MT
Oxidant Stress	1.00 ± 0.08	3.03 ± 0.13	1.48 ± 0.24
ABCB7 Expression	1.13 ± 0.26	0.45 ± 0.20	0.78 ± 0.26
ABCB8 Expression	1.37 ± 0.48	0.47 ± 0.15	0.74 ± 0.18

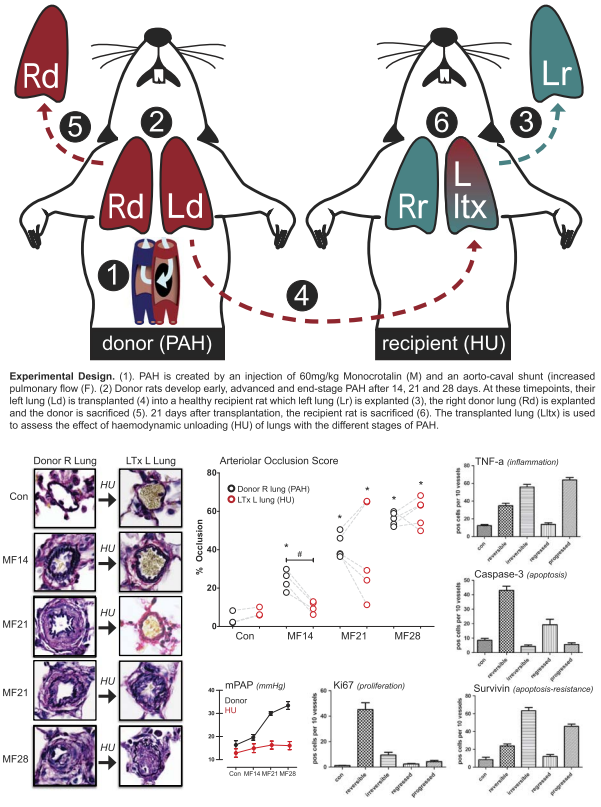
O1287 - A REVERSIBLE AND IRREVERSIBLE RESPONSE TO HAEMODYNAMIC UNLOADING IN FLOW INDUCED PULMONARY ARTERIAL HYPERTENSION. IDENTIFICATION OF THE POINT OF NO RETURN IN PULMONARY VASCULAR DISEASE

Diederik Van Der Feen[1], Lysanne Jorna[1], Guido Bossers[1], Quint Hagdorn[1], Arjen Petersen[2], Michel Weij[3], Tom Van Leusden[4], Rudolf De Boer[4], Beatrijs Bartelds[5], Rolf Berger[1]
University Medical Center Groningen, Center For Congenital Heart Diseases, Groningen-The Netherlands[1]; University Medical Center Groningen, Department of Medical Biology, Groningen-The Netherlands[2]; University Medical Center Groningen, Research and Development Unit, Groningen-The Netherlands[3]; University Medical Center Groningen, Department of Experimental Cardiology, Groningen-The Netherlands[4]; Erasmus Medical Center Rotterdam, Department of Paediatric Cardiology, Rotterdam-The Netherlands[5]

Background: Pulmonary arterial hypertension (PAH) is a progressive pulmonary vascular disease (PVD) that remains without a cure. In PAH associated with congenital cardiac shunts (PAH-CHD), timely haemodynamic unloading (HU) of the lungs by shunt closure may reverse this PVD, but not after a certain point of no return. The potential for reversibility in PAH has been established for decades, but mechanisms, timing and identification of such reversibility are still obscure today. We developed a novel rat model for HU in flow-induced PAH to study these mechanisms and to identify factors that specifically orchestrate the transition of reversible to irreversible PVD.
Methods: Flow-induced PAH was created in Lewis rats by injection of 60 mg/kg monocrotalin (t = 0) followed by a surgical aorto-caval shunt (t = 7days). To simulate HU, their left lung was transplanted into a healthy recipient rat at different stages of PAH development: early, advanced and end-stage PAH (t = 14/21/28). Recipient rats were sacrificed 21 days after HU.
Results: PAH developed time-dependently in donor rats, characterized by increased pulmonary artery pressure, vascular occlusion score and formation of neointimal lesions. HU normalized vascular occlusion ($p < 0.05$) in early-stage PAH by reducing medial hypertrophy: reversible PVD. In end-stage PAH, neointimal lesions did not reverse and arteries progressively occluded despite HU: irreversible PVD. In advanced PAH, the PVD was reversible in 3 and irreversible in 2 rats. The vascular phenotype



Experimental Design. (1). PAH is created by an injection of 60mg/kg Monocrotalin (M) and an aorto-caval shunt (increased pulmonary flow (F). (2) Donor rats develop early, advanced and end-stage PAH after 14, 21 and 28 days. At these timepoints, their left lung (Ld) is transplanted (4) into a healthy recipient rat which left lung (Lr) is explanted (3), the right donor lung (Rd) is explanted and the donor is sacrificed (5). 21 days after transplantation, the recipient rat is sacrificed (6). The transplanted lung (Lltx) is used to assess the effect of haemodynamic unloading (HU) of lungs with the different stages of PAH.

Figure.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

was more proliferative and pro-apoptotic in reversible PVD, and more inflammatory and apoptosis-resistant in irreversible PVD ($p < 0.0001$).
Conclusion: We have developed a rat model for flow-induced PAH with a reversible and irreversible response to HU, similar to the observation in children with PAH-CHD. This novel model offers opportunities to study pathophysiological and molecular mechanisms that orchestrate the transition from reversible to irreversible PAH. Identification of these mechanisms may provide new targets for pharmacological reversal of "irreversible" PAH.

O1308 - MACITENTAN VERSUS STANDARD OF CARE IN DELAYING DISEASE PROGRESSION IN CHILDREN WITH PULMONARY ARTERIAL HYPERTENSION THE TOMORROW STUDY DESIGN

Maurice Beghetti[1], Dunbar D Ivy[2], Andjela Kusic-pajic[3], Matthieu Villeneuve[4], Damien Bonnet[5]
University of Lausanne, Centre Universitaire Romand De Cardiologie Et Chirurgie Cardiaque Pédiatrique, University Hospital, Paediatric Cardiology Unit, Geneva-Switzerland[1]; Children's Hospital Colorado, University of Colorado School of Medicine, Department Of Pediatrics, Aurora-United States[2]; Actelion Pharmaceuticals Ltd, Department of Global Clinical Science & Epidemiology, Allschwil-Switzerland[3]; Actelion Pharmaceuticals Ltd, Department of Biostatistics, Allschwil-Switzerland[4]; Hôpital Necker Enfants Malades, Université Paris Descartes, M3c-Necker, Paediatric Cardiology, Reference Centre For Complex Congenital Heart Diseases, Paris-France[5]

Background/Hypothesis: Management of pulmonary arterial hypertension (PAH) in children is primarily based on adult studies and short-term, non-randomized pediatric studies. The TOMORROW study was designed using information from large-scale pediatric PAH registries to evaluate macitentan versus standard of care (SoC) on clinically relevant long-term outcomes in pediatric PAH.
Materials and Methods: In this ongoing, prospective, long-term, randomized, open-label, phase 3 study (NCT02932410), patients aged 2-17 years with a PAH diagnosis ≤12 months before randomization and in WHO functional class (FC) I-III are randomized 1:1 to receive macitentan (concomitant phosphodiesterase type-5 inhibitor allowed) or continue SoC (according to investigator s judgment; ≤2 PAH-specific medications, including other endothelin receptor antagonists; excluding macitentan and intravenous/subcutaneous prostanoids). Macitentan dispersible tablet is administered orally once-daily, dosed based on body weight (3.5-10.0 mg/day). The composite primary endpoint is time to first disease progression event until end of study. Disease progression events: all-cause death; atrial septostomy, Potts anastomosis or lung transplant registration; hospitalization due to worsening PAH; clinical worsening of PAH (defined as need for/initiation of new PAH therapy or intravenous diuretics or continuous oxygen use, and ≥1 of the following: 1) worsening WHO FC, 2) new occurrence/worsening syncope, 3) new occurrence/worsening of ≥2 PAH symptoms [i.e. dyspnea, chest pain, cyanosis, near syncope, fatigue], or 4) new occurrence/worsening of right heart failure not responding to oral diuretics). Primary endpoint events are adjudicated by an independent Clinical Event Committee. Safety, tolerability and pharmacokinetics of macitentan are assessed.
Results: TOMORROW is powered based on the treatment effect observed in adults. To obtain 187 events, approximately 300 patients are planned for enrollment from >30 countries.
Conclusion: The TOMORROW study represents an advancement in the field of pediatric PAH. It is the first event-driven study among children with PAH and will assess long-term outcomes with a composite primary endpoint of disease progression.

O1354 - PROGRESS IN THE GENERATION OF MULTIPLE LINEAGE HUMAN IPSC DERIVED 3D ENGINEERED CARDIAC TISSUES FOR CARDIAC REPAIR.

Fei Ye[1], Shuji Setozaki[2], William Kowalski[1], Marc Dwenger[1], Fangping Yuan[1], Joseph Tinney[1], Takeichiro Nakane[2], Hidetoshi Masumoto[2], Bradley Keller[1]
University of Louisville, Kcphrp and Pediatrics, Louisville-United States[1]; Kyoto University, Cardiovascular Surgery, Kyoto-Japan[2]

Despite improvements over the past 30 years, the 10-year pediatric heart transplantation survival rate remains low at 63%. In contrast to isolated cell therapies, implantable engineered cardiac tissues (ECTs) recover myocardial mass and function, creating the opportunity for recovery rather than replacement. Our ECT research has progressed from embryonic avian and rodent cell compositions to h-iPSC multiple cell lineage formulations with the goal of clinical translation. We generated ECTs from h-iPSC derived cardiomyocytes, endothelial cells, and vascular mural cells in both linear (15×1 mm) and large format (LF, 20×20 mm) geometries and are investigating the replacement of rodent matrix with human reagents. h-iPSC ECTs underwent rapid gel compaction and intrinsic beating initiated day3. CM fraction was similar at day14 for linear, LF, and all-human reagent ECTs (56 ± 8 vs. $57 \pm 21\%$ vs. $43 \pm 13\%$). ECT maximum capture rates were similar (4.5 ± 0.6 vs. 4.5 ± 1.1 vs 4.2 ± 1.2 Hz) as were active stresses (0.55 ± 25 vs. 0.54 ± 0.21 vs. 0.72 ± 0.18 mN/mm2). Prolonged culture to 28 days increased CM alignment concentration index for LF-ECT ($6.05 \pm 0.64^{\star}$ vs. 3.13 ± 0.33). Chronic optogenetic pacing did not change linear ECT CM alignment but did increased MCR at d14 (5.19 ± 0.37 Hz*) and ECT force-frequency relations shifted from negative to neutral. LF-ECTs implanted onto xenotolerant infarcted rat hearts improved ejection fraction (66.6 ± 5.8 vs. $49.3 \pm 13.2\%^{\star}$), normalized regional echo strain patterns, and reduced scar area (11.6 ± 7.6 vs. $23.9 \pm 7.2\%^{\star}$) at 4 weeks. ECT survival, engraftment, and perfusion were confirmed by histology. ($^{\star}P < 0.05$)
Conclusions: ECTs generated from h-iPSC using rodent and human matrix factors form functioning human myocardium that can survive in vivo implantation to recover cardiac structure and function. These compositions show promise as a strategy for pediatric myocardial recovery.

O1628 - CONTINUING CHALLENGES IN PEDIATRIC MECHANICAL CIRCULATORY SUPPORT ANALYSIS OF THE PEDIMACS REGISTRY

Cardiac Surgery, Birmingham, AL-United States[5] Cincinnati Children, Cardiology, Cincinnati, OH-United States[6]

Background: Expanded use of pediatric ventricular assist devices (VADs) has decreased mortality in children awaiting heart transplantation. PediMACS, an NIH-sponsored U.S. database, provides a unique platform to understand patient characteristics, device selection, and current needs. METHODS: Between 9/12–9/16, 42 US hospitals implanted 435 devices in 367 patients under 19 years old. Pre-implant characteristics, outcomes, and serious adverse events (SAE) (Infection, Bleeding, Neurologic, Device Malfunction) were analyzed.
Results: Diagnoses included cardiomyopathy in 224 (61%) pts and congenital heart disease in 78 (21%), of which 47 had single ventricle. Most (85%) were Intermacs level 1 or 2 at implant, with 152 (42%) intubated preimplant. Device type correlated with patient age. Median (IQR) age (yrs) at implant for paracorporeal continuous flow (PC) pumps (n = 60): 1.7 (0.3-10.0), for paracorporeal pulsatile (PP) pumps (n = 106):1.8 (0.4-5.4), and for implantable continuous flow (IC) pumps (n = 175): 15.0(11.2-16.8). Patients required LVAD in 295 (80%), BiVAD in 56 (15%) and total artificial heart in 8 (2%). Nearly 50% of patients underwent transplantation within 6 mos, with overall mortality before transplant of 18%. Actuarial survival on device at 6 mos. was 45% for PC, 64% PP, and 86% IC ($p < 0.0001$). Patients <5 years old had 60% 6 month survival, worse with CHD than CM (45% vs 68%, $p = 0.01$). At least one SAE occurred in 214 pts (58%), with a higher frequency in pts <5 years vs older (68% vs 53%, $p < 0.01$).
Conclusions: Pedimacs constitutes the largest longitudinal registry of pediatric VAD pts. Older children with continuous flow pumps have excellent outcomes. Smaller children, especially those with CHD continue to challenge caregivers, with higher incidence of SAEs and lower survival. Device development for small children remains a pressing need.

O1841 - EFFECT OF MIR 29B ON THE PROLIFERATION AND APOPTOSIS OF PULMONARY ARTERY SMOOTH MUSCLE CELLS BY TARGETING CCND2 AND MCL 1

Juan Chen, Tingting Xiao
Shanghai Children's Hospital, Department of Cardiology, Shanghai-China

The proliferation and apoptosis of pulmonary artery smooth muscle cells (PASMCs) are considered to be key steps in the progression of pulmonary arterial hypertension (PAH). microRNAs (miRNAs) have been revealed as critical modulators of various diseases in which miR-29b is known to regulate cell growth and apoptosis by targeting CCND2 and Mcl-1. However, roles of miR-29b in PAH remain almost unknown. We hypothesized that miR-29b may control the proliferation and apoptosis progress by inhibiting its own specific targets in PASMCs. miR-29b significantly suppressed the proliferation and promoted apoptosis of PASMCs through the inhibition of CCND2 and Mcl-1.We also found that miR-29b expression levels significantly declined in pulmonary artery tissue of PAH model induced by monocrotaline (MCT) in rat and hypoxia in mouse and that the overexpression of miR-29b can inhibit the expression of CCND2 and Mcl-1 and reduce the right ventricular systolic pressure (RVSP) and right ventricular hypertrophy (RVHI). Consistent with the important role of miR-29b in vitro, we observed down-regulated expression levels of CCND2 and Mcl-1 from the PAH model induced by MCT in rat. These results demonstrated that miR-29b suppressed the proliferation and promoted apoptosis of PASMCs, possibly through the inhibition of CCND2 and Mcl-1, and suggest that miR-29b may serve as a useful therapeutic tool to treat PAH.

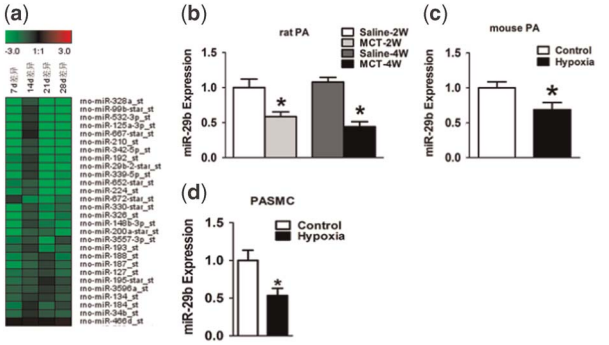

Figure 1.
*miR-29b is down regulated in PAH. (a) Partially differential expression of miRNAs in model of PAH induced by MCT for 7days, 14days, 21days, 28days, Cluster analysis of miRNAs expression from individual specimens were assessed by microarray analysis. (b) miR-29b expression in pulmonary artery tissue of PAH model induced by MCT in rat by real-time PCR assay. O1921 - ALTERED AORTIC VALVE LEAFLET GENE EXPRESSION FOLLOWING CONTINUOUS FLOW VAD THERAPY IN PEDIATRIC PATIENTS

Katsuhide Maeda[1], Xiaoyuan Ma[1], Christina Greene[1], Olaf Reinhartz[1], David Rosenthal[2], Frank Hanley[1], R. Kirk Riemer[1]
Stanford University, CT Surgery, Stanford-United States[1]; Stanford University, Pediatric Cardiology, Stanford-United States[2]

Introduction: Use of continuous flow LVAD for bridge to transplant therapy in pediatric heart failure patients is becoming a mainstay. It has been known that in these patients AV leaflets start to develop insufficiency, resulting in LVAD failure due to circulatory shunt. We sought a better understanding of the effects consequent to disrupted AV closure on leaflet tissue. Accordingly, we have used a transcriptome-wide gene expression analysis approach to compare patients with and without durable LVAD therapy.
Methods: We analyzed specimens from two groups of pediatric heart AV leaflets (AVL): Patients on durable continuous flow LVAD (LVAD, N = 4) and normal pediatric donor hearts (Con, N = 4). All specimens were normal in gross appearance. RNA was extracted, labeled and used to interrogate Affymetrix human whole transcriptome arrays.
Results: Genome-wide expression level comparison demonstrated that LVAD AVL exhibited more than 400 genes differentially regulated significantly more than Con AVL (>2.5 fold; P < 0.05).
Conclusions: We conclude that AVL undergo pathogenic changes during durable chronic LVAD therapy, manifest as alteration in gene expression. Our results therefore support the concept that altered AV cycling pattern during continuous flow LVAD therapy induces early stages of AVL pathogenesis. The data suggest that AVL homeostasis requires a normal pattern of frequent valve coaptation and opening that is abrogated by LVAD therapy.

O2035 - PILOT STUDY OF WARFARIN GENOTYPE POLYMORPHISMS IN CHILDREN WITH VENTRICULAR ASSIST DEVICES. (VAD)

Francesca Iodice[1], Anwar Baban[2], Antonio Amodeo[3], Arianna Di Molfetta[3], Antonio Novelli[4], Emanuel Agolini[5], Giuseppina Testa[6]
Children's Hospital Bambino Gesu' Rome, Anesthesia and ICU, Rome-Italy[1]; Children's Hospital Bambino Gesu', Genetics Department, Rome-Italy[2]; Children's Hospital Bambino Gesu', Cardiac Surgery Department, Rome-Italy[3]; Children's Hospital Bambino Gesu', Genetic Laboratory, Rome-Italy[4]; Children's Hospital Bambino Gesu', Genetics Laboratory, Rome-Italy[5]; Children's Hospital Bambino Gesu', Anesthesia and ICU, Rome-Italy[6];

Hypothesis: The objective of our study was to determine the incidence of warfarin polymorphisms (VKORC1, CY2CP9 and CYP4F29) in children with VAD implantation and evaluate the correlation between bleeding and thrombo-embolic events. We analysed the genotype polymorphism profile in 24 children with VAD implantation.
Materials and Methods: Children who had undergone VAD implantation from the cardiac department of the Children's Hospital Bambino Gesu' were recruited. A combined retrospective, prospective study was performed. Charts were analyzed and we recorded: polymorphisms, disease, type of VAD implanted, race, age, gender, height, weight, bleeding and thrombo-embolic episodes. Blood samples were obtained during ambulatory visits. Informed consent was obtained.
Results: Mean weight was 19,96 kg (SD 20,69 kg), mean age was 68,18 months (SD 74 cm). Twenty one patients had a diagnosis of dilated cardiomyopathy and 3 patients with a restrictive cardiomyopathy. Five Jarvik 2000's were implanted, 18 Berlin Hearts and 1 patient with a Heartmate3. Seventy-two percent underwent heart transplantation. Sixteen percent of the patients bleed during VAD implantation and the site of bleeding was always cerebral. The incidence of thrombosis was 52%, 9 patients showed device thrombosis and 7 brain thrombosis. Twelve percent of patients had neurological damage pre-VAD, 36% percent had post_VAD neurological damage. Statistical analysis showed a partial correlation between thromboembolic events and the presence of the CYP4F2 polymorphism with a significant trend (p = 0.07). Moreover, the CYP2C9 showed a positive predictive value of 86% for thromboembolism. In addition, we found an incidence of 36% of the CYP4F2 polymorphism.
Conclusions: Our study underlines the usefulness and importance of analysing warfarin polymorphisms in this particular group of patients. We found a partial correlation between thromboembolic events and the CYP4F2 polymorphism which also had a higher incidence compared with the general population. Our results are preliminary and the group of patients was small.

O2039 - POTTS SHUNT RESULTS IMPROVES RIGHT VENTRICULAR FUNCTION IN PATIENTS WITH SUPRASYSTEMIC PULMONARY HYPERTENSION.

Manish Aggarwal[1], Swati Choudhry[1], R Mark Grady[1], Shafkat Anwar[1], Pirooz Eghtesady[2], Gautam Singh[1]
Washington University School of Medicine, Pediatrics, St. Louis-United States[1]; Washington University School of Medicine, Cardiothoracic Surgery, St. Louis-United States[2]

Backgrounds and Objective: Pulmonary arterial hypertension (PAH) carries a poor prognosis. Right ventricular (RV) function and work are pivotal to survival in PAH. Recent application of left pulmonary artery to descending aorta shunt, Potts shunt, to off-load the RV has demonstrated promising clinical results. Studies to evaluate the impact of Potts shunt on RV mechanics that may impact survival are lacking. We sought to mechanistically evaluate RV function and work before and after surgical Potts shunt in pediatric PAH patients.
Method: In a retrospective study with prospective analysis, we assessed echocardiographic indices before and after (median 7 ± 8.2 days) a Potts shunt was performed in 10 consecutive pediatric patients (median age 11.8 ± 4.8 years, weight 35.4 ± 20.3 kg) with suprasystemic PAH. We measured tricuspid annular plane systolic excursion (TAPSE) to assess RV systolic function; tricuspid regurgitation (TR) jet velocity to estimate pulmonary artery systolic pressure (PASP);

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

pulmonary artery acceleration time (PAAT) as well as its ratio to right ventricular ejection time (RVET) as indices of pulmonary artery pressure and resistance; and TAPSExPASP and TAPSExPAAT to develop length-force relationship as indices of RV work. We analyzed pre and post shunt data using Wilcoxon signed-ranked test. A $p < 0.05$ was considered significant.

Result: After the Potts shunt, RV systolic function (TAPSE % increased 17.5 ± 15.5) and pulmonary artery hemodynamics (PAAT % increased $38.4\% \pm 23.7$) significantly improved (both $p = 0.005$) but PASP did not ($p = 0.721$). RV work significantly improved (% increased of TAPSExPAAT 66.4 ± 34.9 and TAPSExPASP 17.5 ± 15.6; $p < 0.05$). (Figure 1)

Conclusions: RV function and RV work improve rapidly after the Potts shunt. This initial evidence of improved RV function and work may indicate a protective effect of the Potts shunt on the RV that may aid survival in pediatric patients with PAH.

	Pre	Post	Difference	P-Value
TAPSE	1.28±0.15	1.50±0.15	18.4%±15.9	0.005*
PASP	87.8±21.7	90.8±20.7	6.8%±23.2	0.721

O2081 - PROSPECTIVE ECHOCARDIOGRAPHIC EVALUATION OF VENTRICULAR LOADING TRENDS IN PEDIATRIC PATIENTS WITH PULSATILE FLOW LVAD

Arianna Di Molfetta, Roberta Iacobelli, Sergio Filippelli, Gianluigi Perri, Giorgia Grutter, Paolo Guccione, Luciano Pasquini, Antonio Amodeo
Pediatric Hospital Bambino Gesù, Pediatric Cardiology and Cardiac Surgery, Rome-Italy

The aim of this study was to describe the echocardiographic trend of LV and right ventricular (RV) function after implantation of a pulsatile flow LVAD in children.. From December 2013 to January 2017, we prospectively enrolled all consecutive pediatric LVAD (Berlin Heart Excor) patients collecting clinical and echocardiographic data at baseline, within 24 hours after implantation and monthly until LVAD explantation. Fourteen patients were enrolled with an average age and weight at the implantation of 12.4 ± 11.0 months and 7.0 ± 3.6 kg. Thirteen (93%) were affected by dilated cardiomyopathy and 1 by restrictive cardiomyopathy. The average LVAD stay was 226.2 ± 121.2 days. Ten (71%) were successfully transplanted, 4 (30%) died (3 because of major neurological complications and 1 after LVAD explantation used as a bridge to recovery). After an average LVAD stay of 120 days, 4 patients required prolonged inotropic support for RV failure. LV end-systolic and end-diastolic volumes were reduced in the acute phase ($p = 0.034$ and $p = 0.004$), at one month ($p = 0.0075$ and $p = 0.0005$) and two months ($p = 0.019$ and $p = 0.001$). RV function improved in the acute phase, but then it started to decrease over time with a progressive increase in RV dimensions. After 4 months follow up, RV fractional area change (RVFAC) worsening was related with the deterioration of LV unloading ($p = 0.0036$) with need of prolonged inotropic ($p = 0.032$). Pulsatile LVAD in pediatrics is followed by an early and mid-term LV reverse remodeling due to a change in loading conditions, yet at long term follow it does not remain stable. RV function improved in the acute phase, but a progressive RV dilatation was noted leading to the need of prolonged inotropic. The potential of heart recovery seems to be more promising during the early phase post LVAD. Further studies are needed to understand how to prolong the benefits provided by the LVAD.

Utrecht, Wilhelmina Children's Hospital, Pediatric Cardiology, Utrecht-The Netherlands[8]

Background: Ebstein's anomaly is a rare disease with a wide clinical spectrum. Forecasting the prognosis of neonates with Ebstein's anomaly is difficult and only few outcome studies are available.
Materials and Methods: In the Netherlands, all consecutive live-born patients diagnosed with Ebstein's anomaly in the neonatal period (0-30 days) between 1980 and 2014 were included. Survival curves were obtained using the Kaplan–Meier method. By using the Cox proportional hazard model, we analyzed factors associated with death.
Results: We included 112 neonates (51 male) of whom 65 (58%) presented in NYHA Class IV. Twenty-four (21%) showed severe right ventricular outflow tract obstruction, in 34 (31%) the tricuspid regurgitation was severe. The mean follow-up was 85 months (0-216 months). Ten patients underwent a percutaneous intervention (four balloon pulmonary valvuloplasty procedures, three Rashkind procedures, two radio-frequency perforations of the pulmonary valve and one radio-frequency ablation because of refractory supraventricular tachycardia). Neonatal surgery was required in 21 patients (19%), five required one or more re-operations within the first year of life. In total, twenty-seven patients (24%) died; 16 within the neonatal period and all but two died within the first year of life. The majority (12 patients) died of heart failure. The one-month survival was 86%, the one-year-survival 77%. Factors associated with death included presentation in NYHA Class IV (HR 10.7, 95% CI 2.5-45,1, $p = 0.001$), severe right ventricular outflow tract obstruction (HR 2.5, 95% CI 1.1-5.4, $p = 0.024$) and neonatal surgery (HR 9.6, 95% CI 1.2-78.7, $p = 0.034$).
Conclusion: We present the results of one of Europe's largest cohorts of neonates with Ebstein's anomaly. Twenty-four percent died, all but two during the first year of life. Presentation in NYHA Class IV, severe right ventricular outflow tract obstruction and neonatal surgery were associated with death.

Survival during childhood and adolescence (0-18 years) of 112 neonates with Ebstein's anomaly.

O2391 - SHORT TERM PROGNOSTIC INDICATORS IN ADULT CONGENITAL HEART DISEASE PATIENTS WITH HEART FAILURE

Alexander Van De Bruaene[1], Edward J Hickey[2], Andrew M Crean[1], Rachel M Wald[1], Adrienne H Kovacs[1], Heather J Ross[1], Lee Benson[2], Jack Colman[1], Erwin N Oechslin[1], S. Lucy Roche[1]

University Health Network, Peter Munk Cardiac Centre, Toronto-Canada;[1] The Hospital For Sick Children, The Labatt Family Heart Centre, Toronto-Canada[2]

Background: Although heart failure (HF) is the leading cause of premature death in adult congenital heart disease (ACHD), little population-specific data exist.
Objectives: This study reports early experience from a dedicated, sub-specialty adult congenital heart disease-heart failure (ACHD-HF) clinic to identify risk factors for adverse outcome.
Methods: Between 2012 and 2015, 126 patients (57% male) attended the ACHD-HF clinic. Baseline and follow-up data were analyzed and compared across 4 anatomical/physiological subgroups: cyanotic ACHD, single ventricle (1 V), biventricular circulation-subaortic right ventricle (2V-RV) and biventricular circulation-subaortic left ventricle (2V-LV). Multivariable Cox proportional hazard models were used to identify predictors of the composite primary outcome: death, transplant or ventricular assist device (VAD).
Results: Mean age at first visit was 38 ± 13 years. Patients were grouped as follows: cyanotic ACHD 10%, 1 V 24%, 2V-RV 29% and 2V-LV 37%. During a median follow-up of 1.7 (interquartile range: 0.8-2.9) years, 38 patients (30%) reached the primary outcome with event-free survival 89%, 78% and 63% at 1, 2 and 3 years respectively. Forty (31.7%) patients experienced 69 HF hospitalisations. Between-group differences were noted for systolic function, valvular regurgitation, pacing prevalence and invasive hemodynamics. Multivariable analysis revealed 2V-RV subgroup ($p = 0.001$), NYHA class ($p = 0.002$) B-type natriuretic peptide >164 pg/ml ($p = 0.003$) and sodium <136 mmol/L ($p = 0.036$) were independently associated with death, transplant or VAD.
Conclusions: Our young ACHD-HF patients experienced high adverse event rates during a limited period of follow-up. The prognostic markers identified by this study will aid clinicians to stratify short-term risk and thereby guide advanced HF management decisions in ACHD.

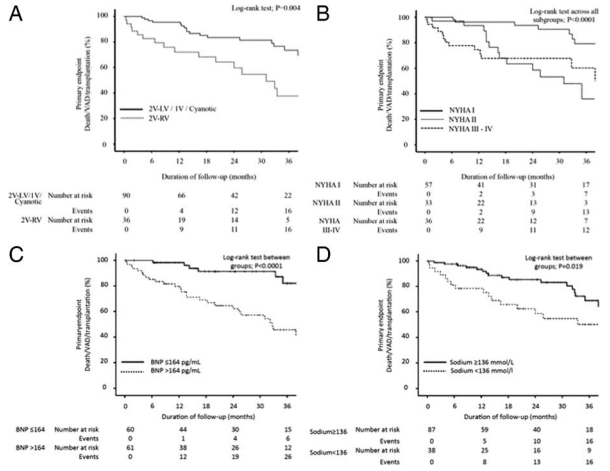

Figure.

O2396 - REDUCED EXERCISE PERFORMANCE IS RELATED TO NUMBER OF THORACIC SURGERIES IN CHILDREN WITH CORRECTED TETRALOGY OF FALLOT OR FONTAN CIRCULATION

Graziëlla Eshuis, Gideon M. Marchie Du Sarvaas, Djoeke Wolff, Rolf. M.f. Berger, Beatrijs Bartelds

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Beatrix Children's Hospital (UMCG), Center For Congenital Heart Diseases, Groningen-The Netherlands

Background: Adults with congenital heart defects (CHD) have a reduced exercise performance related to morbidity and mortality. It is unknown if this is due to changes in the circulation because of their CHD or due to other factors. Exercise performance and the relation with morbidity and mortality has been poorly described in children. The aim of this study was to describe exercise performance in children with CHD, and to describe the effect of thoracic surgery on exercise performance.
Materials and Methods: A retrospective study was performed between January 2012 and December 2016. Children with a corrected Tetralogy of Fallot (cTOF n = 75) or Fontan circulation (Fontan n = 39) between 8 and 18 years of age performed a cardiopulmonary exercise test (CPET) on a bicycle ergometer with a continuous RAMP-protocol. Increment protocols were based upon body height and estimated fitness. Exclusion criterion was respiratory expiratory ratio <1.00. Predictive values were calculated separately for boys and girls based on age (Bongers 2012). The total number of thoracic surgeries per individual were analyzed.
Results: Data is presented in a supplemental table. Both groups were limited in their exercise performance (predicted VO2peak cTOF 81 ± 22% and Fontan 67 ± 19%), Fontan significantly worse than cTOF (p = 0.002). One-way ANOVA showed significant lower exercise performance between the surgical groups (VO2% predicted p <0.001). Univariate linear regression showed a significant effect of number of thoracic surgeries on VO2%predicted (B -7.2%, p <0.001). In a multivariate model including diagnosis (cTOF and Fontan) and body weight, three or more thoracic surgeries showed significant effect of -11.6% (p = 0.021).
Conclusion: We showed that exercise performance is reduced already in young children with CHD. Children with Fontan are more impaired than those with cTOF. Independent of diagnosis and body weight, three or more thoracic surgeries had a negative effect on exercise performance.

Table.

	cTOF (n = 75)	Fontan (n = 39)	*p*-value

O2398 - OUTCOME FOLLOWING ASSESSMENT OF PAEDIATRIC PATIENTS FOR CARDIAC TRANSPLANT

Rebecca Johnson[1], Louise Coats[1], Kate Best[2], Gareth Parry[3], Zdenka Reinhardt[1], John Osullivan[1], Emma Simpson[4], Fabrizio De Rita[5], Asif Hasan[5], David Crossland[1]
Freeman Hospital, Congenital Cardiology, Newcastle Upon Tyne-United Kingdom[1]; Newcastle University, Institute of Health and Society, Newcastle Upon Tyne-United Kingdom[2]; Freeman Hospital, Department of Cardiothoracic Transplant, Newcastle Upon Tyne-United Kingdom[3]; Freeman Hospital, Paediatric Cardiac Intensive Care, Newcastle Upon Tyne-United Kingdom[4]; Freeman Hospital, Congenital Cardiac Surgery, Newcastle Upon Tyne-United Kingdom[5]

Background: Outcomes following paediatric cardiac transplant are well documented. Less is known about outcomes from the time of assessment and listing. We aimed to describe the outcomes of children assessed for cardiac transplant comparing those with congenital heart disease (CHD) and cardiomyopathy (CM).
Methods: A retrospective case note analysis of all children (0-18 years) assessed for cardiac transplant at Freeman Hospital, Newcastle upon Tyne, UK between 2005 and 2015 was performed.
Results: 256 patients were assessed (54.3% male, median age 2.5 IQR 0.7-9.8 years, 43.4% CHD, 56.6% CM). There was no difference in age between the two groups (CHD: 3.6 IQR 0.8-9.7 years v. CM: 2.0 IQR 0.7-10.4 years, p = 0.371) or the proportion listed for transplant (CHD:72% v. CHD:77%, p = 0.344). Mechanical support was used less frequently in the CHD group (CHD:21% v. CM:48%, p < 0.0001). Survival following assessment was worse in CHD patients (CHD – 1 year:65%, 5 year: 59% v. CM – 1 year:83%, 5 year:79%, p = 0.008) and a higher proportion of CHD patients died on the waiting list (CHD:29% v. CM:13%, p = 0.009). Of those listed, fewer CHD patients underwent transplant (CHD: 61% v. CM:78%, p = 0.014). Post-transplant survival was comparable between groups (CHD - 1 year:90%, 5 year:82% v. CM - 1 year:93%, 5 year:88%, p = 0.584).
Conclusions: Following assessment for cardiac transplant CHD patients have a higher mortality, they are more likely to die on the waiting list and are less likely to be transplanted than those with CM. This is despite similar rates of listing and equivalent post-transplant survival. This is partly explained by the limited suitability of CHD patients for mechanical support. These findings should be considered when determining urgent transplant listing criteria and priority for heart allocation in children and highlights the need for more effective mechanical support in the CHD population.

O2577 - OUTCOMES AFTER ORTHOTOPIC HEART TRANSPLANT AT TEXAS CHILDREN'S HOSPITAL FOCUS ON RETRANSPLANTATION

Rodrigo Zea-Vera[1], Nathan Rodgers[2], Huirong Zhu[3], William J. Dreyer[2], Susan W. Denfield[2], Jack F. Price[2], Antonio G. Cabrera[2], Hari Tunuguntla[2], Claire Bocchini[4], Carlos M. Mery[1], Lauren C. Kane[1], Jeffrey S. Heinle[1], Charles D. Fraser[1], Iki Adachi[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Controversies exist regarding repeat heart transplant due to its poorer outcome compared to primary transplant in the setting of organ shortage. We sought to review outcomes at our institution, to guide the patient selection process.
Materials and Methods: All patients listed for isolated heart transplant at our institution between 1995-2016 were included. Wait-list and post-transplant outcomes were compared between the two groups: listing for primary (P) and repeat transplant (R). Poor wait-list outcome was defined as either death or removal from the wait-list due to poor condition. Post-transplant graft loss was defined as death or need for re-transplant. Waitlist outcomes were assessed using competing risk analysis. Post-transplant outcomes were evaluated using log-rank test with logistic regression.
Results: In total, 380 patients were listed 413 times: 360 and 53 in Group P and R, respectively. Overall, there was a difference in the proportion of patients that reached transplant: 72% and 58%, respectively ($p < 0.05$). At 1 year after listing, patients in Group R were less likely to have received transplant (P, 66% [95% CI:64-69] and R, 44% [95% CI:37-50]) and more likely to remain on the wait-list (P, 18% [95% CI:16-20] and R, 35% [95% CI:29-42]). Post-transplant graft survival was significantly different: 10-year graft survivals were 60% and 36%, respectively ($p = 0.02$). This was despite identical 1-year survival (92% and 90%, respectively), suggesting late attrition being the fundamental problem. In Group P, there was a reduction in graft loss over time: 10-year graft survival before and after 2005 were 49% and 68%, respectively ($p < 0.01$). In Group R, however, such a positive era-effect was absent: 7-year graft survival were 52% and 45%, respectively ($p = 0.57$). Years from previous transplant was a protective factor (OR:0.7 [95% CI: 0.5-0.9]) from graft loss in Group R.
Conclusions: Patients undergoing repeat heart transplant carry poorer wait-list and post-transplant outcomes. Further studies are warranted for better patient selection.

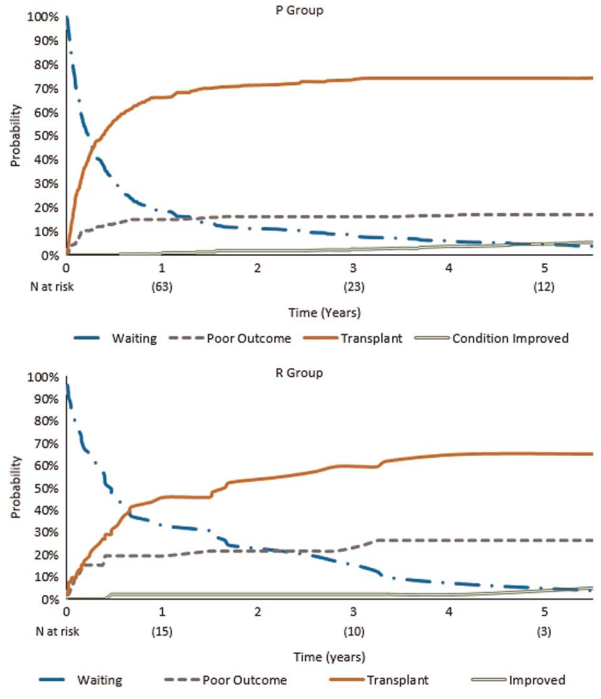

Figure.
Competing Risk Analysis for Waitlist Outcomes.

O2622 - EARLY RESULTS AND LONG TERM FOLLOW UP DOUBLE PATCH FLAP VALVE VSD CLOSURE IN PATIENTS WITH PULMONARY HYPERTENSION AND ELEVATED PULMONARY VASCULAR RESISTANCE.

William Novick[1], Vasily Lazorhyshynets[2], Alexander Govolenko[2], Frank Molloy[3], Marcelo Carderelli[4], Sara-Catherine Zzing[5], Thomas Di Sessa[6]
University of Tennessee Health Science Center, Surgery, Memphis-United States[1]; Amosov National Institute of Cardiovascular Surgery, Congenital Cardiac Surgery, Kyiv-Ukraine[2]; William Novick Global Cardiac Alliance, Intensive Care, Memphis-United States[3]; William Novick Global Cardiac Alliance, Surgery, Fairfax-United States[4]; University of Tennessee Health Science Center, College of Medicine, Memphis-United States[5]; William Novick Global Cardiac Alliance, Cardiology, Lexingotn-United States[6]

Background: Children with VSD, pulmonary hypertension (PHT) and elevated pulmonary vascular resistance (PVR) are at increased risk for both early and late death following VSD closure. We developed a fenestrated flap valve unidirectional VSD closure patch (DFV) to use in these patients. Our first implant was in 1996 and late follow-up (f/u) has been conducted on all patients at the initial institution.
Methods: Records from the institute where the first implant was performed (5/96) and from the NGO were queried for DFV patients. Beginning in 2005 all patients considered for DFV we placed on 3 months of sildenafil before catheterization. Initial and f/u records were pulled and analysis was performed on demographics, catheterizations, echocardiographic follow-up and mortality.
Results: Forty (40) patients received the DFV, hospital discharge survival was 97.5% (39/40). Twenty-two were female. Median age was 7.5 years. Baseline catheterization data: mean PAp 69.2 ± 9.6, median PVR 9 Wu, median PVR/SVR 0.50 and Qp/Qs 1.3. Pre-cath sildenafil did not significantly change PVR, Qp/Qs, or percentage of patients who responded to vasoactive testing (VAT), $p = 0.5$. Two patients were lost to follow-up at 5 and 5.5 years, there was 1 late death. The median f/u was 15.9 years. Risk factors for development of severe PHT at last f/u by univariant analysis were PVR/SVR of $\geq$ 0.56 ($p < 0.001$) pre-op, PVR >13.9 Wood units ($p < 0.01$) and a less than 10% change with VAT (oxygen only). The degree of PHT at last f/u in all patients was: none 8/38 (21.1%); mild 15/38 (39.5%); moderate 8 (21.1%) and severe 7/38 (18.4%).
Inferences: Young patients with PHT and severely elevated PVR have a significant chance of not developing severe PHT and therefore should not be denied operation routinely. An individualized approach is warranted.

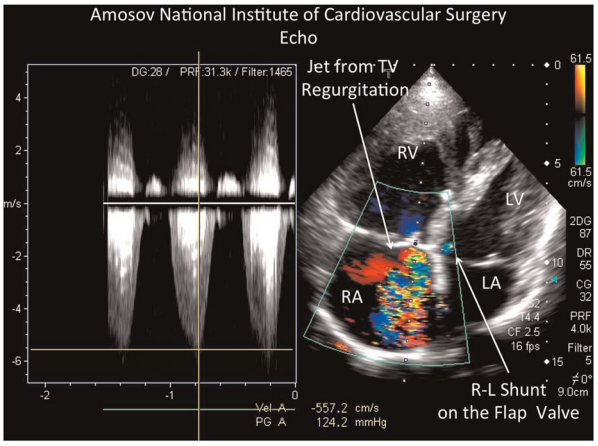

Figure.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

O2778 - RIGHT ATRIAL FUNCTION IN CHILDREN WITH PULMONARY HYPERTENSION.

Shine Kumar[1], Karun Vadlamudi[1], Prashant Bobhate[2], Shreepal Jain[3], Timothy Colen[4], Nee Khoo[5], Tarek Kaddoura[6], Ian Adatia[7]
Stollery Childrens Hospital,University of Alberta, Pediatric Cardiac Critical Care and Pulmonary Hypertension, Edmonton-Canada[1]; Stollery Childrens Hospital,University of Alberta, Pediatric Cardiac Critical Care and Pulmonary Hypertension Service, Edmonton-Canada[2]; Stollery Childrens Hospital, University of Alberta, Pediatric Cardiac Critical Care Unit, Edmonton-Canada[3]; Stollery Childrens Hospital University of Alberta,, Pediatic Cardiology, Edmonton-Canada[4]; Stollery Childrens Hospital,University of Alberta, Pediatric Cardiology, Edmonton-Canada[5]; University of Alberta, Electrical and Computing Engineering, Edmonton-Canada[6]; Stollery Childrens Hospital, University of Alberta, Pediatric Pulmonary Hypertension, Edmonton-Canada[7]

Background: We sought to investigate whether right atrial (RA) area change, a marker of RV diastolic function, influences survival in childhood PAH.
Methods: We studied RA function in children with PAH undergoing cardiac catheterization and an echocardiogram between 2009-16. RA and RV endocardial area were traced in the apical 4 chamber view. We recorded maximum RA area, RA area at the onset of the P wave (RA area p) and minimum RA area. We calculated the following: RA(RAFAC) and RV (RVFAC) % fractional area change from (maximum RA or RV area - minimum RA or RV area)/ maximum RA or RV area), RA passive emptying (RAEp) from (maximum RA area – RA area p)/ maximum RA area, active RA emptying (RAEa) from (RA area p - minimum RA area)/ RA area p, RA active emptying fraction % (RAEF) from (RAFAC – RAEp)/RAFAC. Event free survival was the time from catheterization to starting parenteral treprostinil therapy, transplant or death.
Results: We studied 57 children (27 F), median age 3 yrs (range 0.3-17), BSA 0.56 m2 (0.2-1.8). Median event free survival was 3yrs (0.2–8.4),RAFAC was 34% (13-74), RAaEF was 60% (13-94%). Patients with RAaEF $\geq$ 58% had greater mean PA pressure 57 ± 22 mmHg vs. 38 ± 11 mmHg ($p = 0.0002$), PVRI 14.5 ± 7.7 vs. 8 ± 4 WU.m2 ($p = 0.0003$). RAaEF $\geq$ 58% was associated with decreased 5 yr event free survival (sensitivity of 100%, specificity of 56%). RVFAC $< 25\%$ was associated with worse survival at 5 yrs with a sensitivity of 72% and specificity of 79%. RAaEF $\geq$ 58% with RVFAC $< 25\%$ were independently associated with event free survival at 5 yrs ($p = 0.02$ and $p = 0.0003$ respectively).
Conclusion: In children with PAH impaired RV function is associated with poor outcomes. Increased RAaEF predicts decreased event free survival independently of RV systolic dysfunction.

O2823 - HEART RATE REDUCTION STRATEGY IN DUCHENNE DILATED CARDIOMYOPATHY

Rachele Adorisio[1], Nicoletta Cantarutti[1], Adele D[2], Anwar Baban[1], Fiore Iorio[1], Antonio Amodeo[1], Fabrizio Drago[1]
Bambino Gesù Hospital, Pediatric Cardiology and Cardiac Surgery, Rome-Vatican City[1]; Bambino Gesù Hospital, Neurology, Rome-Vatican City[2]

Background: Dilated cardiomyopathy (DCM) is a major source of morbidity and mortality in Duchenne muscular dystrophy (DMD) patients. No studies are available on the effect of heart rate reduction (HRR) on DCM-DMD.
Objective: To evaluate the effectiveness of a HRR strategy using optimal dosage of beta blockers with/without ivabradine on the onset of acute adverse events in DCM-DMD patients.
Methods: We retrospectively analysed all patients aged >9 years with DCM-DMD and systolic dysfunction (ejection fraction <45%) referred to our institution, treated with a HRR strategy. Our institutional protocol established to uptitrate beta blockers with ivabradine in order to reach the target HRR of 20% or reaching 60 beats/min every two weeks [group 1]. These data were compared to control group, not receiving the HRR strategy [group 2]. We evaluate if the HRR strategy had an effect on: i. left ventricular ejection fraction, measured by echocardiography at baseline, and during follow up; ii. reduction on the rate of death and/or new hospitalizations ii.
Results: From our database of 80 DCM-DMD patients, 20 patients matched all entry criteria (mean age 19.6 + /- 5.7 yrs; group 1: $n = 13$; group 2: $n = 7$) and clinical, echocardiographic data were collected during follow up 2.2 ± 1.1 yrs.. In the group 1, mean HR was 95 ± 12 bpm at baseline, during follow up decreased to 62 ± 7 bpm ($p < .001$) while in the group 2 mean HR was 87 ± 13 bpm at baseline with no significant variation during follow up (mean 91 ± 10). HRR strategy showed left ventricular function improved (from baseline EF $28 \pm 3.2\%$ to 35 ± 4.2 EF%). Adverse events occurred in 15,4% vs 85,7% in the group 1 and group 2, respectively ($p < 0.0001$).
Conclusion: HRR strategy seems to be effective in reducing the incidence of acute adverse events and improving ventricular function in DCM-DMD patients.

O2873 - OUTCOME OF PAEDIATRIC PATIENTS WITH CONGENITAL HEART DISEASE TRANSFERRED FROM THEIR REGIONAL CARDIAC INTENSIVE CARE UNIT TO A UNIT WITH TRANSPLANT AND MECHANICAL SUPPORT CAPABILITY

Barbara Cardoso[1], Emma Simpson[1], Lee Ferguson[1], Judit Llevadias[1], Teresa Chilà, Margarita Guillèn[1], Yamuna Thiru[1], Fabrizio De Rita[2], Asif Hasan[2], David Steven Crossland[3]
Freeman Hospital, Department of Paediatric Intensive Care, Newcastle Upon Tyne-United Kingdom[1]; Freeman Hospital, Department of Cardiothoracic Surgery, Newcastle Upon Tyne-United Kingdom[2]; Freeman Hospital, Epartment of Paediatric Cardiology, Newcastle Upon Tyne-United Kingdom[3]

Background: Children with congenital heart disease (CHD) admitted to a Paediatric Cardiac Intensive Care Unit (PCICU) who exhaust conventional therapy or surgical options may be transferred to a PCICU with transplant and mechanical support capability for further management. We aimed to describe the management and outcome of this group- not all of whom are referred 'for transplant'.
Materials and Methods: Retrospective analysis of the records of patients with CHD and circulatory failure transferred from their regional PCICU between January 2011 and January 2016. Patients with cardiomyopathy were excluded.
Results: Twenty-seven patients were transferred and overall survival was 78% at 1 month and 61% at 1 year. 59.3% were male, median age 9.8 months IQR 4.4–44.6 months and 11 (41%) had univentricular physiology. Eight (29.6%) were transferred on ECMO. Seventeen patients were listed for cardiac transplant: 12 transplanted, 5 deaths on waiting list, 2 post-transplant deaths (day 102 and 109). Six VADs were undertaken as bridge to transplant (3 transplanted, 3 deaths onlist). Six patients were managed conventionally (4 further surgery, 2 medical/ ECMO only), all survived. Four patients were considered unsuitable for any further intervention including transplant. There was no difference in mortality between univentricular and biventricular circulations

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(p = 0.346) or those transferred on ECMO vs non-ECMO (p = 0.476). Survival was lower at <1 year of age compared to >1 year (survival at 30 days 64% v. 92%; one year 44% v. 77%, p = 0.051).
Conclusions: Although transplant is effective for CHD patients transferred acutely to a quaternary PCICU, mortality on the waiting list is a serious issue, partially due to limited mechanical support options for these patients. A carefully selected sub-group can be managed successfully with medical therapy and conventional surgery and this should be an integral part of the management offered by such PCICUs.

O2961 - LACK OF REJECTION AND EVIDENCE OF AUTOLOGOUS CELL REPOPULATION FOLLOWING HETEROTOPIC IMPLANTATION OF DECELLULARIZED PULMONARY HOMOGRAFTS. PATHOLOGICAL RESULTS IN A MURINE MODEL

Massimo Padalino[1], Mila Della Barbera[1], Arben Dedja[1], Cosimo Rasola[1], Michela Pozzobon[2], Gaetano Thiene[3], Giovanni Stellin[3]
University of Padova, Cardiac, Thoracic and Vascular Sciences, Padova-Italy[1]; Fondazione Istituto Di Ricerca Pediatrica Città Della Speranza, Regenerative Medicine, Padova-Italy[2]; Niversity of Padova, Cardiac, Thoracic and Vascular Sciences, Padova-Italy[3]

Objective: Tissue guided regeneration by means of decellularized scaffolds is based on the repopulation principle by the recipient autologous cells. Aim of this study was to evaluate inflammatory and regenerative responses after heterotopic implantation of decellularized pulmonary valve homografts (PVH) in a murine model.
Methods: Six PVH, harvested from wild-type Sprague-Dawley (SD) rats, underwent decellularization protocol consisting of 3 cycles of detergent-enzymatic treatment (DET) constituted by sodium deoxycholate (SDC) and DNase-I. Six native, undecellularized PVH served as control. Four decellularized and 4 native PVH were implanted in the abdominal aorta of green fluorescent protein (GFP) SD rats; the 4 unimplanted PVH, both native and decellularized served as decellularization control. Grafts, explanted 15 and 30 days after surgery, underwent gross, X-ray, histology, immunohistochemistry, electron microscopy immunogold labelling with the antibodies: anti-Von Willebrand factor (vWF), Smooth Muscle cell Actin (SMA), Vimentin (VIM), CD45, CD68 and anti-GFP. Cell density/mm2 was also measured.
Results: Before decellularization, PVH showed repopulation endothelial lining, valve interstitial cells as well and muscle cells in lamellar units. After decellularization, PVH exhibited complete decellularization (A), with DNA content of 5 ng/μl (removal greater than 95%). After 15 and 30 days from implant, native PVH showed severe cellular rejection, while decellularized PVH exhibited SMA positive myointimal cell layer, cell repopulation in outer media wall (B, C) and partial endothelial lining, in the absence of rejection. Cell density/mm2 was 126.14 ± 69.29 vs 132.07 ± 30.00 (p = NS) in the decellularized PHV media 15 and 30 days after implant, respectively while in the native was 533.72 ± 95.48 (p < 0.01). In the decellularized PVH wall, CD45 positive large, undifferentiated cells were found. All repopulation cells were GFP positive (D).
Conclusions: In this murine model, an effective removal of valve and arterial wall cells was obtained by DET-SDC decellularization treatment. Autologous GFP positive cell repopulation occurred with autologous cell origin evidence and no rejection.

O3026 - CARDIAC REGENERATIVE THERAPY USING CARDIAC PROGENITOR CELL FOR HYPOPLASTIC LEFT HEART SYNDROME AND SINGLE VENTRICLE.

Shunji Sano[1], Shuta Ishigami[2], Toshikazu Sano[2], Shingo Kasahara[2], Kenji Baba[3], Shinichi Otsuki[3], Hidemasa Oh[4]
Ucsf, Pediatric Cardiac Surgery, San Francisco-United States[1]; Okayama University, Cardiovascular Surgery, Okayama-Japan[2]; Okayama University, Pediatric Cardiology, Okayama-Japan[3]; Okayama University, Regenerative Medicine, Okayama-Japan[4]

Backgrounds: Although the surgical result of hypoplastic left heart syndrome(HLHS) and single ventricle(SV) have improved in recent era, patients with SV, especially right dominant SV are particularly at risk for heart failure accompanied by high mortality We conducted cardiac regenerative strategy using cardiac progenitor cell infusion in children with HLHS and SV since 2011. The aim of this study is to determine whether intracoronary delivery of autologous progenitor cell improves cardiac function in patients with HLHS and SV.
Methods: Between January, 2011, and March, 2015, 41 children (2.8 ± 1.4 yr) with HLHS and SV were assigned to receive intracoronary infusion of cardiac progenitor cells after staged palliation. Of these, 17 patients were initially assigned to the control group. All received late CDC-infusion as an alternative option at a 3-month follow-up examination, and completed 3-month to 1-year follow-up studies after protocol intervention. Cardiac tissues were harvested during bidirectional Glenn procedure in 10 and Fontan in 31 patients. Progenitor cells were isolated and cultured. Progenitor cell was selectively infused into each coronary artery 1-2 months after surgery.
Results: There were no major adverse events up to 2 years. Based on cMRI, children received progenitor cell infusion showed a significant improvement of ventricular ejection fraction (Δ Ejection fraction- (%) :1.3 vs 6.4), ventricular mechanical efficiency (Ea/Ees; systemic ventricle and ventriculoarterial coupling) (ΔEa/Ees : 1.6 vs 1.2) and ventricular stiffness(Δ Ventricular stiffness:0.18 vs 0.12). In addition, plasma BNP levels and heart failure status were all markedly improved during follow-up observation
Conclusion: Intracoronary infusion of cardiac progenitor cells has improved ventricular function, ventricular mechanical efficiency, and ejection fraction and ventricular stiffness.

O3027 - THE PUMPKIN TRIAL STUDY DESIGN AND RATIONALE

Christopher Almond[1], Jake Jaquiss[2], Patti Massicotte[3], Rebecca Ichord[4], Jonathan Kaltman[5], Mario Stylianou[5], Sandra Siami[6], Kurt Dasse[7], Debra Egan[5], Victor Zak[8], Timothy Baldwin[5], William Mahle[9]
Stanford University, Pediatrics, Palo Alto-United States[1] University of Texas Southwestern, Surgery, Dallas-United States[2]; Stollery Children, Pediatrics, Edmonton-Canada[3]; Children's Hospital of Philadelphia, Pediatrics, Philadelphia-United States[4]; Nih, Nhlbi, Bethesda-United States[5]; New England Research Institute, Regulatory Affairs, Watertown-United States[6]; Geno Llc, Medical Devices, Cocoa-United States[7]; New England Research Institute, Biostatistics, Watertown-United States[8]; Children's Healthcare of Atlanta, Pediatrics, Atlanta-United States[9]

Background: Severe heart failure in children carries high mortality. Durable ventricular assist device (VAD) options for smaller children are currently limited to pulsatile devices that carry a high risk of stroke and lack portability. The Jarvik 2015, a fully implantable axial flow pump, similar in design to contemporary adult

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

devices, has emerged as a promising treatment alternative for bridge-to-transplant support in smaller children.
Methods: The PumpKIN trial is an Investigational Device Exemption (IDE) study designed to evaluate the Jarvik 2015 VAD in children to support regulatory review of the device under the HDE regulation. The IDE study, which was conditionally approved by the FDA in 2016, is set to begin enrollment in 2017.
Results: The PumpKIN trial is a randomized clinical trial comparing the safety and probable benefit of the Jarvik 2015 VAD to the Berlin Heart EXCOR® Pediatric VAD. Children between 8 and 20 kilograms with 2-ventricle circulations and class IV heart failure (INTERMACS profile 1 or 2) despite optimal medical therapy and candidates for heart transplant will be enrolled. The primary probable benefit endpoint is the survival to transplant or 180 days of support without severe neurological dysfunction or randomized device failure. The primary safety endpoint is the incidence of protocol-defined adverse events using PEDIMACS criteria (version 5.0). The study is powered to show non-inferiority of the primary safety endpoint and will enroll a total of 88 subjects randomly assigned in a one-to-one ratio to each study arm.
Conclusions: The PumpKIN trial will be the first randomized clinical trial of a pediatric ventricular assist device. It is anticipated that data generated from the study will provide critical safety and effectiveness information for the first axial flow pump designed specifically for children with advanced heart failure.

O3031 - A NOVEL MINIATURE IMPLANTABLE CONTINUOUS FLOW PEDIATRIC VENTRICULAR ASSIST DEVICE

Peter Wearden[1], Trevor Snyder[2], Ryan Stanfield[3], Phillip Coghill[2], Dan Crompton[4], Salim Olia[4], Marina Kameneva[4], Sang Ho Ye[4], William Wagner[4], Ergin Kocyildirim[5], Shobhit Madan[6], Melita Viegas[5], Patrick Callahan[7], Jingchun Wu[8], James Long[9]
Nemours Children's Hospital, Nemours Cardiac Center, Orlando-United States[1]; Vadovations, Inc., Research & Development, Oklahoma City-United States[2]; Vadovations, Inc., Engineering, Oklahoma City-United States[3]; University of Pittsburgh, Bioengineering, Pittsburgh-United States[4]; University of Pittsburgh, Cardiothoracic Surgery, Pittsburgh-United States[5]; Children's Hospital of Pittsburgh, Radiolgy, Pittsburgh-United States[6]; University of Pittsburgh, Anesthesiology, Pittsburgh-United States[7]; Advanced Design Optimization, Los Angeles-United States[8]; Integris Baptist Medical Center, Nazih Zudhi Transplant Institute, Oklahoma City-United States[9]

Continuous flow ventricular assist devices (CFVADs) are demonstrated significant improvements in survival and quality of life in adults with heart failure. Unfortunately, no CFVAD designed for use in children and infants is available. We are developing a miniature blood pump specific to the pediatric heart failure population, based a miniature platform blood pump technology.
Methods: The pump is the size of a 'AA' battery with a non-contacting bearing and was designed for placement directly into the left ventricle with blood flow directed through an 8-10 mm graft anastomosed to the aorta. The pump generates 0.5–4 LPM of blood flow against pediatric systemic pressures. Hydraulic and hemolysis performance were evaluated in vitro. Anatomic fit was assessed using imaging from children from 2.5–25 kg imported into Mimics (Materialise, Plymouth, MI). Acute and chronic implants were performed in sheep for durations up to 3 months. Hemocompatibility was assessed by blood chemistry, plasma free hemoglobin (PFH), flow cytometric assays of platelet and leukocyte activation, aggregation, and microparticles, and by von Willebrand Factor function and distribution.
Results: From anatomic studies, intraventricular pump placement is acceptable for children <10 kg, potentially down to 3 kg, depending on ventricular dilation. In vitro hemolysis testing demonstrated low hemolysis (NIH <0.08). During acute and chronic implant testing in 26–47 kg sheep, 0.8–4.2 LPM was produced with low hemolysis (<20 mg/dL). There was no sustained increase in platelet or leukocyte activation or aggregation post-implant, and VWF function was preserved, in spite of no post-operative anticoagulation. Renal infarcts were only observed in 1 of 10 chronic implants in an animal with profound hypertension.
Conclusions: These promising data confirm the feasibility of using a miniature CFVAD to support children and infants with heart failure while achieving improved hemocompatibility.

P1107 - SAFETY NUMBERS IN THE CARDIAC INTENSIVE CARE UNIT (CICU)

Zandro Tejada
Children's National Medical Center, Cardiac ICU, Washington, DC - United States

Background: The availability of an efficient electronic event reporting system intended to increase the number of reported events in CICU. This system coupled with other programs strengthens and facilitates reporting.
Objective: The CICU Safety Council and unit leadership aim to increase the CICU's safety event reporting through identification of barriers and development of programs to encourage reporting.
Methods: The council and leadership advocated to improve the electronic safety event reporting system by implementing various strategies to overcome identified barriers. These include: improvement of the RL system, provision of access to council members, multiple campaign methods such as email, nurse huddle announcements, person to person feedback, and the selection of a monthly winner for a good "catch". Also implemented are: transparency and the utilization of the Just Culture Algorithm, peer accountability and peer coaching, mini-apparent cause analysis, monthly reports through blame-free emails and monthly staff meetings.
Results: A significant increase in reported safety events in the CICU were observed when comparing the two most recent years. There were 473 events reported during the FY 2016 compared to 347 events reported in 2015.
Conclusion: Increase in the number of safety event reporting was achieved through strong collaboration between CICU leadership and the Safety Council and of various strategies and programs applied.

P1211 - KNOWLEDGE INTERVENTION AT CAMP FOR CHILDREN WITH CHD

Amrita Ramanathan, Lloyd Feit, Odessa Holt, Kristen Benito
Rhode Island Hospital, Pediatric Heart Center, Providence-United States

Transitioning from pediatric care to adult care can be difficult for patients as they must obtain responsibility for their healthcare. Many adolescents and adults with congenital heart defects (CHD) are unable to name their diagnosis and have inadequate knowledge of treatment and prevention of cardiac complications, such as knowledge about endocarditis, effects of smoking and alcohol and contraception options. Successful transition is associated with improved medical and psychosocial outcomes in adults with

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

congenital heart disease, as well as decreasing cost of medical care. Specialized camps targeted at children with chronic conditions have shown to be psychosocially beneficial. However, no research focuses on the benefits of a knowledge intervention of children with CHD in a camp setting. Many adolescents with congenital heart defects (CHD) have inadequate knowledge of treatment and prevention of cardiac complications, but will need such knowledge for successful transition to adult care. We will test knowledge improvement after a camp-based educational intervention. We were particularly interested in level of knowledge about endocarditis among our campers. We also aimed to assess camper satisfaction and feedback.35 youth with CHD age 10-14 attended a 5-day sleepover camp with medical staff and peers. Camp included group and individual education targeting knowledge about diagnosis, management/prevention of complications, and endocarditis. Youth completed a cardiac knowledge measure (modified version of the Leuven Knowledge Questionnaire) before and after camp. Youth demonstrated a significant improvement in knowledge about CHD diagnosis and prevention of complications, with particularly large gains in knowledge about endocarditis. There was no change in knowledge about sexuality and contraception, and these areas had a relatively low percentage of correct responses. CHD education is feasible and acceptable to parents and youth in the camp setting. Education in this setting may facilitate transition goals, but knowledge about sexuality may require tailored intervention for youth with CHD.

P1290 - GOAL ALIGNMENT IS CRITICAL TO THE SUCCESS IN CONGENITAL CARDIAC SURGERY TEAMWORK AND COMMUNICATION ARE THE CORNERSTONE

Alistair Phillips[1], Avni Shah[2], Nicole Berndsen[1], Vincent Olshove[1], Ken Catchpole[3]
Cedars-Sinai Medical Center, Surgery, Los Angeles-United States[1]; Saint Louis University School of Medicine, Medical School, St Louis-United States[2]; Medical College of South Carolina, Surgery, Charlestown-United States[3]

Background: To evaluate whether technical error, inadequate teamwork and communication in congenital cardiac surgeries result in flow disruptions, which can pose serious risk to patients, and to improve teamwork to improve patient safety.
Methods: Qualitative interview study was conducted with the congenital heart surgery team. Members of the surgical team were interviewed about the following four themes: general processes, goals, communication and leadership. All responses were grouped into the 20 categories, and were analyzed further for the frequency of relevant quotes in each category, by the interviewees.
Results: All the participants agreed that the surgeon oversees the OR, 60% acknowledge that leadership can change at different points in the operation, >70% mentioned the following four categories: (1) patient-centered goals, (2) primary vs. secondary goals, (3) leadership and (4) conflict resolution. 80% of the participants mentioned the safety of the patient as their primary goal, while 70% of the staff mentioned having primary and secondary goals, and describing that secondary goals conflict amongst individuals. 60% believed having a diverse team creates better care by providing a broader range of treatment options and expertise, 50% mentioned "new team" leading to tensions amongst members. 70% of participants mentioned communication as the primary method of conflict resolution. This unit employed different communication methods: pre-huddle, post-huddle, read- backs and checklists. Condescension was mentioned by 50%, which threatens the efficiency of the team. Frequency of responses that mentioned goals, conflict, teamwork, communication, and learning were 23%, 24%, 23%, 13%, and 17%, respectively.
Conclusions: While conflict is an inherent part of the OR because everyone's secondary goals are profession specific, conflict must be addressed and reduced through improved communication to maximize efficiency and improve patient safety. Developing methods of constructive communication that allows each team member to define their primary and secondary goals is vital.

P1405 - GASTROINTESTINAL BLEEDING IN PATIENTS AFTER FONTAN OPERATION

Chee-Yew Lee[1], Ming-Tai Lin[2], Shuenn-Nan Chiu[2], Chun-An Chen[2], Jou-Kou Wang[2], Mei-Hwan Wu[2], Yih-Sharng Chen[3], Chung-I. Chang[3], Shu-Chien Huang[3], Chun-Wei Lu[2]
Min-Sheng General Hospital, Pediatric Cardiology, Taoyuan-Taiwan[1]; National Taiwan University Children Hospital, Pediatric Cardiology, Taipei-Taiwan[2]; National Taiwan University Children Hospital, Cardiovascular Surgery, Taipei-Taiwan[3]

Background: Gastrointestinal (GI) bleeding is a rare but potentially life-threatening complication in patients after Fontan operation. However, the clinical presentation and risk factors of GI bleeding remain poorly understood.
Methods: We retrospectively reviewed the medical records of 117 patients who received follow-up in our institute between January 2000 and March 2016. Major GI bleeding is defined as fatal, hemodynamic instability, symptomatic, decrease in hemoglobin ≥ 2 g/dL over 24 hour or requiring transfusion.
Results: Nine patients (7.7%) had major GI bleeding and all of them underwent endoscopic examination. Eight of 9 patients had received thromboprophylaxis therapy, including warfarin in 7 patients. Median interval between the onset of GI bleeding and Fontan completion was 2.3 years, ranging from 10 days to 12 years. We categorized these patients into 2 groups: early-onset (≤3 months, n = 2) and late-onset (>3 months, n = 7). Both patients with early-onset GI bleeding are associated with sepsis and multiple organ dysfunction. Of 7 patients in late-onset group, 5 (71%) patients had clinical presentation of protein-losing enteropathy (PLE); 6 (86%) patients had INR > 2 (all under warfarin) during first GI bleeding episodes; and 7 (100%) patients had significant obstruction of Fontan pathway or stenosis of pulmonary arteries. The mortality rate is much higher in early-onset group (100%, 2/2 vs 29%, 2/7). Among them, one in late onset group developed significant GI bleeding complicated with Fontan failure and subsequently death due to brain edema and herniation. Massive GI bleeding with concurrent intracranial hemorrhage lead to the demise of the 3 remaining patients.
Conclusion: After Fontan completion, patients with early-onset GI bleeding are associated with high mortality rate. The causes of late-onset GI bleeding maybe multifactorial, including bleeding tendency and increased systemic venous pressure due to obstruction of Fontan pathway. Late-onset GI bleeding may be a part of the clinical spectrums of PLE.

P1512 - PRACTICE MAKES PERFECT IMPROVING TEAM COMMUNICATION WITH TEAM BASED SIMULATION

Alistair Phillips[1], Nicole Berndsen[1], Maureen Davis[2], Courtnay Caufield[2], Pooja Nawathe[3], Ai Jin Lee[4], Vincent Olshove[1], Russell Metcalfe-smith[4]
Cedars-Sinai Medical Center, Surgery, Los Angeles-United States[1]; Cedars-Sinai Medical Center, Nursing, Los Angeles-United States[2]; Cedars-Sinai Medical Center, Pediatrics, Los Angeles-United States[3]; Cedars-Sinai Medical Center, Education, Los Angeles-United States[4]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Development of a culture of open communication centered on goal alignment is critical to ensure safe and effective care. Team training that simulates an entire surgical scenario from preoperative preparation to surgical intervention to recovery ensures the team can respond effectively and efficiently. Team based training is used extensively in other industries like aviation and nuclear power.
Methods: From October 2013 to September 2015, we have completed four in-depth congenital heart team scenarios that are geared to the entire operative day from patient entering the operating room to operative procedure to transfer to the intensive care unit to team handoff to intensive care scenarios. allowing for goal alignment and team-based decision making over the entire continuum of the patient care team. After completing the simulation, the entire team meets to analyze the day and to identify communication failures, workflow disturbances, and equipment issues.
Results: Over the 2 years, the use of the in-depth, intensive simulations we have developed several dynamic communication tools and methods to avoid conflicts, following the American Heart Association's guidelines. We have seen a reduction in blood draws, complications like infections.
Conclusions: In the operating room and the ICU, we can develop team-based learning and develop a culture of communication centered on goal alignment. We can change scenarios and introduce very real, if infrequent, disasters. This unique environment tests the team's response as a cohesive unit. We share the same primary goal of the safe return of the patient to the family; however, each group has sub-goals and varying opinions on how to attain the primary goal. During the simulation, we can test different aspects of communication; teams with excellent goal alignment and understanding will respond to significant events in a timely and smooth manner, decreasing possible negative effects to the patient.

P1552 - THE BIRTH PREVALENCE AND RISK FACTOR OF CONGENITAL HEART DISEASE (CHD) IN INFANTS BORN FOLLOWING ASSISTED REPRODUCTIVE TECHNOLOGY(ART)

Hyun Ok Jun, Eun-Jeong Shin, Jae Suk Baek, Jeong Jin Yu, Young-Hwue Kim, Jae-Kon Ko
Asan Medical Center Children's Hospital, Division of Pediatric Cardiology, Department of Pediatrics, Seoul-Korea, South

Background: The use of assisted reproductive technology (ART) to treat infertility is increasing rapidly. Although the growing number of infants born following ART, there is lack of data about the prevalence of congenital heart defect and the risk factors of CHD in these neonates. We conducted this study to assess the association between CHD and ART.
Method: The medical records of mothers who were pregnant with ART in Asan Medical Center, since 2005 and their infants were reviewed retrospectively. The echocardiographic study was done in neonatal period for the evaluation of cardiac murmur and abnormal result of fetal echocardiography. CHD was defined as structural abnormality of the heart or intrathoracic great vessels with actual or possible functional significance. We assumed maternal risk factors for CHD as age, gestational age at birth, multifetal gestation, structural anomaly of uterus, parity, thyroid dysfunction, diabetes mellitus and hypertension.
Result: Three hundreds and sixty mothers and 484 infants were enrolled and 36 infants (7.4%) were born with CHD; 16 treatment required patent ductus arteriosus (PDA) (3.3%), 17 atrial septal defects (ASD) (3.5%), 9 ventricular septal defects (1.9%), 1 pulmonary valve stenosis, 1 aortic valve stenosis, 1 transposition of great arteries and 1 Ebstein's malformation. After excluding PDA and ASD, 12 patients (2.3%) had complex-CHD (cCHD). Among the possible risk factors for cCHD, structural anomaly of uterus (Odds Ratio [OR], 2.950, p = 0.070 ; 95% CI 0.916-9.506) and hypothyroidism (OR, 2.151, p = 0.343 ; 95% CI 0.441-10.479) increase the prevalence of cCHD.
Conclusion: The birth prevalence of CHD in neonates born with ART was increased in this study. However, there's a limitation as we could not figure out the proportion of fetal termination and the exact cause of termination. The multi-centered large scale study for the association between ART and CHD should be performed.

P1616 - THE FETUSES WITH EBSTEIN ANOMALY OR TRICUSPID VALVE DYSPLASIA A SINGLE CENTRE EXPERIENCE

Nazan Ozbarlas[1], Sevcan Erdem[1], Fadli Demir[1], Mustafa Akçali[2], Ferda Ozlu[2]
University of Cukurova, Pediatric Cardiology, Adana-Turkey[1]; University of Cukurova, Neonatology, Adana-Turkey[2]

Ebstein anomaly and tricuspid valve dysplasia are rare congenital tricuspid valve malformations associated with high perinatal mortality. In this report, we review 19 fetuses diagnosed Ebstein anomaly or tricuspid valve dysplasia from 2013 to 2016.
Methods and Results: Twelve of the patients were tricuspid valve dysplasia (TVD) and seven of them were Ebstein anomaly (EA). The mean gestational age at the diagnosis was 29,7 + 6,3 (18–38) weeks. All of them had right atrial dilatation and cardiomegaly. Cardiothoracic area (CTA) ratio was 0,46 + 0,17 (0,31–0,73). Thirteen fetuses had severe tricuspid regurgitation (TR), six of these fetuses had retrograde duct flow and three fetuses had pulmonary regurgitation (PR). Two fetuses had hydrops fetalis. Three fetuses had small ventricular septal defects, one fetus had pulmonary atresia and one noncompaction. Among all patients, there were 8 lost to follow-up, 1 fetal demise and 1 termination. Nine fetuses were live-born but five of them died first days of the life. The mean CTA ratio was higher in neonatal death group than in the living patients (0,54 (0,44–0,73), 0,44 (0,31–0,61) respectively). In neonatal death group; two patients had comorbid diseases (diaphragm hernia and bilateral renal agenesis), one patient who had no antegrade pulmonary valve flow underwent to shunt operation and died with sepsis. Other two patients died within 24 hours of life with reduced cardiac output and acidosis. Four patient are following up with mild – moderate TR. These patients ages are between 3 months and 2,5 years.
In conclusion; despite major advances in prenatal care and the diagnosis and management of congenital heart disease over the past several decades, perinatal mortality in fetuses with EA/TVD remains alarmingly high.

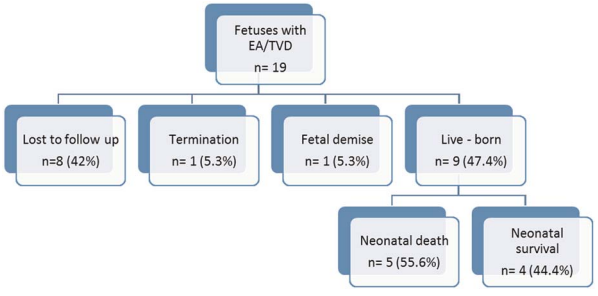

Figure.

P1624 - APPLYING A CLINICAL SERVICE RE DESIGN METHODOLOGY TO ESTABLISH A STATEWIDE MODEL OF CARE TO SUPPORT THE DEVELOPMENTAL NEEDS OF CHILDREN WITH CONGENITAL HEART DISEASE FOLLOWING EARLY OPEN HEART SURGERY

Miranda Campbell[1], Caroline Macaulay[2], Karen Eagleson[3], Bethany Hooke[1], Robert Justo[3], Kerri Webb[1]
Children's Health Queensland, Queensland Child & Youth Clinical Network, Brisbane-Australia[1]; Children's Health Queensland, Icare, Brisbane-Australia[2]; Children's Health Queensland, Queensland Paediatric Cardiac Service, Brisbane-Australia[3]

Background: Each year 100 Queensland infants with congenital heart disease (CHD) require open-heart surgery before 12 months of age, increasing their risk of poor neurodevelopmental outcomes. Developmental surveillance is recommended for infants following neonatal open-heart surgery to mitigate risk through early intervention. The Queensland Paediatric Cardiac Service (QPCS) Neurodevelopmental Follow-up Program offers robust developmental screening limited to specific high-risk cohorts and centralised to the quaternary hospital, posing challenges within a large geographical state. This project aims to establish a holistic, statewide approach to optimising developmental outcomes of Queensland children with CHD.
Methods: A collaborative partnership was established between QPCS and the Queensland Child and Youth Clinical Network to maximise statewide engagement and project outcomes. Funding was provided by the Healthcare Improvement Unit. Partnership with Innovation Change and Redesign Excellence program (iCARE) enabled application of a robust, clinical service re-design methodology, including collaboration with three hospital and health services (HHSs), and executive endorsement. Stakeholder consultation, including consumer engagement, throughout the planning and diagnostic phases established the platform from which solution and implementation phases could launch.
Results: Over 60% of infants who undergo open-heart surgery in the first 12 months of life live outside the Brisbane metropolitan area, with few linked into local supports and services. Consultation with consumers and services providing developmental supports identified barriers to optimising the developmental outcomes of this cohort. Key themes identified during the diagnostic phase include; improving communication processes, empowering parents, information and resource sharing, capability building within services, and the need for centralised data collection.
Conclusions: Application of this methodology has enabled rigorous planning and effective stakeholder engagement across partner sites, ensuring contextualised project outcomes that meet the needs of families within each HHS. It is anticipated that this methodology will support application of project outcomes across other Queensland HHSs, and to the broader CHD population.

P1643 - SERUM CREATININE LEVELS IN THE FIRST 7 DAYS OF LIFE IN NEONATES WITH CONGENITAL HEART DISEASE

Hironori Ebishima[1], Kenichi Kurosaki[2], Isao Shiraishi[2]
Osaka University Hospital, Intensive Care Unit, Osaka-Japan[1]; National Cardiovascular Center Japan, Pediatric Cardiology, Osaka-Japan[2]

Background: Acute kidney injury after cardiac surgery is an important complication. The presence of maternal creatinine and daily changes in neonatal renal function make it indefinable in neonates. We aimed to examine changes in serum creatinine level over the first week of life in neonates with congenital heart diseases (CHDs).
Materials and methods: The clinical data of 159 consecutive neonates with CHD and 125 neonates as controls were retrospectively reviewed. The exclusion criteria were birth weight of <2 kg and other major complications such as intracranial and abdominal lesions, congenital kidney diseases, and congenital diaphragmatic hernia. The neonates were classified into 3 groups, namely the simple and complex CHD with bi-ventricle groups (sBV and cBV, respectively) and single-ventricle group (SV). Follow-up was completed when an invasive procedure was performed. Serum creatinine levels over the first 7 days were compared.
Results: No significant differences in birth weight and gestational age were found between the CHD and control groups. The mean serum creatinine levels in the two groups were similar over the first 48 hours. Creatinine level kept increasing during 2 days after birth in both groups (CHD vs control group: 0.79 ± 0.14 vs 0.83 ± 0.16 mg/dl at 2 days of age, $p > 0.05$), and decreased in the control group. However, the CHD group maintained a higher serum creatinine level for 7 days after birth (0.59 ± 0.17 vs 0.36 ± 0.08 mg/dl, $p < 0.01$). No significant differences were found in the chronological changes in serum creatinine level among the 3 groups of CHD neonates (sBV, cBV, and SV).
Conclusions: Serum creatinine level was significantly higher in the CHD neonates than in the healthy neonates during the first week of life. Cardiac morphological differences seem to have little influence on the serum creatinine levels of neonates.

P1804 - EVALUATION OF CHILDREN HAVING CONGENITAL HEART DISEASE AND HOSPITALIZED WITH THE DIAGNOSIS OF LOWER RESPIRATORY TRACT INFECTION

Zulal Ulger[1], Yasemin Sahan[2], Erhan Kilicoglu[3]
Ege University Hospital, Pediatric Cardiology, Izmir-Turkey[1]; Ege University Hospital, Pediatric Cardiolgy, Izmir-Turkey[2]; Ege Üniversity Hospital, Pediatrics, Izmir-Turkey[3]

Lower respiratory tract infections (LRTI) have an important mortality and morbidity for children with congenital heart disease (CHD). In this study, 50 children who have congenital heart disease and hospitalized with the diagnosis of LRTI are analyzed in Children's Hospital of Ege University Medical Faculty. 50 pediatric patients who have CHD and hospitalized with LRTI in cardiology service between 2013 and 2015 were studied. For these patients who were previously diagnosed or have recently been diagnosed with CHD, clinical symptoms, acute phase reactants, chest X-ray and nasopharyngeal swab in respiratory virus panel (Multiplex Polimerase Chain Reaction) evaluated. Patients were classified into two groups as cyanotic and acyanotic. The groups were examined in terms of age, gender, RSV prophylaxis, hospitalization time, causative pathogen.Results: Of the 50 cases, 16(% 32) were diagnosed with cyanotic CHD and 34 (%68) were diagnosed with acyanotic CHD. Boy/girl was in ratio of 26/24. 9 cases (%18) were diagnosed with VSD and ASD, 7 cases (%14) were diagnosed with only VSD, 6 (%12) cases were diagnosed with DORV and 1 case were diagnosed with PDA + ASD. All other cases had mixed type diagnostics including VSD. The average age of patients diagnosed with cyanotic and acyanotic CHD, were $23,88 \pm 28,81$ months, $12,25 \pm 15,45$ months old respectively. %50 of patients diagnosed with cyanotic CHD and % 73.5 of patients diagnosed with acyanotic CHD were less than 12 months old. Hospitalizations most frequently occured in winter (17 cases, %34), then secondly in spring (14 cases, %28). In 3 of patients diagnosed with cyanotic CHD (%18.75) and 6 of patients

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

diagnosed with acyanotic CHD (%17.64), viral agents were detected. LTRI and specifically RSV pneumonia are important causes of mortality and morbidity in patients diagnosed with CHD

P1886 - EFFECTIVENESS OF CARDIOVASCULAR SCREENING IN 1 065 097 SCHOOL AGED CHILDREN

Yu-Chuan Hua[1], *Jou-Kou Wang*[2], *Shuenn-Nan Chiu*[2], *Hung-Chi Lue*[2]
Cardiac Children's Foundation, Screening Center, Taipei-Taiwan[1]; *National Taiwan University Hospital, Pediatric Cardiology, Taipei-Taiwan*[2]

Background: Undetected heart disease is one of the most common cause of sudden death in children. We conducted cardiac screening in school age children to detect the heart diseases.
Methods: From 1999 to 2014, a citywide cardiovascular survey of elementary school students had been performed in Taipei. A questionnaire regarding past history of heart disease, family history and cardiac symptoms was used. A 4-lead computerized electrocardiogram (ECG) & phonocardiogram were performed in each child. Patients with any abnormalities above were referred to hospital for final diagnosis.
Results: Totally 1,065,097 first grade of elementary school children underwent cardiac screening. Congenital heart disease or other types of heart diseases was identified in 5,416 children (5.1 /1000) of whom 401 children had not been diagnosed before. Atrial septal defect was the most common undiagnosed congenital heart disease, accounting for 265 children (66%). Complete heart block, WPW syndrome & prolonged QTc interval were found in 14, 818, and 99 children, respectively. Cardiomopathy was diagnosed in 72 children of whom 19 children had not been diagnosed.
Conclusions: Cardiac screening in school-aged children using questionnaire, ECG & phonocardiography is effective. Atrial septal defect was the most common undiagnosed congenital heart disease. Many kinds of cardiac conduction disorders and even life-threatening condition can also be identified through this cardiovascular screening.

P1988 - MULTI CENTER CONGENITAL HEART DISEASE DATABASES ACTIVE WORLDWIDE

David Vener[1], *Michael Gaies*[2], *Jeffrey Jacobs*[3], *Sara Pasquali*[2]
Baylor Com/Texas Childrens Hospital, Anesthesiology, Houston-United States[1]; *U Michigan/Cs Mott Childrens Hospital, Cardiology, Ann Arbor-United States*[2]; *Johns Hopkins/All Childrens Hospital, Cardiac Surgery, St Petersburg-United States*[3]

There are at least 39 known multi-center efforts collecting information on patients with congenital heart disease that we have identified worldwide. Some of these are geographically limited while others are very disease or specialty specific. We have collated and present here all of the currently active databases and registries. These were identified by personal involvement, word of mouth, PubMed searches and Google(TM) searches utilizing terms such as "cardiac, congenital, surgery, intensive care, critical care, cardiology, databases, and registries" in various combinations. Hospitals in developed countries may spend millions of dollars in participation fees and indirect expenses (salaries, travel). There needs to be better coordination between existing registries and databases and mechanisms for cross-linking data between them. Access to these databases also needs to be made more usable for resource-poor countries and for "mission" trips. Prior to starting more databases or registries it would be useful for planners to see if existing ones might suit their purposes.

Table.

ACTIVE Clinical Databases and Registries	Acronym	Sponsoring Organization and/or Data Center	Target Patient Population
Australia and New Zealand Fontan Registry		Australia and New Zealand Congenital Heart Research Centre	All patients in Australia and New Zealand who have undergond a Fontan-type single ventricle repair
Canadian Outcomes Registry Late After Tetralogy of Fallot Repair	CORRELATE	Canadian Institutes of Health Research/The HUB-University of Toronto	All patients in Canada who have undergone surgical repair of Tetralogy of Fallot, age > 12 yrs
Congenital Evaluation, Reporting, and Tracking Endeavour	CONGENERATE	Adult Congenital Heart Association/McGill University, University of Sherbrooke, University of Montreal	Adult patients with Congenital Heart Disease/ Defects
Congenital Cardiac Anesthesia Society Database	CCAS	Congenital Cardiac Anesthesia Society/Duke Clinical Research Institute	Any procedures involving congenital cardiac patients, limited to STSCHSD participating sites
Congenital Cardiac Catherizations Project on Outcomes	C3PO	Children's Hospital Boston	Patients undergoing congenital cardiology interventional procedures
Congenital Cardiovascular Interventional Study Consortium	CCISC	Children's Hospital of Michigan	Interventional cardiology procedures, tends to be very lesion specific
Congenital Heart Surgeons Society Database	CHSS	Congenital Heart Surgeons Society Data Center at The Hospital for Sick Children, Toronto	Specific Congenital Heart Lesions depending upon study area (currently 4 active studies (LVOTO, AVSD, AAOCA, Tricuspid Atresia; one pending, Ebsteins)
European Congenital Heart Surgeons Association Database**	ECHSA	European Congenital Heart Surgeons Association	Patients undergoing any ongenital heart surgical procedure
European **R**egistry for **I**CD and CRT Devices in Pediatrics and Adults with Congenital Heart Disease	EURIPEDES	Association for European Paediatric and Congenital Cardiology/European Society of Cardiology/Competence Network Congenital Heart Defects	Pediatric and Congenital Patients with ICD or CRT devices
European Registry for Patients with Mechanical Ciruculatory Support	EUROMACS	European Association of Cardio-Thoracic Surgery	All age patients with durable and temporary mechanical support devices
Extracorporeal Life Support Organization Registry	ELSO	Extracorperal Life Support Organization	Patients undergoing extracorporeal membrane oxygenation (ECMO)
German Heart Institute Myocarditis Registry for Children	MYKKE	Association for European Pediatric Cardiology/Competence Network for Congenital Heart Defects	Pediatric myocarditis
Guangdong Registry of Congenital Heart Disease			All patients with a diagnosis of CHD
Improving Pediatric and Adult Congenital Treatments	IMPACT	American College of Cardiology/ National Cardiovascular Data Registry/Mid America Heart Institute	Patients undergoing congenital cardiology interventional procedures

P2212 - HIGH MEAN PLATELET VOLUME IN CONGENITAL HEART DISEASE WITH PULMONARY HYPERTENSION

Motoki Takamuro[1], Madoka Ishida[1], Ai Kasuga[2], Norihisa Horita[3], Keiji Haseyama[1], Masato Yokozawa[1]
Hokkaido Medical Center For Child Health And Rehabilitation, Pediatric Cardiology, Sapporo-Japan[1]; Sapporo Medical University, Pediatrics, Sapporo-Japan[2]; Otaru Kyokai Hospital, Pediatrics, Otaru-Japan[3]

Backgrounds: Because thrombosis is one of the significant problems in congenital heart disease, platelet activity in this situation is an important issue to concern. Mean platelet volume (MPV) is measurable in routine blood cell counts and reflects to platelet activity.
Purpose: To investigate the relationship between platelet activity and hemodynamic parameters including quantity of pulmonary blood flow and pulmonary arterial pressure.
Methods: From 2012 to 2015, 279 cardiac catheterizations for congenital heart diseases without surgery were examined. Quantity ratio of pulmonary and systemic blood flow (Qp/Qs), mean pulmonary arterial pressure (mPAP), and brain natriuremic peptide (BNP) were compared to MPV. Each parameter was analyzed by regression analysis.
Results: Age at catheterization was 0 to 76 years old (median 5.3). Each parameter range, average and standard deviation were followed as; MPV 7.5 to 12.5 fL (mean 9.3, SD 0.8), SpO2 72 to 100% (average 96.6, SD 3.9), Qp/Qs 0.4 to 7.1 (average 1.7, SD 0.74), mPAP 11 to 60 mmHg (average 19.1, SD 6.2), BNP less than 5 to 3608.1 pg/ml (average 38.6, SD 226.0). In regression analysis to MPV, Qp/Qs had significant but weak positive relation (R 0.16, $p = 0.01$). SpO2, mPAP and BNP had no significant relation. However in 34 cases whose mPAP is higher than 25 mmHg, MPV had significant negative relation to mPAP ($R = 0.53$, coefficient = 0.043, $p = 0.001$) and not significant but positive relation to Qp/Qs ($R = 0.34$, coefficient = -0.29, $p = 0.05$).
Discussion: Although there is no relationship between MPV and hemodynamic parameters in all of native congenital heart disease, cases with pulmonary hypertension had higher platelet activity as higher pulmonary arterial pressure and lower pulmonary blood flow. In cases with high pulmonary vascular resistance platelet might be activated by endotherial injury due to pulmonary hypertension.

P2288 - PAEDIATRIC CARDIOLOGY TRAINING IN THE UK

Mohammad Abumehdi, Richard Ferguson
Royal Hospital For Children, Paediatric Cardiology, Glasgow-United Kingdom

Introduction: Paediatric cardiology has experienced enormous advances since its conception to current practice, incorporating highly developed medical, surgical and radiological techniques allowing significantly improved prognosis from hours or days to near normal life expectancies. We identify several important factors facing paediatric cardiology training in Britain; including the new junior doctor's contract, Shape of Training review and the future of the speciality in the post 'Brexit' U.K.
Method: We identified several key issues that have been subject to debate within paediatric cardiology and medicine in the UK. We surveyed the opinion of paediatric cardiology trainees throughout the U.K regarding the effect this may have on training. We also suggest several possible consequences on the service that these may have
Conclusion: Paediatric Cardiology is a unique speciality. However, as a speciality in the UK, it faces several potential challenges for the future. "The shape of training" proposal, with the ambition to improving functionality within the NHS, does not take into account small complex paediatric specialties'. One area of concern is the lack of clinical experience in training needed to function within this speciality. Potentially compounding this is the effects of the junior doctor contract on working hours, reducing exposure to the speciality. More subjective feelings of lower staff morale and difficult working conditions in such an emotive speciality were also an area of concern. Finally, concerns following the E.U referendum on the detriment this may have on research, information sharing and clinical experience were also highlighted. We have drawn attention to several areas of concern for paediatric trainees that, if approached early, may delineate the future generations of paediatric cardiologists.

P2487 - DETECTING HIGH RISK AREAS FOR CONGENITAL HEART DISEASE IN NORTHEAST BRAZIL

Renata Gomes[1], Luiz Carvalho Junior[2], Juliana Araújo[3], Felipe Mourato[4], Thiago Tavares[5], Fernanda Albuquerque[3], Lucia Moser[3], Sandra Mattos[6]
Círculo Do Coração De Pernambuco, Estatística, Recife-Brazil[1]; Lika, Biologia Molecular, Recife-Brazil[2]; Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Científico, Recife-Brazil[4]; Círculo Do Coração De Pernambuco, Informática, Recife-Brazil[5] Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[6]

Background: Congenital heart disease (CHD) is one of the major causes of neonatal morbidity and mortality in children. In developing countries, however, it is often under-reported leading to poor documentation of its true incidence. The objective of this study is to describe the epidemiological profile of CHD in the state of Paraiba from the implementation of a pediatric cardiology network; and also, to list the impact from its spatial distribution and associated risk factors.
Methods: Ecological study with quantitative and exploratory approach using data from neonates diagnosed with CHD from Jan-2012 to Dec-2016 in Paraíba, northeast Brazil. Data analysis was exploratory and spatial. Risk maps were generated to compare CHD cases among municipalities. Choropleth maps where created to spatially portray the Risk Ratio (RR). Clusters of CHD were identified via spatial scanning method and sociodemographic indices were compared among areas.
Results: Exactly 146,422 neonates were screened in the period. The Network team diagnosed 1,951 CHD as compared to 68 reported by the Brazilian official statistic site. For the RR, 52 municipalities (23.31%) presented RR >1.5, and in 4 (1.79%) it was greater than 4.0. Conversely, 119 municipalities (53.36%) presented lower RR for CC (RR < 1.0). The Scan spatial methods identified various clusters for CHD in the state. These clusters were associated with areas of high socioeconomic inequalities.
Conclusions: The present study identified a much higher incidence of CHD, in Paraíba, than what has been reported in the official sites. It also pointed to clusters of CHD within the State and to novel risk factors. These findings can be used to develop public strategies to promote health and prevent disease.

P2607 - USEFULNESS OF SOLUBLE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR (SUPAR) AS AN INFLAMMATORY BIOMARKER IN OBESE CHILDREN

Mustafa Kosecik[1], Pinar Dervisoglu[1], Mehmet Koroglu[2], Pinar Isguven[3], Bahri Elmas[4], Tayfur Demiray[2], Mustafa Altindis[2]
School of Medicine, Sakarya University, Department of Pediatric Cardiology, Sakarya-Turkey[1]; School of Medicine, Sakarya University, Department of Medical Microbiology, Sakarya-Turkey[2]; School of Medicine, Sakarya University, Department of Pediatric Endocrinology, Sakarya-Turkey[3]; School of Medicine, Sakarya University, Department of Pediatrics,, Sakarya-Turkey[4]

Objective: Soluble urokinase plasminogen activator receptor (suPAR) has emerged as a relatively new biomarker that reflects increased inflammatory status and been associated with cardiovascular risk. We wanted to investigate the predictive value and usefulness of suPAR as an inflammatory biomarker in obese children.
Methods and Results: Of the total 136 participants, 76 (36 male, 40 female) were in obese group and 60 (24 male, 36 female) were in control group. The median age was 12.05 (6.16-17.30) years old for obese group, and 12.83 (8.00-16.75) years old for control group. Obese children had statistically significantly higher heart rate, systolic and diastolic blood pressure, EAT and LV mass than control group ($p < 0.01$). The median suPAR level in obese group was not statistically different than in control group (0.54 vs. 0.59, $p = 0.26$). The median hsCRP level in obese group was found statistically significantly higher than in control group (1.97 vs. 0.41, $p < 0.01$). It was found a significant positively correlation between hsCRP and BMI in the obese participants ($r = 0.45$, $p < 0.01$), but not relationship between suPAR and BMI ($r = -0.21$, $p > 0.05$).
Conclusion: Our research did not demonstrate the usefulness of suPAR as an inflammatory biomarker and a predictive value for future atherosclerosis in obese children. Further studies with larger sample size are required to determine whether the suPAR is useful as an inflammatory biomarker in childhood obesity.

P2611 - THIOL DISULPHIDE HOMEOSTASIS AS A NOVEL OXIDATIVE STRESS MARKER IN OBESE CHILDREN

Bahri Elmas[1], Mehmet Karacan[2], Pinar Dervisoglu[2], Mustafa Kosecik[2], Pinar Isguven[3], Ceylan Bal[4]
School of Medicine, Sakarya University, Department of Pediatrics, Sakarya-Turkey[1]; School of Medicine, Sakarya University, Department of Pediatric Cardiology, Sakarya-Turkey[2]; School of Medicine, Sakarya

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

University, Department of Pediatric Endocrinology, Sakarya-Turkey[3]; School of Medicine, Yildirim Beyazit University, Department of Biochemistry, Ankara-Turkey[4]

Objective: Obesity leads to subclinical systemic inflammation and protein/lipid oxidation, and these biochemical changes have also been shown in adult studies in which cardiovascular disease accelerates. Thiol acts as an important antioxidant by forming disulfide bonds to remove reactive oxygen molecules. In this study, we aimed to investigate the usefulness of this novel and sensitive oxidative stress marker, thiol/disulphide homeostasis, in obese children.
Method and Results: Of the total 139 participants, 75 (34 male, 41 female) were in obese group and 64 (27 male, 37 female) were in control group. The median age was 12.0 (5.0-17.0) years old for obese group, and 12.8 (4.7-17.0) years old for control group. Obese children had significantly higher systolic blood pressure, EAT and LV mass than control group ($p < 0.05$). WBC, PLT and hsCRP were higher ($p < 0.01$), but N/L ratio and MCV values were lower in the obese group ($p < 0.001$). Native thiol, total thiol and native thiol/total thiol ratios were lower ($p < 0.05$), disulphide/native thiol and disulphide/total thiol ratios were higher in the obese group compared to the control group ($p < 0.01$). Dynamic disulphide levels were high in the obese group ($p = 0.057$) but not statistically significant.
Conclusion: We found that in obese children, impairment in thiol/disulphide homeostasis, which is indicative of oxidative stress, together with elevation in inflammatory and cardiac markers. We believe that early diagnosis and treatment of patients at risk for complications by evaluating oxidative status in obese children may result in reduced cardiovascular morbidity and mortality in adulthood.

P2857 - LEAN HEALTH STRATEGIES SHOWED IMPROVEMENT IN THE CYCLE OF CARE OF CONGENITAL HEART PROGRAM AN INNOVATIVE TEAMWOK AT FUNDACION CARDIOINFANTIL INSTITUTO DE CARDIOLOGÍA (FCI IC) BOGOTÁ COLOMBIA

Andrea Torres, Nestor Sandoval
Fundación Cardioinfantil Instituto De Cardiología, Congenital Heart Program, Bogotá, D.c-Colombia

Background: A fundamental part of the standardized objectives of our Congenital Heart Program (CHP) is to provide high quality, timely and accurate diagnosis to improve quality of care. Thus by identifying and implementing proper Lean Management Strategies (LMS) we intend to improve times along the process for better quality of care service.
Objective: to describe the cycle of care of the CHP; to diagram and calculate the time spent at each step along the process by patients and their families. Furthermore we implemented and evaluated LMS according to the identified factors affecting time efficacy.
Methods: This pseudo experimental pilot study evaluated the process and the benefit of LMS in health care services. The time spent in the cycle of care was measured in 180 patients (90 in physician consultation; and 90 in echocardiogram service) since the admission toward discharge. Cycle of care performance (minutes) data were analyzed using analysis of variance (ANOVA) and statistical process control techniques to assess time before and two months after the implementation of LMS. We also used the spaghetti and the Value Stream Mapping (VSM) diagram to investigate time-outs in care. Furthermore we used a DOFA analysis to describe the specialist´s activities.
Results: In terms of health system outcomes, the results of the study showed a scheduling overlap between the specialist consultation and the interventionist procedure. Furthermore the analysis showed patients had to perform many steps ($n = 9$) to attain a medical consultation or a diagnostic examination during the cycle of care requiring 135 minutes. The new intervention reduced the cycle of time to 5 steps spending 45 minutes (a reduction of 90 min).
Conclusions: The lean strategies implemented in the institute of Congenital Heart Disease enhanced the schedules and activities of the service at the time there was an improvement of the level of satisfaction.

P2982 - ETHICS AND RATIONING HOW DOES ONE CHOOSE WHO TO HELP IN A RESOURCE POOR ENVIRONMENT

John Hewitson
University of Cape Town, Cardiothoracic Surgery, Cape Town-South Africa

With limited operating time patient selection is fraught with ethical difficulties and questions of distributive justice. We practice paediatric cardiac surgery in such a setting, in a well-equipped state-sponsored unit, meeting the needs of only 25% of children with heart disease. Over the past five years 1517 patients have received corrective surgery with a mortality rate of 2.9%. 81% of operations utilized cardiopulmonary bypass. Based on demographic data our potential caseload is over three times greater (900 per year). Access is limited by poor health systems and poverty, so we get away with a first-come first-served system. We feel challenged to consider a more just approach. Options include: • Selection by probable outcomes of quality and duration of life; this is subjective, and impossible to implement fairly. • Basics-only, focusing on volume at the expense of complex lesions; results in poor surgical skills and frustration. • Triage based on urgency and severity; means selecting patients with the worst outcomes. At the centre of the issue is the healing relationship we claim with all children with heart disease, so we are caught between denying the scope of the problem and denying our commitment to all children. When presented with two equally deserving children for a single slot, the only just way is to choose randomly. Hard as it sounds, this excuses us from acting as the arbiter over a child's life, and bypasses the dilemma of who is "most deserving." A first-come first-served system already has a degree of such randomness built into it. The patient-doctor relationship of trust must be preserved. We need to avoid the conundrum of choosing who is more deserving. However because of the relationship, as advocates for our patients we must also pursue innovative approaches and fight to "expand the investment" of authorities.

ADULT CONGENITAL HEART DISEASE

P1015 - BORN WITH A HEART CONDITION THE CLINICAL IMPLICATIONS OF POLYVAGAL THEORY

Liza Morton
The Somerville Foundation, Independent Practitioner, Falkirk-United Kingdom

Introduction: Since antiquity our hearts have been linked to our feelings in our collective conscious yet, modern medicine has relegated this organ to a functional pump. However, a wide range

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

of psychosocial vulnerabilities including anxiety, depression, developmental delay, poorer Quality of Life, infant feeding & oral motor difficulties are associated with being born with a heart condition (Kovacs et al, 2009). To date, these difficulties have been accounted for by secondary factors with recognition & management limited (Morton, 2015; 2014; 2012; 2011).
Methods/Results: Here, I propose Porges' (2011) Poly Vagal Theory (PVT) offers a more holistic account of this condition (Morton, submitted). PVT provides a comprehensive understanding of our nervous system, senses, emotions, social self & behaviours. Porges proposes the nervous system employs a phylogenetic hierarchy of strategies to self regulate & respond to threat, adapting to our environment when we are safe (enabling the 'Social Engagement System') & unsafe (enabling defensive mechanisms), with homeostatic variability shaped during our early years. Since the heart is central to our nervous system congenital cardiac anomalies may compromise our response to stress, emotional regulation & the Social Engagement System. This has implications across the lifespan providing strategies to optimise normal development of social & defensive behaviours & inform therapeutic interventions, explored here drawing on psychological theories & advocacy/personal experience of living with a heart condition from birth.
Based on: Morton, L. (submitted) Born with a heart condition: The Clinical Implications of PVT in Clinical application of PVT around the world (working title) Ed: Porges, S & Dana, D. Norton Professional Books: New York.

P1029 - CORRELATION OF FRAGMENTED QRS COMPLEX WITH RIGHT VENTRICULAR INDICES AFTER REPAIR OF TETRALOGY OF FALLOT

Ahmed Elboraey, Ahmed Eldamaty, Heba Eldeeb, Khaled Sorour
Faculty of Medicine, Cardiology, Cairo-Egypt

Background: Post-operative right ventricular (RV) progressive dilatation and dysfunction especially with the development of pulmonary regurgitation (PR) is increasingly recognized after repair of tetralogy of Fallot (TOF).Fragmented QRS (fQRS) complex reflects conduction delay due to myocardial fibrosis is a proposed preliminary simple screening tool for such changes.
Materials and Methods: Thirty patients with repaired TOF were included. All patients had contemporary ECG and CMR. fQRS complex was defined as the presence of >2 R waves or >2 notches in the R/S waves in case of wide QRS complex and the presence of an additional R wave or notched S wave in two contiguous leads in case of narrow QRS complex.
Results: The mean age was 15 ± 3.13 years, time passed since repair 11.5 ± 1.87 years; fQRS was present in 70% of pts. fQRS was correlated to higher RV end-diastolic volume index (RVEDVI) (p <0.001), RV end-systolic volume index (RVESVI) (p <0.001), higher PR fraction (p = 0.004), and lower RV ejection fraction (RVEF) (p = .018). A cutoff point of fQRS in 5 leads showed a sensitivity of 87.5% and specificity of 85.7% for detection of RVEDVI >150 ml/m2, and 83.3% sensitivity, 66.7% specificity in identifying patients with PR fraction more than 45%.Prolonged QRS duration was correlated to higher (RVEDVI) (p = 0.004), (RVESVI) (p = 0.006), with a trend towards lower RVEF (p value = .145) and higher (PR) fraction (p = .175).
Conclusions: fQRS was correlated with higher (RVEDVI), (RVESVI), (PR) fraction, and lower (RVEF), furthermore the presence of 5 fQRS leads is a sensitive and specific predictor of RVEDVI >150 ml/m2, and PR fraction more than 45%.

P1030 - QRS PRODUCT AS A NEW ECG TOOL FOR SCREENING OF PROGRESSIVE RIGHT VENTRICULAR DILATATION AND SEVERE PULMONARY REGURGITATION AFTER REPAIR OF TETRALOGY OF FALLOT

Ahmed Elboraey, Ahmed Eldamaty, Heba Eldeeb, Khaled Srour
Faculty of Medicine, Cardiology Department, Cairo University-Egypt

Background: Prolonged QRS duration and QRS fragmentation were used as a simple ECG tools for screening of progressive right ventricular (RV) dilatation in patients with repaired tetralogy of Fallot (TOF).To the best of our knowledge, this is the first study that correlate the product of both ECG tools with RV indices in repaired TOF.
Materials and Methods: Thirty patients with repaired TOF were included. All patients had contemporary ECG and CMR. Fragmented QRS complex (fQRS) was defined as the presence of >2 R waves or >2 notches in the R/S waves in case of wide QRS complex and the presence of an additional R wave or notched S wave in two contiguous leads in case of narrow QRS complex. The product of (sum fQRS leads × QRS duration in ms) was calculated and named "QRS product". A sum of one was given for patients with no fQRS.
Results: The mean age was 15 ± 3.13 years, time passed since repair 11.5 ± 1.87 years; fQRS was present in 70% of patients. QRS product showed significant linear correlations with RV end-diastolic volume index (RVEDVI) (p value <0.001), RV end-systolic volume index (RVESVI) (p value <0.001), Pulmonary regurgitation (PR) fraction (p value = .006) and significant inverse correlations with RV ejection fraction (RVEF) (p value = .019). The optimum QRS product cutoff point for detection of patients with (RVEDVI) more than 150 ml/m was 710 with a sensitivity of 87.5% and specificity of 85.7%, and 780 for (PR) fraction more than 45% with a sensitivity of 83.3%, and specificity of 83.3%.
Conclusions: QRS product was correlated with higher (RVEDVI), (RVESVI), (PR) fraction, and lower (RVEF), furthermore QRS product of 710 was a sensitive and specific predictor of (RVEDVI) > 150 ml/m2, and QRS product of 780 was a sensitive and specific predictor of (PR) fraction more than 45%.

P1041 - DIFFERENTIAL PULMONARY ARTERY REGURGITATION POST TETRALOGY OF FALLOT REPAIR A CARDIAC MAGNETIC RESONANCE STUDY

Karim El-Bakry[1], Mohamed Abdel Meguid[2], Ahmed Adel[1], Ahmed Essam[3], Khaled Sorour[1]
Cairo University, Cardiology, Cairo-Egypt[1]; Cairo Uniersity, Cardiology, Cairo-Egypt[2]; Cairo University, Radiology, Cairo-Egypt[3]

Background/Hypothesis: Pulmonary regurgitation (PR) is an important cause of late morbidity after tetralogy of Fallot (TOF) repair but little is known about some of its underlying mechanisms. This phase-contrast cine magnetic resonance (PC MR) study was performed to evaluate the contribution of each pulmonary artery (PA) to the regurgitant volume and its effects on right ventricular (RV) parameters.
Patients and Methods: Forty patients with significant PR underwent a PC MR after TOF repair.
Results: Forward flow in the right PA (RPA) was significantly higher than in the left artery (LPA) [53.2 ± 15.6 vs 34.8 ± 17.7, p < 0.001] and RPA net flow was also higher than LPA [33.9 ± 10.9 vs 17.9 ± 10.7, p <0.001]. Although LPA regurgitant fraction (RF) was significantly higher than that of RPA [45.2 ± 15.9 vs 36.4 ± 13.4, p: 0.008], its relative contribution to

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

main PA regurgitation (MPA-R) was significantly lower [40.9 ± 18.6 vs 51.6 ± 15.9, p: 0.0047]. LPA contribution to MPA-R was significantly higher when TOF repair was done at an age >10 years (51.7 ±17.1 vs 36.6 ± 17.4, p: 0.016). Severe MPA-RF ≥ 40% had significantly higher RV endsystolic volume (RVESV) [94.3 ± 45.9 vs 67.5 ±31.9, p: 0.037] and RV end-systolic volume index (RVESVI) [72.6 ± 30.5 vs 52.5 ± 17.7, p: 0.012] than MPA-RF <40%, but they had similar ejection fraction (RV-EF) [53.8 ±11.2 vs 56.6 ±7.5, p : 0.35].
Conclusions: RPA relative contribution to PR severity was higher than LPA in follow up of patients with severe PR after TOF repair. LPA contribution was more in repairs done after the age of 10 years which may help in future management using focal interventions to reduce the regurgitation. RVESV and RVESVI were significantly associated with severe MPA-RF but not RVEF, thus they can be used in the follow up of these patients.

P1042 - CHANGING FACE AND OUTCOME OF INFECTIVE ENDOCARDITIS AND CONGENITAL HEART DISEASE A SINGLE INSTITUTION STUDY IN EGYPT

Khaled Sorour[1], Marwa Meshaal[1], Dina Ossama[1], Mervat Gaber[2], Hussein Rizk[1]
Cairo University, Cardiology, Cairo-Egypt[1]; Cairo University, Clinical Pathology, Cairo-Egypt[2]

Background/Hypothesis: Infective endocarditis (IE) is still a major source of morbidity and mortality worldwide. Rheumatic valvular disease – which is becoming less prevalent - is still the main risk factor for developing endocarditis in Egypt but CHD is steadily increasing as a risk as they become adults. The purpose of this study was to describe the epidemiology of infective endocarditis in Egypt.
Methods: This is a retrospective descriptive study. Electronic data bases were reviewed. All patients referred to the endocarditis working group of Cairo University Hospitals with a diagnosis of definite/possible infective endocarditis from February 2005 till June 2015 were included.
Results: Patients enrolled were 376, thirty three of them (8.8%) had congenital heart disease with a mean age of 32.5 years. Males were by far more common and were generally referred late. Health care associated endocarditis was present in 18.2%. Prior antibiotic use was documented in 72.7% and culture negative endocarditis was seen in 56.7% of whom 15% were diagnosed by serology and/or tissue culture. Seventy nine% of patients were indicated for surgery which was performed in 69.2%.
Conclusions: CHD is a well-established risk factor for infective endocarditis and complex techniques used for treatment are themselves added risks. Although at higher risk, congenital heart disease patients did not have a worse prognosis. A high incidence of zoonotic infections among the whole group and a long time interval from symptom onset till referral was also noted increasing the rates of morbidity and mortality in this group. More effort should be made to diagnose children with asymptomatic congenital heart disease for better future endocarditis prevention regimens as well as encouraging better oral hygiene at homes and schools.

P1044 - MOBILE HEALTH PROGRAM TO PROMOTE SELF MANAGEMENT IN YOUTHS WITH CONGENITAL HEART DISEASE DESIGN AND DEVELOPMENT OF THE COOL RANDOMIZED CONTROLLED TRIAL

Chi-Wen Chen[1], Yong-Yi Fanjiang[2], Yueh-Tao Chiang[3], Ciao-Lin Ho[1]
National Yang-Ming University, School of Nursing, Taipei-Taiwan[1]; Fu-jen Catholic University, Department of Computer Science and Information Engineering, New Taipei City-Taiwan[2]; Chang Gung University, School of Nursing, Taoyuan-Taiwan[3]

Background: The transition from family-centered nursing care to self-care for youths with congenital heart disease (CHD) commonly occurs in late adolescence to early adulthood. However, regarding how to manage the complex healthcare needs of these youths undergoing transitional care would be a challenge. Mobile health initiatives may deliver CHD information and provide a platform for promoting their self-management.
Aims: to describe the design and development of the Care and Organize Our Lifestyle (COOL) program for youths of CHD and to highlight the importance of mobile health intervention design that made it possible.
Methods/Design: The COOL program was a 12-month randomized controlled trial comparing two active interventions to a usual-care control group. Participants were 150 patients with mild and moderate CHD aged 15-24 years in pediatric and adult CHD outpatient departments. All participants were offered exercise measurement wristband. Both active interventions were designed based on self-regulation theory and incorporated techniques for behavioral self-management and motivational enhancement. One active intervention was provided COOL passport, a mobile healthcare App. The other was provided health promotion cloud, an interactive platform along with COOL passport. The primary outcome was change in cardiopulmonary exercise test and the International Physical Activity Questionnaire (IPAQ)-Taiwan Show-Card Version score. Cardiac knowledge measured by Leuven knowledge questionnaire for congenital heart diseases was a secondary outcome.
Discussion: The trial is expected that the complete COOL program will be scalable to promote self-management in youths with CHD, with the potential for national-level adoption.

P1054 - THE DUCT DIAGNOSIS IN ICU PRETERME INFANT DIAGNOSTIC TOOL

Senka Mesihovic-Dinarevic[1], Mediha Kardasevic[2]
Pediatric Cardiologist, Pediatric Clinic, Sarajevo-Bosnia and Herzegovina[1]; Pediatric Cardiologist At Cantonal Hospital, Bihac-Bosnia and Herzegovina[2]

Introduction: Patent ductus arteriosus /PDA/ is a large vascular structure with an important role in the foetal circulatory pattern, most often is closed within 72 hrs after birth, but in premature infants closing may be delayed a few days, even weeks, leading to a significant comorbidity. The aim of the study was to correlate the sensitivity of diagnostic tools in PDA detection.
Patients and Methods: A prospective study conducted in 2015-2016, at Neonatal Cardiology Intensive Care Unit, Pediatric Clinic of University Clinical Centre Sarajevo, included 20 premature infants, age 28-34 WG, with PDA. Control group formed 20 premature infants. Correlation of echocardiographic, clinical and phonocardiographic examination was realized in each child.
Results: There was no statistically significant difference between the study and control group in gender, the average gestational age, birth weight, Apgar score, pulse, precordial activity, femoral pulsation ($p > 0.05$). There was a statistically significant difference ($p < 0.05$) between the control and study group compared to auscultatory finding on heart, as well as statistically significant ($p < 0.05$) relationship between physical finding at the heart and the diameter of the ductus. Correlation of phonocardiographic findings, showed statistically significant ($p < 0.05$) differences between the study and control group with respect to the frequency of the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

murmur but without statistically significant ($p > 0.05$) difference in relation to the murmur character.
Conclusion: Color Doppler echocardiography is more sensitive tool in PDA detection in preterm infants in relation to clinical and phonocardiographic findings which, as screening diagnostic modality, contribute to the start of adequate therapy and shorter stay of preterm pts at ICU.

P1058 - COARCTATION LONG TERM FOLLOW UP AND QUALITY OF LIFE PREDICTIVE VALUE OF CLINICAL VARIABLES

Pinar Bambul Heck[1], Harald Kaemmerer[1], Jelena Pabst Von Ohain[2], Peter Ewert[1], Alfred Hager[1]
Deutsches Herzzentrum München, Pediatric Cardiology, Munich-Germany[1]; Deutsches Herzzentrum München, Cardic Surgery, Munich-Germany[2]

Objective: Long-term sequelae and events after coarctation repair are well described. However, the predictive value of variables from clinical follow-up investigation for late events has rarely investigated.
Methods: All patients, who have participated in the prospective cross-sectional COALA Study in 2000 with a structural clinical investigation including blood pressure measurement and symptom-limited exercise test were contacted for reevaluation of current clinical status, medical treatment, office and ambulatory blood pressure measurement and the health-related quality of life questionnaire SF-36.
Results: From 273 eligible patients, 153 patients responded, 27 patients explicitly denied to participate in the study. Nine patients died during the follow-up time with the age of 46 years (range 30-64 years), 25 patients had an important event (12 procedures at the aortic valve due to bicuspid aortic valve, 8 procedures for recoarctation, 2 endocarditis, 2 cerebral insults,1 endocarditis). Thirty-five patients (30%) showed normal ambulant blood pressure, 56 (48%) were on antihypertensive medication and 25 (22%) had arterial hypertension without receiving medication. Quality of life was good in the fields of physical role and pain. However, patients reported a significant impairment in general health, depending on the age. Arterial hypertension, echocardiographic measurements or exercise capacity from the COALA study were not predictive on functional health status.
Conclusion: Repaired coarctation of the aorta shows fairly low mortality on long-term follow-up. Important events are not only recoarctation, but also procedures at the bicuspide aortic valve. The rate and the severity of arterial hypertension is progressively increasing. However, the predictive value of clinical variables is limited, except the presence of a bicuspid aortic valve for aortic valve procedures.

P1059 - EARLY PULMONARY ARTERIAL HYPERTENSION AFTER CLOSURE OF A VENTRICULAR OR COMPLETE ATRIOVENTRICULAR SEPTAL DEFECT BEYOND 6 MONTHS OF AGE

Pinar Bambul Heck[1], Andreas Eicken[1], Jelena Pabst Von Ohain[2], Peter Ewert[1], Alfred Hager[1]
Deutsches Herzzentrum München, Pediatric Cardiology, Munich-Germany[1]; Deutsches Herzzentrum München, Cardiac Surgery, Munich-Germany[2]

Background: Pulmonary arterial hypertension (PAH) is virtually absent after closure of ventricular septal defect (VSD) in the first six months of life. However the prevalence of PAH in patients, who underwent VSD closure later, is not clear. The aim of this study was to analyse the prevalence of PAH after a successful VSD closure after the age of 6 months and whether there are risk factors for developing PAH.
Methods: Echocardiographic and right heart catheter data of patients with VSD or complete atrioventricular septal defect, who underwent VSD closure after the age of 6 months in our institution between 01/2005 and 06/2014, were retrospectively analyzed. PAH was defined as mean pulmonary arterial pressure (mPAP) of ≥25 mmHg or tricuspid regurgitation jet velocity of ≥ 3.5 m/s.
Results: In 228 patients (median age at shunt closure 4.0 years, range 0.5-69) and 174 complete follow-up data (median follow-up 3.7 years, range 0.5-39.4), 9 patients needed pulmonary vasodilator therapy after shunt closure, 4 of them temporarily for up to 79 months. Three patients are still on vasodilator treatment 1, 2.6 and 6 years after surgery, other two were lost to follow-up. Another 6 patients with preoperatively borderline hemodynamics due to elevated mPAP and pulmonary vascular resistance, recovered well without signs of postoperative PAH.
Conclusion: With the current practice for safe late VSD closure, PAH is very rare at least in the first years of follow-up. In most patients with perioperative PAH, this condition appears to be transient and shows good response on pulmonary vasodilator treatment.

P1061 - MANAGEMENT OF TACHYARRHYTHMIAS IN PATIENTS WITH ADULT CONGENITAL HEART DISEASE AFTER CARDIAC SURGERY

Keiko Toyohara, Tomomi Nishimura, Daiji Takeuchi, In-Sam Park
Tokyo Women's Medical University, Pediatric Cardiology, Tokyo-Japan

Background: Tachyarrhythmia is a common late complication in patients with adult congenital heart disease (ACHD) after surgery.
Purpose: The aim of this retrospective study is to investigate clinical results of interventional therapies for various tachyarrhythmias complicated with ACHD.
Methods and Results: 180 patients with the median age of 33 years old were investigated. 160 patients had supraventricular tachycardia (SVT) and 20 patients had ventricular tachycardia (VT). The previous surgery with SVT was APC-Fontan in 70 patients, TCPC-Fontan in 22, ASO (atrial switch operation) in 12 and biventricular repair (BVR) in 56. We performed catheter ablation (CA) in 139 patients with SVT. Acute success rate of CA was 66% (34/51) in APC, 70% (14/20) in TCPC, 91% (11/12) in ASO and 85% (48/56) in BVR. Recurrence rate after CA was 26% (9/34), 36% (5/14), 27% (3/11) and 13% (6/48), respectively. Antiarrhythmic drugs was also used in 80% (56/70), 68% (15/22), 50% (6/12) and 48% (27/56), respectively. A pacemaker was implanted to control SVT in 31% (22/70), 22% (5/22), 41% (5/12) and 26% (15/56), respectively. The previous surgery with VT was RVOT reconstruction in 10, Rastelli in 7, APC-Fontan in 1, ASO in 1, AVR in 1. CA was performed in 40% (8/20), acute success rate was 50% (4/8). ICDs or CRT-Ds were implanted in 85% (17/20) and drugs were used in 95% (19/20).
Conclusion: CA can be a curative approach especially for SVT of postoperative ACHD. However, hybrid therapy with antiarrhythmic drugs or cardiac implantable electric devices may be required in the selected population.

P1076 - FACTORS INFLUENCING LOSS TO FOLLOW UP AMONG PATIENTS WITH CONGENITAL HEART DISEASE IN MALTA PRIOR TO THE INTRODUCTION OF FORMAL TRANSITION – UNDERSTANDING THE AVOIDABLE

Maryanne Caruana[1], Oscar Aquilina[1], Jane Somerville[1], Victor Grech[2]
Mater Dei Hospital, Department of Cardiology, Msida-Malta[1]; Mater Dei Hospital, Department of Paediatrics, Msida-Malta[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: While most congenital heart disease (CHD) is successfully managed in childhood, lifelong follow-up is required to detect and manage significant recurrent or residual lesions and arrhythmias. Loss to follow-up of patients is a set-back to this surveillance process. The aim of this retrospective study was to investigate factors influencing loss to follow-up among Maltese adult patients with CHD of moderate/great complexity prior to institution of formal transition.
Materials and methods: 187 patients - tetralogy of Fallot 70, coarctation/interrupted aortic arch 56, atrioventricular septal defect 34, Fontan-type palliation 13, transposition of great arteries 14 - aged 16 years or over by end 2013 were included. Clinical details and follow-up records were obtained from hospital notes. Ordinal logistic regression was applied to investigate the potential influence of (a) gender (b) CHD complexity (c) dedicated paediatric cardiology input in childhood (d) number of cardiac surgeries/interventions and (e) long-term cardiac medications, on loss to follow-up.
Results: 41/187 patients (21.9%; 27 males) were lost to follow-up. Limited input by paediatric cardiologists in childhood, a smaller number of surgeries/interventions and lack of long-term cardiac medications were all identified as independent predictors for loss to follow-up in our study population. CHD lesion complexity of itself was not significantly associated with loss to follow-up (Table).
Conclusions: This study identifies CHD patient characteristics that increase the chances of loss to long-term specialist follow-up. Patients with such characteristics warrant closer attention, particularly at time of transfer to adult cardiology care. In particular, it underlines the importance of an infrastructure that provides input by paediatric cardiologists in the care of these patients from an early stage as a means of ensuring appropriate specialist follow-up throughout life.

Table. Impact of studied factors on loss to follow-up.

Factor	OR	95% CI lower, upper	p value
Male vs. female gender	2.12	0.80, 5.65	0.13
Moderate vs. great complexity	1.60	0.32, 8.03	0.57
Limited vs. structured paediatric cardiology input in childhood	5.08	1.77, 14.63	0.003*
Up to 1 vs. more than 1 cardiac surgery/intervention	3.34	1.09, 10.26	0.04*
No vs. on long-term cardiac medication	7.34	1.74, 31.02	0.007*

* Statistically significant association (statistical significance defined as $p < 0.05$)

P1083 - ECHOCARDIOGRAPHIC ANALYSIS USING NEW TECHNICS TO EVALUATE VENTRICULAR FUNCTION RESULTING FROM CHRONIC PULMONARY REGURGITATION IN PATIENTS WITH FALLOT

Ana Maria S De Dios[1], Maria Fernanda Biancolini[1], Julio Cesar Biancolini[2], Jesus Damsky Barbosa[3]
Pedro Elizalde, Cardiologia Pediatrica, Caba-Argentina[1]; Pedro De Elizalde, Jefe Residentes, Caba-Argentina[2]; Pedro Elizalde, Hemodinamia, Caba-Argentina[3]

Methods: 73 patients with 19 ± 4 years (y). Average age at surgical repair: 2.7 ± 1 y. Evaluated with Tissue Doppler (TDI), Tissue track, TEI Index, Ejection Fraction, 2 D Speckle Tracking (STD), basal and mid Strain in free Wall of both ventricles; magnetic resonance was done when patients registered increase in ventricule dysfunction or when the volume was >120 ml/m^2 by echocardiography. Patients were divided into 3 groups: 1) right ventricle (RV) <100 ml/m^2, 2) RV more than 120 ml/m^2 but less than 150 ml/m^2, 3) RV > 150 ml/m^2.
Results: In the first group with RV < 100 ml/m2 there were no significat changes, except for systolic velocity of TDI which decreases in mid RV , no changes in regional strain and strain rate. Theses patients have no important repercussion in RV 2DSTD; 88% of the cases recovered normal function after valve repair. The second group evidenced RV and LV dysfunction in TDI (inversion of diastolic wave), global Strain decrease, and regional basal and mid Strain were opponents to normal in RV and basal LV. The third group had severe dysfunction in LV and RV 2DSTD, and opponent curves in regional basal and mid strain in both ventricles.
Conclusions: the regional myocardial deformation can be evaluated from echocardiography-derived speckle-tracking analysis to measure myocardial Strain and provides direct information of the contractile performance of the right and left ventricle. The new eco technology can identify early LV repercussion and early PVR may be the new criteria to prevent LV irreversible damage when the LV dysfunction increases.

Table. Fallot global deformation 2DSTD

P1102 - ARRHYTHMIA BURDEN AND RELATED OUTCOMES IN EISENMENGER SYNDROME

Shankar Baskar[1], Phillipa Horn[2], Samantha Fitzsimmons[3], Philip Khoury[1], Joseph Vettukattill[4], Koichiro Niwa[5], Teiji Agaki[6], Mark Spence[7], Gruschen Veldtman[1]
Cincinnati Children, Cardiology, Cincinnati-United States[1]; Royal London Hospital, Cardiology, London-United Kingdom[2]; Southampton University Hospital, Cardiology, Southampton-United Kingdom[3]; Helen Devos Children's Hospital, Cardiology, Grand Rapids-United States[4]; St, Cardiology, Tokyo-Japan[5]; Okayama University Hospital, Cardiology, Okayama-Japan[6]; Royal Victoria Hospital, Cardiology, Belfast-Ireland[7]

Background: Patients with Eisenmenger syndrome have a shorter life-span than the general population. A significant proportion develop arrhythmia and some, sudden death.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Objective: The aims of this study was to characterize the frequency, type and effects of arrhythmias in a moderately large cohort of adult patients with Eisenmenger's syndrome and to identify potential risk factors for arrhythmia.
Methods: This retrospective study included patients aged ≥ 18 years of age with Eisenmenger's syndrome from Southampton University Hospital; Japanese Adult Congenital Heart group and Royal Victoria Hospital. Information was collected from chart review and arrhythmias were noted from electrocardiograms and Holter studies.
Results: A total of 167 patients were included with a mean age of 37 ± 10 years (range: 18–63 years) with the majority in NYHA functional class II or III. Twenty eight patients (17%) had a documented arrhythmia: paroxysmal supraventricular tachycardia (8 patients, 29%), atrial fibrillation (6 patients, 21%), atrial fibrillation and flutter (2 patients, 7%), non-sustained ventricular tachycardia (6 patients, 21%) and sustained ventricular tachycardia (6 patients, 21%). Among the entire study group, 25 patients (15%) were currently on anti-arrhythmic therapy and 77 patients (49%) were on disease targeting therapy for pulmonary hypertension. Downs syndrome was present in 76 patients (46%). Patients with arrhythmia were older [p = 0.01] and were more likely to have atrioventricular valvar regurgitation [Odds ratio: 4.33]. Arrhythmias were found to independently predict all-cause mortality [p = 0.004] and sudden death in bivariate analysis [p = 0.03]. Disease targeting therapy was a protective factor against all-cause mortality in logistic regression analysis [Odds ratio: 0.31], while anti-arrhythmics predicted sudden death [Odds ratio: 6.24].
Conclusion: Arrhythmias are common among patients with Eisenmenger syndrome, especially among those with atrioventricular valve regurgitation. Arrhythmias may predict sudden death, the risk of which might not be reduced by anti-arrhythmics.

P1136 - TRANSITION CONGENITAL HEART DISEASE SERVICE

Loredana Haidu, *Virginia Castro Meira*
Royal Brompton & Harefield Trust, Paediatrics, London-United Kingdom

Introduction: Transfer from paediatric to adult services is a stressful time for the adolescent and their parents/carers. Becoming independent is a giant step in their lives. Our service aims to educate, inform and empower, preparing them for the adult world with responsibilities and decision making.
Background: Survival rates are ever increasing for young adults with Congenital Heart Disease into adult life. This is mainly due to improvements in medical and surgical management and in more recent times, the support of the nurse specialist. Research suggests that many of these patients are inadequately prepared for their future care. There is lack of on-going education to help prepare these young people to manage their health care needs into adulthood; many will require lifelong cardiac surveillance. A very significant issue for this population are those lost to follow-up and unfortunately present when a significant cardiac problem arises which could have been prevented, through regular check-ups. The educational process needs to be structured, ensuring uninterrupted health care, patient centred, age and developmentally appropriate, flexible and comprehensive aiming improvements in health status, quality of life and survival outcomes. Transition starts at the age of 12 and finishes at 25.
Method: The service offers nurse-led clinics and nurse led day cases where the adolescent can attend with or without their parents/carers. Telephone clinic consultations are offered as well as support via email.
Results: Between 14/01/2016 and 30/11/2016 413 adolescents were seen in clinic. The feedback has been very good demonstrating support for our unique service.
Conclusions: A co-ordinated transfer with a summary document is an important step in a successful transition process. Patients seen expressed satisfaction defining the service as effective, professional and supportive of their autonomy for taking the lead for their own care.

P1146 - COMPARISON BETWEEN 2 DIMENTIONAL ECHOCARDIOGRAM AND CARDIAC MAGNETIC RESONANCE IN ASSESSING RIGHT VENTRICULAR SIZE AND FUNCTION IN PATIENTS WITH REPAIRED TETRALOGY OF FALLOT

Phong Teck Lee[1], *Shuang Leng[2], Fei Gao[3], Liang Zhong[2], Ju Le Tan[1]*
National Heart Centre Singapore, Cardiology, Singapore-Singapore[1]; National Heart Centre Singapore, National Heart Research Institute Singapore (NHRIS), Singapore-Singapore[2]; National Heart Centre Singapore, Biostatistics, Singapore-Singapore[3]

Background: Right ventricular (RV) enlargement and dysfunction are common sequela from significant pulmonary regurgitation (PR) following tetralogy of Fallot total correction (TFTC). Accurate assessment of RV size and function is important during follow-up and consideration of pulmonary valve replacement (PVR). Limited studies compared 2-dimentional echocardiogram (2DE) with cardiac magnetic resonance (CMR) in the assessment of RV size and function in adult TFTC patients. We sought to compare measurements of RV size and function by 2DE with CMR.
Methods: We studied 88 selected patient with moderate-severe PR (43 male; median age = 30, range = 17-73y) after TFTC. 2DE measurements included RV basal, major and minor at end-diastole, annular plane systolic excursion (TAPSE) and tricuspid annulus tissue Doppler velocity (RV S'). On CMR, the RV was reconstructed from manually traced borders to calculate RV volumes and ejection fraction (RVEF). Correlation between 2DE and CMR parameters was analysed using linear regression. Indications for PVR based on CMR derived RV volumes and RVEF (i.e. RVEDVI > 150 ml/m2, RVESVI > 80 ml/m2 or RVEF < 47%) were used as outcomes in univariate and multivariate Cox regression analyses.
Results: 2DE RV dimensions correlated weakly to RV volumes (r = 0.38-0.53; p < 0.01). There were no correlations between TAPSE and RV S' with RVEF (r = -0.06; p = 0.57 and r = 0.16; p = 0.12 respectively). Among RV measurements, only RV major was independently associated with dilated RV on CMR in the univariate analysis but rendered non-significant after adjusting for age, BSA and gender. TAPSE and RV S' were both independently associated with RV dysfunction in the univariate analysis but rendered non-significant after adjusting for age, BSA and gender (Table 1).
Conclusion: 2DE quantification of RV size correlated weakly with RV volumes and TAPSE and RV S' did not correlate with RVEF in adult patients with TFTC. Quantification of RV size and function by 2DE was not associated with significant RV dilatation and dysfunction, especially those requiring PVR.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Table 1. Relationship between 2DE and CMR parameters in patients with TFTC. (n = 88)

P1150 - NEUROLOGICAL OUTCOME OF CONGENITAL HEART DISEASE WITH VERY LOW BIRTH WEIGHT INFANTS

Yasumi Nakashima[1], Yoshiki Mori[1], Masaaki Toyoshima[2], Satoshi Masutani[3], Hitoshi Yoda[4], Yasuhiko Tanaka[5]
Seirei Hamamatsu General Hospital, Pediatric Cardiology, Hamamatsu-Japan[1]; Kanagawa Children's Medical Center, Neonatology, Yokohama-Japan[2]; Saitama Medical Center, Pediatric Cardiology, Kawagoe-Japan[3]; Toho- University Oomori Medical Center, Neonatology, Tokyo-Japan[4]; Shizuoka Children's Hospital, Neonatology, Shizuoka-Japan[5]

Objectives: The purpose of the study was to elucidate the neurological outcome in children with congenital heart disease (CHD) born with very low birth weight (VLBW) in Japan.
Methods: A retrospective multicenter cohort study enrolled patients with CHD with VLBWI born from January 2000 to December 2006. Twelve neonatal intensive care unit (NICU) participated in this study. Neurodevelopmental assessment using the Kyoto Scale of Psychological Development (KSPD) was performed in children survived until 3-6years old. We reviewed demographic and KSPD dates of these VLBW infants.
Results: Forty-five patients were enrolled in this study. The median birth weight was 1148 g (range504-1477g) and median gestational week was 31weeks (range 23-39weeks). The most common lesions were ventricular septal defect (VSD) (44.4%), tetralogy of Fallot (15.6%), pulmonary valve stenosis (8.9%). The genetic syndromes and extra-cardiac malformations were seen in 20.0%, 31.1%, respectively. Surgical and/or catheter interventions were performed in 21 infants (46.7%) and 17 infants (81.0%) were achieved to the final operation. Overall Developmental Quotient (DQ) was 80.5 (range 19-105). Language-Social (L-S) domain DQ was 81 (range 16-114). Postural-Motor (P-M) domain DQ was 76.5 (range 12-124). Cognitive-Adaptive (C-A) domain DQ was 83(range 14-117).The score of treated patients was poorer than untreated patients in all parameters (overall DQ 62.0 ± 27.8 vs. 84.1 ± 20.0, p < 0.01, L-S DQ 60.3 ± 28.5 vs. 83.1 ± 20.0, P < 0.01, P-M DQ 60.7 ± 31.6 vs. 86.8 ± 24.7,p < 0.01, C-A DQ 65.9 ± 29.2 vs. 84.7 ± 21.1, P < 0.05) respectively.
Conclusions: Neurological functions of VLBWI with CHD survived until childhood are lower limit of reference. Surgical intervention may affect the neurological outcome of VLBWI with CHD.

P1174 - VITAMIN D STATUS AND BONE MASS DENSITY IN ADOLESCENTS WITH FONTAN CIRCULATION

Simone Goa Diab[1], Kristin Godang[2], Anne Grethe Myhre[3], Ingrid Sparr[4], Runar Almaas[4], Gaute Døhlen[1], Jens Bollerslev[2], Thomas Möller[1]
Oslo University Hospital, Pediatric Cardiology, Oslo-Norway[1]; Oslo University Hospital, Endocrinology, Oslo-Norway[2]; Norwegain National Advisory Unit On Rare Diseases, Frambu Resource Centre For Rare Disorders, Oslo-Norway[3]; Oslo University Hospital, Pediatric Medicine, Oslo-Norway[4];

Background: Although patients with a Fontan circulation are at risk of malnutrition and growth delay, the implications on vitamin D metabolism and bone health have barely been investigated.
Materials and Methods: We prospectively measured serum levels of 25-OH-vitamin D in a nationwide cohort of Fontan patients aged 16 to 18 years old. We also measured bone mass density by narrow fan-beam dual energy x-ray absorptiometry (DXA) scan. The DXA results were compared to age and gender matched reference data and expressed as Z-scores.
Results: Seventeen consecutive patients were recruited from our pre-transition national Fontan clinic. All 17 patients had vitamin D levels <75.0 nmol/l, which has been suggested as a lower limit in patients with chronic illness. Thirteen patients (76%) had vitamin D insufficiency with levels <50.0 nmol/L, 9 (53%) patients had deficiency with values <37.5 nmol/L and two patients (12%) had severe vitamin D deficiency with non-measurable values <12.5 nmol/L. The DXA showed abnormally low z-scores of -1.7 ± 0.9 (mean ± SD) (p < 0.001) for columna and -0.8 ± 1.1 (p = 0.009) for total body measurement respectively. There was no correlation between DXA result and vitamin D level.
Conclusion: Adolescent Fontan patients have a high prevalence of vitamin D deficiency and low bone mass density, however, without these two being correlated. Whether the vitamin D deficiency is due to limitations in sun exposure and dietary intake of vitamin D, or if vitamin D deficiency and insufficient bone mass density are differently related to the Fontan circulation is unknown. Future studies should investigate pathogenesis of both vitamin D deficiency and low bone mass density, as well as determine fracture implications and identify interventions.

P1178 - ACOUSTIC RADIATION FORCE IMAGING OF THE FONTAN LIVER – ADDING TO THE DIAGNOSTIC ARMAMENTARIUM

Dominica Zentner[1], Khoa Phan[1], Robert Gibson[2], Siddharth Sood[3], Leeanne Grigg[1], Amanda Nicoll[4]
Royal Melbourne Hospital, Department of Cardiology, Melbourne-Australia[1]; Royal Melbourne Hospital, Department of Radiology, Melbourne-Australia[2]; Royal Melbourne Hospital, Department of Gastroenterology and Hepatology, Melbourne-Australia[3]; Eastern Health, Department of Gastroenterology, Melbourne-Australia[4]

Background/Hypothesis: Fontan associated liver disease (FALD) is thought to result from congestion, as a consequence of time post surgery. Biochemistry and imaging do not follow the same rules as other liver injury with most imaging modalities resembling cirrhosis. Routine assessment of adults with a Fontan circulation using biochemistry and Acoustic Radiation Force Imaging (ARFI) to ascertain transient elastography (TE) was undertaken. In other liver diseases, an ARFI of >1.80 m/s has been validated with a high likelihood of cirrhosis.
Materials and Methods: ARFI was performed, by 2 experienced sonographers, in 33 adults (female = 20; median age 28 (22–32.5) years) with a Fontan circulation (atriopulmonary n = 16, lateral tunnel n = 2, extracardiac n = 15). Nodularity on ultrasound (n = 20) identified a subgroup with a higher ARFI score: 2.20 m/s (1.86–2.77) versus 1.87 m/s (1.66–2.13) (2p = 0.039)
Conclusions: There is little published on ARFI in FALD, and our results are higher than reported in other liver disease, with less technically adequate values. The significant difference in time post Fontan completion in our subgroups did not result in differences between ARFI or MELD-XI scores. However, nodularity on US was associated with a higher ARFI score, suggesting that ARFI may have a role in further delineating advanced liver disease. Its accuracy in liver fibrosis short of established cirrhosis, will require further assessment.

Table. Results.

Variable	AP Fontan (n = 16)	LT + ECC Fontan (n = 17)	2p

P1189 - SURGICAL MANAGEMENT OF CONGENITAL HEART DEFECTS BEYOND THE AGE OF 60

István Hartyánszky, Sándor Varga, László Csepregi, Barna Babik, Kálmán Havasi, Anita Kalapos, Attila Nemes, Gábor Bogáts
Szeged University, Dpt. Cardiac Surgery, Szeged-Hungary

Introduction: The population with congenital heart disease is increasing and ageing. Aim was to assess the results of surgical management of congenital heart diseases beyond the age of 60 years.
Method: Between 2013 and 2016, 112 adults were operated (50 younger, and 62 older than forty years, including 19 patients aged 60-75 years). The numbers of procedures were as follows (in brackets the number of operations in the three age groups): Ross surgery 7 (4, 3, 0); aortic valve replacement 26 (13, 4, 9); subaortic membrane resection 1 (0, 0, 1); Bentall/ascending aortic plasty 18 (7, 8, 3); myectomy with or without mitral valve replacement in left ventricular outflow obstruction 10 (1, 6, 3); aortic coarctation 1 (1, 0, 0); ligation of ductus arteriosus 2 (1, 1, 0); reconstruction of right ventricular outflow tract with biological valve 7 (2, 4, 1); homograft 8 (6, 2, 0); BioValsalva graft 1 (0, 1, 0); primary reconstruction of complete atrioventricular septum defect 4 (2, 2, 0); valve replacement 3 (2, 1, 0); ventricular septum defect 10 (4, 6, 0); atrial septum defect closure 8 (5, 3, 0); total cavopulmonary anastomosis 1 (1, 0, 0); valve replacement in congenital transposition of great arteries 1 (0, 1, 0), Ebstein operation with valve plasty 2 (0, 1, 1); valve replacement 2 (1, 0, 1).
Results: There was no operative mortality, while early mortality occurred in one patient with total cavopulmonary anastomosis due to multiorgan failure.
Conclusions: Congenital heart defects can be operated beyond the age of 60 years with good results in a tertiary heart centre having great experience in the management of congenital and acquired heart disease.

P1193 - MIDTERM OUTCOME OF IMPLANTABLE CARDIOVERTER DEFIBRILLATOR IN REPAIRED TETRALOGY OF FALLOT INFLUENCE OF LONG QT GENES MUTATION POLYMORPHISMS

Shuenn-Nan Chiu, Jou-Kou Wang, Chun-Wei Lu, Ming-Tai Lin, Chun-An Wu, Wei-Chieh Tseng, Mei-Hwan Wu
National Taiwan University Children Hospital, Pediatrics, Taipei-Taiwan

Background: Ventricular tachycardia (VT) is a not rare late complication in repaired tetralogy of Fallot (TOF) patients, and implantable Cardioverter Defibrillator (ICD) implantation is indicated in these patients to prevent late cardiac death. Here, using a large repaired TOF cohort, we analyzed the midterm result after ICD implantation and the influence of the long QT gene mutations/polymorphisms.
Method: From 2003 to 2014, all patients of repaired TOF with VT receiving ICD implantation were enrolled. The charts were reviewed and data of ICD was retrieved. We performed mutation analysis of the three common long QT genes (KVLQT1, hERG, SCN5A) through direct sequencing. Patients of repaired TOF without VT served as control group.
Results: A total of 12 patients received (male/female 8/4) ICD implantation. Mean age of TOF repair was 4.4 + -4.5 years, mean age of VT was 25 + -11.1 years, and mean age of ICD implantation was 27.1 + -11.5 years. After mean 5.4 years follow-up, 9 (75%) had at least one episode of nonsustained/sustained VT, 6 (50%) had at least one appropriate shock and 6 (50%) had at least one inappropriate shock. Causes of inappropriate shock include sinus tachycardia in 4, T wave over-sensing in 1, and lead dysfunction in 1. For 6 patients with appropriate shock, 3 attacks were related to drug taper. Use of beta blocker can decrease both appropriate shock and inappropriate shock rate. When compared with 121 control patients, we found those with ICD had higher frequency of long QT genes mutation/polymorphisms (10/12 vs. 54/121, p = 0.014), especially for hERG and SCN5A genes. However, appropriate shock rate has no association with long QT genes mutation/polymorphisms.
Conclusion: The midterm result of ICD implantation in repaired TOF patients showed the appropriate shock rate is high but also inappropriate shock rate. Long QT gene mutations/polymorphisms are associated with necessity of ICD in rTOF patients.

P1195 - EXPERIENCES OF CHILDREN AND ADOLESCENTS LIVING WITH CONGENITAL HEART DISEASE A SYSTEMATIC REVIEW OF QUALITATIVE STUDIES

Lauren Chong[1], Dominic Fitzgerald[2], Jonathan Craig[1], Karine Manera[1], Camilla Hanson[1], David Celermajer[3], Julian Ayer[4], Nadine Kasparian [4], Tong Allison[1]
The Children, Kids Research Institute, Westmead-Australia[1]; The Children, Respiratory Medicine, Westmead-Australia[2]; The Children, Heart Centre For Children, Westmead-Australia[3]; The Children, Pediatrics and Child Health, Westmead-Australia[4]

Background/Hypothesis: Congenital heart disease (CHD) is the most common birth defect and can be associated with limitations in physical capacity, neurocognitive impairments, and a predisposition to sudden death. Children with CHD may require ongoing and complex medical intervention, and report psychosocial and lifestyle consequences. We aimed to describe the experiences and perspectives of children and adolescents with CHD.
Materials and Methods: MEDLINE, PsycINFO, CINAHL and Embase were searched in August 2016. Qualitative studies on the perspectives of children aged up to 21 years with CHD were included. Data was analyzed using thematic synthesis.
Results: We included 44 studies from 11 countries reporting the experiences of 995 children and adolescents with CHD. 6 themes were identified: disrupting normality (denying the diagnosis, oscillating between sickness and health, destabilizing the family dynamic); powerlessness in deteriorating health (preoccupation with impending mortality, vulnerability to catastrophic complications, exhaustion from medical testing); enduring medical ordeals (traumatized by invasive procedures, disappointed by treatment failure, displaced by transition, valuing empathy and continuity in care, overcoming uncertainty with information); warring with the body (losing stamina, distressing inability to participate in sport, distorted body image, testing the limits); hampering potential and goals (feeling disabled, unfair judgment and exclusion, incapacity to achieve academically, limiting attainment and maintenance of life milestones); and establishing own pace (demarcating disease from life, determination to survive, taking limitations in their stride, embracing the positives, finding personal enrichment, relying on social/spiritual support).
Conclusions: Children with CHD encounter lifestyle restrictions, fear of invasive procedures, and concerns about body image and discrimination. They endure uncertainties due to the unpredictable progression of disease and a risk of premature death. Access to psychosocial services addressing the distress of medical procedures and community-based support programs may strengthen their coping capacity. This may ultimately lead to improved satisfaction and outcomes in this vulnerable population.

P1205 - CASE REPORT SURGERY ON LUTEMBACHER SYNDROME WITH DEXTROCARDIA AND SITUS INVERSUS

Ihsanul Amal, Heroe Soebroto, Paul Tahalele, Ito Puruhito
Soetomo General Hospital/Airlangga University, Department of Thoracic and Cardiovascular Surgery, Surabaya-Indonesia

Background: Lutembacher Syndrome is an uncommon cardiac anomaly characterised by a combination of congenital ostium secundum atrial septal defect and acquired mitral stenosis. Its presence in dextrocardia with situs inversus is an even more unique condition where merely a few reports available. Correcting this unique anomaly thus becomes a challenge for any surgeons. Rheumatic disease is the dominant aetiology of mitral stenosis. Clinical manifestations usually involve dyspnea on exertion due to right ventricular overload leading to right heart failure.
Case Report: A forty-one-year-old male presented with complaints of dyspnea on exertion and palpitation since the last two years. Clinical examination, chest x-ray, echocardiography and catheterisation elicited the diagnosis of Lutembacher syndrome with dextrocardia and situs inversus. The echocardiography showed mitral stenosis insufficiency and an ostium secundum atrial septal defect. The patient was subsequently scheduled for corrective surgery, during which the pericardium adhered firmly onto the heart, indicating a preceding pericarditis. The surgeon substituted the mitral valve with a mechanical replacement and sealed the atrial septal defect with a pericardial patch.
Result: The surgery was a success with no ensuing complications. An echocardiographic evaluation shows a satisfactory result with minimal central valve leakage.
Conclusion: Lutembacher syndrome with dextrocardia and situs inversus is a highly rare entity which presents a challenge in its surgical management. The surgeon corrected this cardiac anomaly with the versatility and excellent technique, resulting in a favourable outcome.

P1208 - A CASE REPORT OF TRUNCUS ARTERIOSUS WITH INTERRUPTED AORTIC ARCH FROM NEWBORN TO ADULT AGE

Skaiste Sendzikaite[1], Rita Sudikiene[1], Virgilijus Tarutis[1], Nomeda Valeviciene[2], Darius Palionis[2]
Vilnius University Hospital Santariskiu Klinikos, Centre of Heart and Chest Surgery, Vilnius-Lithuania[1]; Vilnius University Hospital Santariskiu Klinikos, Centre of Radiology and Nuclear Medicine, Vilnius-Lithuania[2]

We present a case report of a long term follow up results after arterial trunk with type B interrupted aortic arch repair. The prevalence of common arterial trunk is only 1 percent of all CHD. The combination of these diseases is even rarer. The patient was admitted with cardiogenic shock in the newborn age. Immediate surgical approach was reconstruction of aorta and pulmonary artery (PA) banding. Next surgery was done after three more years – the closure of VSD and PA reconstruction with homotransplantat. 13 years later due to progression of PA stenosis and right ventricular failure PA conduit was replaced by percutaneous approach. A 22mm Melody valve was implanted into presented RV outflow tract and 17 mm stent was placed in the right pulmonary artery due to severe stenosis. 20 years after repair patient remains with minimal heart failure symptoms in NYHA I-II class. The positive dynamics of right ventricle systolic function was observed after Melody valve implantation by heart MRI. RV ejection fraction increased from 30 to 43 percent. RV decreased in size without signs of pressure overload. Minimal RV outflow tract dilatation with hypertrophy is still visualized by ultrasound. Both ventricles are in good systolic function. Minimal PA stenosis with minimal PA regurgitation remains. A trivial aortic annulus and root dilatation with minimal aortic regurgitation persists without negative dynamics in past few years. The patient is well socially adapted she evaluates her life quality as great. Prognosis of this particular case: a PA conduit replacement in few more years and real possibility for the aortic valve replacement in late future. Treatment of complex CHD is a challenge for patient, his family and doctors. Correct diagnostic approaches, successful surgical and invasive treatment preserves good systolic function of both ventricles which determines clinical status and life quality of the patient.

P1210 - PREVALENCE OF BRADYCARDIA ATRIOVENTRICULAR BLOCK AND BUNDLE BRANCH BLOCK IN PATIENTS WITH ATRIAL SEPTAL DEFECT

Diana H. R. Albæk, Camilla Nyboe, Vibeke Hjortdal
Aarhus University Hospital, Dept. of Cardiothoracic, Aarhus-Denmark

Background: Atrial septal defect (ASD) is the second most common type of congenital heart disease. Lately it has been revealed that patients with ASD have increased risk of stroke, pneumonia and atrial fibrillation, emphasizing the need of reconsidering a long-term medical follow up. In order to construct a better follow up procedure for ASD patients, we aim to elucidate whether ASD patients have an increased risk of conduction abnormalities compared to the background population, as consequences of these conditions can be prevented, e.g. with an implantable pacemaker.
Methods: We included 146 patients in this retrospective cohort study where data was collected by reviewing medical records and analysing electrocardiograms (ECGs) for the following outcomes; atrioventricular block (AVB), bradycardia, complete right bundle branch block (CRBBB), incomplete right bundle branch block (IRBBB), left anterior fascicular block (LAH), left posterior fascicular block (LPH), pacemaker and mortality.
Results: Most frequent findings among ASD patients were IRBBB (50%), LAH (5.5%) and bradycardia (4.8%). In total 7 patients (4.8%) had received a pacemaker. Average age at implantation was 20 years. Less common conditions were: 1-AVB (2.1%), 2-AVB (2.7%), 3-AVB (1.4%), CRBBB (3.4%) and LPH (2.1%). Furthermore, we found a low mortality (4.3%).
Conclusion: To date no other European study has examined the prevalence of conduction abnormalities in ASD patients, and our study contributes to an incremental advance of knowledge concerning possible long-term effects of ASD. We found a higher prevalence of AVB, IRBBB and CRBBB compared to a background population, and we discovered that different ages contain different types of conduction problems. The latter may indicate that IRBBB may regress or evolve into a CRBBB with time. Furthermore, we found that patients with ASD are prone to receive pacemaker in a very young age compared to what is expected in a general population of Denmark.

P1215 - INSPIRATORY MUSCLE TRAINING IMPROVES INSPIRATORY MUSCLE STRENGTH RESTING CARDIAC OUTPUT AND THE VENTILATORY EFFICIENCY OF EXERCISE IN PATIENTS WITH A FONTAN CIRCULATION

Karina Laohachai[1], David Winlaw[1], Hiran Selvadurai[2], Ganesh Kumar Gnanappa[1], Yves D'udekem[3], David Celermajer[4], Julian Ayer[1]
The Children's Hospital at Westmead, The Heart Centre For Children, Sydney-Australia[1]; The Children's Hospital at Westmead, Respiratory Medicine, Sydney-Australia[2]; The Royal Children's Hospital, Cardiothoracic Surgery, Melbourne-Australia[3]; The Royal Prince Alfred Hospital, Cardiology, Sydney-Australia[4]

Background: Patients with a Fontan circulation have reduced exercise capacity and respiratory muscle weakness. Inspiratory muscle training (IMT) improves exercise capacity and quality of life in adults with heart failure, who have a similar physiology to Fontan patients. We assessed if IMT improves inspiratory muscle strength, measured by maximal inspiratory pressure (MIP), and objective measures of exercise capacity, specifically ventilatory efficiency as measured by VE/VCO2 slope, in adolescents with a Fontan circulation.
Methods: Twenty-three adolescents (aged 16 ± 2 years) with a Fontan circulation underwent 6 weeks of IMT for 30 minutes daily. Respiratory muscle strength (MIP and maximal expiratory pressure, MEP), lung function and exercise capacity (cardio-pulmonary exercise testing) were assessed. Fourteen of the 23 subjects also underwent an exercise cardiac magnetic resonance imaging (ex CMRI) to examine the effects of IMT on systemic and pulmonary blood flow.
Results: Baseline MIP was 69 ± 22 cmH2O, higher in males than females (75 vs 62cmH2O, $p = 0.02$). Six weeks of IMT improved MIP by 36 ± 24cmH2O ($61\% \pm 46\%$). There was an associated improvement in VE/VCO2 (34.2 vs 32.2, $p = 0.04$). There was also improvement in resting cardiac output (from 4.2 ± 1.2 to 4.5 ± 1.0 L/min, $p = 0.03$) and ejection fraction (from 50.1 ± 4.3 to 52.8 ± 6.1, $p = 0.03$) in those who underwent ex CMRI.
Conclusions: Six weeks of IMT improves inspiratory muscle strength, VE/VCO2 slope, and resting cardiac output and ejection fraction, in young Fontan patients. IMT may be a simple beneficial addition to the current management of Fontan patients, potentially improving exercise capacity, morbidity and mortality.

P1224 - SUCCESSFUL TRANSFER OF YOUNG ADULTS FROM PAEDIATRIC TO ADULT CONGENITAL HEART DISEASE SERVICES; REDUCING LOSS TO FOLLOW UP

Bethaney Chidlow, Andrew Bullock, James Ramsay
Princess Margaret Hospital, Cardiology, Perth-Australia

Background: Loss to follow-up at transfer from paediatric to adult congenital cardiology services is a recognized challenge in maintaining high quality care of young people with congenital heart disease (CHD). International studies report 7 - 76% of adolescents with CHD are either lost to follow-up or experience lapses in care on transfer to adult congenital heart disease (ACHD) services. This is associated with increased morbidity and mortality. Having a coordinated process with dedicated staffing and resources overseeing transition is the key to effective transfer. This study was performed to assess successful transfer from paediatric cardiology to adult congenital cardiology services within the public health sector in Western Australia, with the introduction of a structured transition programme and a clinical nurse specialist (CNS) who works within both services.
Method: We reviewed all patients aged 16 years and over at time of last paediatric cardiology outpatient clinic review over a 5 year period (01/01/2011-31/12/2015). Included were all patients planned for transfer from paediatric to ACHD services. Patients planned for transfer to other adult cardiology services and ACHD patients receiving services from regional cardiology services were excluded from the review.
Results: 166 patients were eligible for transfer to ACHD services during the study period. 114 successfully transferred to ACHD services, 47 are pending transfer and only 5 (4%) have not attended ACHD clinic as scheduled.
Conclusion: An audit of the ACHD transition program has demonstrated a high rate of successful transfer of young adults to ACHD services with very low rates of loss to follow-up. These results have been achieved with the establishment of a coordinated transition program within paediatric services and the appointment of a dedicated transition CNS working in both paediatric and adult congenital cardiology.

P1232 - AORTIC STENOSIS IN PREGNANCY OUTCOMES OF A COMBINED CARDIAC & OBSTETRIC ANTENATAL CLINIC

Kate English[1], Gemma Ulivi[2], James Oliver[1], Sarah Winfield[2], Thomas Everett[2], Alex Simms[3], Alison Lansbury[4]
Leeds General Infirmary, Department of Adult Congenital Heart Disease, Leeds-United Kingdom[1]; Leeds General Infirmary, Department of Obstetrics, Leeds-United Kingdom[2]; Leeds General Infirmary, Department of Cardiology, Leeds-United Kingdom[3]; Leeds General Infirmary, Department of Anaesthesia, Leeds-United Kingdom[4]

Introduction: Existing risk scores for assessing risk of pregnancy in women with cardiac disease include left ventricular outflow tract obstruction (LVOTO) as a risk factor for maternal mortality and morbidity. Ante-natal counselling and counselling regarding possible termination of pregnancy is undertaken with these risks in mind. We assessed the maternal and neonatal outcomes of pregnancy in women with significant LVOTO attending our multidisciplinary cardiac antenatal clinic.
Methods: Data was collected for all women with LVOTO with an EDD between April 2015-April 2016. Data collected included diagnosis, complications, medication, mean and peak LVOT gradient at the beginning and end of pregnancy, mode of delivery and birth weight.
Results: We identified 11 pregnant women (age: 20-42yrs) with LVOTO. 7 had moderate LVOTO, and 4 had severe LVOTO. The peak velocity (median +/- IQR) through the aortic valve pre-pregnancy was 3.7 m/s (+/- 0.5 m/s), increasing to a maximum during pregnancy of 4.3 m/sec (+/- 0.8 m/s). Mean valve gradient pre pregnancy was 31 mmHg (+/- 7 mmHg), increasing to a maximum during pregnancy of 40 mmHg (+/-13 mmHg). All babies were born at or around term apart from two babies who were born just before 37 weeks gestation. One patient with severe aortic stenosis and obesity was admitted at 36 weeks with increasing breathlessness. Symptoms settled with rest and introduction of a beta blocker, and she had a successful vaginal delivery at 37 +2/40. 3 women required LSCS for obstetric indications; 8 women had vaginal deliveries. Median birth weight was 3050 g (+/- 1352.5 g).
Conclusion: Outcomes in women with significant LVOTO in our cohort is better than the published risk scores would suggest. Nevertheless, women with LVOTO are potentially at high risk of complications during pregnancy and delivery and should be offered tertiary centre antenatal multi-disciplinary team input. Larger series should be collected to improve accuracy of ante-natal counselling.

P1240 - LONG TERM FOLLOW UP OF REPAIRED TETRALOGY OF FALLOT INTO MIDDLE AGE

Mark Dennis, Benjamin Moore, Irina Kotchetkova, Lynne Pressley, Rachael Cordina, David Celermajer
Royal Prince Alfred Hospital, Cardiology, Sydney-Australia

Objective: Survival of patients with repaired tetralogy of Fallot (rToF) into young adulthood is very good. Concerns exist, however, over long term morbidity and mortality as these subjects reach middle age. We aimed to assess survival and the prevalence of complications in rToF patients seen in our Adult Congenital Heart Disease service.
Method: 168 consecutive patients with 'simple rToF', aged over 16 years were included. We documented mortality and analysed the prospectively defined composite endpoints of (a) "Serious adverse events" including death, heart failure hospitalisation and/or documented ventricular arrhythmia and (b) "Adverse events" inclusive of the above and endocarditis, atrial arrhythmia, defibrillator and/or pacemaker implantation.
Results: Mean age at last follow up was 34 ±12 years, 55% were males. There were 10 (6%) deaths and 26 patients (16%) experienced a "serious adverse event". Fifty-one patients (30%) experienced an "adverse event", 29 patients with atrial arrhythmias. One hundred and one (61%) patients had at least one pulmonary valve replacement and 10% required a second pulmonary valve replacement. By age 40 years, 93% of were free of serious adverse events and 83% were free of any adverse event. By age 50 years, only 56% had not had an adverse event. Older age and history of atrial arrhythmia were predictive of serious adverse events.
Conclusion: Survival into mid-adulthood in patients with repaired tetralogy of Fallot is very good, however a substantial number of survivors have clinically significant adverse events by the age of 50 years.

P1241 - LATE DIAGNOSIS OF ADDITIONAL STRUCTURAL ABNORMALITIES IN PATIENTS WITH HISTORIC SURGICAL REPAIR OF ATRIAL SEPTAL DEFECT

Blanche Cupido[1], Helen Parry[1], Damien Cullington[1], James Oliver[1], Kate English[1], Hamish Walker[1], Laurence O'Toole[2]
Leeds General Infirmary, Department of Adult Congenital Heart Disease, Leeds-United Kingdom[1]; Sheffield Teaching Hospitals, Department of Cardiology, Sheffield-United Kingdom[2]

Surgical closure of atrial septal defects (ASD) began in 1953. We report 5 patients who underwent ASD closure years ago, who represent with residual defects. Case 1: Surgical repair ASD 1981 aged 4. 2013, complained of dyspnoea with drop in oxygen saturations to 82% on exertion. Trans-oesophageal echo demonstrated venosus ASD with bi-directional shunting. Patient underwent further surgery to close the residual defect and made a full recovery. Case 2: Surgical repair ASD 1964 aged 14. In 2009 CT demonstrated left pulmonary veins to coronary sinus. Surgically repaired in October 2010. The right heart now normalised in size, but ongoing problems with atrial arrhythmia necessitated drug therapy, two ablations and permanent pacemaker. Case 3: Surgical closure ASD 1971 aged 14. In 2015, CT scan demonstrated drainage of the right sided pulmonary veins to the IVC just above the diaphragm, and a severely dilated right heart. The patient describes poor effort tolerance, and is currently awaiting further surgical intervention. Case 4: Surgical repair ASD 1993 aged 16. Represented 10 years later with paroxysmal atrial arrhythmia, persistently dilated right heart and impaired exercise. Cross sectional imaging demonstrated non-functioning right lung and anomalous drainage of the left upper lobe to innominate vein. The patient underwent further surgery in 2016. Case 5: Surgical repair ASD 1994 aged 18. CT scan in 2014 demonstrated hemianomalous venous drainage of the right lung to the SVC. This patient is currently under consideration for further surgical intervention.
Conclusion: Patients who underwent congenital heart surgery before 2000 did not benefit from modern day imaging techniques and the vast majority are lost to follow up. They should be offered reassessment in specialist services to exclude untreated lesions or late complications. Symptom driven re-referral occurs late in the natural history when irreversible damage may have already occurred.

P1265 - SURGICAL VERSUS TRANSCATHETER DEVICE CLOSURE OF ATRIAL SEPTAL DEFECT (ASD) A COMPARATIVE ANALYSIS OF RIGHT HEART REMODELLING

Si Ying Pang, Jie Sheng Foo, Maksym Lazu, Ju Le Tan
National Heart Centre Singapore, Cardiology, Singapore-Singapore

Atrial septal defect (ASD) is a common congenital heart abnormality and can remain undetected until adulthood. Closure may be

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

attempted even in advanced age, resulting in improvements in symptoms and echocardiographic parameters. Closure is traditionally achieved surgically, with transcatheter device closure gaining popularity in the last few decades.

Aims: The study aims to evaluate the extent and rate of right heart chamber remodeling following transcatheter device closure of ASD in comparison to surgical closure.

Methods: We retrospectively analysed echocardiographic data of 121 patients who underwent either transcatherer device or isolated selective surgical closure of secundum ASD at National Heart Centre, Singapore (NHCS) from 2005 to 2015. Echocardiographic parameters measured pre- and post-intervention included: RA annulus diameter, RV inlet dimension, PASP, TAPSE (tricuspid plane annulus systolic excursion) and S' (systolic velocity of tricuspid annulus).

Results: Patients' age ranged from 18 to 69 years old, with 19 patients of aged 60 and above. There were 57 patients who underwent surgical closure and 64 underwent device closure. Patients who underwent catheter closure were older (46 years vs 37 years, $p < 0.05$). Both groups had similar pre-intervention parameters. A statistically significant decrease in PASP, RV inlet size, RA annulus diameter, S' and TAPSE was observed for both groups at 1 year post-intervention compared to the respective pre-intervention parameters. The biggest change was noted at 6-8 weeks. There was no difference between the two groups in terms of reduction in PASP, RV inlet size and RA annulus. In the device group, the reduction in TAPSE was significantly less up to 1 year with compared to the surgical group.

Characteristic	Total patients n=121
Age (y)	39 (18-69) *Median, (range)*
18-30	38 (31.4%)
31-50	43 (35.5%)
51-70	40 (33.1%)
Sex (Female)	75 (61.9%)
Surgical closure	57 (47.1%)
Transcatheter closure	64 (52.9%)

Figure 1.
Study Population.

Characteristic	Surgical n=57	Device n=64
Age (**P<0.05**)	37 (18-63) (median)	46 (18-69)
Mean systolic BP	122.6	126.8
Mean diastolic BP (mmHg)	70.1	70.3
Mean heart rate (bpm)	76.1	72.0
Baseline PASP (mmHg)	36.0	36.8
RV inlet size (cm)	4.6	4.4
RA annulus diameter (cm)	3.3	3.8
TAPSE (cm)	2.5	2.5
TA TDI S' (cm)	0.14	0.13

Figure 2.
Baseline characteristics: surgical vs device groups.

Conclusions: Device and surgical closure of ASD both result in similar improvement in pulmonary pressures and right heart dimensions. However, device closure is associated with better preservation of TAPSE at 1 year.

P1279 - QUANTIFICATION OF PULMONARY REGURGITATION BY VECTOR FLOW MAPPING IN CONGENITAL HEART PATIENTS AFTER REPAIR OF RIGHT VENTRICULAR OUTFLOW OBSTRUCTION

Ashley Hm To[1], Vivian Wy Li[1], Ming-Yen Ng[2], Yiu-Fai Cheung[1]
The University of Hong Kong, Department of Paediatric and Adolescent Medicine, Hong Kong-Hong Kong[1]; The University of Hong Kong, Department of Diagnostic Radiology, Hong Kong-Hong Kong[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Objective: The new vector flow mapping (VFM) enables direct visualization of flow pattern and estimation of flow volume. We aimed to determine its accuracy in the quantification of pulmonary regurgitation (PR) in congenital heart patients after repair of right ventricular (RV) outflow obstruction.
Methods: This study comprised two parts: i) validation of VFM (Hitachi Aloka, Tokyo, Japan) in the quantification of PR in repaired tetralogy of Fallot (ToF) patients by cardiac magnetic resonance (CMR), and ii) clinical application of VFM to determine PR in patients after biventricular repair of pulmonary atresia (PAIVS) and stenosis (PS) with intact ventricular septum. Pulmonary regurgitation was quantified by calculation of VFM-derived pulmonary diastolic backward flow ratio (PRback), defined as ratio of backward to forward flow volume. In ToF patients, cardiac MRI was performed within 2 months of VFM assessment.
Results: The coefficients of variations for intra- and inter-observer variability in the measurements of PRback were 7.0% and 10.4%, respectively. Fourteen repaired ToF patients aged 31.3 ± 7.3 years were studied. Their PR–back correlated strongly with CMR-derived pulmonary regurgitation fraction ($r = 0.95$, $p < 0.001$) and RV end-diastolic volume ($r = 0.84$, $p < 0.001$). In the second part, 14 PAIVS patients aged 25.6 ± 6.0 years, 14 PS patients aged 24.2 ± 7.0 years, and 14 healthy controls were studied. The VFM-derived PR–back was found to increase across groups of subjects with absent (4.6 ± 3.3%), mild (11.1 ± 7.1%), moderate (29.6 ± 7.8%) and severe (50.1 ± 8.2%) PR as defined semi-quantitatively by colour flow mapping. Furthermore, VFM-derived PR–back correlated strongly with the ratio of PR colour jet/width of RV outflow ($r = 0.92$, $p < 0.001$).
Conclusion: Vector flow mapping is a reproducible technique for accurate quantification of PR in congenital heart patients after repair of right ventricular outflow obstruction.

P1288 - COMPOUND HETEROZYGOUS LOSS OF FUNCTION MUTATIONS IN KIF20A ARE ASSOCIATED WITH A NOVEL LETHAL CONGENITAL CARDIOMYOPATHY IN TWO SIBLINGS

Jacoba Louw[1], Ricardo Nunes Bastos[2], Xiaowen Chen[3], Cèline Verdood[4], Annniek Corveleyn[4], Jeroen Breckpot[4], Marc Gewillig[5], Hilde Peeters[4], Massimo Santoro[3], Francis Barr[2], Koenraad Devriendt[4]
University Hospitals and Ku Leuven, Congenital And Pediatric Cardiology, Centre of Human Genetics, Leuven-Belgium[1]; University of Oxford, Department of Biochemistry, Oxford-United Kingdom[2]; Vib, vrc, Ku Leuven, Laboratory of Endothelial Molecular Biology, Leuven-Belgium[3]; University Hospitals and Ku Leuven, Centre of Human Genetics, Leuven-Belgium[4]; University Hospitals and Ku Leuven, Congenital And Pediatric Cardiology, Leuven-Belgium[5]

Aims: Congenital or neonatal cardiomyopathies are commonly associated with a poor prognosis and have multiple etiologies. In two siblings, a male and female, we identified an undescribed type of lethal congenital restrictive cardiomyopathy affecting the right ventricle. We hypothesized a novel autosomal recessive condition. To identify the cause, we performed genetic, in vitro and in vivo studies.
Methods and Results: Genome-wide SNP typing and parametric linkage analysis was done in a recessive model to identify candidate regions. Exome sequencing analysis was done in unaffected and affected siblings. In the linkage regions, we selected candidate genes that harbor two rare variants with predicted functional effects in the patients and for which the unaffected sibling is either heterozygous or homozygous reference. We identified two compound heterozygous variants in KIF20A; a maternal missense variant (c.544 C > T: p.R182W) and a paternal frameshift mutation (c.1905delT: p.S635Tfs*15). Functional studies confirmed that the R182W mutation creates an ATPase defective form of KIF20A which is not able to support efficient transport of Aurora B as part of the chromosomal passenger complex. Due to this Aurora B remains trapped on chromatin in dividing cells and fails to translocate to the spindle midzone during cytokinesis. Translational blocking of KIF20A in a zebrafish model resulted in a cardiomyopathy phenotype.
Conclusion: We identified a novel autosomal recessive congenital restrictive cardiomyopathy, caused by a near complete loss-of-function of KIF20A. This finding further illustrates the relationship of cytokinesis and congenital cardiomyopathy.

P1300 - NON OSMOTIC ARGININE VASOPRESSIN SECRETION IN ADULT PATIENTS WITH CONGENITAL HEART DISEASE

Tomoaki Murakami[1], Shigeru Tateno[2], Yasutaka Kawasoe[2], Koichiro Niwa[3]
Chiba Children, Cardiology, Chiba-Japan[1]; Chiba Cardiovascular Center, Pediatrics, Ichihara-Japan[2]; St Luke, Cardiology, Tokyo-Japan[3]

Background: Recently, the cardio-renal connection is receiving a lot of attention in management of heart failure. Arginine vasopressin (AVP) system is one of the most important systems to connect heart and kidney. However, the knowledge about the relationship between the AVP system and the hemodynamics is limited. There are two mechanisms in AVP secretion, osmotic and non-osmotic control, and the change of hemodynamics could influence on the AVP secretion via non-osmotic control. The purpose of this study is to clarify the relationship between the non-osmotic AVP secretion and the hemodynamics in adult patients with congenital heart disease (CHD).
Methods: This study enrolled 74 adult CHD patients. Peripheral blood was drawn in fasting for analysis of plasma osmolality and AVP concentration. Using the osmolality, the estimated AVP concentration was calculated. A condition with higher measured AVP level than estimated AVP concentration was defined as the elevation of the non-osmotic AVP secretion. The various parameters were compared between the patients with and without the elevated non-osmotic AVP secretion.
Results: The patients' age was 35.2 ± 14.8 years. NYHA class was I:46, II:21, III:7, IV:0. 17 patients suffered from cyanosis. The level of brain natriuretic peptide was 81.4 ± 174.0 pg/ml. The plasma AVP level was 2.3 ± 2.1 pg/ml and osmolality was 291.9 ± 3.6 mOsm/l. The non-osmotic AVP secretion elevated in 10 patients and the AVP level (6.4 ±3.1 pg/ml) of them was higher than that in the patients without the elevation (1.7 ± 0.9 pg/ml). Diuretics use was significantly frequent in the elevated non-osmotic AVP secretion group (60% vs. 16%; Odds Ratio 8.10 (1.93-33.98), $p = 0.0053$).
Conclusions: In adult patients with CHD, diuretics administration is one of the causes of the elevation of the non-osmotic AVP secretion. Volume depletion by diuretics may induce the non-osmotic AVP secretion.

P1304 - CAN THE USE OF A FITBIT INCREASE ACTIVITY IN ADULT CONGENITAL PATIENTS WITH PULMONARY HYPERTENSION

Jo Birkett, Jo Quirk, Sarah Hibbert, James Oliver
Leeds General Infirmary, Adult Congenital Cardiology, Leeds-United Kingdom

Introduction: Little is known on the activity levels of adults with pulmonary hypertension in association with congenital heart disease. We sought to quantify activity levels in this group with FitBit

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

exercise trackers and used the data to motivate individuals to increase their activity levels.
Method: 18 patients were given a FitBit and joined a closed online group. Activity data (daily number of steps) were collected over 3 months. After collecting baseline data for 2 weeks, feedback was given to individuals and they were each asked to try to increase their activity by 10%. Regular contact and encouragement were provided through the online group, email and phone. Formal feedback was collected at 3 months.
Results: The patient group ranged from 19 years to 69 years, 11 were female & 7 male, 6 had Trisomy 21. All patients completed the programme for the full 3 months. Mean baseline daily activity was 4566 steps (range 1833 to 8792). Daily step counts increased by 13% at 4 weeks, 13.9% at 8 weeks and 10.9% at 12 weeks compared to baseline. 10 of 18 patients completed the feedback questionnaire: 20% stated that they felt much better, 60% a little better and 20% about the same. Comments from patients included: "made me feel better", "increased confidence", "has given me something positive to focus on."
Conclusion: Activity levels improved in our patients with the use of an activity tracker supported by encouragement from health professionals. The effect was sustained at 3 months. There also appeared to be a positive effect on patient-reported well-being. The programme continues and we will continue to evaluate effectiveness over the longer term.

P1329 - VENTRICULAR ASSISST DEVICE IN ADULT CONGENITAL HEART DISEASE A SYSTEMATIC REVIEW AND META ANALYSIS

Abdur Rahman Ahmad[1], Faraj Kargoli[2], David Briston[3], Pedro Villablanca[4], Danny Sims[4], Daphne Hsu[3], Daniel Goldstein[4], Giles Peek[4], Ulrich Jorde[4], Ali Zaidi[4]
SBH Health System, Internal Medicine, Lake Grove-United States[1]; Montefiore Medical Center, Albert Einstein College of Medicine, Internal Medicine, Bronx-United States[2]; Pediatric Heart Center, Childrens Hospital at Montefiore, Albert Einstein College of Medicine, Pediatrics-Cardiology, Bronx-United States[3]; Montefiore Einstein Heart & Vascular Care Center, Montefiore Medical Center, Albert Einstein College of Medicine, Medicine-Cardiology, Bronx-United States[4]

Introduction: Advanced heart failure is an increasing problem in adult congenital heart disease (ACHD) patients. Data regarding survival after ventricular assist device (VAD) placement in ACHD are scarce. We reviewed current literature to assess survival in ACHD patients with VADs.
Methods: A systematic review was performed utilizing Pubmed, Ovid, and Cochrane for all reported ACHD patients (age >21) who received VADs. Data on baseline demographics, duration of VAD support, BTT (Bridge to Transplant) vs DT (Destination Therapy), ACHD lesion, death, and transplantation were collected. Kaplan-Meier estimates were used to assess survival.
Results: Literature review yielded 43 ACHD patients who underwent VAD implantation (mean and median age 41 yrs, range 23-75 yrs.). Duration of VAD support: mean 329 days (median 244, range 7-1477). Gender was reported in 39 patients (33 males). VAD was placed as DT in 11 pts, of whom 2 died. BTT was the indication in 32 pts: 16 were transplanted, 7 pts died, and 9 were still awaiting transplant on VAD support. DTGA (n = 19) and ccTGA (n = 18) were the most commonly reported ACHD lesions. Single ventricle S/P Fontan was reported in 5 pts: 2 were transplanted, 2 were DT and one died awaiting transplant at 262 days. Continuous-flow VADs were more commonly used (n = 35) vs 7 pulsatile-flow, 4 VAD types were not reported. Most VADs were implanted to the morphologic RV (n = 38), 8 to the LV including 3 BIVADS. The 30 day and 1 year survivals post-VAD placement in ACHD patients were 88.5% and 80.5% respectively with a survival estimate of 70.5% at 2 years. This is similar to INTERMACS reported 1 year survival of 80% and 2 year survival of 70% with CF devices in all patients.
Conclusions: In carefully selected ACHD patients, VADs can be successfully used for mechanical circulatory support.

P1347 - A SUCCESFUL SURGICAL REPAIR OF TETRALOGY OF FALLOT IN ADULT WITH DEXTROCARDIA AND SITUS INVERSUS TOTALIS

Chikita Nur Rachmi, Heroe Soebroto, Yan Efrata Sembiring, Paul Tahalele, Ito Puruhito
Soetomo General Hospital, Aielangga University, Thoracic and Cardio Vascular Surgery, Surabaya-Indonesia

Background: Tetralogy of Fallot, a combination of four related heart defects, is the most common cyanotic heart disease in Indonesia. Dextrocardia is a condition in which the major axis of the heart points to the right and associated with intracardiac lesion. However, Tetralogy of Fallot in patient with dextrocardia and situs inversus is rare and present technical challenges in the surgical repair. The surgical repair of dextrocardia with congenital lesion is easier to performed from the left side.
Purpose: To report a successful surgical treatment in adult with Tetralogy of Fallot, situs inversus totalis and dextrocardia that previously had imprecise preoperative diagnosis of pulmonary stenosis with vegetation and infective endocarditis.
Method: A 22 years old girl was referred to our hospital with shortness of breath and history of recurrent syncope. The diagnosis of situs inversus totalis and dextrocardia with severe supravalvular pulmonal stenosis, moderate pulmonal regurgitation were established, based on chest radiograph, transthoracal echocardiography and cardiac CT scan. The patient was also diagnosed as infective endocarditis and has got antibiotic for a month. Patient was originally planned to underwent pulmonary valve replacement. During surgery, transesophageal echocardiography evaluation confirmed the diagnosis of Tetralogy of Fallot.
Discussion: During surgery, we found the heart located in the right hemithorax with its base to apex axis directed to the right, superior and inferior vena cava at the left side, and right aortic arch. After opening right atrium, there were patent foramen ovale, infundibular thickening, and subaortic ventricular septal defect at diameter 1 cm without vegetation. Infundibular thickening was resected, ventricular septal defect was closed with dacron patch and transanullar patch was done with pericardium graft.
Keywords: Tetralogy of Fallot, situs inversus totalis, dextrocardia, pulmonal stenosis, ventricle septal defect (VSD), patent foramen ovale (PFO).

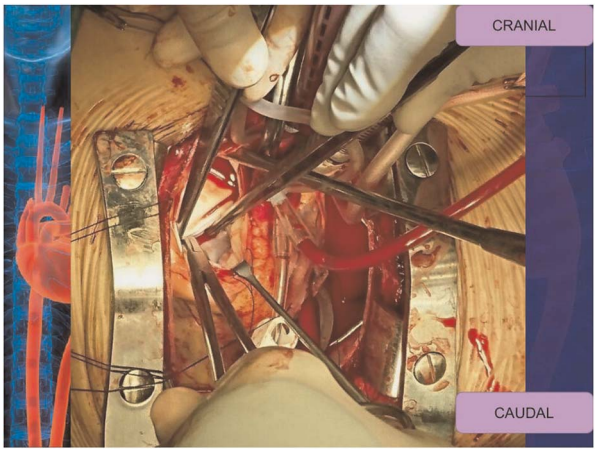

Figure 3.

P1366 - INCIDENCE AND OUTCOME OF INFECTIVE ENDOCARDITIS FOLLOWING PERCUTANEOUS VERSUS SURGICAL PULMONARY VALVE REPLACEMENT

Gentian Lluri[1], Dan Levi[2], Emily Miller[1], Abbie Hageman[1], Sanjay Sinha[2], Brian Reemtsen[3], Hillel Laks[3], Reshma Biniwale[3], Morris Salem[4], Jamil Aboulhosn[1]
UCLA, Medicine, Los Angeles-United States[1]; UCLA, Pediatrics, Los Angeles-United States[2]; UCLA, Surgery, Los Angeles-United States[3]; Kaiser Permanente, Medicine, Los Angeles-United States[4]

Background: Transcatheter pulmonary valve replacement (TPVR) may be associated with a higher risk of infective endocarditis (IE) than surgical pulmonary valve replacement (SPVR), however, there is a paucity of data to support this assertion.
Materials and Methods: Patients who underwent TPVR or SPVR at UCLA between October 2010 and September 2016 were included. Baseline and subsequent clinical data were retrospectively collected. IE was diagnosed based on the modified Duke criteria.
Results: A total of 342 patients underwent pulmonary valve replacement at UCLA including 134 SPVR and 208 TPVR. Patients in the TPVR group were more likely to have had a history of endocarditis (5.3% vs 0.7%, P = 0.03) and more likely to have a right ventricle to pulmonary artery (RV to PA) conduit (37% vs 17%, P = 0.0001). Two SPVR (1.5%) and eight TPVR cases (3.8%, P = 0.21) developed IE following the procedure with a 5-year freedom from endocarditis of 94.0% in the SPVR versus 83.8% in the TPVR group (P = 0.08). In patients who underwent TPVR and developed endocarditis, the mean gradient across the RVOT prior to intervention was significantly higher when compared to the patients who underwent TPVR and did not develop endocarditis (28.1 ± 4.5 mmHg vs 17.4 ± 0.6, P = 0.02). In addition, patients who developed endocarditis were more likely to have an RV to PA conduit when compared to patients who did not develop endocarditis.
Conclusions: There is a trend that suggests that patients undergoing TPVR may be at a higher risk of IE than patients undergoing SPVR. TPVR patients were far more likely to have had a prior history of IE and a conduit. The patients at highest risk are those with stenotic RV to PA conduits who are treated with TPVR.

P1376 - HEART FAILURE ADMISSIONS AND POOR SUBSEQUENT OUTCOMES IN ADULTS WITH CONGENITAL HEART DISEASE

Sean Lal, Irina Kotchetkova, Jacob Cao, Daniel Jackson, Rachael Cordina, David Celermajer
Royal Prince Alfred Hospital, Cardiology, Sydney-Australia

Background: Heart failure is a leading cause of morbidity and mortality amongst adults with congenital heart disease (CHD). Outcomes following hospital admission with heart failure in adults with CHD, however, are largely unknown.
Aim: To determine the prevalence, complications and prognosis of clinical heart failure in a cohort of patients with adult congenital heart disease (ACHD).
Methods: Data on hospital admissions for heart failure (HF) were collected from our tertiary referral centre between 2000 and 2014. We analysed CHD diagnosis, survival status and cause of death. Vital status was known for all subjects from a National Death Registry. We also gathered information on subject demographics, co-morbidities, medical treatment and ventricular function (based on echocardiography).
Results: Data from 3862 consecutively registered and qualifying adult CHD patients were collated. 179 (4.6%) patients had been admitted to hospital with a clinical diagnosis of heart failure, with a mean age of 57 years. HF was more likely in those with more complex defects or with bicuspid aortic valve disease. HF was also more common in those with concomitant atrial arrhythmias and/or severe left ventricular dysfunction. 5-year mortality rates were 45% for patients in the HF group and 8% for the ACHD patients with no HF admissions ($p < 0.001$). More than 70% of the HF patients died within 10 years of their first admission, with 25% dying in the first year. Over 90% of these deaths were attributable to cardiovascular causes.
Conclusion: Admission to hospital with heart failure is a strong, negative prognostic event in patients with ACHD. It is associated with high rates of mortality, especially in the first year following hospital admission. As such, there is a need to identify modifiable risk factors to prevent first (and subsequent) heart failure admission(s).

P1378 - USEFULLNESS OF EUROSCORE II TO PREDICT COMPLICATION OF CARDIAC RE OPERATION AMONG ADULT TETRALOGY OF FALLOT PATIENTS; A SINGLE CENTER EXPERIENCE

Fumie Takechi[1], Hiroko Morishima[1], Shigeru Tateno[1], Yasutaka Kawasoe[1], Yoshitomo Okajima[1], Masashi Kabasawa[2], Kozo Matsuo[2], Koichiro Niwa[3]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Chiba Cardiovascular Center, Pediatrics, Chiba-Japan[1]; Chiba Cardiovascular Center, Cardiovascular Surgery, Chiba-Japan[2]; St Luke, Cardiovascular Center, Tokyo-Japan[3]

Background: Cardiac re-operation is sometimes needed among adult tetralogy of Fallot (TOF) long-term after repair. Risk factor of re-operation among TOF patients is not clarified. EuroSCORE II, which can predict mortality of adult cardiac surgery, is calculated based on risk factors (NYHA, LVEF, weight of procedure et cetera) and their coefficient.
Objective: The aim of this study is to investigate utility of EuroSCORE II for predicting complications of re-operation among TOF patients.
Methods: A retrospective review identified 26 adult TOF who underwent re-operation at Chiba Cardiovascular Center from January 2008 to November 2016. Patients were classified into two groups; those with perioperative complications (Group A) and those without (Group B). Perioperative complications were defined as follows; A death within 30 days, cardiac failure requiring mechanical circulatory support, renal failure requiring dialysis, cerebral infarction or bleeding, myocardial infarction, intubation/NIPPV over 48 hours, length of ICU stay over 6 days, re-operation. We compared two groups about following indices; predicted mortality calculated by EuroSCORE II and items which EuroSCORE II doesn't include (RVEDVI, RVEF, co-existence of PA or MAPCAs).
Results: The breakdown of complications was 2 re-operation, 5 intubation/NIPPV over 48 hours, 4 long ICU stay (duplicates exist). Predicted mortality was significantly high in Group A than Group B($p = 0.026$)(Group A; median 11.7%: range 4.3-46.5%), Group B; median 5.2%: range 2.7-9.1%). There were no significant differences between two groups about other indices; index: median(range) or proportion of Group A and B, p value. RVEDVI(ml/m2): 147(range 98-320), 144(range 71-323), $p = 0.53$, RVEF(%): 34(range 24-47), 45(range 21-59), $p = 0.11$, Co-existence of PA: 25%, 10%, $p = 1$, Co-existence of MAPCAs: 0%, 14%, $p = 1$.
Conclusion: EuroSCORE II can be applied to predict perioperative complications of re-operation among adult TOF patients, and further study is required to develop tools that predict complications of re-operation in them.

P1382 - A CLUSTER RANDOMIZED TRIAL OF A TRANSITION INTERVENTION FOR ADOLESCENTS WITH CONGENITAL HEART DISEASE

Andrew Mackie[1], Gwen Rempel[2], Adrienne Kovacs[3], Miriam Kaufman[4], Ahlexxi Jelen[5], Kathryn Rankin[1], Erwin Oechslin[6], Renee Sananes[5], Maryna Yaskina[7], Brian Mccrindle[5]
University of Alberta, Department of Pediatrics, Edmonton-Canada[1]; Athabasca University, Faculty of Health Disciplines, Athabasca-Canada[2]; Oregon Health Sciences University, Cardiology, Portland-United States[3]; The Hospital For Sick Children, Adolescent Medicine, Toronto-Canada[4]; The Hospital For Sick Children, Cardiology, Toronto-Canada[5]; Toronto General Hospital, Congenital Cardiac Centre For Adults, Toronto-Canada[6]; University of Alberta, Women and Children, Edmonton-Canada[7]

Background: The population of adults with congenital heart disease (CHD) is growing exponentially. However, there is little evidence regarding the preparation of adolescents to assume responsibility for their health and self-management within the adult health care system.
Methods: We conducted a randomized clinical trial of a nurse-led transition intervention for 16-17 year olds with moderate or complex CHD, versus usual care. The intervention group received two 1-hour individualized sessions with a cardiology nurse, focusing on CHD education and self-management skills. The primary endpoint was excess time to adult CHD care, defined as the interval between the final pediatric and first adult cardiology appointments, minus the recommended time interval between these appointments. Secondary endpoints were MyHeart score (CHD knowledge) and Transition Readiness Assessment Questionnaire (TRAQ) score.
Results: 121 participants were randomized to intervention (57) or usual care (64). Freedom from excess time to adult CHD care was similar in both groups (log rank $p = 0.09$). At the recommended time of first adult cardiology appointment (excess time = 0), intervention participants were 1.78 times more likely to have their adult cardiology appointment within one month relative to those in usual care (95% CI 1.11-2.86, Cox regression $p = 0.018$). This hazard increased with time; at an excess time of 6 months, intervention participants were 2.97 times more likely to have an appointment within one month (95% CI 1.07–8.26). MyHeart scores were higher in the intervention group compared to usual care at 1, 6, 12 and 18 months ($p < 0.001$, mixed models), as were TRAQ self-management scores ($p = 0.032$, mixed models).
Conclusions: A nurse-led intervention program reduced the likelihood of a delay in obtaining adult CHD care after graduation from pediatric cardiology and resulted in greater CHD knowledge and self-management skills up to 18 months post intervention. A structured intervention program should be provided to all adolescents with CHD.

P1430 - BICUSPID AORTIC VALVE PHENOTYPE AFFECTED VALVULAR FUNCTION AND AORTIC ROOT GEOMETRY IN CHILDREN AND YOUNG ADULTS

Se Yong Jung[1], Hong Ju Shin[2]
Severance Cardiovascular Hospital, Yonsei University College of Medicine, Seoul, Pediatric Cardiology, Seoul-Korea, South[1]; College of Medicine, Chungbuk National University, Cheongju, Department of Thoracic and Cardiovascular Surgery, Chongju-Korea, South[2]

Objective: In adult patients, the relationship of phenotype of bicuspid aortic valve (BAV) between severe aortic stenosis (AS) or regurgitation (AR) has been reported. However, the relationship in children was not documented well. Therefore, we evaluated the aortic valve dysfunction according to BAV phenotype in pediatric patients.
Methods: Between Jan. 2005 and Dec. 2014, 89 BAV patients were reviewed retrospectively. According to BAV morphology, patients were divided into two groups; BAV-R/N (right coronary cusp (RCC) and non-coronary cusp fusion) and BAV-R/L (RCC and left coronary cusp fusion). Demographics, size of ascending aorta (AA), aortic valve function, and event of surgery or intervention were compared between two groups.
Results: The median age of 89 patients was 3.5 (range, 0-17.8) years. The number of BAV-R/N was 52 (58.4%), and there was no age and sex difference between groups. AS was more frequently associated with BAV-R/N (55.8% vs 29.7%, $p = 0.013$). Aortic root dilatation was more prevalent in BAP-R/L group (7.7% vs 29.7%, $p = 0.017$). Sinus of Valsalva Z-score was consistently larger in BAV-R/N group. During follow up, two (2.2%) patients underwent aortic valvuloplasty for AR, and seven (7.6%) patients underwent intervention (n = 5) or surgery for AS. Aggravated aortic root and AA dilatation was occurred in five and six patients, respectively.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: BAV is frequently associated with AS, AR and AA dilatation. AR could occur in young adults. Therefore, complete follow-up is warranted. Recognition of BAV morphology is helpful for predicting of the type of aortic valve dysfunction and the location of AA dilatation.

P1431 - VENTRICULAR MORPHOLOGY IN ADULTS BORN WITH A VENTRICULAR SEPTAL DEFECT

Marie Maagaard[1], Johan Heiberg[1], Filip Eckerström[1], Benjamin Asschenfeldt[1], Christian Rex[1], Steffen Ringgaard[2], Vibeke Hjortdal[1]
Aarhus University Hospital, Cardiothoracic and Vascular Surgery, Aarhus N-Denmark[1]; Aarhus University Hospital, Mr Research Centre, Aarhus N-Denmark[2]

Background: Ventricular septal defects (VSD) – whether they are large and surgically closed or small and untreated – are considered to have great outcomes in adulthood. However, we have previously demonstrated lower functional capacity in both patient groups compared with healthy, matched controls. The mechanisms behind these findings remain unclear and therefore, we performed cardiac magnetic resonance imaging (MRI) on adult patients in order to evaluate biventricular morphology.
Methods: Adults with surgically closed or small, untreated VSDs and healthy controls underwent cine MRI for the evaluation of the biventricular volumes, and phase contrast scans for the measurement of cardiac index. MRI measurements were analysed post hoc in a blinded fashion by one main investigator.
Results: Twenty operated patients (22.4 ± 2years) and 20 matched controls (23.1 ± 2years) were included, along with 32 small, open VSDs (26.3 ± 6years) and 28 matched controls (26.8 ± 5years). Operated VSDs were found with larger right ventricular end-diastolic volume index (RVEDVi) (102.7 ± 20 ml/m2) compared with their controls (90.4 ± 15), $p = 0.03$. Heart rate and right ventricular cardiac index (RVCi) were comparable between operated VSDs and controls. Open VSDs also revealed larger RVEDVi (105 ± 17 ml/m2) compared with their matched controls (88.2 ± 12 ml/m2), $p < 0.01$. Furthermore, RVCi was higher in patients with open VSDs (4.4 ± 1.2 l/min/m2) compared with controls (3.6. ± 1 l/min/m2), $p < 0.01$, but heart rates were similar. Left ventricular measurements displayed no differences between patient groups and their matched control groups.
Conclusion: An altered RV morphology was demonstrated in adults with small, untreated VSDs and in adults 20 years following surgical VSD-repair. These findings may explain some of the mechanisms behind the exercise limitations previously found in adulthood in this patient group.

P1448 - IMPAIRED CARDIAC OUTPUT AND INCREASED RETROGRADE PULMONARY FLOW DURING EXERCISE IN ADULTS OPERATED FOR VENTRICULAR SEPTAL DEFECT IN CHILDHOOD

Benjamin Asschenfeldt[1], Johan Heiberg[1], Steffen Ringgaard[2], Marie Maagaard[1], Andrew Redington[3], Vibeke Hjortdal[1]
Aarhus University Hospital, Depart. of Cardiothoracic and Vascular Surgery, Aarhus-Denmark[1]; Aarhus University Hospital, Mr Research Centre, Aarhus-Denmark[2]; Cincinnati Children's Hospital Medical Center, Heart Institute, Cincinnati-United States[3]

Background: The long-term outcome after surgical closure of ventricular septal defect (VSD) in childhood is not as benign as previously believed. Recent studies have shown markedly reduced functional capacity and disruption of the right ventricular force-frequency relationship during exercise in adult survivors of VSD. In order to further describe the long-term cardiac function, we performed a non-invasive assessment of cardiac index during exercise in adults operated for ventricular septal defect in early childhood.
Materials and Methods: Twenty patients (surgical age 2.1 ±1.4 years, age at examination 22.1 ±2.2 years) and twenty healthy, matched controls (23.4 ±2.1 years at examination) underwent continuous supine bicycle ergometry during magnetic resonance imaging. Blood flow was recorded in the ascending aorta and the pulmonary trunk at increasing exercise levels. Cardiac index, retrograde flow and vessel diameter were determined by blinded analyses.
Results: Mean cardiac index was comparable at rest with 2.9 ±0.7 l/min/m2 in the patient group and 3.0 ±0.6 l/min/m2 in the control group. During exercise, the patients had a lower increase in cardiac index reaching 7.3 ±1.3 l/min/m2 at sub-maximal exercise compared with 8.2 ±1.2 l/min/m2 in controls, $p < 0.05$. In the ascending aorta, patients had significantly higher retrograde flow than the controls at rest and throughout exercise. In the pulmonary artery, retrograde flow was minimal at rest in both groups, but increased significantly in the patient group during exercise compared with the control group. The patients had significantly larger aortic diameter of 32 ±5 mm compared with 28 ±3 mm in controls, $p < 0.01$. There was no difference in pulmonary trunk diameter.
Conclusions: Young adults with a surgically closed VSD have reduced cardiac index during exercise when compared to healthy young adults. The impaired cardiac index appears to be related to increasing retrograde flow in the pulmonary artery with progressive exertion.

P1450 - ECHOCARDIOGRAPHY MYOCARDIAL FUNCTION CORRELATE WITH CHANGE IN CARDIAC VARIANT FABRY DISEASE

Yeak-Wun Quek[1], Tsung-Cheng Shyu[2], Ming-Chih Lin[3], Sheng-Ling Jan[3], Yun-Ching Fu[3]
Chung Shan Medical University Hospital, Pediatrics, Taichung-Taiwan[1]; Kuang Tien General Hospital, Pediatrics, Taichung-Taiwan[2]; Veterans General Hospital of Taichung, Pediatrics, Taichung-Taiwan[3]

Background: Fabry disease (FD) is an X-chromosomal recessive deficiency of the lysosomal hydrolase alpha-galactosidase A (alpha-Gal), which is related to the IVS4 mutation and is used to treated with recombinant enzyme replacement therapy (ERT). Although left ventricular (LV) hypertrophy is the hallmark of cardiac involvement, its underlying pathologic represents of the total cardiac mass is not fully understood.
Methods: We enrolled 10 patients, 7 males and 3 females, median age was 59 who hobored cardiac variant Fabry disease in Taiwan. Firstly, we detected phosphatase and tensin homolog gene (PTEN) rs3830675, VS4 polymorphism in DNA samples extracted from whole blood by using DNA mass spectrometry. To use cardiac magnetic resonance imaging (MRI) and echocardiography for criticizing cardiac fibrosis and LV diastolic dysfunction, respectively. Histologically, we performed the estimation on inter-cell fibrosis and cell replacement by using haematoxylin and eosin (H & E) and Masson's trichrome and touluidine blue. On the other hand, the periodic acid-Schiff (PAS), lyosome-associated membrane protein-2 (LAMP2), CD31, CD34, GLA and globo-triaosylceramide (Gb3) of histochemistry in endomyocardial biopsy of these patients were also performed.
Results: A total of 10 cardiac variant Fabry disease of patients had intronic mutation IVS4 + 919G- > A ,and found LV diastolic dysfunction. Importantly, we found PAS (≦ 20%), cardiac muscle cell nucleus size (>6 μm), Vacuolization (>50%) were positively correlated with moderate to severe LV diastolic dysfunction, and

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

two cellular cluster differentiation markers CD 31 and 34 expressions were not associated with LV diastolic dysfunction. However, we used tranditional Electrocardiogram (ECG) to confirmed these 10 cardiac variant Fabry of patients was found one patient with normal ECG had short run of PSVT and triplet VPCs via 24-hour holter monitoring.

P1451 - OUTCOME OF BIOPROSTHETIC VALVES IN PULMONARY POSITION IMPLANTED FOR RECONSTRUCTION OF THE RIGHT VENTRICULAR OUTFLOW TRACT IN ADULT CONGENITAL HEART DISEASE

Roman Gebauer[1], Jana Popelova[2], Ferdinand Timko[2], Dominika Slezakova[1], Ivo Skalsky[2], Jan Janousek[1]
2nd Faculty of Medicine and Motol University Hospital, Children´s Heart Centre, Prague-Czech Republic[1]; Na Homolce Hospital, Department of Cardiac Surgery, Prague-Czech Republic[2]

Objectives: Pulmonary valve replacement (PVR) is the most frequent surgical procedure in adult patients with congenital heart diseases (ACHD). However, none of used valve substitutes is ideal. The aim of the study was to determine the impact of PVR on clinical outcome and right ventricular function.
Methods: We retrospectively reviewed the outcome and performance of bioprosthetic valves implanted in the pulmonary position. Since 2005 to April 2015, 133 consecutive patients with a median age of 35 (range 18.4 to 70.4) years underwent valve implantation: Carpentier-Edwards Perimount MagnaTM (N = 106), St. Jude TrifectaTM (N = 10), St.Jude Medical EpicTM (N = 11), St. Jude TorontoTM (N = 4) and other (N = 2). Median follow-up was 4.3 (0.1-11.0) years. Patients

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

diagnoses included tetralogy of Fallot (n = 84), pulmonary stenosis (n = 33), complex diagnoses (n = 14) or other (n = 2). One hundred twenty nine patients had 182 previous surgical procedures. Eighty-two patients (61%) had concomitant surgical procedures.
Results: There were no perioperative deaths, and 1 (0.8%) late death. Probability of freedom from reoperation was 100%, 99%, and 86.1% at 1, 4, and 8 years, respectively. Probability of freedom from valve dysfunction (pulmonary insufficiency more than moderate and or stenosis >40 mmHg) was 98.3%, 90.2%, and 56.9%, respectively. There was a significant improvement ($p < 0.001$) in NYHA functional class. Echocardiography confirmed lasting reduction in pulmonary ($p < 0.001$) and tricuspid valve regurgitation ($p < 0.001$), decrease in the size of tricuspid valve annulus ($p < 0.001$) and improvement of right ventricular function ($p < 0.001$).
Conclusions: PVR using bioprosthetic valves has a low mortality and carries lasting improvement in functional status and right ventricular function in ACHD patients. Freedom from re-operation and valve dysfunction is acceptable. Further studies are needed to compare long-term performance of different valves types in the pulmonary position. (Supported by MH CZ - DRO, University Hospital Motol, Prague, Czech Republic 00064203)

P1463 - CLINICAL AND HEMODYNAMIC FEATURES OF EISENMENGER SYNDROME A TERTIARY REFERRAL CENTER EXPERIENCE

Hyo Soon An[1], Ji Seok Bang[2], Gi Beom Kim[2], Bo Sang Kwon[2], Eun Jung Bae[2], Chung Il Noh[2]
Smg-Snu Boramae Medical Center, Pediatrics, Seoul-Korea, South[1]; Seoul National University Children's Hospital, Pediatrics, Seoul-Korea, South[2]

Background/Hypothesis: Eisenmenger syndrome (ES) is the most severe form of pulmonary arterial hypertension and arises on the basis of congenital heart disease with a systemic-to-pulmonary shunt. We aim to investigate characteristics and outcomes of ES patients at a tertiary center.
Materials and Methods: The data of 64 patients (mean age = 39 years, 32 male and 32 female, mean follow-up time = 20.6 years) with ES were reviewed retrospectively. Demographic characteristics, symptoms, laboratory and hemodynamic parameters, and medications were analyzed.
Results: The ES was diagnosed at 19.5 ± 13.1 years and underlying congenital heart disease was confirmed at 13.6 ± 13.9 years. The most frequent underlying heart diseases were isolated ventricular septal defect and patent ductus arteriosus (n = 17, 22%; respectively). 48 patients (77%) of ES were undergone cardiac catheterization (mean pulmonary arterial pressure = 73.5 ± 17.7 mmHg, arterial oxygen saturation = 87.4 ± 6.1%). Dyspnea (n = 45, 70%) and polycythemia (n = 26, 40%) were common, and hemoptysis (n = 14, 22%) and brain abscess (n = 6, 9.3%) were frequent complications. Functional capacity of NYHA Class III-IV and II was 22% and 62%, respectively. Pulmonary arterial hypertension specific drugs were used in 22% patients at 27.3 ± 5.5 years. Among 9 patients with pregnancy, 5 women underwent delivery without complication. Mortality was 10 patients (15.6%) and aggravating factors were as follows: heart failure, infection, sudden death, and delivery.
Conclusions: Although there are various complications and poor functional capacity, ES patients survive into their third or fourth decades. Therefore more active treatment and clinical follow up might be helpful for their quality of life.

P1473 - THE OUTCOME OF TRANSCATHETER COIL OCCLUSION OF FENESTRATION AFTER TOTAL CAVOPULMONARY CONNECTION

Yuliia Pozniak, Yuliia Kuzmenko, Igor Lebid, Valentina Khanenova, Nadia Rudenko
Ukrainian Children's Cardiac Center, ACHD Department, Kyiv-Ukraine

Fenestration of conduit of total cavopulmonary connection (TCPC) have patients of high risk. Risk factors included pulmonary artery (PA) pressure of 15 mm Hg or more, end-diastolic pressure of 12 mm Hg or more, valve regurgitation, significant cardiac arrhythmias, stenosis or hypoplasia branches PA, pulmonary vascular resistance of 2 Woods' units or more, ventricular outflow obstruction. We studied 10 patients 14.4 ± 7.6 years of age after TCPC operation.
Objectives: To determine the effects of closure of fenestration of conduit of TCPC on hemodynamics and clinical outcome of patients.
Methods: From 2003 to 2016 in UCCC 132 patients were operated TCPC. All patients had high preoperative risk before TCPC. Patients presented with moderate cyanosis, clubbing, effort intolerance (NYHA class II). Surveys revealed a hemoglobin level of 19.0 ± 10 gm•dL-1, hematocrit of 55 ± 5%, and peripheral saturation of 80 ± 5%. Fenestrations were occluded with a balloon to determine the effects on hemodynamic: right atrial pressure was acceptable (<20 mm Hg), aortic pressure remained stable with test occlusion Contraindication to the closure of fenestration: increase pressure in the Fontan anastomosis 3-5 mm Hg, an increase in difference arterio-venous blood by 10% higher, reducing the systemic systolic blood pressure 10% and above.
Results: Average postoperative follow-up was 18.8 ± 5.8 mon. During the follow-up visit the clinical condition of the patients was examined, tests with exercises stress were conducted to assess functional status, the level of blood oxygen saturation and hemoglobin, evaluated data of ECG, Echo, chest X-Ray. All patients reported improved exercise tolerance (NYHA I). Hemoglobin level of 16.5 ±5 gm•dL-1, hematocrit of 45 ±5%, and peripheral saturation of 95 ±2%.
Conclusions: Percutaneous occlusion of fenestration – it effective and safe method of closing the shunt in patients after TCPC. After the procedure, patients noted improvement:the absence of complaints, increased saturation and reducing the level of hemoglobin.

P1483 - HEART RATE RESPONSE TO EXERCISE IS IMPAIRED IN ADOLESCENTS AND YOUNG ADULTS WITH CONGENITAL HEART DISEASE COMPARED TO HEALTHY CONTROLS

Stephanie Meier, Jannos Siaplaouras, Anita Apitz, David Zöller, Johannes Krämer, Fabian Von Scheidt, Peter Bride, Michael Kaestner, Christian Apitz
University Childrens Hospital Ulm, Division of Pediatric Cardiology, Ulm-Germany

Background/Hypothesis: Adolescents and young adults with congenital heart disease (CHD) frequently have impaired exercise capacity. Purpose of this investigation was to assess heart rate response to exercise and its impact on exercise capacity in adolescents and young adults with CHD compared to healthy controls.
Materials and Methods: 192 adolescents and young adults (128 CHD with varying diagnoses (mean age [+/-SD] 14.52 +/-4.75 years) and 64 age-matched controls (14.23 ± 6.55 years) having performed cardiopulmonary exercise testing were included in this

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

retrospective analysis. Patients treated with beta-blockers or with pacemakers were excluded. Peak oxygen consumption (peak VO2), resting heart rate, and the increase in heart rate from resting level to peak exercise (heart rate reserve) were measured. Chronotropic incompetence (CI) was defined as the inability to achieve 80% of age predicted maximal heart rate reserve ([peak heart rate-resting heart rate]/[220 − age − resting heart rate]).
Results: Peak VO2/kg was significantly lower in CHD compared to controls (34.49 ± 7.96 vs 40.87 ± 7.55 ml/kg/min; p <0.0001). Resting heart rate was similar in CHD compared to controls (93.95 ±12.59 vs 97.65 ± 15.02; p = 0.07). Heart rate reserve during exercise was 80.26 ± 13.89 in CHD compared to 86.29 ± 18.71 in controls (p = 0.02). The prevalence of CI was 67% in patients with CHD compared to 48% in controls (p = 0.001), and was most impaired in patients with Fontan circulation (94%; p = 0.0005). Patients with CI had a lower peak VO2/kg (35.13 ± 8.91 vs 38.95 ± 6.87 ml/kg/min, p = 0.002), and shorter exercise duration (11:43 ± 02:02 vs 13:00 ± 01:20 min; P < 0.0001) than those without CI.
Conclusions: Adolescents and young adults with CHD show an impairment of heart rate response to exercise compared to healthy controls. According to our results, chronotropic incompetence is common, especially in patients with Fontan circulation, and correlates with exercise limitation.

P1486 - DETERMINANTS OF CARDIAC OUTPUT IN ADULT PATIENTS WITH FONTAN CIRCULATION

Hikari Miike[1], Hideo Ohuchi[2], Yosuke Hayama, Mitsuhiro Fujino[1], Kanae Noritake[1], Aya Miyazaki[1], Hajime Ichikawa[3], Isao Shiraishi[1]
National Cerebral and Cardiovascular Center, Pediatric Cardiology, Osaka-Japan[1]; National Cerebral and Cardiovascular Center, Adult Congenital Heart Disease, Osaka-Japan[2]; National Cerebral and Cardiovascular Center, Pediatric Cardiac Surgery, Osaka-Japan[3]

Background: Low cardiac output (CO) is one of major hemodynamic characteristics of pediatric patients after Fontan operation and may be associated with poor prognosis. However, preserved CO is not always a better hemodynamic phenotype in adult Fontan patients and the clinical determinants have not been clearly demonstrated.
Methods: We prospectively estimated cardiac index (CIdye) and standardized circulating blood volume (BV: ml/kg) during catheterization in consecutive 57 Fontan patients and 19 patients with biventricular physiology (BVP), mostly tetralogy of Fallot based on a pulse dye dilution method with an injection of indocyanine green (ICG) into the pulmonary artery. Results were compared with the hemodynamics obtained by conventional Fick method.
Results: BV was grater in patients with Fontan than those with BVP (72 ± 15 vs. 94 ± 32, p = 0.005), while no difference in CI (p = 0.89). In Fontan patients, CIdye was correlated with CI obtained by Fick method (r = 0.604, p < 0.0001). According to the univariate analysis, low systemic vascular resistance (Rs), arterial oxygen saturation (SaO2) and plasma levels of albumin, high hepatic venous wedge pressure (HVWP) and BV were associated with increased CIdye (p < 0.05-0.0001). Of those, increased BV (p < 0.0001) and low Rs (p < 0.05) were independently associated with the increased CIdye. On the other hand, CIdye showed no relationship with ejection fraction and end-diastolic volume index of the systemic ventricle.
Conclusion: CO is mainly determined by BV and Rs in adult Fontan patients and the hepatic dysfunction may be associated with the low Rs.

P1487 - HEMODYNAMICS AND EXERCISE CAPACITY AFTER CONVERSION TO TOTAL CAVOPULMONARY CONNECTION

Seiji Asagai[1], Kei Inai[1], Mitsugi Nagashima[2], In-sam Park[1]
Tokyo Women's Medical University, Pediatric Cardiology, Tokyo-Japan[1]; Tokyo Women's Medical University, Cardiovascular Surgery, Tokyo-Japan[2]

Background: Although several studies have shown that conversion to total cavopulmonary connection (TCPC) is a safe and effective strategy for patients with a failing Fontan, changes in hemodynamics and exercise capacity after TCPC conversion remain unknown.
Materials and Methods: Sixty-five patients underwent TCPC conversion in our institution from 1992 to 2015. Among them, 41 patients (18 males; age, 4.7-37.9 years; median age, 22.4 years; postoperative duration, 2.4-28.7 years; median postoperative duration, 16.9 years) who underwent catheter examination after TCPC conversion were retrospectively reviewed. We investigated the change in hemodynamics and exercise capacity by TCPC conversion.
Results: When comparing between before and after TCPC conversion, end-diastolic pressure (7 ± 3 vs. 9 ± 3 mmHg, p = 0.02) and cardiac index were significantly increased (2.2 ± 0.6 vs. 2.6 ± 0.5 l/min/m2, p = 0.001), pulmonary vascular resistance was significantly decreased (2.3 ± 1.3 vs. 1.6 ± 0.7 unit times m2, p = 0.003), and central venous pressure (CVP) showed no improvement (13 ± 4 vs. 13 ± 3 mmHg, p = 0.73) after the procedure. New York Heart Association (NYHA) classification was improved (I: 18, II: 22, III: 1 vs. I: 29, II: 11, III: 1). The 6-minute walking distance was significantly increased (458 ± 67 vs. 520 ± 59 m, p = 0.002). When comparing the 16 patients who underwent the cardiopulmonary exercise test after TCPC conversion with the 70 age- and sex-matched Fontan patients who had not undergone conversion, we found no significant difference in peak oxygen consumption, peak anaerobic threshold, ventilation-to-carbon dioxide production slope, and maximum O2 pulse.
Conclusions: TCPC conversion contributed to the improvement in cardiac output and exercise capacity. However, CVP did not improve, and the patients who had a TCPC conversion had no difference in exercise tolerance as compared with those who had an APC-type Fontan procedure.

P1496 - FONTAN COMPLETION – DOES IT REALLY RELIEVE CYANOSIS

Marie Schafstedde, Sarah Nordmeyer, Johannes Nordmeyer, Stephan Schubert, Björn Peters, Felix Berger, Stanislav Ovroutski
DHZB, Pediatric Cardiology, Berlin-Germany

Objectives: Total cavopulmonary connection (TCPC) aims for reduction of ventricular volume overload and cyanosis. However, due to the use of fenestration and the development of venovenous collaterals, some patients remain cyanotic or desaturate during follow-up (FU).
Methods: We retrospectively studied 267 patients (median age 15 (3-57) years), who underwent TCPC at our institution between 1986 and 2015. Transcutaneous oxygen saturation (SaO2) was noted and compared longitudinally. Cyanosis was defined as SaO2 ≤ 93%.
Results: Total long-term (30 year) survival was 90% (N = 226). Total long-term mortality (N = 25) significantly correlates with cyanosis during FU (20 cyanotic vs. 5 non-cyanotic patients, p < 0.001). After TCPC, on discharge from hospital, median SaO2 of the total cohort was 94% (78-100%), 95% (80-100%) in patients without fenestration and 91% (78-98%) in patients with fenestration. In 43 patients fenestration was closed during FU. SaO2

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

increased to median of 96% (88-100%) ($p < 0.01$). On last FU SaO2 was 95% (69-100%) in median, 92% (72-99%) in patients who still have an open fenestration and 96% (69-100%) in those without fenestration (including patients with closed fenestration during long-term FU). SaO2 ≤ 85% was noted in 15 patients, of whom 6 died during long-term FU. Collectively, 142 patients received catheterization during long term FU; venovenous collaterals were identified in 56 and interventionally closed in 53. A total of 37% (N = 94) were cyanotic at the time of last FU. In 47% (N = 44) this can be explained by an open fenestration, in 17% (N = 16) by venovenous collaterals. In 22% (N = 21) no reason for cyanosis could be found during catheter examination and 14% (N = 13) have not yet received catheterization.
Conclusion: Our study shows that a significant proportion of TCPC patients stay or again become cyanotic at longterm FU, with open fenestration and venovenous collaterals the most frequent reason.

P1532 - PULMONARY ARTERIOVENOUS FISTULAS IN ABERNETY SYNDROME ABOUT A CASE IN AN 18 YEAR OLD GIRL

Mleyhi Sobhi, *Ghédira Faker, Ziadi Jalel, Kalfat Taoufik*
Rabta Hospital, Cardiovascular Surgery, Tunis-Tunisia

Introduction: "Abernethy syndrome" is a rare congenital vascular defect defined by diverting portal blood away from liver. It is often associated with multiple congenital abnormalities. We present a case of Abernethy malformation associated with diffuse pulmonary arteriovenous fistulas.
Observation: We report the case of an 18-year-old girl with dyspnea and cyanosis since the age of 6 years with progressive aggravation. Clinical examination noted the presence of conjunctival jaundice with digital hippocratism, hepatomegaly of 15 cm and arterial oxygen saturation of 65%. On the other hand, the hemodynamic constants are stable. Transthoracic Doppler echocardiography showed a left superior vena cava discharging into the right atrium with several pulmonary arteriovenous fistulas (AVF). The thoracoabdominal angioscanner confirms the presence of multiple pulmonary AVFs predominant in the bases associated with a porto-cava congenital shunt (drainage of the portal vein in the inferior vena cava) with portal hypertension and a porto-systemic Collateral venous communication. We retain the diagnosis of Abernethy's malformation. The curative treatment remains the liver transplantation to make disappear the pulmonary AVF causes of a major cyanosis.

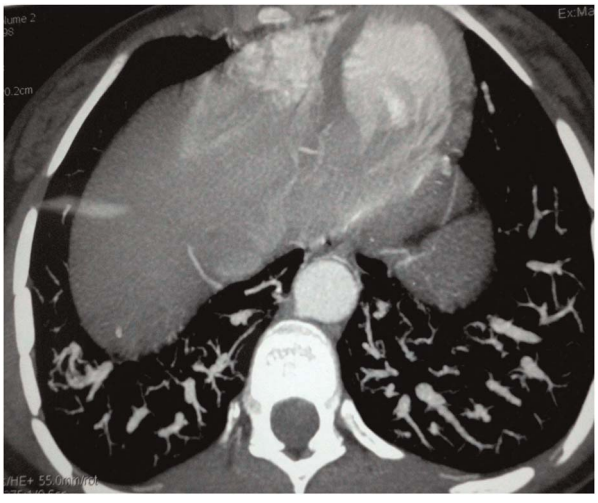

Figure 1.

P1534 - CLINICAL IMPLICATIONS OF CIRCULATING ENDOTHELIAL CELL IN ATRIAL SEPTAL DEFECT WITH PULMONARY HYPERTENSION

Hsin-Ming Liu[1], *Shuenn-Nan Chiu[2], Chun-An Chen[2], Ming-Tai Lin[2], Chun-Wei Lu[2], Jou-Lou Wang[2], Mei-Hwan Wu[2]*
National Taiwan University Hospital Hsin-Chu Branch, Pediatric, Hsin-chu-Taiwan[1]; National Taiwan University Hospital, Pediatric, Taipei-Taiwan[2]

Background: Patients with atrial septal defect (ASD) may stay symptom-free till adulthood. However, without treatment, pulmonary hypertension (PHN) and even Eisenmenger can be developed. Therefore, early detection of PHN and predicting its reversibility are important. We tried to define the prediction value of circulating endothelial cells in ASD with PHN.
Method: During 2014 to 2016, adult patients, older than 20 year-old, with ASD who intended to receive transcatheter closure were enrolled. All patients underwent hemodynamic study, transthorasic echocardiography (TTE) and transesophageal echocardiography (TEE). Circulating endothelial cell (CEC) and endothelial progenitor cells (EPC) numbers detection were performed using flow cytometry during cardiac catheterization. After ASD closure, they were followed for at least 6 months. Post-closure hemodynamics were evaluated either by repeating catheterization or TTE.
Result: Totally 78 ASD patients (M/F: 18/57) were enrolled; mean age: 46.6 ± 14 years-old. Among them, 27 patients (34.6%) developed PHN. 66 patients (84.6%) underwent transcatheter closure, 9 patients (11.5%) underwent surgical closure, and 3 patients (3.8%) did not receive any intervention. For the 75 patients receiving interventions, we divided them into 3 groups: Group A- initial PHN without regression, 7.6%; Group B- initial PHN with regression, 21.2%; Group C- no PHN, 71.2%. We found 74% of patients with initial PHN regressed after ASD closure. Using multivariate regression analysis, the pre-closure mean PAP was the most important predictor of PHN resolution. The CEC count was highly correlate to mean PAP and PVR. However, adding CEC counts didn't increase prediction value of PHN regression.
Conclusion: In our study, 74% of PHN regressed after closure of ASD. Pre-closure PAP is the most important predictor of the resolution of PHN. CEC numbers, though highly correlative to PAP and PVR, isn't a good predictor of resolution of PHN.

P1537 - FRAGILE AORTA IN REOPERATION CLOSURE RESIDUAL LEFT TO RIGHT SHUNT VENTRICULAR SEPTAL DEFECT IN ADULT FEMALE WITH TETRALOGY OF FALLOT

Gracelia Damanik, *Heroe Soebroto, Paul Tahalele, Ito Puruhito*
Dr. Soetomo General Hospital - Airlangga University, Thoracic and Cardiovascular Surgery, Surabaya-Indonesia

Introduction: Reoperation post Total Correction in Tetralogy of Fallot is indicated if the patient presents deterioration hemodynamic status regarding the existing residual defects. The most disastrous complication is fragile aorta due to massive fibrosis and adhesion. Adult Tetralogy of Fallot has imbalance inflammatory process in response to traumatic factor to the cardiovascular structure due to decreased anti-inflammatory process comparing to infant and children. It results massive inflammation and fibrosis to post total correction Tetralogy of Fallot.
Purpose: To report an 18-year-old female with Tetralogy of Fallot undergoing reoperation closure residual left to right shunt VSD complicating right heart failure with fragile ascending aortic wall suspected aortitis resulting exanguination during the procedure.
Case: An 18-year-old female with Tetralogy of Fallot was hospitalized a month following total correction procedure due to

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

massive right pleural effusion and pericardial effusion.The echocardiography showed large residual VSD left to right shunt and decreased right ventricle systolic function. She underwent reoperation to close residual VSD. There was massive adhesion between sternum and aorta complicating the dissection process resulting aortic rupture. Its anterior portion was extremely fragile and thin. Pericardial patch was applied to close the ruptured portion of aorta, but there were several failures in attempting to repair. The patient was death due to exanguination during procedure.
Discussion: Massive adhesion in pericardial space in post total correction in adult Tetralogy of Fallot is due to the decreased activity of anti-inflammatory agent regarding injured cardiovascular tissue. The dissection process and cannulation to aorta in reoperation results aortic injury due to the fragile aorta resulted massive inflammatory process in previously injured aorta. Femoral artery cannulation should be mandatory if there is massive adhesion in anterior aortic wall proved by preoperative thoracic CT-scan before reoperation procedure done in adult Tetralogy of Fallot.

P1538 - SINGLE INSTITUTION 20YEARS EXPERIENCE OF PULMONARY AUTOGRAFT OPERATION

Yuliia Klymyshyn, Igor Lebid, Valentina Khanenova, Oleksander Romanyuk, Nadia Rudenko, Yevgenia Artemenko, Yuliia Pozniak
Ukrainian Children's Cardiac Center, ACHD Department, Kyiv-Ukraine

We presented our experience of Pulmonary Autograft Operation (Ross procedure) for children and adults with congenital aortic valve (AV) pathology. Ross procedure (RP) may be an alternative for mechanical and biologic valves replacement.
Objective: To examined long-term outcomes after RP for twenty-year period in our centre.
Matherial and Methods: 1996y to 2015y 200 consecutive patients have performed RP in Ukrainian Children's Cardiac Center (UCCC). The mean age on date of operation was 145 ± 101 months (from 1 to 648 months). Male - 149 (74.5%) and female – 51 (25.5%). There were 48 (24%) patients in the age younger 5 years, 36 (18%) - 6-10 years, 59 (30%) - 11-17 years and 57 (28%) older then 18 years. Aortic stenosis in 103(51.5%) patients, aortic insufficiency - 68 (34%) and mixed lesion - 29(14.5%) patients.
Results: Mortality was 18 deaths (9%), in early postoperative period - 13 deaths (6,5%), in late - 5 deaths (2.9%). Long-term results followed in 170 (93.4%) patients. Ten (5.9%) patients required reoperations for the neo-AV (4 AV repair and 6 AVR), 32 (18.8%) patients had the RV-PA conduit procedure - RVOT procedures (n = 4) and conduit replacement (n = 28), for n = 32 (18.8%) cases were performed balloon valvulotomy. Freedom from reoperation on autograft was - 98.9%, 95.4%, 93.7% after 10, 15 and 20 years. Freedom from reoperations on RV-PA conduit was 84.1%, 83.6%, 82.4 respectively. Freedom from balloon valvulotomy on RV-PA conduit was 83.7%,82.5%, 82.5% respectively.
Conclusions: UCCC have the highest experience follow-up for patients with congenital AV pathology after RP in Ukraine. Reoperations on autograft were rare 5.9%, reoperations on RV-PA conduit (18.8%). The RP is a safe procedure with low mortality.

P1539 - LONG TERM PULMONARY FUNCTION IN VENTRICULAR SEPTAL DEFECT OPERATED ADULTS – THE VENTI TRIAL

Filip Eckerström[1], Christian Rex[1], Marie Maagaard[1], Johan Heiberg[1], Sune Rubak[2], Vibeke Hjortdal[1]
Aarhus University Hospital, Cardiothoracic and Vascular Surgery, Aarhus-Denmark[1]; Aarhus University Hospital, Paediatrics, Aarhus-Denmark[2]

Background: Ventricular septal defects (VSD), successfully closed within the first years of life, are considered to have great prognoses and consequently; the majority receive little or no follow-up in their adult life. However, we have recently demonstrated decreased oxygen uptake and abnormal ventilation pattern during exercise in VSD-operated adults compared with healthy controls. Whether a link to a possible physiological alteration can be found in the respiratory system remains unclear. We perform dynamic spirometry on adults, surgically treated for VSD in childhood, in order to evaluate long-term dynamic pulmonary function.
Material and Methods: Adult patients surgically treated for VSD and healthy, matched controls are included. Control subjects are matched on age and gender. Participants undergo spirometry at rest for the measurement of forced expiratory flow in one second (FEV1), forced vital capacity (FVC), and peak expiratory flow (PEF). Thirty participants will be included in both groups by March 2017.
Results: Currently, ten VSD-operated patients (23.7 ± 1.2 years) and seven control subjects (24.5 ± 1.5 years) have been included. Patients' mean age at surgery was 1.9 ± 1.7 years. No differences were found between the two groups regarding age, body mass index, body surface area or gender. Operated VSD-patients revealed lower FEV1 (3.7 ± 0.7 L) compared with healthy controls (4.9 ± 1.1), p = 0.014, as well as a reduced PEF (7.6 ± 2.8 L/min) relative to that of healthy controls (10.6 ± 2.8), p = 0.026. Furthermore, VSD-patients showed a tendency towards a poorer FVC (4.9 ± 1.1 L) compared with controls (6.1 ± 1.6), p = 0.078.
Conclusion: An impaired dynamic pulmonary function was demonstrated in adults 20 years following surgical VSD-repair. These findings may explain some of the mechanisms behind the cardiopulmonary exercise limitations previously found.

P1541 - COMPARISION OF QUALITY OF LIFE IN ADULTS WITH CONGENITAL HEART DISEASE WITH AND WITHOUT SURGICAL INTERVENTIONS

Sarah Eaton[1], Michael Rouse[2], Samuel Menahem[3]
Melbourne Health, Medical, Melbourne-Australia[1]; Western Health, Surgical, Melbourne-Australia[2]; Monash University, Faculty of Medicine, Melbourne-Australia[3]

Is the quality of life of adults with congenital heart disease worse if they had previous cardiac surgery - an Australian cohort
Background: Improved survival rates of children with congenital heart disease (CHD), has led to a greater study of the quality of life (QOL) and its determinants. Does those reaching adulthood have a reduced QOL and increased symptoms of anxiety and depression if they had undergone prior cardiac surgery compared with those who had not.
Materials and Methods: As part of a multi-centre study adults with CHD were recruited from a single community-based cardiology practice and completed self-reported questionnaires on their QOL including symptoms of anxiety and depression. An independent t-test was used to compare means between the two groups; those who had prior surgery and those who had not.
Results: 135 patients, 71 males and 64 females were recruited with a mean age of 26. 89 (65%) patients had previously undergone one or more cardiac surgical interventions. There was no significant difference in the mean QOL of patients who had previous cardiac surgery (82.6 ± 13.6) when compared with those who had not (83.6 ± 14.7), t(132) = -0.401, p = 0.689. Symptoms of anxiety and depression were also compared in the post surgical (8.6 ± 6.0) and non surgery (8.9 ± 5.2) groups. No statistically significant difference was found: t(129) = -0.203, p = 0.84. 86% of the post

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

surgical group and 96% of the non-surgical group had a New York Heart Association (NYHA) functional score of 1.
Conclusions: Results from this cohort demonstrated no statistical difference in the QOL or symptoms of anxiety and depression between adults who had undergone surgical intervention when compared to those who had not. This welcome finding may have reflected the good functional capacity of both groups irrespective of the CHD abnormality and whether there was a need for surgical intervention.

P1550 - BENEFITS OF HOME BASED SUBCUTANEOUS INJECTION OF IMMUNOGLOBULIN FOR FONTAN PATIENTS WITH PROTEIN LOSING ENTEROPATHY

Yuki Ito, Hideo Ohuchi, Hikari Miike, Masahiro Fujino, Isao Shiraishi
National Cardiovascular Center, Pediatric Cardiology, Osaka-Japan

Background: Protein losing enteropathy (PLE) is one of the most serious post-operative complications that has a significant adverse impact on morbidity and mortality in patients after Fontan operation. Frequent admissions for the PLE management often lead to poor quality of life (QOL) in those patients.
Materials and Methods: Our purpose was to clarify potential clinical benefits of home-based subcutaneous injection of immunoglobulin (Hizentra®, SC-IgG) for PLE Fontan patients. We introduced SC-IgG in 7 PLE Fontan patients and evaluated the influence of SC-IgG on their QOL: serial changes in plasma levels of total protein (TP; g/dl), albumin (Alb; g/dl) and immunoglobulin G (IgG; mg/dl) at early (ES; 2 weeks) and late (LS; 3~14months) after SC-IgG. We also estimated change in quality of life based on frequency of unexpected hospitalizations (number of admissions divided by follow-up [month]) and percentage of hospital stay due to the hospitalization (total hospital stay divided by follow-up period: %).
Results: During a mean follow-up of 8 months, plasma levels of TP, Alb, and IgG before, early and late after SC-IgG introduction were 5.0 ± 0.5, 3.4 ± 0.4, and 458 ± 178, 5.3 ± 0.5 ($P < 0.05$), 3.5 ± 0.4 ($P = 0.06$), and 552 ± 190 ($P = 0.18$), 5.5 ± 0.8 ($P < 0.05$), 3.7 ± 0.5 ($P = 0.07$), and 600 ± 127 ($P < 0.05$), respectively. In addition, the frequency of unexpected hospitalization decreased from 0.31 to 0.19 ($P < 0.05$) and the unexpected hospital stay decreased by 5% from 25% to 20%, respectively. No serious SC-IgG-related complications occurred.
Conclusions: Home-based management with SC-IgG significantly increased plasma levels of TP, Alb, and IgG, which accompanied by improved QOL in PLE Fontan patients. Therefore, home-based treatment with SC-IgG can be one of options to improve long-term outcome in PLE Fontan patients.

P1604 - IDENTIFICATION OF GENETIC VARIANTS AND CHROMOSOMAL ABNORMALITIES ASSOCIATED WITH EBSTEIN ANOMALY

Rodrigo Cabrera[1], Marta Catalina Miranda[1], Carlos Martin Restrepo[2], Victor Manuel Huertas-quiñones [3], Paul Laissue[2], Claudia Tamar Silva[2], Camilo José Tomás Hernández[1], Rossi Quero[2], Angela María Ortiz[2], Programa Pinocchio[4]
Fundación Cardioinfantil - Instituto De Cardiología, Biología Molecular, Bogotá-Colombia[1]; Universidad Del Rosario, Centro De Investigacion En Genetica Y Genomica (CIGGUR). Grupo Geniuros. Escuela De Medicina Y Ciencias De La Salud., Bogotá-Colombia[2]; Fundación Cardioinfantil - Instituto De Cardiología - Universidad Nacional De Colombia - Universidad Del Rosario, Instituto De Cardiopatías Congénitas - Facultad De Medicina - Facultad De Medicina, Bogotá-Colombia[3]; Fundación Cardioinfantil - Instituto De Cardiología, Departamento De Investigaciones, Bogotá-Colombia[4]

Background/Hypothesis: Ebstein Anomaly (EA) is an infrequent congenital heart defect (CHD) with considerable phenotypic heterogeneity in which right ventricle, tricuspid valve and electrical abnormalities prevail. Phenotypic diversity likely reflects an underlying genetic heterogeneity, which combined with studies based on small cohorts, has hindered high-confidence associations with genetic variants. Although a few chromosomal abnormalities and mutations have been linked to the disease, genetic etiologies have not been identified in most cases. Our Cardiovascular Care Center, a referral institution for CHD, has an unusually large cohort of EA patients that allows a comprehensive study of EA genetics.
Materials and Methods: We carried out a thorough phenotypic characterization of 147 EA patients, followed by unsupervised two-step cluster analysis to classify patients according to the presence or absence of comorbidities. Selected syndromic/familial cases were subjected to whole exome sequencing and/or comparative genomic hybridization. Variant filtering was accomplished using family members to identify high confidence associations with identified variants.
Results: In the cohort analysis, we identified a large proportion of syndromic (10.9%) and familial cases (11.6%). Molecular testing revealed high likelihood causative variants/abnormalities in most of the syndromic/familial cases studied. Our results suggest a novel association of EA with a rare chromosomal abnormality, the identification of a single gene in the 1p36 EA-associated region, as well as novel variants in familial cases with high likelihood of causality. Cluster analysis identified homogeneous endophenotypes that possibly reflect different underlying genetic etiologies. We are currently expanding our analysis to isolated cases.
Conclusions: Our data suggest that major causative genetic variants/chromosomal abnormalities can be found in a significant proportion of EA cases with thorough phenotypic evaluations and genome-scale molecular testing, raising the possibility of a role for genetic testing in the management of EA.

P1623 - CHARACTERISTICS AND OUTCOMES OF INFECTIVE ENDOCARDITIS IN AN ADULT CONGENITAL HEART DISEASE COHORT

Benjamin Moore[1], Jacob Cao[2], Irina Kotchetkova[3], David Celermajer[1]
University of Sydney, Royal Prince Alfred Hospital, Cardiology, Sydney-Australia[1]; University of Sydney, Medicine, Sydney-Australia[2]; Royal Prince Alfred Hospital, Cardiology, Sydney-Australia[3]

Background: The risk of infective endocarditis (IE) is known to be increased in those with congenital cardiac defects and to carry a significant mortality risk. Whilst pediatric cohorts have been well described, studies focused on IE in the adult congenital heart disease (ACHD) population are limited.
Materials and Methods: Of 4280 subjects in our ACHD database, we identified 56 patients over the age of 16 years (seen between 1991-2016) with 67 episodes of IE. We analyzed their clinical course and outcomes.
Results: Age at the time of IE was 37 (SD 13) years with a 4:1 male predominance. The most common underlying defects were bicuspid aortic valve (46%), complex two-ventricle circulations (30%) and ventricular septal defect (13%). Left sided lesions were dominant (57%) and infection involved prosthetic material in 39%. Importantly, cardiac surgery had been performed in the preceding 6 months in 12%. The most common symptoms on presentation were fever (72%) and dyspnea (21%). Blood cultures were positive in 91% (streptococcus 39%, methicillin sensitive staphylococcus aureus (MSSA) 28%, coagulase negative staphylococcus 10%,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

HACEK organisms 4%). Complication rates were high with severe valvular regurgitation in 31%, cardiac abscess in 13% and embolic phenomena in 34%, predominantly cerebral. Surgery was required in 45% of patients most commonly to replace a severely regurgitant bicuspid aortic valve. Streptococcus was causative in 50% of cases requiring surgery, with vegetations over 10mm in 40%. Death occurred during the admission in 8 patients (14%); these patients were more likely to have recurrent IE (50%, $p = 0.03$) or MSSA in blood cultures (50%, $p = 0.05$). The 12-month survival and IE recurrence rates were 85% and 9% respectively.
Conclusions: IE in ACHD patients leads to substantial morbidity and mortality and frequently requires early surgery, usually for hemodynamic reasons.

P1636 - QUALITY OF LIFE PSYCHOLOGICAL RESILIENCE PERSONALITY TRAITS AND ILLNESS PERCEPTION IN GROWN UP CONGENITAL HEART DISEASE

Pak Cheong Chow
Queen Mary Hospital, Paediatric Cardiology, Hong Kong-Hong Kong

Background and Objectives: There is increasing focus on quality of life (QOL) among patients with congenital heart disease. Studies suggested heterogeneity of physical and psychosocial predictors on QOL. Current study aimed to examine the relationships of QOL, psychological resilience, anxiety and depression, personality traits, illness perception, and clinical data of grown-up congenital heart disease (GUCH).
Methods: Two hundred and eight Chinese GUCH patients (male = 103) were recruited to complete the self-administered questionnaires: 36-items Short Form Health Survey version 2 (SF36), satisfaction with life scale (SWLS), Connor-Davidson Resilience Scale (RISC), Hospital Anxiety and Depression Scales (HADS), and NEO Five Factor Inventory (NEOFFI-3); and were compared to control subjects (N = 104, male = 41). GUCH patients also completed Brief Illness Perception Questionnaire (BIPQ), and their respective disease complexity, disease severity, New York Heart Association (NYHA) class and Warnes-Somerville Ability Index (WSAI) were retrieved for correlation analysis. Furthermore, multivariate regression was performed to identify the predictors of QOL measures, SWLS and SF36, respectively.
Results: GUCH patients had lower SWLS, SF36-physical component summary (SF36-PCS) and RISC (all $p < 0.001$), and greater depression ($p < 0.05$) than control subjects. Among GUCH patients, greater disease severity was associated with lower SF36-PCS and SF36-mental component summary (SF36-MCS) respectively (both $p < 0.01$). Higher WSAI was associated with lower SWLS, SF36-PCS, and SF36-MCS respectively (all $p < 0.01$). SWLS, SF36-PCS, and SF36-MCS were correlated with RISC, HADS, and illness perception respectively (all $p < 0.001$). RISC was positively correlated with positive illness perception ($p < 0.01$). RISC, several domains (Consequences, Concern) of BIPQ, and neuroticism were predictors of SWLS respectively (all $p < 0.05$). WSAI, RISC, and BIPQ (Consequences) were predictors of SF36-PCS respectively (all $p < 0.05$). Neuroticism, anxiety and depression were predictors of SF36-MCS respectively (all $p < 0.01$).
Conclusions: Reduced QOL among GUCH patients was associated with both physical and psychological attributes. Resilience and illness perception appeared having a role and might be potential targets for improving QOL in these patients.

P1681 - LEFT VENTRICULAR FIBROSIS AS A PROGNOSTIC MARKER IN PATIENTS WITH BICUSPID AORTIC VALVE DISEASE.

Gentian Lluri[1], Pierangelo Renella[2], J. Paul Finn[2], Jamil Aboulhosn[1], Arjun Deb[1]
UCLA, Medicine, Los Angeles-United States[1]; UCLA, Radiology, Los Angeles-United States[2]

Background: Bicuspid aortic valve (BAV) is associated with early aortic valve fibrosis and calcification. To what degree the left ventricle is affected by fibrosis and its prognostic value is currently unknown.
Methods: This was a retrospective, single center study evaluating all adult patients with BAV who had cardiac magnetic resonance (CMR) and followed at UCLA Medical Center from March 2002 to March 2016. CMR, transthoracic echocardiogram, and clinical data were reviewed.
Results: In total, 254 patients with BAV who had at least one CMR were evaluated, out of which 68 patients had adequate images to assess for the presence of absence of late gadolinium enhancement (LGE). Patients with prior cardiac surgery were excluded. A total of 29 patients were included in the study, out of which 18 patients did not demonstrate LGE and 11 patients had LGE. Patients with LGE were much more likely to have significant mean gradients across the AV (30.3 ± 7.2 mmHg vs 14.7 ± 3.6 mmHg, $p = 0.049$) as well as more likely to have left ventricular hypertrophy (10.3 ± 0.9 mm vs 7.6 ± 0.3 mm, $P = 0.01$). Patients with LGE were ten times more likely to need AVR in one year (55% vs 5.5%, $P = 0.0028$). Presence of LGE on CMR is associated with higher gradients and LVH while absence of LGE suggests lesser severity of disease and freedom from AVR at five years of 92.8%.
Conclusions: Evaluation of LGE by CMR as a marker of cardiac fibrosis is an additional tool of prognostic value when evaluating patients with aortic stenosis secondary to BAV. Assessment of LGE by CMR should be included in the care of patients with BAV.

P1692 - MULTIDISCIPLINARY EVALUATION OF LIVER DISEASE AFTER FONTAN PROCEDURE (FP)

Natally Horvat[1], Maria Angelica Binotto [2], Brunna Oliveira[1], Nana Miura Ikari[2], Aline Lopes Chagas[3], Hilton Muniz Leao Filho[1], Denise Cerqueira Paranaguá Vezozzo[3], Mariana Poltronieri Pacheco[3], Joao Rafael Terneira Vicentini[1], Manoel Souza Rocha[1]
Faculdade De Medicina USP, Radiology, Sao Paulo-Brazil[1]; Heart Institute (INCOR) USP, Pediatric Cardiology, Sao Paulo-Brazil[2]; Faculdade De Medicina USP, Hepatology, Sao Paulo-Brazil[3]

Background: The increasing long term survival after FP has brought significant liver consequences. However, there is no consensus regarding liver evaluation in these patients. The purposes of this study were (1) to evaluate the frequency of radiological signs of portal hypertension (RSPH), and hepatic nodules (HN) using ultrasound (US), computed tomography (CT) and magnetic resonance imaging (MRI), (2) to measure the liver stiffness (LS) with acoustic radiation force impulse (ARFI), and (3) to compare imaging findings with clinical data.
Materials and Methods: In this Institutional Review Board approved cross-sectional study, 49 patients over 18 years of age and with at least 5 years after FP were prospectively recruited from our Cardiology Department from August 2014 to June 2016. These patients were submitted to laboratory screening of liver disorders, CT, MRI, US and ARFI directed to hepatic evaluation.
Results: Patients' mean age was 26.2 ± 7 years and the mean time interval from FP was 14.8 ± 7.1 years. RSPH were found in 3(6%),

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

3(75%), and 32(66.7%) patients on US, CT and MRI, respectively. HN were detected in 3(6%), 19(39.6%), and 16(39.6%) patients on US, CT and MRI, respectively. Forty-one nodules were identified on MRI, the majority were hypervascular on arterial phase and 2 presented washout. There was no significant correlation between presence of HN or RSPH and clinical data, including interval after FP. The mean LS on ARFI was 2.2 ± 0.7 m/s. The LS values on ARFI were significantly higher in patients with hepatic nodules (2.64 ± 0.81 m/s vs 1.94 ± 0.49 m/s; $p = 0.002$). *Conclusion:* We found a high frequency of RSPH and HN in patients after FP with no correlation with cardiological or laboratory data. US did not detect almost half of RSPH and the vast majority of HN. ARFI values were significantly higher in patients with HN.

P1712 - CONGENITAL HEART SURGERY IN PATIENTS OLDER THAN 16 YEARS IN A PUBLIC PEDIATRIC INSTITUTION SCENARIO AND PROFILE OF A GROWN POPULATION

Diana Mariela Mouratian[1], Maria Victoria Lafuente[1], Claudia Natalia Villalba[1], Florencia Romina Strawich[1], Fernando Diez Mori[1], Alejandra Villa[1], Gladys Salgado[1], Diego Michelli[1], Maria Altabe[2], Barreta Jorge[3], Pablo García Delucis[3], Horacio Capelli[1]

Childrens Garrahan Hospital, Cardiology Department, Buenos Aires-Argentina[1]; Childrens Garrahan Hospital, Intensive Care Unit, Buenos Aires-Argentina[2]; Childrens Garrahan Hospital, Cardiovascular Surgery, Buenos Aires-Argentina[3]

Background: Major advances and refinement in the diagnosis and surgical treatment of congenital heart defects in the last four decades has resulted in an increasing number of adult survivors. It should be noted that congenital heart surgery is "reparative" and not curative.Many patients (p) will develop residual lesions and sequelae requiring reinterventions.
Methods and Results: From 2013 to 2015, 56 patients with a median age of 2 years (range 16.1-27) were operated with extracorporeal circulation. 35/56 were reoperations. 13% of the lesions were simple and 87% complex. Distribution by number of surgeries per year, reinterventions and type of lesion are resumed in table 1.41p had previous surgical interventions. The interventions were performed:on right ventricle outflow tract:14p,left ventricle outflow tract:7p,atrioventricular valve:7p,partial cavopulmonary connection (Glenn):1p,Fontan (extracardiac conduit):3p,reconversion to extracardiac conduit + Maze-Cox procedure: 2p, atrial septal defect closure: 4p, scimitar syndrome: 1p,unifocalization and right ventricle to pulmonary artery conduit: 1p. Median time of hospitalization in the cardiovascular critical care unit was 4 days (range: 2-21 d). Mortality rate was 1.7% (1p), and was related to RACHS score IV (p 0.0000)
Conclusions: 73% of patients had previous interventions. The congenital heart defects was moderate to severe in 87% of the cases Mortality rate was 1.7%, related to great complexity congenital heart disease with poor prognosis. The operated group conform a growing population in quantity and complexity. Most of them are followed by the pediatric cardiac team. Transference to adult public institution is challenging.

Table.

Period	Surgeries	Reoperations	Rachs1	Rachs2	Rachs3	Rachs4
2013	15	11	2	1	12	0
2014	21	13	1	1	18	1
2015	20	17	2	0	18	0

P1721 - TETRALOGY OF FALLOT 20 YEARS OF FOLLOW UP

Diana Mariela Mouratian[1], Claudia Natalia Villalba[1], Maria Victoria Lafuente[1], Florencia Romina Strawich[1], Fernando Diez Mori[1], Marisa Di Santo[1], Carlos Fernando Rosental[1], Jose Luis Alonso[2], Alberto Sciegata[2], Jorge Barreta[3], Pablo García Delucis[3], Horacio Capelli[1]

Hospital De Pediatria J P Garrahan, Cardiology Department, Buenos Aires-Argentina[1]; Hospital De Pediatria J P Garrahan, Cardiac Catheter Laboratory, Buenos Aires-Argentina[2]; Hospital De Pediatria J P Garrahan, Cardiovascular Surgery Department, Buenos Aires-Argentina[3]

Background: Adult survivors with repaired Tetralogy of Fallot (TOF) are a growing population. Many patients require reinterventions during follow-up.
Methods and Results: 182 patients (p) with repaired TOF were studied from 1988 to 2016, mean age 25.3 years, median follow-up 20.2 years. Right ventriculotomy was performed in 76p(42%) and transannular patch in 73p(40%). NYHA functional class was I: 112p, II: 57p and III: 13p. Pulmonary regurgitation (PR) was moderate: 56p and severe: 40p. Complete right bundle branch block with QRS duration 160-200ms was present in 52p and > 200ms in 6p. Tachyarrhythmias were present in 27 p(15%), non-sustained ventricular tachycardia (VT): 8p , sustained VT: 7p, atrial fibrillation (AF) or flutter:11p. VT + AF: 5p. Some haemodynamic substrate was present in 66% of them. Seventynine p (43%) underwent one or more re-interventions at a mean of 11.6 years from repair: It was surgery in 56p and transcatheter intervention in 23p. In 69%, the major cause of reoperation was PR. Ten p developed infective endocarditis, 5 of them required surgery. There were 43 pregnancies in 16 women with 36 alive newborns. Overall survival at 10, 15, 25 and 35 years was: 99%, 98%, 94% and 82%, respectively. Mortality rate was 3.3%: 6p died at a mean age of 32.4 years, after a median time from surgery of 22.5 years. By univariate analysis, the mortality was associated with arrhythmia (p 0.001), QRS duration > 160 mseg (p 0.001), severe PR (p 0.004) reoperations (p 0.05) and infective endocarditis (p0.001).
Conclusions: The long-term survival of repaired TOF is excellent, with good functional class in most patients. At a mean time of 11.6 years after repair, 43% of patients underwent one or more reinterventions. Tachyarrhythmias were present in 15% of patients, 66% of them with some hemodynamic substrate. Late mortality was 3.3%, associated to arrhythmia, severe PR, QRS duration and infective endocarditis.

P1770 - LUNG FUNCTION IN ADULTS WITH PERSISTENT SMALL VENTRICULAR SEPTAL DEFECTS – THE VENTI TRIAL

Christian Emil Rex[1], Filip Carl Arne Eckerström[1], Marie Maagaard[1], Johan Heiberg[1], Sune Leisgaard Mørck Rubak[2], Vibeke Elisabeth Hjortdal[1]

Aarhus University Hospital, Dept. of Cardiothoracic and Vascular Surgery, Aarhus-Denmark[1]; Aarhus University Hospital, Dept. of Paediatrics, Aarhus-Denmark[2]

Background/Hypothesis: Ventricular septal defects (VSD) with no symptoms and Qp/Qs ratios below 1.5 are considered benign with excellent long-term prognoses. Nonetheless, we have recently demonstrated an inferior oxygen uptake during exercise among these adult VSD patients compared with healthy controls. Oxygen uptake depends on cardiac as well as pulmonary function, and whether these findings are due to pulmonary pathology needs to

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

be clarified. The aim of this study was to investigate the long-term pulmonary function in adults with small persistent VSDs.
Materials and Methods: In a prospective long-term follow-up, adults with small persistent VSD's and healthy, age- and gender-matched controls between 18 and 30 years were included. Participants underwent extended lung function testing including Multiple-Breath-Washout (MBW), Impulse Oscillometry (IOS), Body Plethysmography, Dynamic Spirometry, and Diffusion Lung Capacity (DLCO).
Preliminary Results: At December 2016, 5 VSD patients (23.4 ± 4.2 years) and 8 controls (24.5 ± 1.5 years) were included. VSD patients had a lower FEV1 of 3.66 ± 0.62 L compared with 4.9 ± 1.1 L in the control group, p = 0.04. There was a tendency towards lower FRC in the VSD group (3.3 ± 0.8 L) than in the control group (4.4 ± 1.1 L), p = 0.07. There were similar tendencies between the VSD and the control group in terms of FVC (4.6 ± 1.1 L vs. 6.1 ± 1.6 L, p = 0.9), PEF (7.9 ± 2.4 L/min vs. 10.6 ± 2.3 L/min, p = 0.07) and alveolar volume (5.2 ± 1.1 L vs. 6.8 ± 1.6 L, p = 0.07), respectively. There were no differences between groups regarding sex, age, BSA, BMI.
Conclusion: The preliminary data suggests that adults with persistent VSD's have impaired dynamic lung function compared to healthy controls.

P1779 - RESULTS OF HEMODYNAMIC CORRECTION OF COMPLEX CONGENITAL HEART DEFECTS IN ADULTS

Vladimir Podzolkov, Michail Zelenikin, Ivan Yurlov, Dmitry Kovalev, Marat Mavlutov, Leysan Mustafina, Sergey Zaets
Bakoulev Scientific Center for Cardiovascular Surgery congenital heart desease Moscow-Russia

Background: The influence of age on the results of hemodynamic correction of complex congenital heart defects remains disputable. This retrospective study is aimed to analyze immediate results of hemodynamic correction in adults.
Materials and methods: During the years 1983-2016, five hundred seven patients underwent hemodynamic correction of complex congenital heart defects (Fontan operation or bidirectional cavopulmonary anastomosis). The most frequent diagnoses were tricuspid atresia, single ventricle, and complete atrioventricular canal with pulmonary stenosis. Sixty six of 507 patients were older than 18 years of age. Out of this adult group, thirty five patients underwent bidirectional cavopulmonary anastomosis and 31 – Fontan operation. The most frequently used modification of Fontan operation was extracardiac conduit (n = 23). In 23 cases, Fontan operation was performed as a staged surgical intervention after bidirectional cavapulmonary anastomosis. Immediate results of surgical treatment were followed during the hospital period.
Results: Hospital mortality reached 9% (6/66). Lethal outcomes were caused by heart failure, hemorrhage or pulmonary thromboembolism. There were no differences in hospital mortality rate between Fontan operation and bidirectional cavopulmonary anastomosis (9.6% vs. 8.5%, p > 0.05). Different complications occurred in 21 (32%) patients. The most frequent complication was congestive heart failure and hemorrhage. Arterial blood saturation at discharge after Fontan operation and bidirectional cavopulmonary anastomosis was 92.6 ± 5.6% and 77.6 ± 6.6%, respectively (p < 0.05).
Conclusion: Hemodynamic correction of complex congenital heart defects in adults is accompanied by good immediate results and significantly improves patients' condition.

P1824 - THREE MONTHS OF RIGHT VENTRICULAR VOLUME LOADING IN RATS DOES NOT INDUCE FIBROSIS

Quint A J Hagdorn[1], Guido P L Bossers[1], Anne-Marie C Koop[1], Diederik E Feen, Van Der[1], Lysanne M Jorna[1], Tom Leusden, Van[1], Rudolf A Boer, De[2], Rolf M F Berger[1], Beatrijs Bartelds[1]
University of Groningen, Beatrix Children's Hospital, University Medical Center Groningen, Center For Congenital Heart Diseases, Department of Pediatric Cardiology, Groningen-The Netherlands[1]; University of Groningen, University Medical Center Groningen, Department of Cardiology, Groningen-The Netherlands[2]

Background/Hypothesis: Many Tetralogy of Fallot patients are subjected to chronic right ventricular (RV) volume load after surgical repair, due to pulmonary regurgitation. The role of fibrosis in the adaptation to chronic volume loading is unknown. To determine a putative role for antifibrotic therapies in the long-term preservation of the volume-loaded RV, we aimed to establish the relation between chronic volume loading and cardiac fibrosis.
Materials and Methods: Wistar rats were subjected to aorto-caval shunt surgery (n = 24) or sham surgery (n = 15), and sacrificed after 1, 2 or 3 months. Cardiac function was measured monthly by echocardiography. Cardiac fibrosis was measured with Masson-trichrome staining. Fibrosis-related RV gene expression levels were measured using q-PCR.
Results: Effective volume loading was achieved , as cardiac output in shunt animals more than doubled compared to sham (see table). Neither cardiac output nor TAPSE changed over time, indicating adequate adaptation. RV remodeling was demonstrated by dilatation, increased ventricular and atrial weights and increased cardiomyocyte size compared to sham (p < 0,05). At all time points, Masson-trichrome stainings were not different from sham. This was validated by identical RV gene expression levels of collagens 1 and 3. Likewise, MMP2, vimentin, PCOLCE and LOXL2, markers for extracellular matrix degradation, fibroblast activation, collagen maturation and collagen crosslinking respectively, showed no differences between the groups.

Table.

	1 month		2 months		3 months	
	Sham (n = 3)	Shunt (n = 8)	Sham (n = 6)	Shunt (n = 8)	Sham (n = 6)	Shunt (n = 8)
Weights						
RV (g)	0.18 ± 0.01	0.30 ± 0.04*	0.18 ± 0.01	0.30 ± 0.05*	0.21 ± 0.04	0.39 ± 0.12*

RV histology						
CSSA (um^3)	299 ± 29	530 ± 189*	351 ± 54	621 ± 251*	442 ± 113	644 ± 139*
Fibrosis (%)	1.2 ± 0.1	1.0 ± 0.2	1.7 ± 0.7	2.3 ± 1.7	1.9 ± 0.9	2.3 ± 0.8

RV = right ventricle. RA = right atrium. LV = left ventricle. IVS = interventricular septum. LA = left atrium. CO = cardiac output. RVIDd = right ventricular internal diameter in diastole. TAPSE = tricuspid annular plane systolic excursion. CSSA = cardiomyocyte cross-sectional area. Fibrosis represents percentage of blue pixels on Masson-trichrome staining. Values are ± SD. Values marked with * are significantly different from sham (p < 0.05).

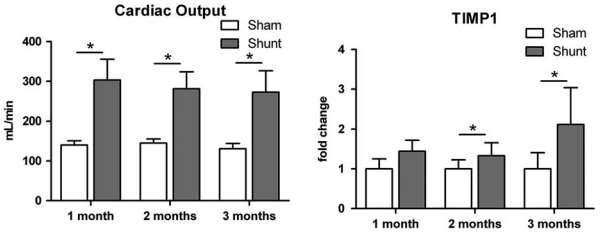

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Only profibrotic marker TIMP1 was upregulated in shunt animals at 2 and 3 months compared to sham ($p < 0,05$).
Conclusions: We show that 3 months of volume loading in a rat model, equivalent to 9 years of volume loading in patients, does not result in cardiac fibrosis. It is to be elucidated whether longer duration of volume load will induce fibrosis, or that additional triggers play a role in volume load-associated fibrosis.

P1838 - THE OUTCOMES OF PREGNANCY IN WOMAN WITH CONGENITAL HEART DISEASE A NATIONAL DATABASE STUDY

Chun-Wei Lu[1], Li-Kwang Chen[2], Nai-Chi Teng[2], Jin-Chung Shih[3], Mei-Hwan Wu[4]
National Taiwan University Children's Hospital, Adult Congenital Heart Center, Department of Pediatric Cardiology, Taipei-Taiwan[1]; National Health Research Institutes, Center For Health Policy Research and Development, Zhunan-Taiwan[2]; National Taiwan University Hospital, Department of Obstetrics, Taipei-Taiwan[3]; National Taiwan University Children's Hospital, Department of Pediatric Cardiology, Taipei-Taiwan[4]

Background: For women with congenital heart disease (CHD), the hemodynamic alteration during pregnancy may increase the risks of adverse cardiovascular events. However, the population based investigation about outcomes of pregnancy in woman with CHD is still lacking.
Methods: Data on pregnancy longer than 20 weeks in woman with and without were retrieved from the National Health Insurance database records in Taiwan from 1997 to 2013. Complications and therapies were identified by their respective codes.
Results: Comparing 7933 deliveries in 5185 women with CHD and 371393 deliveries in 238833 women without CHD, the pregnant women with CHD had significant higher rates of mortality (0.11% vs 0.01%, $p < 0.0001$) and cardiac events (5.59% vs 0.59%, $p < 0.0001$). Women with CHD had higher prevalence of pregnancy-induced hypertension (3.58% vs 2.75%, $p < 0.0001$) and abortion (3.53% vs 2.73%, $p < 0.0001$). Among the cardiac events occurred in women with CHD, the leading complications were arrhythmias (3.96%), heart failure (1.37%) and stroke (0.19%). Invasive cardiac interventions during pregnancy or within 6 weeks postpartum were required in 0.42% of women with CHD.
Conclusion: Pregnancy in women with CHD are associated with significant higher rate of maternal mortality and cardiac events. Women with CHD considering pregnancy should receive careful pre-pregnant evaluations and risk stratification.

P1839 - HEALTH PROFILE IN ADULTS WITH SMALL ATRIAL SEPTAL DEFECTS

Sebastian Udholm, Camilla Nyboe, Vibeke Hjortdal
Aarhus University Hospital, Department of Cardiothoracic and Vascular Surgery, Aarhus-Denmark

Background: Our register based analyses of all Danish patients with a small unclosed atrial septal defect (ASD) showed a higher mortality in ASD patients with no closure compared with both the general population and with patients with a closed ASD. Furthermore, the patients without closure had an increased risk of pneumonia, atrial fibrillation and stroke.
Aim: We wish to characterize patients with small, unclosed ASDs in a prospective fashion and challenge the perception that these patients are as healthy as previously expected.
Method: In a nationwide descriptive study, the patient group consists of patients with small, unclosed ASD born before 1998. All included patients underwent TTE, ECG, 7 days Holter-monitoring, spirometry, blood samples and 6 minutes walking test. They also received questionnaires. The National Health Profile (NHP) is a self-assessment tool that allows us to compare patients with the general population ($n = 160.000$).
Results: To this point, 71 patients are included (mean age: 33 yr) and 177 excluded. In 14 patients, the defect was still open (19.7%). Aneurysmal septum was found in ten patients (14.0%). Eleven patients had mitral regurgitation (15.5%) and seven patients had aortic regurgitation (9.9%). Over one-fourth (28.2%) of ASD patients experienced high levels of stress compared with the general population (22.5%; $p = 0.07$). Most ASD patients (90%) self-assessed their health to be excellent or good, comparable to the general population (92.3%, $p = 0.66$). A minority (19.5%) self-assessed their physical function to be excellent or good. This contrasts with self-assessed physical function (37.5%; $p = 0.001$) in the general population between 25-34 yr.
Conclusion: Most defects were spontaneously closed. All valve insufficiencies were minor. Only one ASD needed catheter-based closure. Small, unclosed ASD patients more often evaluate their general health and physical function less well than the general population.

P1854 - TRANSPOSITION OF THE GREAT ARTERIES (TGA) A LATERALITY DEFECT IN THE GROUP OF HETEROTAXY SYNDROMES OR AN OUTFLOW TRACT MALFORMATION

Samaher Alharbi[1], Rawan Altuwajri[1], Rana Alzahrani[1], Bayan Alzomaili[1], Alaa Althubaiti[2], Talat Mesud Yelbuz[1]
King Abdulaziz Cardiac Center, Ministry of National Guard Health Affairs, King Saud Bin Abdulaziz University For Health Sciences, Cardiac Sciences, Section of Pediatric Cardiology, Riyadh-Saudi Arabia[1]; Basic Medical Sciences, College of Medicine, King Saud Bin Abdulaziz University For Health Sciences, Biostatistics, Riyadh-Saudi Arabia[2]

Background/Aim: TGA is classically considered as a so-called "conotruncal heart defect" with non-spiral great arteries. Recent studies proposed that there is probably a different mechanism involved in the genesis of TGA; it has been speculated that TGA may be a laterality defect in the group of the so-called heterotaxy syndromes (left or right isomerism) rather than an outflow tract malformation. The main aim of our study was to identify if there is indeed any association between TGA and heterotaxy syndromes, representing lateralization defects.
Methods: Restrospective cross-sectional analysis of a total of 610 patients diagnosed with TGA at King Abdulaziz Cardiac Center over a period of 13 years (2002-2015). Hospital informatics and digital data recording systems were used for collecting patients' data and reviewing echocardiograms and X-rays. All patients were reviewed to check the echocardiograms for verification of the diagnosis, type (dextro-TGA (DTGA) and levo-TGA (LTGA)) and complexity of TGA, and all other variables (such as abdominal sidedness, cardiac position, presence or absence of AVSD). Patients who did not have a proper echocardiogram, including documentation of abdominal situs, and who were repaired already in another institution were excluded (77 patients).
Results: Of 533 included patients who were verified to have TGA, 494 (92.7%) had situs solitus, 17 (3.2%) situs inversus, 11 (2.1%) left and 11 (2.1%) right isomerism. 443 (83%) of all TGA patients had DTGA. 417 (94.1%) of DTGA and 77 (85.6%) of LTGA patients had situs solitus. The incidence of right and left isomerism was found to be equal in DTGA (6 (1.4%); 5 (5.6%)) and LTGA (6 (1.4%); 5 (5.6%)), respectively. However, heterotaxy syndrome

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

was more associated with LTGA than DTGA with a statistically significant difference (p = 0.004).
Conclusion: In contrary to the speculations in recent studies, our study did not reveal any significant finding supporting an association between TGA and heterotaxy syndromes.

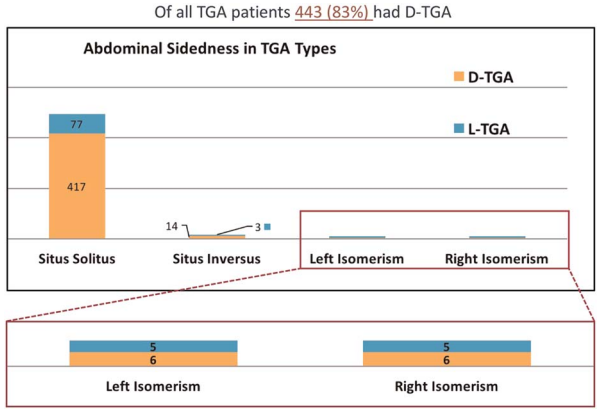

Figure 2.

P1870 - SURVIVAL RATES AND CAUSES OF DEATH IN A CONTEMPORARY ADULT CONGENITAL HEART DISEASE COHORT

Christopher Yu, Irina Kotchetkova, Rachael Cordina, David Celermajer
Royal Prince Alfred Hospital, Cardiology, Sydney-Australia

Background: Adults (age ≥16yrs) with congenital heart disease (ACHD) are at increased risk of premature mortality. There is relatively limited information concerning timing and causes of death in this population.
Materials and Methods: We studied outcomes among 2,934 adult patients (median age 33 years) consecutively seen since 2000 at our tertiary ACHD referral centre. Complete vital status and cause of death data were obtained from the Australian National Death Registry and medical records. We excluded patients with isolated patent foramen ovale or small atrial septal defects. Patients were categorised by the Bethesda classification of CHD severity (42 patients not classifiable). Those with multiple lesions were assigned to the lesion of highest complexity.
Results: By end 2016, 330 subjects (11%) had died; median age of death was 54yrs (IQR 34-72yrs) with median follow-up of 3 years. Cardiovascular death accounted for 48% of all deaths (Table 1). The leading cardiovascular causes of death were heart failure (16%), sudden cardiac death (11%), acute myocardial infarction, endocarditis and chronic ischaemic heart disease (5% each). Perioperative death was relatively uncommon at 4%. The main non-cardiac causes were malignancy (12%), pneumonia (6%) and neurological disorders (5%). Survival rate diminished as Bethesda complexity rose (p = 0.007; Table 2). Simple CHD adults had a 92% survival rate at age 65yrs. By contrast, complex CHD patients had only a 60% survival rate to age 50 years, and only 34% survived to age 65 years.
Conclusions: Our study provides contemporary insights into survival rates and causes of death in adult CHD patients seen at a tertiary referral centre.

Table 1. Percentage of cardiovascular versus non-cardiovascular death.

	Cardiovascular death (%)	Non-Cardiovascular death(%)
Simple CHD	41%	59%
Moderate CHD	46%	54%
Complex CHD	62%	38%
Total	48%	52%

Table 2. Survival table per Bethesda Classification.

% surviving at (CI 95%)	Simple CHD	Moderate CHD	Complex CHD
35 years old	99% (98-99%)	96% (94-97%)	85% (81-89%)
50 years old	98% (97-99%)	88% (84-92%)	60% (51-69%)
65 years old	92% (90-94%)	69% (61-77%)	34% (18-50%)

P1885 - SINUS OF VALSALVA ANEURYSMS A RARE CONDITION WITH A CHALLANGE DIAGNOSIS.

Luciana S. Nina De Azevedo, Fernanda Canut, Jamille Campos, Raianne Cord, Miguel A. Maluf, Marcio Miranda Brito, Joao Chaker Saba, Celia Maria Camelo Silva
Federal University of Sao Paulo, Cardiology, Sao Paulo-Brazil

Background: Aneurysm of the sinus of Valsalva is a rare congenital cardiac anomaly and its rupture can produce aortic regurgitation, cardiac tamponade, congestive heart failure, conduction abnormalities, endocarditis and stroke.
Case Report: Female, 35 years old, previously healthy. In June of 2015, she started an acute picture of heart failure (HF) characterized by dyspnea, anasarca, orthopnea and nocturnal paroxystic dyspnea. In October of 2015 she was hospitalized. The picture was interpreted as pneumonia. No improvement was obtained after treatment. An echocardiogram showed an aneurismatic image between left and right coronary sinus measuring 10mm in the major axis and severe aortic insufficiency (fig. 1). The

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

transesophageal echocardiogram confirmed the finding. The hypothesis of aortic disease was made and then she was put on furosemide and hydralazine. The patient showed slight clinical improvement and was discharged to home. After 2 months she had the first medical appointment with congenital heart disease team. Physical examination showed signs of HF such as tachycardia, orthopnea, ascites, bilateral crepitation. She was again admitted to Hospital. A hypothesis of Valsalva aneurysm (SVA) was made. MRI could not confirm due to clinical severe deterioration. A catheterization was then performed. The pulmonary capillary wedge pressure was 39 mmHg. The angiographies showed the left sinus of Valsalva aneurysm ruptured into the left ventricle (Fig 2). Soon after the procedure, the patient presented an acute myocardial infarction. She was sent to ICU and after clinical stabilization she was sent for surgery, but died during the procedure.

Conclusion: Ruptured sinuses of Valsalva aneurysms (RSVAs) may present a diagnostic dilemma because of their varied clinical presentations. In this study we reported a rare case, where no previously disease was seen and the SVA involved the left sinus.

P1917 - THE OUTCOME OF DEFECT CLOSURE IN SEVERE PULMONARY HYPERTENSION ASSOCIATED WITH CONGENITAL HEART DISEASE

Heirim Lee[1], Jin Young Song[1], June Huh[1], I-Seok Kang[1], Ji-Hyuk Yang[2], Tae-Gook Jun[2]

Samsung Medical Center, Pediatrics, Seoul-Korea, South[1]; Samsung Medical Center, Thoracic and Cardiovascular Surgery, Seoul-Korea, South[2]

Objectives: This study was aimed to investigate the factors influencing clinical and hemodynamic improvement after partial defect closure in patients with severe pulmonary arterial hypertension associated with congenital heart disease.

Methods: This retrospective study enrolled patients aged more than 18 years who underwent partial closure of defects in severe pulmonary arterial hypertension (pulmonary vascular resistance >6.0 WU) associated with congenital heart disease since January 2000 to October 2016. Patient's demographics, diagnoses, functional class, hemodynamic values, and exercise capacity were investigated.

Results: Twenty eight patients underwent partial defect closure. The original diagnoses were ASD (20, 71.4%), PDA (4/28, 14.3%), VSD (3/28, 10.7%), and PDA with VSD (1/28, 3.6%). Twenty three patients showed clinical and hemodynamic improvement which was defined as improvement of functional class and decrement of mean pulmonary arterial pressure below half of mean systemic blood pressure. Seven patients discontinued pulmonary arterial hypertension-specific medications. There was no significant perioperative morbidity and mortality. The follow-up cardiac catheterizations after defect closure were performed in 14 patients, the hemodynamic values showed significant improvement ($p < 0.05$). We investigated risk factors like age at defect closure, initial functional class, initial pulmonary vascular resistance, initial pulmonary arterial pressure, initial pulmonary to systemic flow ratio, and response to vasodilators. Logistic regression analysis did not showed any significant factor that influenced on the outcome.

Conclusion: In conclusion, partial defect closure in patients with severe pulmonary hypertension associated with congenital heart disease can be a good option to improve prognosis. However careful patient selection is essential for better outcome with combined medical and surgical treatment. And close follow up is very important because pulmonary vascular resistance was still remained increased even in the patients with decreased pulmonary arterial pressure.

P1934 - USING MOCK CIRCULATION SYSTEM TO ASSESS A NOVEL EFFICIENT HANDMADE TRILEAFLET POLYTETRAFLUOROETHYLENE VALVED CONDUIT WITH SINUS

Kang-Hong Hsu[1], *Te-I Chang*[2], *Chung-I Chang*[3]
Mackay Memorial Hospital, Surgery, Taipei-Taiwan[1]; *Taipei Municipal Wanfang Hospital, Surgery, Taipei-Taiwan*[2]; *Mackay Memorial Hospital, National Taiwan University Hospital, Surgery, Taipei-Taiwan*[3]

No ideal prosthetic material has been recognized for pulmonary valve replacement(PVR) and right ventricular outflow tract (RVOT) reconstruction yet. We had developed an efficient handmade trileaflet polytetrafluoroethylene (PTFE) valved conduit with sinus. The mock circulation system was used to evaluate the rheological effects of five different size conduits of 16, 18, 20, 22, and 24 mm in vitro. It showed the sinus function well. The average valve opening areas was around 70% of the cross section area in all sized conduits. The pressure gradient acrossing the valve was less than 10 mmHg in flow 5 L/min in all the five sized conduits except 16mm one which had the pressure gradient 15 mmHg in flow 2 L/min. The 16 mm valved conduit may be feasible for the patients with body weight less than 10 kg. These valved conduits have been applied to 36 patients in 7 years (2011-2016). The mean age was 15.08 ± 11.9 years (5months-49years). The early surgical mortality was 5.5%(2/36). The mean pressure gradient of the survival is 12.0 ± 12.0 mmHg under echocardiography. The PR degree less than or equal to mild in 28, mild to moderate in 5. There is no conduit explantation. The freedom from reintervention rate is 94.0%.

Conclusion: The rheology assessment results under mock circulation system examination including the pressure gradient acrossing these valve conduits and the opening areas were satisfactory for the clinical application for the patients needed PVR. The long term results have to be evaluated.

Background: Adults with congenital heart disease (ACHD) have distinct health care needs. However limited data is available from lower middle income countries (LMIC). This descriptive exploratory study conducted in Pakistan aimed to assess ACHD needs from patients' and health care providers' (HCP) perspective.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: A brief e-mail survey was sent to the pediatric and adult cardiologists of five institutions (3 public) that provide ACHD services in Pakistan. An additional detailed survey was conducted at only one private institution. A telephone survey was conducted of ACHD patients. Descriptive statistics were used for data analysis.
Results: Surveyed ACHD patients (n = 128) had a mean age of 29.4 ± 10.4 years and age at surgery 26.3 ± 1.1, with a follow-up period 3.1 ± 0.7 years. 50% were male and 70% were acyanotic. The majority (75%) had a high school education and were working or housewives. Most of the surveyed ACHD (89%) patients perceived they don't need life-long care after surgery and (96%) were interested in learning about CHD, life style modifications and complications related to marriage/pregnancy. The majority of the HCPs responded that 75% CHD children would need lifelong care, yet only 10-25% return to their cardiology clinics. Cost, travelling, lack of awareness about continuity of care and unavailability of ACHD specialty were the most commonly identified barriers in the provision of care. Most HCPs (75%) were interested in learning about transition of ACHD care and management particularly during pulmonary hypertension and pregnancy. Educational sessions and support group were identified as potential resources for patients.
Conclusion: Majority of ACHD patients in Pakistan did not know that life-long follow-up was needed, which may explain why only 10-25% of these patients returned for follow-up visits after surgery. Education regarding the need for lifelong care for ACHD patients was identified as a need to alleviate the knowledge.

P1967 - CONTEMPORARY FOLLOW UP OF PATIENTS POST ATRIAL REDIRECTION SURGERY FOR TRANSPOSITION OF THE GREAT ARTERIES

Margaret Louise Morrison[1], *Brian Grant*[1], *Christopher Lockhart*[2]
The Royal Belfast Hospital For Sick Children, Paediatric Cardiology, Belfast-United Kingdom[1]; *The Royal Victoria Hospital, Adult Congenital Heart Disease, Belfast-United Kingdom*[2]

Background: A significant body of adult congenital patients born with transposition of the great arteries (TGA) have undergone Mustard or Senning procedures and require follow up. These patients often have long-term complications such as arrhythmia, baffle related problems and ventricular dysfunction. We sought to describe the outcomes of such patients at our centre.
Methods: Patients currently attending the ACHD clinic with a diagnosis of TGA who had undergone Mustard or Senning procedures were identified using the Northern Ireland regional congenital cardiac database. Data was collected regarding demographics, medications, clinical and functional status; MRI and echocardiography follow up, cardiopulmonary exercise testing and BNP. Data was analysed using IBM SPSS statistics and simple correlation performed.
Results: Forty-six patients were identified, 31 were male (67%). Mean age was 32.2 years (±6.2 years), 32 patients had undergone a Senning procedure (70%). Fourteen patients (30%) were NYHA class II or more. Nineteen patients (41.3%) were on no cardiac medications at all. Cardiac MRI demonstrated mean RVEDV of 213.4mls ±74.1mls (indexed 115 mls/m2 ±34.8 mls/m2). Mean RV ejection fraction was 53.8% ±8.1%. There was no evidence of baffle obstruction; four patients were noted to have baffle leaks. Mean BNP was 232.8 ±192.7. BNP appears to correlate with RVEF on MRI. Twenty-six patients had undergone cardiopulmonary exercise testing. VO2max achieved was 23.8 mls/kg/min ±5.7 mls/kg/min. This was 60.6% ±12.1% of estimated. NHYA class and use of cardiac medications correlate with VO2max.
Discussion: Long-term outcomes for surviving patients following atrial repair of TGA is encouraging in this group. Although RV dilatation is evident on MRI, ventricular function is appears well preserved. The majority of patients are in NYHA class I and perform well on cardiopulmonary exercise testing.

P2016 - PER CUTANEOUS CLOSURE OF RUPTURED SINUS OF VALSALVA PERILS OF THE ROAD LESS TAKEN

Mani Ram Krishna Singaravelu[1], *Edwin Francis*[1], *Srinath Reddy Narahari*[1], *Raman Krishna Kumar*[2]
AIMS, Paediatric and Adult Congenital Cardiology, Kochi-India[1]; *AIMS, Paediatric and Adult Congenital Cardiologyy, Kochi-India*[2]

Background: Sinus of Valsalva Aneurysm is a rare congenial cardiac anomaly. It is reported to be more common in the Asian population and is closely associated with the presence of a subpulmonary ventricular septal defect. Rupture of the Sinus of Valsalva is a known and potentially catastrophic complication. While medical management is directed towards stabilization, the definitive management involves closure of the ruptured aneurysm. While surgical closure remains the gold standard, in recent yeas per-cutaneous closure of the aneurysm is gaining popularity. We report two cases of per-cutaneous aneurysm closure and also a rare complication we encountered in one of the patients.
Methods: This was a retrospective case record review of 2 patients who underwent per-cutaneous closure of RSOV aneurysm in our institute between 2014-2016.
Results: The 2 adult patients presented with sub-acute onset of congestive cardiac failure. Clinical examination suggested a large left to right shunt with evidence of aortic run-off. Echocardiogram confirmed a ruptured sinus of valsalva aneurysm to right ventricle (Patient 1) and right atrium (patient 2) respectively. Both patients underwent per-cutaneous closure of the RSOV with Lifetech Ductal Occluders (size 20/18 in patient 1 and 18/16 in patient 2). The procedure would be presented in detail. 6 hours post procedure patient 1 developed acute onset pulmonary edema and left ventricular dysfunction. The device was in good position and coronary angiography was normal. Acute afterload mismatch after closure of a large shunt was suspected and intra-aortic balloon counter pulsation (IABP) was instituted. The patient recovered in the next 48 hours.

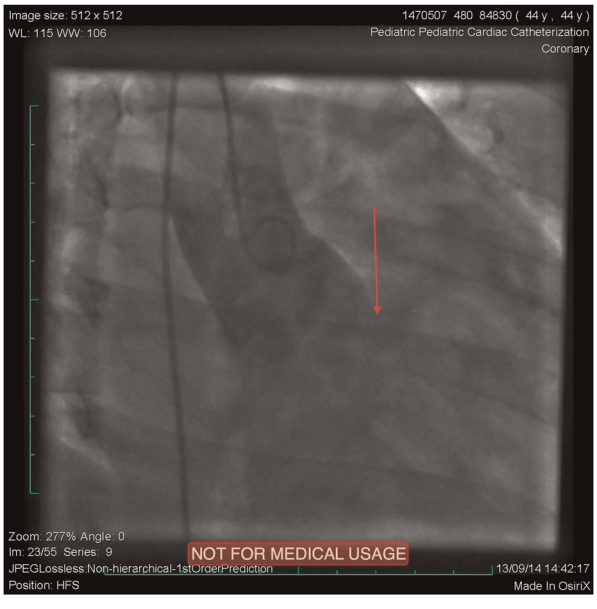

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Afterload mismatch is a potential complication of closure of large left to right shunts. We report the first case of this occurring after per-cutaneous RSOV Closure and it's successful management,

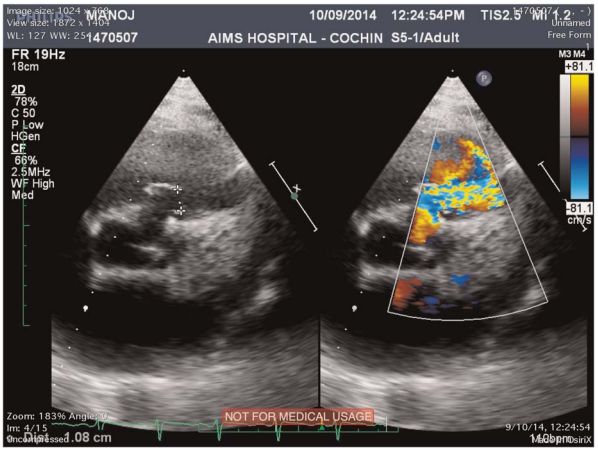

Figure 2.

P2058 - PREGNANCY IN WOMEN WITH CORRECTED AORTIC COARCTATION UTEROPLACENTAL DOPPLER FLOW AND PREGNANCY OUTCOME

A. S. Siegmund[1], M. A. M. Kampman[1], C. M. Bilardo[2], M. A. Oudijk[3], B. J. M. Mulder[4], J. W. Roos-Hesselink[5], S. V. Koenen[6], T. J. Ebels[7], D. J. Van Veldhuisen[1], P. G. Pieper[1]
University Medical Center Groningen, University of Groningen, Department of Cardiology, Groningen-The Netherlands[1]; University Medical Center Groningen, University of Groningen, Department of Obstetrics, Groningen-The Netherlands[2]; Academic Medical Center, University of Amsterdam, Department of Obstetrics, Amsterdam-The Netherlands[3]; Academic Medical Center, University of Amsterdam, Department of Cardiology, Amsterdam-The Netherlands[4]; Erasmus Medical Center, University of Rotterdam, Department of Cardiology, Rotterdam-The Netherlands[5]; University Medical Center Utrecht, University of Utrecht, Department of Obstetrics, Utrecht-The Netherlands[6]; University Medical Center Groningen, University of Groningen, Department of Cardiothoracic Surgery, Groningen-The Netherlands[7]

Background: Women with repaired coarctation of the aorta (rCoA) are at risk of hypertensive disorders and other complications during pregnancy. Hypertensive disorders in pregnant women are associated with inadequate uteroplacental flow, which is related to adverse offspring outcome. We aimed to compare cardiac function and uteroplacental flow parameters of healthy women and women with rCoA, and investigate the relationship of maternal cardiac function, placental function and pregnancy complications in women with rCoA.
Materials and Methods: We included 49 pregnant women with rCoA and 69 healthy pregnant women from the prospective ZAHARA-studies (Zwangerschap bij Aangeboren HARtAfwijkingen, pregnancy in congenital heart disease). Clinical evaluation, echocardiography and uteroplacental Doppler flow (UDF) measurements were performed at 20 and 32 weeks gestation. Univariate regression analysis was performed.
Results: Comparison of rCoA and healthy women. In rCoA women, tricuspid annular plane systolic excursion (TAPSE) decreased during pregnancy (26.1mm to 23.4mm, $P = 0.002$). No difference in UDF indices was found between rCoA and healthy women. One woman with rCoA developed ventricular tachycardia during pregnancy. Overall obstetric and offspring events did not differ between patients and controls. However, offspring of rCoA women had a lower birth weight (3233 g vs. 3578 g, $P = 0.01$). Lower birth weight was associated with the use of β-blocker during pregnancy ($\beta = -418.0$, $P = 0.01$). Association of cardiac function and uteroplacental flow. Right ventricular (RV) function before pregnancy (TAPSE) and at 20 weeks gestation (TAPSE and RV fractional area change) were associated with impaired UDF indices (umbilical artery pulsatility index at 20 weeks $\beta = -0.02$, $P = 0.01$, resistance index at 20 and 32 weeks $\beta = -0.01$, $P = 0.02$ and $\beta = -0.02$, $P = 0.01$ and uterine artery pulsatility and resistance index at 20 weeks gestation $\beta = -0.02$, $P = 0.05$ and $\beta = -0.01$, $P = 0.02$).
Conclusions: Women with rCoA tolerate pregnancy well. However, RV function is altered (possibly through interaction of left and right ventricle) and affects placental development negatively.

P2072 - INFLAMMATORY AND NEUROHORMONAL BIOMARKERS IN ADULT PATIENTS WITH ATRIAL SEPTAL DEFECT

Anne Sif Lund Ovesen[1], Camilla Nyboe[2], Sebastian Udholm[1], Vibeke Hjortdal[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Aarhus University Hospital, Cardiothoracic and Vascular Surgery, Aarhus-Denmark[1]; Aarhus University Hospital, Anaesthesiology, Aarhus-Denmark[2]

Background: Atrial septal defect (ASD) is either treated conservative or by surgical/transcatheter closure. Conservative treatment is chosen for patients with hemodynamically insignificant defects or with serious comorbidity. Our previous studies showed a higher prevalence of atrial fibrillation and pneumonia in adult ASD patients with no closure compared to both the general population and to patients with a closed ASD. Both atrial fibrillation and pneumonia are associated with increased levels of inflammatory and neurohormonal biomarkers. The aim of this present study is to evaluate biomarkers in adult patients with unclosed ASD and compare them to patients with closed ASD and a healthy control group. Furthermore, the level of biomarkers will be compared to lung function, size of right atria and right ventricle.
Material and Methods: The study is conducted as a clinical case-control study. The study includes four groups of patients: 1) Spontaneously closed ASD, 2) hemodynamically insignificant ASD, 3) hemodynamically significant ASD, 4) closed ASD five years after closure. A group of healthy controls are used as reference. Plasma concentration of inflammatory and neurohormonal biomarkers are assessed, including: Interleukin (IL)-6, IL-8, tumor necrosis factor-alpha, atrial natriuretic peptide and brain natriuretic peptide. Furthermore, a spirometry is performed to examine the lung function, and the size of the shunt, the right atria and the right ventricle are measured by an echocardiography.
Results: At present 79 patients have been investigated, and data from the blood samples are pending.
Discussion/Perspectives: Results will improve the understanding of the pathological mechanisms of the complications related to atrial septal defects. A complete understanding of the physiological and hormonal changes in these patients will facilitate follow-up and might change indications for closure of atrial septal defects.

P2133 - SUCCESSFUL TOTAL CORRECTION OF MIDDLE ADULTHOOD TETRALOGY OF FALLOT PATIENTS A SERIAL CASE REPORT

Salomo Purba, Wisnu Arya, Dicky Fakhri
Pediatric and Congenital Heart Surgery, National Cardiovascular Centre Harapan Kita, Jakarta-Indonesia

Total correction of middle-adulthood tetralogy of fallot (TOF) patient is still controversy due to increased operative risk. Chronic hypoxemia and heart disease related comorbidities are associated with bad post-operative outcome. However, researches showed that the mortality rate of adult TOF patient who undergone total correction is 5,1%. This encourages congenital heart surgeon to optimize the management of late-presenting TOF patient rather than treat them conservatively. The authors report four TOF patients with age more than 40 years old (ranged between 43 and 53 years old) who were successfully corrected in National Cardiovascular Centre Harapan Kita. These survived TOF patients came to the hospital with low functional value and comorbidities such ischemic stroke and deep vein thrombosis. Fortunately, all of the patient have good left and right ventricle function and suitable to be operated. Intra-operatively, 3 patients were treated using valve-sparing method due to adequate size of pulmonary valve annulus. Patient were observed in intensive care unit with the average length of stay was 2,5 days and none of the patient experienced severe post-operative morbidity. Three months follow-up of the patients showed good improvement of functional value compared to the preoperative condition. The longest followup (2 years) of a patient showed no hospital re-admission related to heart problem and able to do active daily living without any marked limitation. Despite of their ages and condition, total correction is remain feasible to lengthen the life-expectancy and improve functional value of the patient.

P2143 - LATE DIAGNOSIS OF COR TRIATRIATUM CASE REPORT

Marilia Domingues, Salem Fraga, Raizza Costa, Alexandre Abla, Gabriela Mesquita, Iara Malan, Paulo Renato Travancas, Ana Helena Dorigo, Monica Celente, Lina Miura
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

Background: Cor triatriatum is a rare congenital heart disease, characterized by the anomalous connection of the four pulmonary veins in a postero-superior accessory chamber in relation to the left atrium (LA).
Case Report: This study aims to report the case of a 20-year-old female patient with a history of cardiac murmur, as well as a complaint of dyspnea on major efforts and atypical chest pain since age 17 and an echocardiographic diagnosis of ostium secundum atrial septal defect (ASD). Due to the worsening of the symptoms, as well as episodes of syncope without prodromes, she was referred for surgical treatment. The preoperative transthoracic echocardiogram showed a membrane dividing the LA, with partial limitation to the flow of the pulmonary veins from the LA to the mitral valve, therefore establishing the diagnosis of cor triatriatum. Echocardiogram also showed an ASD with bidirectional shunt, right atrial and ventricular enlargement, right ventricular overload, and a Qp : Qs of 2.5:1. The patient underwent surgery, in which repositioning of the partial anomalous drainage of pulmonary veins, membrane section and clearing of LA was performed, as well as atrio-septoplasty with bovine patch. There were no complications in the immediate postoperative period and during the patient's hospitalization. Transthoracic echocardiography was performed after three months, showing unrestricted flow in the LA, normal cavity dimensions and normal biventricular function. After more than a year of follow-up, she is still asymptomatic.
Discussion: Despite the late diagnosis, the patient presented excellent surgical results and clinical evolution. The detailed evaluation of a patient with cardiac murmur associated with mild dyspnea is important, since adequate diagnosis of the disease may allow a curative treatment, as in the case reported.

P2161 - RIGHT VENTRICULO ARTERIAL COUPLING IN REPAIRED FALLOT PATIENTS WITH PULMONARY VALVE DYSFUNCTION BEFORE AND AFTER PULMONARY VALVE IMPLANTATION A CMR STUDY

Gianfranco Butera[1], Francesca Pluchinotta[1], Giorgia Galli[1], Luciane Piazza[1], Francesco Secchi[2], Francesco Sardanelli[2], Antonio Saracino[1], Angelo Micheletti[1], Mario Carminati[1], Massimo Lombardi[2]
Policlinico San Donato IRCCS, Congenital Cardiology, San Donato Milanese-Italy[1]; Policlinico San Donato IRCCS, Radiology, San Donato Milanese-Italy[2]

Background: Right ventricular-pulmonary arterial coupling plays an important role in the occurrence of right ventricular failure. Ventricular-arterial coupling is defined as Ea (arterial elastance)/ Emax (maximal systolic ventricular elastance). Ea/Emax can be measured using CMR as = end-systolic volume/stroke volume.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Aim: Objective of this study was to evaluate by cardiac magnetic resonance (CMR) the right ventricular-arterial coupling before and after surgical or transcatheter pulmonary valve implantation in subjects who underwent surgery for tetralogy of Fallot and have pulmonary valve dysfunction.
Patients and Methods: We evaluated 124 patients (age 25 + /-12 years; BSA 1.23 + /-0.84) treated for tetralogy of Fallot who have pulmonary valve prevalent regurgitation, prevalent stenosis or both and underwent pulmonary valve implantation (surgical or transcatheter). CMR studies were performed before and 12 months after pulmonary valve implantation. The volumes and stroke volumes were adjusted for body surface area.
Results: Forty-nine subjects were submitted to a surgical procedure while 75 underwent a transcatheter approach. All subjects completed the pre-operative and the 12 months follow-up evaluations. Right ventricular volumes reduced significantly (RVEDD pre 109 + /-43 vs post 93 + /-23; $p = 0.001$; RVESD pre 55 + /-32 vs 44 + /-18; $p = 0.01$). Right ventricular stroke volume reduced (55 + /-19 vs 49 + /-10; $p = 0.01$) while Right ventricular ejection fraction increased (44 + /-12% vs 50 + /-11%; $p = 0.01$). The Right ventricular coupling changed significantly between the pre-operative and the post-operative period (pre 1.10 + /-0.8 versus post 1.86 + /-0.45; $p < 0.001$). Left ventricular coupling did not change. No relationships were found with age at procedure, age at evaluation, sex and group of treatment (surgery versus transcatheter). Similar changes were found when analyzing single subgroups of pulmonary valve dysfunction (prevalent regurgitation, prevalent stenosis, bith lesions).
Conclusions: In our series procedures of pulmonary valve implantation change significantly the right ventricular- pulmonary artery coupling at 12 months of follow-up.

P2204 - FONTAN CONVERSION ATTEMPTING TO PRESERVE THE SINUS NODE IN ANTI ARRYTHMIA SURGERY

Kathryn Rice, Timothy Hornung, Thomas Gentles, Jonathan R Skinner, Kirsten Finucane
Starship Hospital, Green Lane Paediatric and Congenital Cardiac Services, Auckland-New Zealand

Objectives: To ascertain if an alternative limited right atrial maze (RAM) technique during Fontan Conversion preserves sinoatrial node function, chronotropic reserve and atrioventricular conduction with low incidence of pacemaker dependency.
Methods: A retrospective cohort study of consecutive patients undergoing Fontan Conversions with anti-arrhythmia surgery at a congenital cardiac surgical unit between 1997 and 2015. Of the 22 patients identified, 19 had the alternative limited RAM technique that aims to preserve sinus node function. Mortality, preservation of atrioventricular conduction, pacing requirement, and recurrence of atrial arrhythmia were reviewed.
Results: The median age at Fontan conversion was 28 years and the median interval from original Fontan surgery was 19 years. Concomitant anti-arrhythmia surgery was performed in all patients. Indications included atrial arrhythmias (91%) and exertional fatigue (73%), with a median follow up of 11 years (range 1 to 19 yrs). 19 patients are known to be alive, 2 of whom are lost to regular cardiology follow-up. There was one early post-operative death (4.5%) and 2 patients have subsequently died at 11 months and 7 years post conversion (overall mortality 14%). A pacing unit was placed in 16 (73%) after surgery one having been paced pre-operatively. 4/22 (18%) are pacemaker dependent for intra-atrial block (1) or atrioventricular block (3, with congenitally corrected transposition) with 50% of patients retaining chronotropic competency as assessed by Holter or exercise testing. Four had recurrence of atrial arrhythmia (18%) and in 2 the recurrence occurred >5 years after conversion.
Conclusions: Fontan conversion with an alternative limited right atrial maze technique can be undertaken with an acceptable mortality risk. Long term follow up demonstrates an enduring benefit from the conversion surgery in the majority of patients with inhibition of atrial arrhythmia recurrence and a low incidence of pacemaker dependence compared with standard anti-arrhythmia surgical techniques.

P2213 - CORONARY ARTERY MICRO FISTULAS ARE COMMON COMPLICATION IN POLYSPLENIA WITH SINGLE VENTRICULAR PHYSIOLOGY

Hiroki Mori[1], Hisashi Sugiyama, Saeko Yoshizawa[2], In-Sam Park[1]
Tokyo Women's Medical University, Pediatric Cardiology, Tokyo-Japan[1]; Tokyo Women's Medical University, Pathophysiology, Tokyo-Japan[2]

Introduction: Coronary artery fistula (CAF) is a rare anomaly in patients with congenital heart diseases. In clinical, coronary artery micro fistula related to congenital heart disease could be demonstrated in patients with polysplenia.
Hypothesis: Coronary artery micro fistulas could be not rare anomaly in patients with polysplenia and cause myocardial damage.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Methods: Total 62 patients (male/female: 24/38, age: 23 ± 1.1 years) with polysplenia, who underwent cardiac catheterization, were retrospectively reviewed. Of those 46 had single ventricle physiology. Furthermore, 2 pathological specimens were evaluated to detect myocardium damage and coronary artery micro fistulas.
Results: Coronary angiography showed coronary artery micro fistula in 11 patients (18%). All had single ventricular physiology. Proximal potion of coronary artery, which supply micro fistula, run with tortuous and dilation. All coronary artery micro fistulas terminated into right ventricle chamber (Figure A). Statistical difference was not observed in oxygen saturation and end-diastolic pressure of systemic ventricle in these patients compared with the patient without fistulas. Pathological examination showed multiple fistula-like vessels in endocardial myocardium (Figure B; arrow head, scale bar 1000 μm). The vessel diameter ranged from 300 μm to 1000 μm. Those had irregular vessel wall with immature smooth muscles, elastic fiber and collagen fiber (Figure C and D; scale bar 100 μm). Furthermore, remarkable perivascular interstitial fibrosis was observed in the right ventricle.
Conclusions: The prevalence of coronary artery micro fistula could be clarified as 18% in patients with polysplenia with single ventricular physiology. Furthermore, coronary artery micro fistulas was proved on pathological specimens. Perivascular interstitial fibrosis in the right ventricle could be caused by coronary micro fistula.

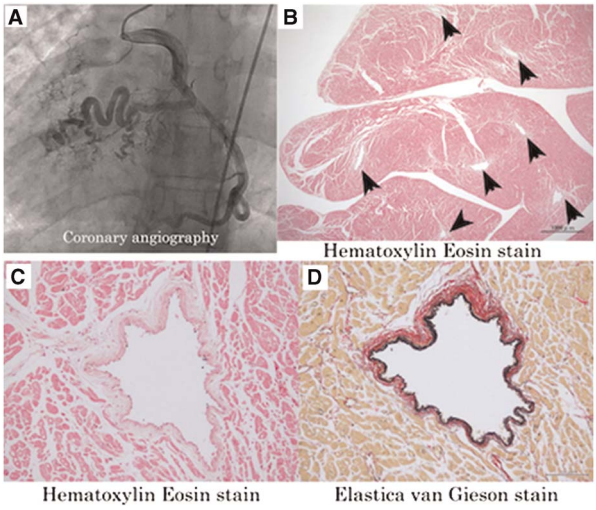

Figure 1.

P2219 - FONTAN CONVERSION FUNCTIONAL OUTCOMES OVER TIME – A SINGLE CENTRE EXPERIENCE

Kathryn Rice, Thomas Gentles, Jonathan R Skinner, Kirsten Finucane, Timothy Hornung
Starship Hospital, Green Lane Paediatric and Congenital Cardiac Services, Auckland-New Zealand

Objectives: To evaluate the functional impact of Fontan Conversion surgery.
Methods: A retrospective cohort study of consecutive patients undergoing Fontan Conversion with antiarrhythmia surgery at a congenital cardiac surgical unit between 1997 and 2015. Twenty two patients were identified. Survival was 86.5% with one perioperative death and two later deaths. Two patients have been lost to followup. New York Heart Association (NYHA) class, ventricular function assessment, cardiac catheter and exercise testing were evaluated.
Results: NYHA Class improved by at least 1 grade in 79% of survivors. At 10 year follow up (FU) 10 of 13 patients are in NYHA class I-II. Two patients have subsequently managed successful pregnancies. Ventricular function has deteriorated in 4 patients (18.2%) after 7-15 years FU with 2 of these having severe dysfunction, whilst 5 (22.7%) have ongoing improved function after 4-19 years FU. Cardiac catheter haemodynamics were available prior to and a median of 6 years after conversion in 8 patients. Seven of these had improvement in at least one parameter of pulmonary artery pressure, pulmonary arterial wedge pressure, pulmonary vascular resistance or cardiac output. One patient required neo-left pulmonary artery stenting post Fontan conversion. Eight patients have had cardiopulmonary exercise testing pre and post conversion with a median of 7.5 years between (range 1-13 years). Pre conversion the median age-predicted peak VO2 was 47% (range 44-64%), and post the median was 58.5% (range 45-72%). Ten patients (45%) have not required antiarrythmic agents since surgery, whilst 4 are being treated for atrial arrhythmia recurrence and 4 for non-sustained ventricular arrhythmia. Two patients have permanent anti-tachycardic atrial pacing.
Conclusion: Fontan conversion at our centre has provided improved functional capacity in the majority with a longitudinal retention of benefit. Careful patient selection, timing and techniques to address arrhythmias will optimise results from Fontan

P2223 - THE EFFICACY AND SAFETY OF DIRECT ORAL ANTICOAGULANT IN ADULT PATIENTS WITH FONTAN CIRCULATION

Naoto Kawamatsu[1], Terunobu Fukuda[1], Yasufumi Kijima[1], Yumi Shiina[1], Shigeru Tateno[2], Koichiro Niwa[1]
St.lukes International Hospital, Department of Cardilogy, Cardiovascularcenter, Tokyo-Japan[1]; Chiba Cardiovascular Center, Department of Adult Congenital Heart Disease And Pediatrics, -Japan[2]

Background: Thromboembolic complications occurring after the Fontan procedure are well documented. Up to now, how to prevent these events remains unclear. On the other hand, Direct Oral Anticoagulants (DOAC) has been used to prevent thromboemboli events for the patients with atrial fibrillation and venous thromboembolism (VTE).
Objective: To investigate the safety and efficacy of DOAC in Fontan patients.
Methods: Sixty patients after Fontan procedure (27 men, 27 ± 8 years old, mean duration after the procedure is 19 ± 7 years, 13 patients with Atriopulmonary connection and 47 with Total cavopulmonary connection) were reviewed retrospectively. Patients, prescribed DOAC, warfarin or antiplatelet, were classified into 3 groups. Cases having no prophylactic therapy were excluded. The clinical outcomes were analyzed. Primary endpoints were thromboembolic complications and bleeding events. Thromboembolic complications were defined as symptomatic cerebral infarction, peripheral arterial embolism, and VTE. Bleeding events were hemorrhage requiring medical intervention including cessation or change of the anti-thromboembolic medication and/or more than 2 g/dl or 10% decrease in hemoglobin.
Results: Twenty-five cases were classified as DOAC group, 17 cases in antiplatelet group. Warfarin were used in 15 cases. On the other hand, three cases were having no prophylactic therapy. Mean duration of the medication were 29 ± 14, 55 ± 36, 67 ± 50 month, respectively. No case had thromboembolic event. But two patients in each of DOAC and Warfarin group had bleeding event. No case had bleeding event in Antiplatelet group.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

These showed no significant difference among three groups regarding estimated event free survival rate.
Conclusion: Direct oral anticoagulants in adult patients with Fontan Circulation may be safe and efficacious as observed in warfarin or acetylsalicylic acid.

P2235 - LV NON COMPACTION IN PATIENTS WITH SINGLE VENTRICLE HEART DISEASE IS ASSOCIATED WITH IMPAIRED SYSTOLIC FUNCTION

Preeti Choudhary[1], Christian Hamilton-craig[2], Shelby Kutty[3], Raj Puranik[4], David Celermajer[4]
University of Sydney, Department of Medicine, Sydney-Australia[1]; The Prince Charles Hospital, Department of Cardiology, Brisbane-Australia[2]; University of Nebraska Medical Centre, Department of Cardiology, Nebraska-United States[3]; Royal Prince Alfred Hospital, Department of Cardiology, Sydney-Australia[4]

Background & Aims: LV non-compaction is a congenital morphologic abnormality of the LV myocardium, postulated to occur due to early embryonic arrest of myocardial compaction and is associated with adverse outcomes including cardiomyopathy and premature death. Although observed in association with various congenital heart lesions, its effect on cardiac function remains unknown. We sought to assess the prevalence of LVNC in patients with univentricular physiology (SVHD) and its effects on ventricular function.
Methods: Cardiac magnetic resonance imaging of 93 patients with SVHD (mean age 24 + /-8 years; 55% male) from 3 tertiary congenital centres were retrospectively reviewed. The presence of LVNC was defined as having a non-compacted: compacted (NC:C) myocardial thickness ratio >2.3:1. The distribution of LVNC, ventricular volumes and function were correlated with clinical data.
Results: The prevalence of LVNC was 37% with a mean of 4 + /-2 affected segments. The distribution of LVNC was apical in 100%, midventricular in 29% and basal in 17% of patients. Patients with LVNC had significantly higher end-diastolic (128 + /- 44 vs. 104 + /-46 mL/m2, p = 0.047) and end-systolic LV volumes (74 + /-35 vs. 56 + /-35 mL/m2, p = 0.039) with lower LV ejection fraction (44 + /-11 vs. 50 + /-9%, p = 0.039) compared to those without LVNC. Stroke volumes did not significantly differ in the two groups (65.0 + /-29 vs. 73 + /-37 mL /m2, p = 0.36). The number of segments involved did not correlate with adverse ventricular function (p = 0.71).
Conclusions: LVNC is common in patients with SVHD physiology with predominantly apical and mid-ventricular involvement. Although the LVNC distribution is not extensive, its presence is associated with increased indexed ventricular volumes and impaired global systolic function.

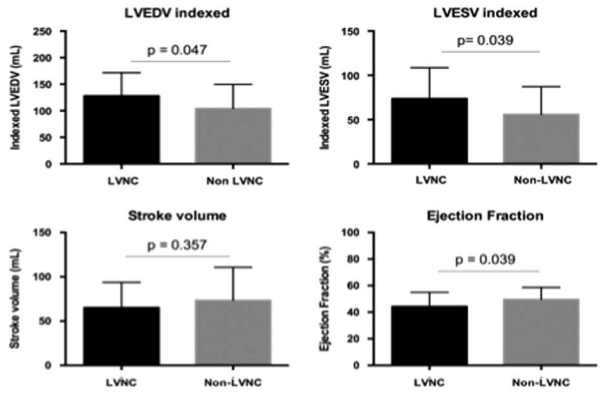

Figure 1.

P2248 - DOUBLE WHAMMY A RARE CASE OF PACEMAKER LEAD THROMBUS AND PULMONARY EMBOLISM IN A PATIENT WITH CCTGA AND ESSENTIAL THROMBOCYTOSIS

Chukwuemeka Oguguo, Jaspal Dua, Petra Jenkins, Heiko Schneider, Ashish Shah, Andreas Hoschtitzky
Manchester Heart Centre, Cardiology, Manchester-United Kingdom

A 73year-old male with congenitally corrected transposition of great arteries (ccTGA), severely dilated/impaired systemic RV/Pulmonary embolism (PE), presented with worsening LV function and pacemaker lead thrombus with PE, refractory to heparinization/warfarin.
Background: The pacemaker was inserted 12 years prior for complete heart block (CHB), without undergoing transthoracic echocardiogram (TTE) when he first presented, delaying ccTGA diagnosis. He had suffered a PE 2 years prior.
Management: 2 weeks of IV Heparin showed no resolution of clot burden therefore he was taken for surgical resection. Through aorto-bicaval cardiopulmonary-bypass, opened resection of large organised thrombi in RA/RV associated with RA/RV pacing leads, pacemaker removal and permanent epicardial dual-chamber pacemaker implantation. Due to post-operative thrombocytosis, he was referred to haematologists, who diagnosed with essential thrombocytosis with a rare mutation, increasing his thromboembolic risk.
⋆Evidence of large clot on TOE on 4CH view
⋆Further evidence of large clot on lead on TTE
- Note filling defects in right pulmonary tree, indicative of pulmonary embolism
Discussion: ccTGA - uncommon form of congenital heart disease (CHD); incidence 0.02-0.07/1000 live births (<1% of CHD), characterized by atrioventricular/ventriculoarterial discordance, and rhythm disorders, most commonly CHB, with 2% increased annual risk, or progressive AV block, seen in over 1/5th of unoperated ccTGA, and can present later in life with CHB. Patients presenting de novo with CHB should undergo TTE to exclude ccTGA. Thromboembolic events can be life-threatening and atypical thromboembolism risk factors include PPM/intracardiac shunts/rhythm disorders/younger age. These risk factors need appropriate management with surveillance investigations including anticoagulation/sinus rhythm maintenance
Summary: ccTGA is rare and complex to manage. Patients have increased thrombo-embolic risk due to dilated systemic ventricles/pacemaker leads/sub-optimal treatment and in this case, compounded by haematological disorders like thrombocytosis. Low threshold for investigations/anticoagulation is important.

P2250 - REFRACTORY ATRIAL ARRHYTHMIAS IN ATRIO PULMONARY FONTAN THE FAILING OF THE FONTAN

Chukwuemeka Oguguo, Jaspal Dua, Petra Jenkins, Andreas Hoschtitzky, Ashish Shah, Heiko Schneider, Bernard Clarke, Sahrkaw Muhyaldeen
Manchester Heart Centre, Cardiology, Manchester-United Kingdom

A 36year-old male, with tricuspid atresia, normally related great arteries, VSD and rudimentary RV, presented with recurrent atrial arrhythmias, post atria-pulmonary (A-P) Fontan procedure. His first Fontan procedure was in 1980 with a modified A-P Fontan procedure in 1998. He had developed severe systemic ventricular dysfunction.

*4CH view showing small, atrialized RV, enlarged RA

*CMR – coronal view - note grossly enlarged RA and VSD, as well as Fontan connection

From 2012, he developed various types of atrial arrhythmias including atrial flutter/AV-nodal-re-entry-tachycardia, refractory to medication, presenting to hospital, frequently. He was unsuccessfully treated on admissions with direct-current-cardioversions (DCCV) and he underwent three electrophysiology studies/ radiofrequency ablations via CARTO® system.

*CARTOablation views showing areas of ablation (red dots) thereby isolating PVs

Due to these refractory arrhythmias despite treatment, he was referred for heart transplantation, currently on the transplant list.

Discussion: 10-years post-Fontan operation, arrhythmias occur in over 50% and 20% of patients have SVTs. Intra-atrial-re-entry tachycardia/ atrial flutter, being most common. Patients present with palpitations, haemodynamic deterioration/compromise, clot formation/embolic events. Fontan arrhythmias are resistant to medication due to re-entrant mechanisms, facilitated by atrial substrates adjacent to valves/patches/suture lines, reduced systemic ventricle function and cellular injury from hypoxia/atrial stretch. Patients usually require advanced/multiple EP procedures, however these usually only modify the substrate. Nonetheless, there are good success rates with catheter-based treatment, provided there is adequate access to myocardium/cardiac chambers. Newer techniques have been introduced with increased success rates like non-invasive mapping/remote magnetic navigation. Either Fontan conversion (guided by surgical protocols), Ventricular-assist

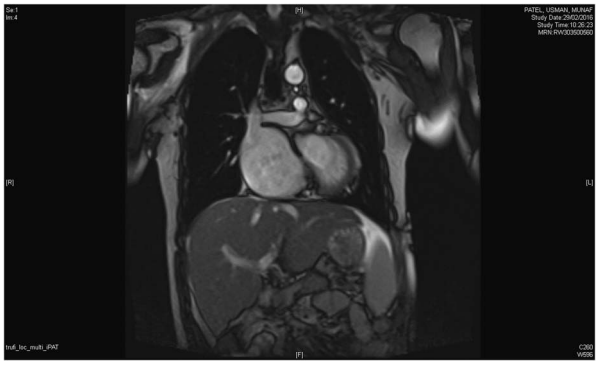

Figure 1.

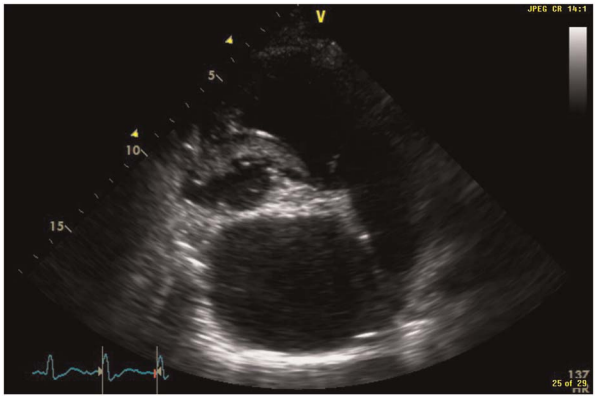

Figure 2.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

devices/cardiac transplantations are considered in refractory arrhythmias despite medical/device therapy.
Summary: Fontan arrhythmias are common, varied, problematic, life-threatening. Patients may undergo multiple DCCV/ablations, if refractory to medication. Potential need for further surgery/ catheter interventions/ transplantation should be considered, if indicated, and discussed with patient/family.

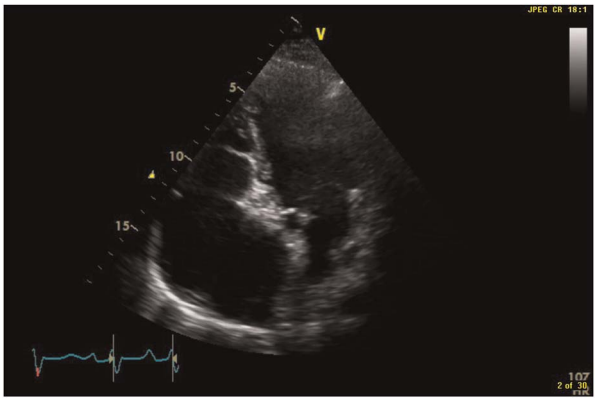

Figure 3.

P2253 - THE IMPACT OF HEART DISEASE FUNCTIONAL STATUS ON THE LIFE OF ADULT PATIENTS WITH CONGENITAL HEART DISEASE

Junko Enomoto[1], Yoshiko Mizuno[2], Shigeru Tateno[2], Koichiro Niwa[3]
Toyo University, Department of Education, Tokyo-Japan[1]; Chiba Cerebral and Cardiovascular Center, Department of Adult Congenital Heart Disease and Pediatrics, Chiba-Japan[2]; St Luke's International Hospital, Cardiovascular Center, Tokyo-Japan[3]

Background: The quality of life (QOL) and mental health of adult patients with congenital heart disease (ACHD) may be affected by their current heart disease functional status. The aim of this study is to explore the impact of heart disease functional status on their life and the strategy to improve their life.
Material and Method: A total of 199 ACHD patients and 158 reference participants (aged 20-60; no students included) completed the QOL questionnaire using a linear analog scale, the satisfaction with life scale (SWLS) and the hospital anxiety and depression scale (HADS). Patient characteristics included sex, age, educational level, marital status, employment status and subjective patient-reported New York Heart Association (NYHA) functional class. The study focused on four groups: 1) reference, 2) NYHA I, 3) NYHA II, 4) NYHA III/IV.
Results: Compared to the reference and NYHA I groups, NYHA III/IV have lower QOL and satisfaction with life, and higher anxiety and depressive symptoms. NYHA II and NYHA III/IV have patients with lower educational levels and more patients that are single. NYHA II and NYHA III/IV have fewer patients that work full time and NYHA III/IV has more unemployed patients. NYHA II and NYHA III/IV patients who work have a higher QOL and SWLS than unemployed patents.
Conclusion: While the reference and NYHA I groups have an acceptable QOL and mental health feedback, NYHA II and NYHA III/IV experience a worse situation. According to our results, if NYHA II and NYHA III/IV patients engaged in any type of work, their QOL and mental health would definitely improve. In Japan, currently, the government offers substantial financial support to ACHD patients. However, the government needs to provide more ways to help these patients become contributing members of society.

P2292 - MATERNAL AND FETAL OUTCOMES IN PATIENTS WITH POST DOUBLE SWITCH OPERATION FOR CONGENITALLY CORRECTED TRANSPOSITION OF THE GREAT ARTERIES

Terunobu Fukuda[1], Naoto Kawamatsu[1], Yasufumi Kijima[1], Yumi Shiina[1], Shigeru Tateno[2], Koichiro Niwa[1]
Cardiovascular Medicine, St Lukes International Hospital, Tokyo-Japan[1]; Adult Congenital Heart Disease and Pediatrics, Chiba Cardiovascular Center, Chiba-Japan[2]

Background: The double switch operation (DSO) has emerged as a way to improve prognosis for the congenitally corrected transposition of the great arteries (ccTGA) with deteriorating systemic right ventricle since mid-1980's, therefore, a number of patients after DSO have been growing up to be reproductive age. However, there are paucity of reports on the pregnancy and neonatal outcomes of this condition.
Methods and Results: To clarify the course of pregnancy and neonate outcomes in patients with ccTGA after DSO, the medical records in two-specialized centers from Jan 2000 to Des 2015 were retrospectively reviewed. Four patients aged 27 ± 3.5 at delivery with preserved bi-ventricular funcntion, all of them underwent Mustard and Rastelli operation, were included. Reported pre-pregnancy problems including moderate intra-conduit stenosis with previous catheter ablation for supra-ventricular tachycardia in one, atrial tachycardia in two, and small baffle leakage in one, however, they were all in good physical conditions. Three pregnancies developed atrial tachycardia during pregnancy, one of whom required cardioversion and taking beta-blocker. One delivered 1245 g neonate at 29 week 5 day for premature rupture of the membranes. Other three women delivered at scheduled day without any maternal cardiac complications, one delivered by forceps delivery with 1984g neonate at 37 week 4 day, one underwent scheduled caesarean section with 2032 g neonate at 36 week 3 day and one underwent emergency caesarean section due to arrested labor with 2288 g neonate at 37 week 4 day.
Conclusions: ccTGA patients after DSO could complete pregnancy, if they had good bi-ventricular function and physical activity before pregnancy. However, there were frequent episodes of atrial tachyarrhythmia and had a tendency to deliver low-birth weight infants. Careful management with multidisciplinary team including cardiologist, obstetrics, anesthesiologist and other multidisciplinary teams should be required to complete these complicated cases.

P2296 - GROWN UPS CONGENITAL HEART SECUNDUM ATRIAL SEPTAL DEFECT WITH MITRAL VALVE REGURGITATION LONG TERM OUTCOME OF MITRAL VALVE REPAIR

S Laura Mazalan[1], J Jeswant Dillon[1], Intan Fariza Gaafar[2]
National Heart Institute, Department of Cardiothoracic Surgery, Kuala Lumpur-Malaysia[1]; National Heart Institute, Research Department, Kuala Lumpur-Malaysia[2]

Background and Hypothesis: Mitral valve regurgitation (MR) in Secundum Atrial Septal Defect (ASD) often attributed to clefts leaflets. In selected Grown-ups Congenital Heart groups, prolonged ASD shunts exposes the mitral valve to a more complex valve pathology with a more challenging valve repair techniques. Study objective to review our long-term experience in surgical valve repair of MR in ASD, determining valve key pathological features, complex valve repair techniques with long-term outcomes.
Material and Methods: 24 years (1992-2016), retrospective analysis of 59 patients in Grown Ups Congenital Heart Disease

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(age range: 16-65 years, mean 32.8years) with Secundum ASD and predominantly mitral regurgitation (MR) underwent surgical correction of ASD with autologous pericardial patch with concurrent mitral valve repair.
Results: 37 female and 22 male; predominantly mitral regurgitation (MR) 53(89.8%), mitral stenosis (MS) 3(5.1%) and mixed MR/MS 3(5.1%). Co-morbidities of pulmonary hypertension 21 (35.6%), atrial fibrillation 14(23.7%), endocarditis 1(1.7%). Valve predominant features were mitral leaflets prolapse 43(72%), thickening 24(40.7%), with annular dilatation 29(49.2%) and chordal elongations 16(27.1%). Prolapsed leaflets repaired with chordal replacement 14(23.7%) and shortening 7(11.8%) and annuloplasty ring placement 52(88.1%). Cleft repaired in 11(18.6%) patients. Concurrently 5(8.5%) required MAZE procedure and 26(44%) tricuspid annuloplasty repair. Mean follow-up duration of 78.1 ± 68.6 months. Above 10 years follow-up, mitral valve competency grade; fully competent 61%, trivial 20.3%, mild 16.9%, severe 1.7%. At 15 years follow-up, freedom form re-operation were 97.3%. Subsequent improvement in symptoms from pre to post-operatively in NHYA functional class I 29(49.1%) to 52(88.1%) and reversion to sinus rhythm 45(76.3%) to 48(81.4%)
Conclusions: Prolapsed mitral leaflets and annular dilatation are predominant features of prolonged uncorrected ASD shunts onto mitral leaflets. Cleft repair alone is insufficient. Chordal procedure and ring annuloplasty increase the feasibility and durability of repair.

P2297 - EVALUATING THE LONG TERM EFFECTS OF THE FONTAN PROCEDURE ON THE HEPATIC SYSTEM

Petra Jenkins[1], Zenib Zadar[2], Jaspal Dua[1], Vaikom Mahadevan[3]
CMFT, ACHD, Manchester-United Kingdom[1]; University of Manchester, Manchester Medical School, Manchester-United Kingdom[2]; UCSF, ACHD, San Francisco-United States[3]

A palliative procedure performed in univentricular congenital cardiac lesions, the Fontan procedure, is associated with impaired liver function and liver fibrosis. Currently these patients are monitored using liver function tests (LFTs) and liver ultrasound (US) scans, however these tests are targeted for viral mediated fibrosis. Acoustic radiation force impulse (ARFI) imaging measures tissue elasticity and may have an important role in assessing liver stiffness. We aimed to assess the efficacy of LFTs, liver USS and ARFI imaging in diagnosing liver fibrosis in Fontan patients. We also aimed to assess any relation between cardiopulmonary exercise test (CPET) variables and ARFI scores. Data was collected retrospectively from the Manchester ACHD Centre. We identified 12 patients who had results available for LFTs, USS Liver, ARFI and CPET. The sensitivity of LFTs and liver USS was found to be 6.6% and 86% respectively. ARFI identified liver congestion/fibrosis in all patients with 33% at F2, 33% at F3 and 33% at F4. There was found to be a slight reduction in % peak VO2 (62.6 vs 46, p = 0.2) and % predicted O2 (101.1 vs 88.9, p = 0.6) in F3 patients, with a higher VE/VO2 (32.5 and 42.0, p = 0.2), indicating a relationship in worsening cardiopulmonary variables, and hence Fontan haemodynamics and the presence of the degree of liver fibrosis.
In conclusion, LFTs alone are not a suitable screening test for Fontan associated liver disease (FALD) and liver USS does not accurately quantify the degree of fibrosis. ARFI requires further research in larger study samples to determine a role in routine hepatic monitoring of Fontan patients. Although we found a weak relationship between impaired CPET variables and greater ARFI scores, this relationship requires further investigation.

P2313 - RV FUNCTION IS IMPAIRED IN ADULTS WITH TETRALOGY OF FALLOT

Ramakrishnan Sivasubramanian, Saurabh Gupta, Ritesh Gupta, Rajnish Juneja, Shyam Kothari, Anita Saxena, Vinay Bahl
AIIMS, Cardiology, New Delhi-India

Introduction: In developing countries, quite a few patients with Tetralogy of Fallot's (TOF) present late, and sometime in adulthood. Long standing cyanosis and progressive right ventricular (RV) hypertrophy and fibrosis may have deleterious consequences on RV function. We studied the differences in clinical, echocardiographic (including speckle tracking) and angiographic parameters among TOF patients presenting late in adolescence/adulthood as compared to children with TOF.
Methods: 20 children of age ≤3 yrs (mean age 1.95 ± 0.76; range 1 3 years) and 10 patients of age ≥ 13 yrs (mean age 20.5 ± 16.5; range 13 38 years) were recruited in the study. Clinical, echocardiographic and angiographic parameters were compared between the groups. The echocardiographic parameters of RV function evaluated in this study included: end-diastolic RV diameter, RV/LV ratio, tricuspid annular plane systolic excursion (TAPSE), percentage of RV fractional area change (RV FAC), and peak systolic longitudinal strain derived from speckle tracking. Angiographically, the diameter of DTA, RPA and LPA were measured in all patients and were indexed to body surface area (BSA). McGoon ratio was also calculated.
Results: Patients with uncorrected TOF were more symptomatic as compared to children with higher functional class and lower saturation. Parameters of RV functions were relatively lower than normal in both children as well as adult with TOF. However, all the parameters of RV function were significantly more impaired in adults with TOF. For instance, TAPSE was 16.8 ± 1.5 in children as compared to 13.9 ± 1.6 in adolescents with TOF (p - <0.01). Mcgoon ratio was not significantly different.
Conclusion: Patients with uncorrected TOF's presenting in late childhood or adulthood are more symptomatic. RV dysfunction as assessed by the various echocardiographic parameters is more common in adolescents and adults than in children with TOF, which may compromise the operative outcomes.

P2325 - PULMONARY VALVE REPLACEMENT WITH AN INJECTABLE STENTED PULMONIC VALVE 10 YEARS OF EXPERIENCE

Stefano M. Marianeschi, Simone Ghiselli, Cristina Carro, Lorenzo M. Ripamonti
Niguarda Hospital, Cardiovascular, Milan-Italy

Background: Chronic pulmonary valve regurgitation (PR) following repair of congenital heart diseases, such as tetralogy of Fallot, is a common late sequela often requiring reoperation. Long-standing chronic PR can result in right ventricle (RV) dilatation and failure and increased late morbidity and mortality. A timely reoperation may lead to a complete RV recovery. The conventional approach is pulmonary valve replacement (PVR) on cardiopulmonary bypass (CPB) often with cardioplegic arrest. The aim of this multicenter study is to evaluate mid to long-term outcomes of patients undergoing a less invasive PVR with the BioIntegral® Injectable Stented BioPulmonic prosthesis.
Material and Methods: From 2007 to 2017, forty-nine symptomatic patients (mean age: 28.7 ± 16.3 years, range: 10-71.4) with severe PR underwent PVR with an injectable stented pulmonic prosthesis at 13 centers. The mean interval between primary correction and PVR was 19.8 years (range: 1-45.4). Mean follow-up was 44.8 months (range: 3 months-10 years). Twenty-six patients

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(53%) underwent isolated PVR; concomitant procedures performed on CPB in twenty-three patients (47%) included tricuspid valve repair, ablation of cardiac arrhythmias, ventricular septal defect repair, pulmonary artery plasty, aortic procedure and right ventricular outflow tract enlargement. The median prosthesis size was 27 mm (range: 19-31 mm).
Results: Off-pump pulmonary valve implantation was performed in 39% of patients (19/49). Overall mortality rate was 4% not device-related. No major complications occurred postoperatively and no prostheses were explanted. Echocardiography and cardiac magnetic resonance in follow-up detected a significant reduction in RV size ($p < 0.001$) and low transvalvular gradients across PV ($p < 0.05$) (Fig. 1).
Conclusions: Injectable Stented Pulmonic valve implantation is a good alternative to conventional approach mostly in patients requiring multiple cardiac operations. The prosthesis, available up to large sizes, presents a laminar flow and no-risk of coronary arteries compression. PVR can be performed off-pump with lower biological impact, shorter implantation time and minimal morbidity. Results concerning prosthesis durability are encouraging. Mid and long-term haemodynamic performances are excellent.

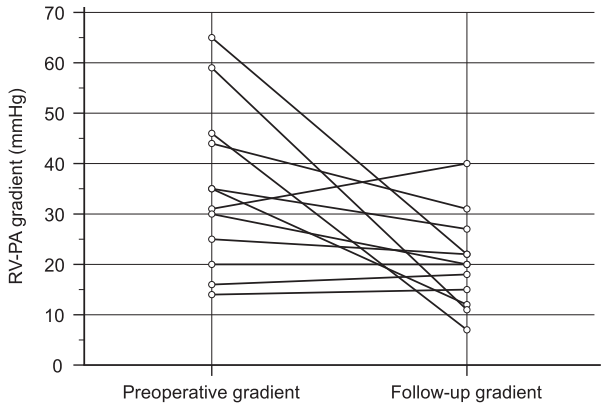

Figure 1.

P2327 - FUNCTIONAL STATUS AND INTRACARDIAC ANATOMY OF DOUBLE INLET LEFT VENTRICLE SURVIVORS WITHOUT FONTAN CIRCULATION

Sophie Meyer[1], Tineke Willems[2], Joost Van Melle[3], Barbara Mulder[4], Jolien Roos-hesselink[5], Monique Jongbloed[6], Arie Van Dijk[7], Rolf Berger[8], Tjark Ebels[9]
University Medical Center Groningen, Cardiothoracic Surgery/Pediatric Cardiology, Groningen-The Netherlands[1]; University Medical Center Groningen, Radiology, Groningen-The Netherlands[2]; University Medical Center Groningen, Cardiology, Groningen-The Netherlands[3]; Academic Medical Center Amsterdam, Cardiology, Amsterdam-The Netherlands[4]; Erasmus Medical Center Rotterdam, Cardiology, Rotterdam-The Netherlands[5]; Leiden University Medical Center, Cardiology, Leiden-The Netherlands[6]; Radboud University Medical Center, Cardiology, Nijmegen-The Netherlands[7]; University Medical Center Groningen, Pediatric Cardiology, Groningen-The Netherlands[8]; University Medical Center Groningen, Cardiothoracic Surgery, Groningen-The Netherlands[9]

Background: Double inlet left ventricle (DILV) patients are currently palliated with the Fontan procedure. Data on long-term survival with a Fontan circulation remain compromised. A small, selected subgroup of "survivors" of DILV, however, has been reported to live to a comparably high age without a Fontan procedure. The aim of this study was to determine the natural course of uncorrected DILV and describe the intracardiac anatomy.
Material and Methods: In this retrospective study, clinical data and the intracardiac anatomy of DILV patients without Fontan procedures from all Dutch congenital heart disease referral centers were analyzed.
Results: Twenty-four patients were included, of whom 16 are still alive (median age 44 years, range 12-68). Seventeen (71%) patients had pulmonary stenosis, of which 7 (44%) had a pulmonary banding procedure. Six (39%) had Eisenmenger's syndrome. The ventriculo-arterial connection was discordant in 18 (75%) and concordant in 3 (12.5%) hearts. NYHA functional class was I or II in 71% of the patients. Kaplan Meier analysis showed survival to start dropping linearly from 49 years of age, while the oldest patient was alive at 68 years. Median survival did not differ significantly between patients with and without pulmonary stenosis (62 and 53 years respectively). Mean overall transcutaneous oxygen saturation at rest was 86% (SD ± 7.2) and was significantly higher in patients with pulmonary stenosis than in patients without (88% ± 6.3 and 79% ± 5.2 respectively).
Conclusions: The data on DILV natural survivors give evidence that it is possible for a selected subgroup of these patients to live up to a relatively high age without Fontan procedures. Although the majority of these patients had pulmonary stenosis, patients with no pulmonary vascular protection who developed Eisenmenger's syndrome had equal life expectancy. Pulmonary banding might be an effective surgical alternative for certain DILV patients.

P2331 - RESULTS OF SURGICAL CORRECTION OF EBSTEIN ANOMALY OF THE TRICUSPID VALVE IN ADULT PATIENTS

Ferdinand Timko, Roman Gebauer, Ivo Skalský, Jana Popelová, Štepán Černý
Center For Diagnostics and Treatment of Congenital Heart Defects in Adults, Homolka Hospital, Department of Cardiac Surgery, Prague-Czech Republic

Background: Operation of Ebstein anomaly technically belongs to the demanding interventions in cardiac surgery, especially if the surgeon aim is a complex repair of the valve and therefore the results of these operations of the adults vary greatly according to the experience of each surgeon or center. Our goal is to evaluate own results in adult patients with Ebstein anomaly.
Methods: A retrospective assessment of 45 patients who underwent totally 49 surgical interventions of Ebstein anomaly between 12/2005 and 12/2016.
Results: Mean age at surgery was 33.9 ± 12.1 (19-63) years. Morphologically, most patients (72%) had Ebstein Anomaly type C. Repair of tricuspid valve was performed in 44.4% cases, bioprosthetic valve replacement in 53.3% cases. The procedures were associated with the bidirectional cavo-pulmonary anastomosis in 26.0%, mitral valve repair in 8.9%, and closure of atrial septal defect in 64.0% and right atrial MAZE procedure in 40%. The average duration of extracorporeal circulation was 147 ± 28 min with an aortic cross-clamp time of 112 ± 31 min. Two patients died within 30-days after surgery and another 2 during further follow-up. 6 patients required re-replacement of bio-prosthetic valve (2 for structural valve deformation, 22 and 11 years after first surgery, 4 for infective endocarditis in ± 4 years after first replacement). Presence of NYHA class II and more was reduced from

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

2.6 ± 0.67 before to 1.58 ± 0.57 after surgery, p < 0.0001 Grade of tricuspid regurgitation after valve repair decreased from mean 3.8 ± 0.49 to 1.39 ± 0.94 after surgery, p < 0.0001.
Conclusion: In a specialized adult congenital heart disease center surgical either repair or replacement of Ebstein anomaly can be performed with acceptable mortality in adulthood. Both tricuspid valve function and functional capacity is significantly improved.

P2390 - MENSTRUAL PROBLEMS IN WOMEN WITH CONGENITAL HEART DISEASE

Eriko Shimada[1], Kei Inai[1], Tokuko Shinohara[1], In-sam Park[2]
Tokyo Women, Pediatric Cardiology, Tokyo-Japan[1]; Tokyo Women, Ediatric Cardiology, Tokyo-Japan[2]

Objectives: To investigate the age at menarche and the prevalence of menstrual disorders, and determine the relationship between menstrual abnormalities and cardiac conditions in women with congenital heart disease (CHD).
Materials and Methods: Women aged 16 to 60 years old with CHD who admitted our institute between February 2016 and December 2016 were enrolled this study. Patients were asked about menstruations including menarche, cycle and duration of menstruation. We analyzed the relations between menstruation and the hemodynamics, New York Heart Associate (NYHA) classification, cyanosis, and medications.
Results: A total of 121 patients were enrolled (median age 34 years, range 16-58 years). Patients were categorized according to the degree of severity of the underlying heart defect. The average NYHA class was 1.5 ± 0.6 and the average oxygen saturation rest was 94 ± 7% (range 70 – 99%) . The average age at menarche was slightly delayed in women with CHD compared with the average age in Japanese women (12.9 years vs 12.6 years). In the patients after Fontan palliation (n = 44), the age at menarche was significantly delayed compared with patients after biventricular repair (13.4 years vs 12.7 years, p = 0.002). There were 4 patients (3%) of primary amenorrhea, 27 patients (22%) of secondary amenorrhea. Overall, menstrual disorders including cycle disturbance and abnormal duration of menstruation were observed in 56 (46%) patients. The occurrence of these disorders depended on the presence of heart failure, the severity of CHD.
Conclusions: Menstrual disorders were frequently observed in patients with heart failure and complex heart disease.

P2405 - RIGHT BUNDLE BRANCH BLOCK AS A PREDICTOR OF FAVOURABLE OUTCOME AFTER PERCUTANEOUS PULMONARY VALVE IMPLANTATION

Roman Gebauer, Ingo Daehnert, Thomas Riede, Robert Wagner, Tobias Kister, Matthias Grothoff, Christian Paech
Heart Centre Leipzig, University of Leipzig, Paediatric Cardiology, Leipzig-Germany

Introduction: Recent data showed a right ventricular dyssynchrony in patients with tetralogy of Fallot (TOF). Percutaneous pulmonary valve implantation (PPVI) has become an important procedure to treat a dysfunction of the right ventricular outflow tract in these patients. Despite providing good results, there is still a considerable number of non-responders to PPVI. The authors speculated that electrical dysfunction of the right ventricle plays an underestimated role in the outcome of patients after PPVI. This study aimed to investigate the influence of right ventricular electrical dysfunction i.e. right bundle branch block (RBBB) on the RV reverse remodeling after PPVI in terms of change in indexed right ventricular enddiastolic volume (RVEDV) and right ventricular ejection fraction (RVEDV) measured by cardiac MRI.
Methods: The study included patients after correction of TOF with or without RBBB, who had received a PPVI previously at the Heart Center of the University of Leipzig, Germany in the period from 2012 to 2015. Cardiac MRI and echocardiography were performed directly before and six months to one year after the procedure in all patients.
Results: 24 patients were included. Patients without RBBB i.e. narrow QRS <120 ms had significantly better RVEF (p = 0.002) and had smaller indexed RVEDV prior to intervention compared to patients with RBBB and QRS ≥ 120 ms. Patients with pre-PPVI QRS < 140 ms showed after PPVI statistically significant difference in grade of reverse remodeling of the right ventricle with decreasing RV volumes (RVEDV pre-PPVI 132.6 ± 38.0 ms vs post-PPVI 105.4 ± 25.9 ms [mean ± SD], p = 0.002). The parameters of LV function and volume remained unaffected by RBBB. RV remodeling was only seen in patients with a QRS Duration < 140 ms.
Conclusion: The presented data indicate that the QRS duration seems to be a valuable parameter in the prediction of right ventricular reverse remodeling after PPVI, as it represents both electrical and mechanical function of the right ventricle.

P2429 - PATIENT SATISFACTION WITH AN ADULT CONGENITAL HEART DISEASE OUTPATIENT SERVICE RESULTS OF A RETROSPECTIVE SURVEY OF 178 PATIENTS

Natasha Donald[1], Jane Hill[1], Anna Dinsdale[1], Linda Griffiths[2], Jaspal Dua[1]
Liverpool Hear and Chest Hospital, Adult Congenital Heart Disease Service, Liverpool-United Kingdom[1]; Manchester Heart Centre, Adult Congenital Heart Disease Service, Manchester-United Kingdom[2]

Introduction: In 2016 the NHS England Congenital Heart Disease Review set out standards of care for Adult Congenital Heart Disease (ACHD) services including Domain 4 – ensuring patients have a positive experience of care. This is a vital part of facilitating and maintaining a long term therapeutic relationship with patients who have a chronic illness. It also highlighted the importance of key holistic elements such as provision of information to patients and their families to facilitate a collaborative approach to care, good communication and ease of access to services.
Method: A questionnaire was created comprising 25 questions and a free comment box. The survey was distributed to 178 patients attending an Adult Congenital Heart Disease clinic in a 'hub and spoke' model at Liverpool Heart and Chest Hospital between February 2012 and December 2015. Questions were detailed to assess key aspects of service provision and hoped to explore: Ease of access; Facilities provided; Collaborative care; Patient education and Overall patient experience.
Results: Results showed the ACHD service was very well received with average score of at least 9.7/10. One area of improvement was the availability of the ACHD specialist nurse (only 62.3% saw specialist nurse during their clinic visit) though when this service was available it was valued very highly in terms of courtesy and communication. Another was the provision of information surrounding ease of access to clinic. Only 82% were given information on how to get to the hospital, 62.6% were given information on public transport and 68.4% were given information on parking. All free text comments were positive in nature with common themes including feeling 'reassured' and finding staff 'helpful'.
Conclusion: Overall, this survey showed that the clinic was performing well in its capacity as an important point of contact between patients with long term illness and their healthcare providers.

Question	Yes	No	Unsure	Percentage
1. Were you given information on how to get to the hospital?	146/178	27	5	82
2. Were you given information about parking?	121/177	45	11	68.4
3. Were you given information about public transport?	109/174	50	15	62.6
4. Was it easy to find the outpatient department?	172/177	4	1	97.2
8. Did the doctor listen carefully to what you had to say?	174/175	0	1	99.4
9. Were you given enough time to discuss your condition?	175/175	0	0	100
10. Did the doctor explain your heart condition?	173/175	1	1	98.9
11. Were some tests done on the day?	171/178	7	0	96.1
12. Did the doctor explain about these?	165/174	8	1	94.8
13. Did you have confidence and trust in the doctor?	176/177	1	0	99.4
14. Did the ACHD specialist nurse explain about the service?	107/108	1	0	99.1
15. Did she give you enough time to discuss your condition?	107/108	1	0	99.1
16. Did she listen carefully to what you had to say?	108/109	1	0	99.1

Table 2.

Question	Average Score
17. The courtesy of the ECHO physiologist	9.7
18. The courtesy of the clinic nurse	9.8
19. The courtesy of the doctor	9.8
20. The courtesy of the ACHD specialist nurse	9.8
21. How useful was your visit today?	9.6
22. Do you have more idea and understanding of your heart condition, after today's visit?	9.6
23. Did you feel you were involved as much as you wanted to be in the decisions about your care and treatment?	9.8
24. Overall how would you rate the doctor in terms of knowledge/friendliness and courtesy?	9.9
25. Overall how would you rate today's visit to the ACHD clinic?	9.8

P2527 - OUTCOME OF COMPRESSION OF LEFT CORONARY ARTERY IN PATIENTS WITH SEVERE PULMONARY ARTERIAL HYPERTENSION ASSOCIATED WITH CONGENITAL HEART DISEASES

Jo Won Jung[1], Sang-Eun Lee[2], Jae Young Choi[1], Han Ki Park[3], Young Hwan Park[3], Hyuk-Jae Chang[2]
Severance Cardiovascular Hospital Yonsei University College of Medicine, Pediatric Cardiology, Seoul-Korea, South[1]; Severance Cardiovascular Hospital Yonsei University College of Medicine, Cardiology, Seoul-Korea, South[2]; Severance Cardiovascular Hospital Yonsei University College of Medicine, Pediatric Cardiovascular Surgery, Seoul-Korea, South[3]

Background: Long-standing pulmonary arterial hypertension (PAH) sometimes causes the dilation of pulmonary artery (PA) associated with compression of left main coronary artery(LCA). We explored the outcome related to the risk of sudden cardiac death in patients with PAH.
Method: PAH patients with PA enlargement (≥40 mm) by echocardiography were studied with CT scanning, and had been reviewed with medical records retrospectively.
Results: Total 51 patients (mean age 49 ± 13, 33.3% male) were enrolled. No patient reported exertional chest pain or aggravated dyspnea at the time of study. However, complications associated with PA dilatation were found in 18 patients (35.1%): LCA compression were in 18 of 51(35.1%), almost in patients with CHD (16 of total 18 patients with LCA compression); airway compression, 4 of 51; PA dissection, 1 of 51 ; and thrombus in PA, 4 of 51. Patients with complications had more dilated main PA than patients without complication. The area under the receiver operating characteristic (ROC) curve for main PA diameter measured at LCA-oblique view was 0.878 (95% confidence interval (CI): 0.756 to 1.000, $p < 0.001$) with the highest discriminating sensitivity and specificity being 86.7% and 67.7%, respectively at main PA diameter of 45mm. Of total 16 patients with CHD shown LCA compression in CT, only 4 patients revealed critical compression of LCA in coronary angiography. One patient with severe LCA compression underwent invasive coronary angiography and received angioplasty with stent placement at the os of main LCA. In the others, open heart surgery for angioplasty of PA reduction had done successfully.
Discussion: The complications of PA enlargement related to long-standing PAH was high. Evaluation of LCA using CT scanning should be considered in PAH patients with dilated PA to prevent sudden cardiac death in regular follow-up.

P2532-40 YEAR FOLLOW UP OF PATIENTS WITH CRITICAL AORTIC STENOSIS CROSS SECTION IMAGING AND FUNCTIONAL STATUS

Beatrice Bonello[1], Michelle Carr[1], Xavier Iriart[2], Martin Kostolny[1], Victor Tsang[1], Catherin Bull[1], Marina Hughes[1], Georgi Christov[1], Alessandro Giardini[1], Marek Jan[1]
Great Ormond Street Hospital, Peadiatric Cardiology, London-United Kingdom[1]; Bordeaux University Hospital, Peadiatric Cardiology, Bordeaux-France[2]

Background: Survival with congenital critical aortic valve stenosis (CAS) can be successfully achieved by surgical or catheter interventions. Long term outcome however remains uncertain.
Methods and Results: We performed a 40 year (1970-2010) review of 96 patients, requiring intervention for neonatal (<30 days) CAS. Surgery was undertaken in 61 patients and balloon dilation in 35 patients. Follow-up data was available for 88 patients. There were 29 (32.9%) reported deaths, of which 19 (19.8%) <90 days after intervention. Overall survival rate at 1, 5, 10, 15 and 20 years was 73%, 71%, 71%, 66%, and 66% respectively. Of the 67 survivors, 53 (79%) had at least one re-intervention and 21 (31%) had more than one re-intervention. Twenty-five patients were further assessed in our centre. Median age was 15.7 ± 6.4 years. Mean peak VO2 was 32.1 ± 8.2 ml/kg/min, peak VO2 was abnormal in all but one patient (96%) and severely depressed in 13 patients (56%). Mean left ventricle (LV) ejection fraction was 65.5 ±11.22% and mean LV end-diastolic volume was

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

79.96 ±17 ml/m2, Z score 0.02 ±1.4. Mean LV outflow tract Vmax was 2.27 ±1.17 m/s. Four patients (16%) had moderate aortic regurgitation. Five patients (20%) had severe LV diastolic dysfunction measured echocardiographically and confirmed by invasive measurement. Mean right ventricular outflow gradient was 19.23 ± 23.57 mmHg. Focal endocardial fibroelastosis (EFE) identified on echocardiography (n = 13, 52%) correlated with focal EFE assessed by MRI (r = 0.61, p = 0.009) but not with late gadolinium enhancement (r = 0.453, p = 0.0677). EFE was associated with early Ross intervention (r = -0.52, p = 0.0324) and diastolic LV dysfunction (r = -0.48, p = 0.0164).
Conclusions: Long-term follow-up of patients with CAS showed a high rate of mortality and re-interventions. Reduced exercise capacity, left ventricle diastolic dysfunction and EFE remain a concern long-term after initial procedure. EFE is associated with poor outcome.

P2537 - A NEW CHALLENGE FOR ADULTS WITH CONGENITAL HEART DISEASE THE PSYCHOSOCIAL APPROACH IN CARDIAC REHABILITATION

Edward Callus[1], Emilia Quadri[1], Silvana Pagliuca[1], Enrico Giuseppe Bertoldo[1], Giulia Trovato[1], Lorenzo Menicanti[2], Massimo Chessa[3], Alessandro Giamberti[4], Mario Carminati[3], Roberto Tramarin[5]
I.R.C.C.S. Policlinico San Donato, Clinical Psychology Service, San Donato Milanese (MI)-Italy[1]; I.R.C.C.S. Policlinico San Donato, Cardiac Surgery, San Donato Milanese (MI)-Italy[2]; I.R.C.C.S. Policlinico San Donato, Pediatric and Adult Congenital Heart Center, San Donato Milanese (MI)-Italy[3]; I.R.C.C.S. Policlinico San Donato, Congenital Cardiac Surgery Unit, San Donato Milanese (MI)-Italy[4]; I.R.C.C.S. Policlinico San Donato, Perioperative Cardiology and Cardiac Rehabilitation, San Donato Milanese (MI)-Italy[5]

Background/Hypothesis: Currently there are no precise guidelines about cardiac rehabilitation for adults with congenital heart disease (ACHD) even though there are indications about the possible benefits from their participation to such programs.
Materials: ACHD attending a rehabilitation program were evaluated when it comes to the psychosocial aspects, relevant to cardiovascular risk. This included biographic and lifestyle data, health perception (EuroQol) quality of life, anxiety and depression (Hospital Anxiety and Depression Scale HADS). The medical variables considered were: Six Minute Walk Test (6MWT) (at hospitilisation and discharge), Ejection Fraction, NYHA Index and diagnostic category.
Methods: The questionnaires were administered to 22 patients (16 females, age range 17-65, average age 41,36) at admittance and the EuroQol and HADS were also re-administered at discharge.
Results: An indication of improvement in health perception (EuroQol) was observed (average 54,74 SD 16,11 to 85,9 SD 13,43). Anxiety and depression levels at admittance were mostly in the normal range and they correlated strongly with one another (r = 0,63; p < 0,01). There was an improvement in anxiety in 81% and in depression in 67% of the cases. Belonging to the severe condition group correlated positively with more anxiety both at admittance (r = 0.434; p = 0.44) and discharge (r = 0.51; p = 0.17). When it comes to the 6MWT, the results improve in all pts with complete data (19 pts, average 394.14 SD 111,45 to 495,00 SD 102,89). A negative correlation was found between the initial 6MWT and depression (r = -0.46; p = 0.04). Also the Ejection Fraction correlated negatively with anxiety (r = -0.51; p = 0.02) and depression at admittance (r = -0.47; p = 0.04). At discharge an association was found between EuroQol and the 6MWT (r = 0,53; p < 0,05)
Conclusions: Further studies are necessary to establish cardiac rehabilitation programs which are aimed at these patients and to explore the variables connected to their psychosocial wellbeing.

P2555 - CARDIAC SURGERY FOR GROWN UP CONGENITAL HEART DISEASE A 12 YEAR RETROSPECTIVE FROM A TRANSITIONAL COUNTRY

Liesl Zuhlke[1], Nazaakat Guzgay[2], Paschale Saneka[2], Paul Human[3], Tim Pennel[3], Blanche Cupido[4], Brooks Andre[3]
Red Cross War Memorial Childrens Hospital, Paediatric Cardiology, Cape Town-South Africa[1]; University of Cape Town Medical School, Medical Student, Cape Town-South Africa[2]; Groote Schuur Hospital, Chris Barnard Division of Cardiothoracic Surgery, Cape Town-South Africa[3]; Groote Schuur Hospital, Cardiac Clinic Department of Medince, Cape Town-South Africa[4]

The remarkable advancements in both paediatric and adult cardiology and cardiac surgery over the past decades have resulted in an increased number of grown-ups with congenital heart defects (GUCH). This set of patients pose unique challenges and requires specialist care particularly in a transitional country. Surgical records can indicate the need for a comprehensive GUCH programme.
Study Design: We conducted a retrospective review of GUCH patients who have undergone surgery at the Groote Schuur Hospital's Chris Barnard division of cardiothoracic surgery between 1 January 2003 and 30 June 2015. We reviewed at the surgeries performed, the most common congenital heart lesion as well as the mortality rate.
Results: There were 109 cases identified as having surgery for GUCH in the 10 year study period. 61% of surgeries were performed on females and 39% on males. The largest proportion of patients, 36 patients (33%), were between 20-29 years old and the smallest proportion, 5 patients (5%), were between 50-59 years old. The majority of patients, 100 patients (92%) had corrective surgery, and 9 patients (8%) had palliative surgery.Mortality rate was 4%. The median age at death was 49. More than half, 63 (58%) of the surgeries were performed by congenital surgeons, 80 patients (73%), live in the Western Cape. The most common lesions were septal defects, seen in VSD (9%), ASD (49%), AVSD (15%), and Tetralogy of Fallot (11%). Of interest, despite the established cardiac surgery programme in the province, 92 patients (87%), had their first surgery in adulthood.
Conclusion: In conclusion, this study has shown that many people in a developing country only present for the first time in adulthood, especially with non-critical CHD lesions. The mortality rate in adulthood is low but a comprehensive GUCH service in our province with specialist teams, is needed to focus on this patient population.

P2561 - FACTORS EFFECTING QUALITY OF LIFE IN ADULTS WITH CONGENITAL HEART DISEASE IN JAPAN

Yoshiko Mizuno[1], Junko Enomoto[2], Shigeru Tateno[2], Hiroko Morishima[2], Yoshitomo Okajima[2], Yasutaka Kawasoe[2], Fumie Takechi[2], Koichiro Niwa[3]
Chiba Cerebral and Cardiovascular Center, Department of Nursing, Chiba-Japan[1]; Chiba Cerebral and Cardiovascular Center, Department of Adult Congenital Heart Disease, Chiba-Japan[2]; St Luke's International Hospital, Department of Cardiology, Tokyo-Japan[3]

Background: International research has reported that lower quality of life (QOL) in adults with congenital heart disease (CHD) is

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

associated with older age, lack of employment, never being married, and low New York Heart Association (NYHA) functional classification. However, there has been a lack of research in Japan. [Objectives] We aimed to determine the factors that affect QOL in adults with CHD in Japan.
Methods: CHD patients aged ≧ 18 years were included. We mailed self-report questionnaires that assessed factors including QOL (assessed on a linear analog scale), previous medical diagnoses, medical treatments, subjective symptoms, employment status, marital status, and age, et al.
Results: The sample consisted of 253 respondents (Response rate was 50.6%). 115 (45.5%) of which were male. Mean age was 36.4 years old. (SD 15.1). Mean QOL was 70.73 (±10.73 (1/2 SD) = 60.00, 81.46). Also we classified subjects into two groups based on QOL score (QOL < 60: low group, QOL >82: high group), and compare them on outcome variables. Low group included 69 cases, High group included 82 cases. The two groups did not significantly differ on the following factors: numbers of previous operations, age, sex, or past psychiatric disorders ($P > 0.05$). However, the low group had a higher number of hospital admissions ($P < 0.05$) and a significantly worse NYHA functional class ($P < 0.01$) than the high group. Further, fewer low group patients were married and a greater number were unemployed than high group participants ($P < 0.01$ for both).
Conclusion: The QOL of Japanese patients also associated with lack of employment, never being married and low NYHA functional class as international study, however, their age didn't relate with them. The QOL of patients having a higher number of hospital admissions were worse. We need to consider effects of their admissions and support.

P2587 - THE EFFECTIVENESS OF THE ECHOCARDIOGRAPHIC INDICES AS A METHOD OF ASSESSING THE CARDIAC FUNCTION IN ADULT PATIENTS WITH FONTAN CIRCULATION

Kohsaku Goto[1], Naoto Kawamtsu[2], Terunobu Fukuda[2], Mahbubur Rahman[3], Yumi Shiina[2], Yasufumi Kijima[2], Nobuyuki Komiyama[2], Koichiro Niwa[4]
St Luke, Department of Clinical Training, Tokyo-Japan[1]; St Luke, Cardiology, Tokyo-Japan[2]; St Luke, Epidemiology, Tokyo-Japan[3]; St Luke, Cardiovascular Center, Tokyo-Japan[4]

Background: Utility of quantitative echocardiographic assessment of left ventricular function in patients with normal heart structure have been recognized for the decision making. However, there is no useful quantitative echocardiographic index for the assessment of systemic ventricular (SV) function in patients with Fontan circulation. Therefore, SV function has been evaluated by visual grading in the clinical setting. In this study, we investigate to find out reliable echocardiographic indices which are well related with visually assessed SV function in Fontan patients.
Methods: Thirty Fontan patients (mean age 26 ± 7 years, 14 males, right ventricle (RV) in 15, left ventricle (LV) in 15) whose recorded echocardiographic images were acceptable to analyze were included and SV function were retrospectively analyzed. Following quantitative indices were analyzed: Fractional area change (FAC), Tricuspid (mitral) annular plane systolic excursion (TAPSE or MAPSE), tricuspid valve S' or mitral valve S', Global Longitudinal Strain (GLS), Global Circumferential Strain (GCS). Visual assessment of SV function was performed by two expert doctors and classified into two groups, good or reduced. Measured values were compared between visual and quantitative assessments. Receiver operating characteristic (ROC) analysis was also conducted to assess the diagnostic value of echocardiographic indices.
Results: Quantitative indices were not statistically different between visually classified groups in the single LV patients, but GCS was relatively low in visually reduced group (table). In the single RV patients, GCS was statistically lower in visually reduced group. The optimal cutoff value for GCS in ROC curve was -22% (sensitivity 89%, specificity 100%).
Conclusion: We find GCS was correlated with visually assessed SV function, particularly in single RV patients. We unconsciously assessed severity of SV function by the circumferential contraction rather than the longitude contraction in Fontan patients.

P2588 - SCIMITAR SYNDROME REVISITED

Jaspal Dua, Natasha Donald
Liverpool Heart and Chest Hospital, Adult Congenital Heart Disease, Manchester-United Kingdom

Background: Scimitar syndrome is a rare congenital disorder in which there is anomalous pulmonary venous drainage and lung hypoplasia occurring almost exclusively on the right side. In patients with a small left to right shunt management is symptomatic. In more severe cases management is surgical via re-implantation of the scimitar vein into the left atrium or insertion of an intra-atrial baffle. This syndrome encompasses a wide spectrum of presentations sometimes influenced by the presence of other congenital cardiac co-morbidities.
Methods: This case series explores the progress of three patients with Scimitar Syndrome within a single Adult Congenital Heart Disease centre over the course of seven years using data obtained from clinic letters and imaging servers. They include one male patient, age 71, and two female patients aged 26 and 40 all with right sided Scimitar veins. Their co-morbidities, presentations and treatment outcomes were outlined along with experiential commentary derived from clinic letters and the physicians involved in their care.
Results: Whilst breathlessness and initial respiratory complaints were a common theme, timing of diagnosis differed greatly. Two patients were diagnosed in infancy, the other aged 64.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

One infant diagnosis was lost to follow up for twelve years between paediatric and adult services. The late diagnosis differed in the presence of a small patent foramen ovale and required treatment with surgical intervention. The younger medically managed patients both had reassuring CPEX and 24 hour tape results, but differed greatly in their experience of symptoms and treatment plan.

Conclusions: This case series provides good examples of the broad range of presentations and outcomes in Scimitar Syndrome. It also highlights differences in patient approach to their condition; lack of correlation between clinical severity and experience of symptoms; and the importance of acknowledging this along with the challenges of continuity of care between

P2593 - RECOARCTATION OF AORTA AFTER NORWOOD PROCEDURE IN CHILDREN WITH HYPOPLASTIC LEFT HEART SYNDROME INCIDENCE RISK FACTORS MIDTERM OUTCOME

Aleksander Szypulski, Julita Sacharczuk, Aleksandra Morka, Tomasz Mroczek, Elżbieta Wójcik, Jerzy Jarosz, Janusz Skalski
University Children Hospital, Pediatric Cardiac Surgery, Cracow-Poland

Background: Recoarctation of the aorta is complication after the Norwood procedure. Undiagnosed and untreated, it may lead to failure of the systemic ventricle and death. The main objective of this study is to analyze the incidence of recoarctation in our center, define risk factors and determine the outcome of patient after balloon angioplasty.

Materials and Methods: We retrospectively reviewed the records of 96 successive patients with hypoplastic left heart syndrome that underwent the Norwood (NP) procedure between 2008 and 2010. Pre-, intra, postoperative, echocardiography and angiography data were analyzed.

Results: Significant recoarctation was noted in 23 patients (32.3%) on the average of 95.1 days (49-156 days) after the NP. The ejection fraction of the right ventricle on echocardiography was decreased in the patients with coarctation as compared to the patients without recoarctation the mean decrease was 9% ($p < 0.05$). All the patients underwent percutaneous balloon angioplasty, which led to a decrease in the mean gradient at the site of narrowing from the average of 27.5 mmHg to 9.7 mmHg ($p = 0.008$) and enlarged the neoisthmus by the average of 2mm (0.7–4.5 mm) ($p < 0.05$). None of the patients needed a surgical procedure. The diameter of the ascending aorta - OR = 7.82 (95% CI [2.45-29.2]) ($p = 0.001$), atresia of the mitral valve - OR = 7.00 (95% CI [1.76-32.1]) ($p = 0.003$) and atresia of the aortic valve - OR = 6.22 (95% CI [1.69-29.4]) ($p = 0,002$) showed the highest risk of recoarctation. In the recoarctation group, the 6-year follow up was 88%, and we observed only one death before Fontan procedure.

Conclusion: An early diagnosis of recoarctation prevents the occurrence of life-threatening complications between the first and the second stage of HLHS. Balloon angioplasty is an effective intervention for treatment. In our observations, some risks factors seem to have an impact on recoarctation. Recoarctation does not increase the interstage mortality.

P2610 - PRIMARY CARE OF HEART FAILURE ARRHYTHMIAS PULMONARY HYPERTENSION AND COMORBIDITIES IN ADULTS WITH CONGENITAL HEART DEFECTS

Rhoia Neidenbach[1], Nora Lang[1], Lars Pieper[2], Linda Sanftenberg[3], Renate Oberhoffer[1], Jörg Schelling[3], Alexey Trepakov[1], Nicole Nagdyman[1], Peter Ewert[1], Harald Kaemmerer[1]
German Heart Centre Munich, Department of Pediatric Cardiology and Congenital Heart Defects, Munich-Germany[1]; Technical University of Dresden, Department of Behavioural Epidemiology, Dresden-Germany[2]; University Hospital of The Ludwig-Maximilians-University Munich, Institute For General Practice, Munich-Germany[3]

Background: Due to medical advances, the number of adults with congenital heart defects (ACHD) in Germany has approached 280,000. Many have chronic cardio-vascular disorders with negative effects on morbidity and mortality, including particularly heart failure, arrhythmias, pulmonary hypertension (PAH) and impeding comorbidities. Nevertheless, clinical experience shows, that in Germany more than 200.000 ACHD are not treated by

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

certified specialists. The focus of this study is to demonstrate "real life" primary care of ACHD and their emerging cardiac and non-cardiac comorbidities in Germany.
Methods and Results: A questionnaire-based survey of 116 ACHD (48.3% female, mean age 34.8 ± 12.5 years) and 126 general practitioners (GP) (35.7% female, mean age 54.6 ± 9.1 years) was analysed. GP's deal with all types and severity grades of CHD, in 58% even with moderate and severe forms. ACHD consult their GPs not only for non-cardiac problems or comorbidities. Even in cardiac-related problems, more then 70% consult their GP first. GPs report to manage arrhythmias in 47%, heart failure in 48% and PAH in 22% of their consulted ACHD. More than 30% of the GPs indicate to miss sufficient support concerning specific ACHD management, e.g. regarding heart failure, PAH or anticoagulation. Frighteningly, 63.5% of the GP's are uninformed about the existence of certified ACHD-facilities, physicians and also rarely about ACHD-support groups. Although suffering from the mentioned serious problems in 41.1% ACHD are also uninformed about specific medical facilities, and ACHD-support groups (44%).
Conclusions: GPs and ACHD lack of specific disease related knowledge and skills. Both are insufficiently informed about related medical problems, about certified ACHD-facilities and patient-support groups. Better awareness and a stronger cooperation between certificated CHD-specialists and GPs as well as a better education of patients is therefore a future goal to provide adequate medical supply in order to reduce morbidity and mortality of ACHD.

P2623 - THE GROUP PROGRAM FOR PATIENTS OF TRANSITIONAL AGE

Sachiko Kido
Kobe Children, Cardiology, Kobe, Hyogo-Japan

Many textbooks and papers state that the education for patients is one of the most important issues for transition. In 2011 AHA published the scientific statement about transition and we got some guidelines for educating them, however, it is rather difficult to practice all of them. From 2010 we hold the group programs to educate young patients. The purpose of these programs is giving them the chance to talk about themselves to others and to feel and understand their own body through the experience-based learning. We plan two or three programs every year. Each program has each topic, such as sex activity and pregnancy, sports for young patients with heart disease, how to behave at school and making 'my own chart'. We select attendees taking the topic, patients' age and the type and severity of their disease into accounts. In this program, we try to shorten the time of lectures and let them talk, do exercise, play cards about their medications, experience examinations as a technician, fill their own chart by themselves or do role-playing. Over 95% of attendants feel that such programs help their understanding about their disease. Some parents say that these programs give them the chance to exchange opinions with their children about their lives and future. Some patients continue to fill a new page of their own charts at out-patients' clinic. On the other hand, it is revealed that these programs have some difficulties. Some patients whom we especially hope to attend the program are not interested in such a program. Some patients feel that it is too early to learn about sex activity and pregnancy. However we are sure that continuing the group program will help young patients' understanding about their disease and lead them to go up the stairs of transition.

P2626 - THE FATE OF RESIDUAL SHUNT IN TRANSCATHETER CLOSURE OF MULTIPLE ATRIAL SEPTAL DEFECTS

Jung Yoon Kim, Se Yong Jung, Ah Young Kim, Jo Won Jung, Jae Young Choi
Congenital Heart Disease Center, Severance Cardiovascular Hospital, Yonsei University College of Medicine, Division of Pediatric Cardiology, Seoul-Korea, South

Background: Clinical outcomes and fate of residual defects after device closure of multiple ASDs in various defect anatomies has not been clearly documented.
Methods: Patients with transcatheter closure of multiple ASDs from 2005 to 2015 were reviewed (224 patients; 17.2% of total 1295 procedures). Subjects were divided into 4 groups; Group I (n = 118, 52.6%): two nearby defects, Group II (n = 52, 22.3%): two discrete/distant defects, Group III (n = 45, 20%): multiple (≥ 3) defects, Group IV (n = 9, 4%): multi-fenestrated defects. Patients' and procedural parameters, outcomes and closure rate during follow-up were investigated.
Results: Patients' median age was 22.9 years and mean follow-up (FU) duration was 62 ± 14 months. Procedural success rate was 99.5%, 2 major complication (0.9%; 1 device embolization, 1 complete heart block) and 4 minor complications (1.8%) occurred. Overall, the residual shunts tended to reduce in size or close spontaneously with time. Complete closure rates after procedure and at last FU in each group were as follows; group I – 84,7% and 98%, group II – 9.6% and 90%, group III – 11.1% and 92%, group IV – 10.3% and 87.5%. A hundred sixteen (98%) in Group I and 44 (84.6%) in Group II patients were treated using a single device. In these groups, complete closure was related with use of oversized device. In Group III, mean 1,4 devices were used. (2 devices in 12 patients, 3 devices in 3 patients) All the residual shunts were small (≤3 mm) without hemodynamic significance.
Conclusion: Transcatheter closure is an effective and safe therapeutic option in patient with multiple ASDs. Small residual shunt tends to reduce in size or closed spontaneously according to the FU duration. Use of a slightly oversized device may facilitate complete closure rate in patients especially with 2 defects treated by a single device.

P2629 - BODY MASS INDEX AND CO MORBIDITIES IN A COHORT OF ADULT FONTAN PATIENTS

Robert Elder[1], Nikhil Sikand[2], Abigail Simmons[1], Nancy Rollinson[3], Alan Friedman[3], John Fahey[3]
Yale University School of Medicine, Pediatrics/Internal Medicine, New Haven-United States[1]; Yale University School of Medicine, Internal Medicine, New Haven-United States[2]; Yale University School of Medicine, Pediatrics, New Haven-United States[3]

Background: The Fontan procedure is palliative for patients with functionally univentricular hearts. Though obesity is prevalent among children with congenital heart disease (CHD), children post-Fontan are thought to have lower rates of obesity compared to other CHD groups. Whether that remains true in adults is unknown.
Methods: A retrospective review was conducted of adult Fontan patients seen at Yale-New Haven Adult Congenital Heart Program since 2013. Clinic records were reviewed for surgical and medical history. Body mass index (BMI) was calculated from height and weight at most recent visit. Overweight/obese patients (BMI >25) were compared to non-obese group.
Results: 44 patients (29.5 yrs, 18-55) were reviewed, 20 (45%) of which were female. Mean time since Fontan operation was 23.6

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

yrs (5-37). There were 24 lateral tunnel, 10 atriopulmonary and 10 external conduit Fontan operations. Using National Heart, Lung and Blood Institute classification system for BMI, 6 patients (13.6%) were underweight (<18.5), 13 (29.5%) were normal weight (18.6-24.9), 14 (31.8%) were overweight (25.0-29.9), 6 (13.6%) had Class I Obesity (30.0-34.9), 3 (7%) had Class II Obesity (35.0-39.9) and 2 (5%) had Class III extreme obesity (>40.0). The BMI range was 16.5-58.9, median was 26.3. Overweight/obese Fontan patients used more anti-hypertensive medications than non-obese group, 1.04 vs. 0.63, $p = 0.019$. One patient developed Type 2 diabetes and one underwent sleeve gastrectemy for morbid obesity. For the sub-set with recent catheterization ($n = 23$), there were no significant differences for mean wedge or Fontan pressure between the two groups.
Conclusions: In a cohort of adult Fontan patients, less than 1/3 are in a healthy BMI range. 54% were overweight or obese. Use of anti-hypertensive medications was higher in obese Fontan patients. Given the risk for development of co-morbidities, adult Fontan patients may benefit from closer monitoring for complications along with targeted weight loss interventions.

P2646 - VENTRICULAR RESPONSE TO DOBUTAMINE STRESS IS A PREDICTOR FOR OUTCOME IN PATIENTS WITH REPAIRED TETRALOGY OF FALLOT

Eva Van Den Bosch[1], Judith Cuypers[2], Saskia Luijnenburg[1], Jochem Van Den Berg[1], Nienke Duppen[1], Eric Boersma[2], Jolien Roos-hesselink[2], Willem Helbing[1]
Erasmus MC, Sophia Children's Hospital, Department of Pediatric Cardiology, Rotterdam-The Netherlands[1]; Erasmus MC, Department of Cardiology, Rotterdam-The Netherlands[2]

Background: Outcome after the surgical correction of tetralogy of Fallot (ToF) is good. However, severe pulmonary regurgitation (PR) and progressive right ventricular (RV) dilatation and dysfunction are frequent causes of late morbidity and even mortality. Optimal timing of pulmonary valve replacement (PVR) for severe PR remains difficult. Evaluation of left and right ventricular function using exercise or pharmacological stress cardiac magnetic resonance imaging (CMR) has been advocated as a tool to reveal impending cardiac dysfunction. Several studies have shown that patients with ToF have abnormal RV stress response. Our aim was to evaluate the prognostic value of dobutamine stress CMR in ToF patients.
Methods: Between 2002 and 2012 Fallot patients prospectively received low dose dobutamine (7.5 µg/kg/min) stress CMR. Cardiac events (reintervention, arrhythmias or cardiac death) during follow-up were recorded. Time-to-event analyses (Kaplan-Meier method) and Cox proportional hazard regression analysis was performed to determine the predictive value of dobutamine stress CMR.
Results: 86 patients (55 male, median age 19.5 (7.4-49.3) years) underwent stress CMR. Overall indexed left and right diastolic volume decreased during stress (RVEDVi from 130.5 ± 41.7 ml/m^2 (rest) to 125.6 ±14.3 (stress) and LVEDVi from 79.3 ±12.9 (rest) to 76.6 ±40.2 (stress)) and right (RVEF) and left (LVEF) ejection fraction increased. After a median follow-up of 11.1 years 33 patients (38%) developed an event The event-group showed a significantly lower increase in RVEF fraction during stress (right ventricular reserve) compared to the non-event-group ($9.2 \pm 3.8\%$ vs $12.6 \pm 6.1\%$, $p = 0.002$). Multivariate Cox regression analysis showed right ventricular reserve (HR 0.88; 95% CI 0.82-0.94 ; $p < 0.001$) and RVEF at rest (HR 0.90; 95% CI 0.85-0.95; $P < 0.001$) to be associated with risk of an event, corrected for age.
Conclusion: Right ventricular response to dobutamine stress seems to be an additional predictor for events in patients with repaired ToF.

Kaplan-Meier curve for event-free survival.

P2660 - PER CUTANEOUS PULMONARY VALVE IMPLANTATION OUR EXPERIENCE

Ramya Shri Chandrasekaran, Amol Gupta, Sivakumar Kothandam
MMM, Pediatric Cardiology, Chennai-India

Background: Corrective surgery for heart diseases with valve conduits needs redo surgeries for replacement of failing conduits. Percutaneous pulmonary valve implantation (PPVI) into these failing conduit is less morbid alternative to surgery.
Method: Patient's demography,symptoms,echo,cardiac MRI and other imaging modalities were analyzed.PR defined by color Doppler and MRI, RV dysfunction and dilatation assessed by echo and MRI.Balloon sizing of the RVOT and simultaneous coronary angiography performed.PPVI done using 22mm straight and 34mm flare designed self-expanding porcine transcatheter valve. After deployment valve function is assessed by echo, hemodynamic data,and angiography.On follow up patients reassessed with echo at regular intervals within first year and cardiac MRI at 6 months and 1 year to assess the competency of valve.
Results: PPVI was performed successfully in 6 patients with a median age of 24.1(12-37) years and median weight of 46.25 (41.6-77) kg.The majority had Tof with pulmonary atresia (n 5), post Ross procedure (n 1).conduit was bovine pericardial valved conduit in 1,aortic homograft in 3, PTFE conduit with pericardial monocusp in one.1 patient had native RVOT repaired by transannular patch.Interval between surgery and PPVI was 5-17 years, RVOT stenting performed before PPVI with a stainless steel (n 3) & platinum iridium stents (n 2) .Except 1 patient with 34mm flare design venus P valve, rest of the patients had 22mm straight cell venus P valve was implanted. No procedural complications Follow up was 7 to 810 days with median of 180 days.Cardiac MRI was performed Post PPVI in 2 patients, in others MRI was contraindicated due to previous RVOT stenting. It showed fall in RVEDVi (from 135.5 to 94.56.ml/m2) and PR RF (from 28.516.2 to 53.53).
Conclusions: PPVI resulted in the ability to avoided multiple surgical right ventricular outflow tract revisions.

P2665 - A WOMAN OF POLYSPLENIA WHO RECOVERED FROM CYANOSIS CAUSED BY PULMONARY ARTERIOVENOUS MALFORMATIONS WITH THE RECONSTRUCTION IN 15 YEARS AFTER THE FIRST TCPC OPERATION

Minako Hoshiai[1], Hiroaki Kise[1], Takako Toda[1], Keiichi Koixumi[1], Shigeru Tateno[2], Kozo Matsuo[3]
University of Yamanashi, Pediatrics, Yamanashi-Japan[1]; Chiba Cerebral and Cardiovascular Center, Pediatrics, Chiba-Japan[2]; Chiba Cerebral and Cardiovascular Center, Cardiovascular Surgery, Chiba-Japan[3]

Background: Pulmonary arteriovenous malformation (PAVM) is one of the major complications in the patients operated with the staged approach to total cavoplumonary connection (TCPC). We report a polysplenia syndrome woman who required surgery intervention again because of the cyanosis progressed rapidly, 15 years after the first TCPC.
Case: She was 18 years old. The diagnoses of her heart anomaly complex were single ventricle, pulmonary stenosis, left side superior vena cava, interrupted of the inferior vena cava with hemiazygos vein continuity. She had a TCPS (LSVC-LPA connection) operation at 16 months old and had TCPC which was hepatic vein and right pulmonary anastomosis at 3 months for 2 years old. The desaturation in her was aggravated rapidly at 16 years old, and her status became to NYHA III because of PAVM in left lung in 15 years after the first TCPC. We considered the effective way for hepatic vein flow influx into LPA. Then, we connected the conduit from hepatic vein to right side innominate vein, for mixing of all venous return. The 3-month follow-up data supported this choice with a clear improvement in the overall clinical condition and oxygen saturation levels that had increased from 72% to 91%, implying regression of the PAVMs.
Discussion and Conclusion: The pathophysiology of PAVM is lack of hepatic factor in pulmonary artery because without hepatic direct perfusion in TCPC. This case had passed from the first TCPC for a long time, but the cyanosis improved in a short period from this operation. Praus et al reported that the only hepatic venous blood closed PAVMs after cavopulmonary connection, Even the case which has passed a long period from the first TCPC operation in the first time like this case considers a re-operation to PAVM aggressively.

P2669 - CARDIAC REMODELING AFTER PERCUTANEOUS CLOSURE OF ATRIAL SEPTAL DEFECT IN ADULTS AN ECHOCARDIOGRAPHIC STUDY WITH NEW TECHNIQUES

Danielle Rocha[1], Carlos Augusto Pedra[1], Simone Pedra[1], Jorge Assef[2], Valmir Fontes[1]
Dante Pazzanese Institute of Cardiology, Pediatric Cardiology, Vitoria-Brazil[1]; Dante Pazzanese Institute of Cardiology, Ecocardiography, Sao Paulo-Brazil[2]

Introduction: The atrial septal defect of the secundum type (ASD)is a frequent congenital heart disease,being the most commonly encountered in the adult population. New echocardiographic techniques have been employed to assess the dimensions, geometry and function of the cardiac chambers. Objectives: Hypothesizing that percutaneous closure,results in a fast cardiac remodeling even in adults with chronic volume overload of the right chambers. Our aim was to assess the temporal pattern of cardiac remodeling and analyse possible differences between patients of different age groups and different ASD sizes.
Material and Methods: This was a study of a cohort of twenty nine adults submitted to percutaneous closure of the ASD with the Cera device followed along a year. Cardiac remodeling was assessed by various echocardiographic techniques. Bidimensional echocardiography was used to measure the dimensions of the right atrium (RA), right ventricle (RV) and left ventricle (LV), to determine the fractional area of the RV (FAC), and to analyse the volumes of the cardiac chambers. Three-D echo was employed for volumetric and functional analysis of the RV. Acoustic speckle tracking was utilized to assess the function of the RA, RV and LV.
Results: The ASD dimension and the size of the device was a mean of $20{,}2 \pm 5{,}0$ mm and $22{,}9 \pm 6{,}2$ mm, respectively. After the procedure, there was an early reduction of the RA (<0.001) and RV (<0.001) sizes and an increase of the LV dimensions ($p < 0.014$). There were no significant changes in the function of the RA as assessed by longitudinal strain ($p = 0.227$ for the P wave and $p = 0.124$ for the T wave). There was an abrupt reduction of the RV function assessed by longitudinal strain ($p = 0.002$) and 3D echo ($p = 0.084$). There was an immediate decrease in the RV stroke volume ($p < 0.001$) and an increase in the LV stroke volume ($p = 0.027$). There was an immediate increase in the LV function as assessed by the Simpson method ($p = 0.052$) and a reduction in its longitudinal strain ($p = 0.049$).
Conclusions: Percutaneous closure of the ASD in middle aged adults results in fast cardiac remodeling sustained results over the first year of follow up.

P2678 - SURGICAL REPAIR OF VENTRICULAR SEPTAL DEFECT IN ADULTS OUTCOMES AND INDICATION

Sungkyu Cho, Chang-Ha Lee, Eun Seok Choi
Sejong General Hospital, Department of Cardiac Surgery, Bucheon-Korea, South

Objectives: Outcome data of VSD (ventricular septal defect) closure in adults on which to base recommendations are limited. We sought to review our experience with surgical VSD closure in adults
Methods: We retrospective reviewed 126 patients (mean age 33.7 ± 12.5, 77 male) who underwent surgical VSD closure (1996 to 2016)
Results: VSDs were classified according to the Society of Thoracic Surgeons as type 2 (n = 58, 46.0%), type 1 (n = 49, 38.9%), and type 4 (n = 19, 15.1%). Aortic cusp prolapse (n = 49, 38.9%), aortic regurgitation (AR) (n = 33, 26.2%), Qp/Qs ratio ≥ 2 (n = 22, 17.5%), pulmonary hypertension (n = 15, 11.9%), left ventricular volume overload (n = 14, 11.1%), sinus of Valsalva rupture (n = 11, 8.7%), and infective endocarditis (n = 9, 7.1%) were indications for closure. Aortic valve repair and aortic valve replacement were performed in 20 patients and 5 patients, at the same time of VSD closure. Mean follow-up duration was 4.6 ± 4.2 years. One patient, who underwent VSD fenestration after VSD closure due to severe pulmonary hypertension, died postoperatively cause of pneumonia and septic shock. Reoperation included aortic valve replacement in 2 patients, repair of residual defect in 2 patients, and VSD fenestration in 1 patient, described as above. At 10 years, freedom from of reoperation was $91.6 \pm 4.3\%$. Late moderate AR developed in 7 patients at mean 5.5 ± 2.6 years (5 of 7 received aortic valve repair at VSD repair). Preoperative greater than moderate AR was risk factor for late moderate AR in univariate analysis ($p = 0.002$).
Conclusions: VSD closure in adults was performed with low mortality and morbidity. We consider that VSD with aortic valve deformity or AR should be treated aggressively before progressing.

P2716 - PULMONARY VEIN STENOSIS A SYNOPSIS OF A CASE MANAGED IN COMPARISON TO CONTEMPORARY LITERATURE

Venkatram Subramanian, Arun Karunakaran, Ashish Shah, Petra Jenkins, Jaspal Dua, Heiko Schneider
Central Manchester NHS Foundation Trust, Cardiology, Manchester-United Kingdom

Background: This report describes the successful treatment of pulmonary vein stenosis which arose as a complication successful catheter ablation of atrial fibrillation.
Methods and Results: Clinical and operative notes of a patient managed for Pulmonary Vein stenosis in Manchester Royal infirmary with comparison of similar cases and review of literature regarding the management of Pulmonary vein stenosis. Pulmonary vein stenosis following ablation of atrial fibrillation is a known complication. Development of pulmonary vein stenosis resulted in significant rise in pulmonary artery pressures and pulmonary hypertension. Patient had dyspnoea on exertion limiting daily activities significantly. Echo cardiogram followed by CMR and right and left heart catheter was performed confirming the diagnosis. The Left pulmonary vein showed severe stenosis and therefore offered stenting of pulmonary vein. Although balloon angioplasty only resulted in mild improvement in pulmonary artery pressures subsequent pulmonary vein stenting resulted in near normal pulmonary artery pressures and marked symptomatic improvement in dyspnoea.

Conclusion: Pulmonary vein stenosis is an uncommon but potentially life-threatening complication of ablation of the pulmonary veins. There is a discrepancy in the definitive method of tackling the stenotic vessel especially in the adult population. Overall consensus on early intervention in stenosis >75% has been advised. Symptomatic benefit may be obtained by balloon dilation and in selected cases, stenting of the pulmonary vein. Although the long-term outcomes are unknown, in the absence of other effective modalities, pulmonary vein stenting should be considered.

P2728 - CASE SERIES A RARE CASE OF ADULT CONGENITAL HEART DISEASE WITH DEXTROCARDIA UNDERGOING DEFINITIVE OPERATION IN FIVE YEAR PERIOD IN DR. SOETOMO GENERAL HOSPITAL SURABAYA (JANUARY 2012 DECEMBER 2016)

Gracelia Damanik, *Heroe Soebroto, Paul Tahalele, Ito Puruhito*
Airlangga University, Dr. Soetomo General Hospital, Division of Thoracic And Cardiovascular Surgery, Department of Surgery, Surabaya-Indonesia

Introduction: Dextrocardia is mostly associated with congenital cardiac defect that is the heart positioned at right thoracic cavity. Dextrocardia itself is a rare congenital cardiac defect with prevalence of 1:12,000. In general cardiac center,adult congenital heart disease with dextrocardia is also a rare case in congenital heart disease population approximately 1.6%. Cardiac surgical procedure done in adult congenital heart disease with dextrocardia has many challenges, not only the position of surgeon, but also the existing complication regarding adult age.
Objectives: We aimed to report serial case of adult congenital heart disease with dextrocardia managed with definitive operation in our center for 5-year period, since January 2012 until December 2016.
Result: We had 12 patients with dextrocardia (1.9%) among 612 patients with congenital heart disease undergoing cardiac surgical procedure in our center for 5-year period. There were 4 patients (0.6%) adult congenital heart disease with dextrocardia treated surgically in our center for 5-year period. We had done definitive surgeries for those patients, those are 2 patients Tetralogy of Fallot undergoing total correction, 1 patient large subaortic ventricular septal defect (VSD) with bidirectional shunt and pulmonary hypertension undergoing VSD closure by double flap patch and 1 patient Lutembacher Syndrome with pulmonary hypertension undergoing mitral valve replacement and atrial septal defect closure. Those four patients were successfully treated surgically. The eight remaining patient dextrocardia underwent palliative procedures.
Conclusion: The challenges of adult congenital heart disease with dextrocardia are position of surgeon during operation in first assistant (left position of patient) complicating surgeon's orientation in repairing the defect and postoperative complication regarding the physiologically changed hemodynamic status due to long-standing congenital malformation. It requires special attention in postoperative preparation including hemodynamic status of patients and surgical,technique regarding orientation, of defect.

P2738 - EBSTEIN'S ANOMALY OF THE TRICUSPID VALVE 13 YEARS OF EXPERIENCE IN A TERTIARY CENTRE FROM FETUS TO ADULT

Valentina Benetti[1], *Srinivas Narayan[2], Sujeev Mathur[1], John M Simpson[3], Alessandra Oggianu[4], Conal Austin[4], David Anderson[5], Sitali Mushemi[6], Rebecca L Savage[6], Natali Chung[6], Catherine Head[6], Alessandra Frigiola[7]*

Kingdom[6]; Guy's And St Thomas' NHS Foundation Trust; King's College London, Adult Congenital Heart Disease, London-United Kingdom[7]

Background: Ebstein's anomaly (EA) is a rare congenital heart defect. Patients often present with malfunctioning TV and right ventricular (RV) dilatation, which may require intervention. The timing of intervention and its outcome are still uncertain.
Method: All patients with EA followed-up in our centre between 01/01/2004-25/12/2016 were identified from the Departmental databases. Demographic characteristics, NYHA class, cardiac MRI, echocardiography, and CPET at their last follow-up were reviewed. For patients who underwent TV surgery, pre- and post-procedure data were analyzed.
Results: Of the 35 patients prenatally diagnosed, 8 were terminated, 2 died before and 6 immediately after birth. Only patients with isolated EA or with an associated atrial septal defect were included (n = 90, median age 21.8 yr, range 1.2 months-81.6 yr). Eleven patients required a systemic-to-pulmonary artery shunt or Glenn/Hemifontan (median 2.58 yr, range 4 days–63.47 yr); of these 3 underwent completion of Fontan circulation. Twenty-two patients required TV repair (n = 18) or replacement (n = 4) for severe regurgitation (median age 18.8 yr; range 1.78 yr-64.25 yr). After TV repair, there was a significant reduction in TV regurgitation (TVRF from 57 ± 16% to 16 ± 13%; $p < 0.001$), the RVEDV decreased (from 176 ± 81 ml/m^2 to 114 ± 26 ml/m^2; $p = 0.06$), the RV effective stroke volume (RVSV) increased (from 32 ± 13 ml/m^2 to 48 ± 20 ml/m^2; $p = 0.19$), the LVEDV volume increased (from 50 ± 14 ml/m^2 to 76 ± 17 ml/m^2; $p = 0.03$) and the LVSV increased as well (from 31 ± 8 ml/m^2 to 43 ± 9 ml/m^2; $p = 0.04$). These results were associated with improvement in symptoms (NYHA I from 0% to 60%; $p = 0.01$) which was mirrored by improved VE/VCO2 slope (from 34.5 ± 7.4 to 26.7 ± 4.1; $p = 0.08$). There were 1 post operative and 5 late deaths.
Conclusion: EA is characterized by a very broad spectrum of disease severity. Most severe cases require univentricular palliation. Among the others those with severe TV regurgitation are likely to receive TV repair. After surgery TV regurgitation decreases and the LVEDV increases significantly reflecting a better preload; symptoms and exercise capacity improve.

P2748 - VENTRICULAR RESPONSE TO DOBUTAMINE STRESS IS A PREDICTOR FOR OUTCOME IN PATIENTS WITH A FONTAN CIRCULATION

Eva Van Den Bosch[1], Sjoerd Bossers[1], Daniëlle Robbers-visser[1], Eric Boersma[2], Jolien Roos-hesselink[2], Hans Breur[3], Nico Blom[4], Wim Helbing[1]
Erasmus Mc, Sophia Children's Hospital, Department of Pediatric Cardiology, Rotterdam-The Netherlands[1]; Erasmus Mc, Department of Cardiology, Rotterdam-The Netherlands[2]; Wilhelmina Children's Hospital, Department of Pediatric Cardiology, Utrecht-The Netherlands[3]; Leiden University Medical Center, Department of Pediatric Cardiology, Leiden-The Netherlands[4]

Background: Despite improved short-term survival the Fontan circulation has serious long-term complications including circulatory failure, thromboembolic events and arrhythmias. Evaluation of ventricular function using exercise or pharmacological stress cardiac magnetic resonance imaging (CMR) has been advocated as additional tool to reveal impending Fontan dysfunction. Several studies have shown that patients with a Fontan circulation have an abnormal response to dobutamine stress. Our aim was to evaluate the prognostic value of dobutamine stress CMR in Fontan patients.
Methods: Between 2004 and 2012 Fontan patients prospectively received low dose dobutamine (7.5 μg/kg/min) stress CMR. After the baseline examination patients were followed up, cardiac events (reintervention, arrhythmias or cardiac death) were recorded. Time-to-event analyses (Kaplan-Meier method) and Cox proportional hazard regression analysis was performed to determine the predictive value of dobutamine stress CMR.
Results: 74 patients (49 male, median age 11.3 (6.7-24.2) years, median time after Fontan completion 7.9 (4.1-21.3) years) underwent stress CMR. Overall indexed end systolic volume (ESVi) and indexed end diastolic volume (EDVi) decreased significantly during stress (ESVi 39.9 ± 16.1 (rest) to 27.1 ± 13.6 (stress), EDVi 86.4 ± 21.3 rest to 74.0 ± 21.4 (stress)). The indexed stroke volume(SVi) did not change during stress. After a median follow-up of 5.8 years 22 patients (30%) developed a cardiac event, median 12.6 (7.6-26.5) years after Fontan completion. The event-group showed a significantly lower increase in ejection fraction (EF) during stress (ventricular reserve) compared to the non-event-group (6.1 ± 7.5% vs 11.8 ± 6.3%, $p = 0.002$). Multivariate Cox regression analysis showed ventricular reserve (HR 0.87; 95% CI 0.81-0.93; $p < 0.001$) is associated with the risk of an event, corrected for age at stress CMR and EF at rest.
Conclusion: Ventricular response to dobutamine stress may be an additional predictor for events in patients with a Fontan circulation.

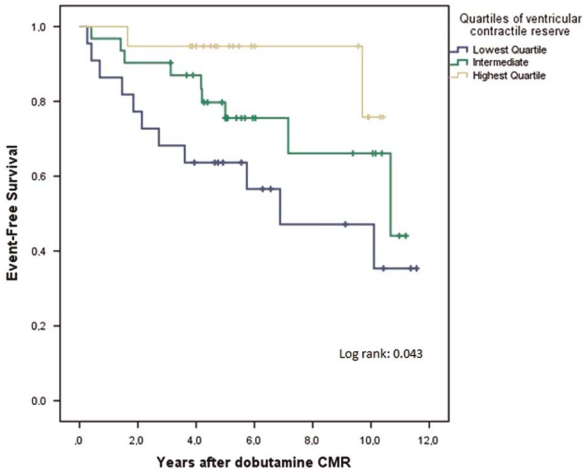

Figure 1.
Kaplan-Meier curve for event-free survival.

P2763 - ANOMALOUS CORONARY ARTERIES FROM PULMONARY ARTERY (ALCAPA & ARCAPA) SPECTRUM A SINGLE ACHD CENTRE EXPERIENCE

Chukwuemeka Oguguo, Jaspal Dua, Petra Jenkins, Ashish Shah, Heiko Schneider, Andreas Hoschtitzky, Helen Dormand, Devinda Karunaratne, Bernard Clarke
Manchester Heart Centre, Cardiology, Manchester-United Kingdom

Background: Anomalous origin of Left (or Right) coronary artery from pulmonary artery (ALCAPA /ARCAPA) syndrome (Bland-White-Garland Syndrome) is rare, less than 0.5% of all congenital heart defects. In 5% of cases, it is associated with cardiac anomalies e.g. atrial septal defect, ventricular septal defect, aortic coarctation. ALCAPA can result in "coronary steal" phenomenon, where left-to-right shunt causes abnormal left ventricular

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

perfusion. If untreated, up to 90% with ALCAPA syndrome die within 1st year of life. Those who reach adulthood may suffer myocardial infarction (MI), left ventricular systolic dysfunction (LVSD), mitral regurgitation (MR), silent myocardial ischaemia, malignant arrhythmias, causing sudden cardiac death. Early diagnosis/prompt surgical intervention, aiming to restore two-coronary-artery circulation can lead to myocardial recovery. Most literature pertaining to ALCAPA are paediatric cases or individual case studies

Methods: We present our single centre experience of ALCAPA/ARCAPA, presenting in adulthood. Electronic search of the departmental database/retrospective case-note review was undertaken. Over a 7 year period, we had 9 ALCAPA/ARCAPA patients.

Results & Discussion: Presentations varied from syncope, to angina, to increasing dyspnoea. Two patients presented with MI, 4 with atrial/ventricular dysrhythmias, 2 with MR, 1 with severe tricuspid regurgitation, 3 with, at least moderate LVSD and 1 with pericardial effusioN. As for outcomes, 3 patients underwent coronary artery corrections; 1 had mitral valve repair; 1 had tricuspid valve repair; 1 had valve conduit repair; 1 had pulmonary patch repair and one had pericardiocentesis. 2 patients had EPS/ablation; 2 had implantable loop recorders;, 1 received an implantable cardioverter-defibrillator and 3 had permanent pacemakers. Two patients are awaiting surgery. Echocardiographic findings included LVSD, MR and lesions e.g. tetralogy of Fallot

Conclusions: ALCAPA/ARCAPA is rare. Presentation in adult age can vary. Management depends upon initial presentation/concurrent issues. Clinicians should be aware of this rare, but potentially treatable anomaly.

P2885 - LONG TERM OUTCOME OF PROTEIN LOSING ENTEROPATHY IN CARDIAC DISEASE

Jakyoung Yoon, Eunjung Bae
Seoul National University Hospital, Pediatrics, Seoul-Korea, South

Introduction: Protein-losing enteropathy (PLE) is a devastating complication of cardiac disease, especially after Fontan operation. The purpose of this study was to investigate the clinical characteristics and outcome of PLE patients at a single institution.

Methods: We reviewed medical records of 34 patients with PLE from cardiac disease from 1992 to 2016.

Results: Median age at PLE diagnosis was 11.4 years (range 0.8-28.3). The follow-up duration was 7.7 ± 5.8 years. The underlying cardiac disease was functional single ventricle in 26 patients (76%), constrictive pericarditis in 3 patients (9%), valvular heart disease in 1 patient (3%), and restrictive cardiomyopathy in 1 patient (3%). Most patients (73%) underwent Fontan operation and 5 patients (14%) did not receive any surgery. PLE occurred in 4.5% of patients after Fontan. The survival rate was 80.7% at 5 years and 73.9% at 10 years. Twelve patients died during follow-up in 6.9 ± 5.9 years after PLE onset. Aortic oxygen saturation < 90%, hemoglobin level < 12 g/dl, decreased ventricular function, NYHA functional class III or IV were predictors of mortality in PLE patients after Fontan operation. For the management of PLE, medical treatments were more frequently used including diuretics, ACEI/ARB, subcutaneous heparin injection, oral corticosteroids. Interventional and surgical therapies such as Fontan pathway fenestration creation, Fontan conversion, and Fontan takedown surgery were applied in selected patients. One third of PLE patients after Fontan operation showed resolution of PLE. In Fontan patients, resolution of PLE was achieved by heparin in 4 patients, surgical Fontan fenestration in 2 patients, Aorto-pulmonary collaterals surgical ligation and transplantation in 1 patient each. Higher Fontan pathway pressure was associated with intractable PLE.

Conclusions: The survival of PLE with cardiac disease has improved with the advancement of the conservative care. Further investigation is needed to determine the individual susceptibility of PLE as well as to develop new method of prevention and therapy.

P2907 - ATRIAL SEPTAL DEFECTS IN ADULTS. EXPERIENCE OF SURGICAL RESULTS IN CARLOS ANDRADE MARÍN HOSPITAL IN ECUADOR FOR 13 YEARS. ¿LOW OR HIGH MORBIMORTALITY

Oscar Andrés Eskola Villacís[1], Carlos Emilio Bernal Rodríguez[2]
Carlos Andrade Marín Hospital, Cardiothoracic Surgery, Quito-Ecuador[1]; Angiocardiocentro, Cardiothoracic Surgery, Manta-Ecuador[2]

Introduction: The population of adults with congenital heart disease has increased in recent decades. Congenital heart disease, atrial septal defect (ASD) type, can lead to symptoms such as exercise intolerance with significant disability in a previously asymptomatic patient. Surgical repair has low mortality at an early age (<1% in patients without significant comorbidity) and good long-term results.

Subjects and Methods: We conducted a retrospective study, considering all cases of atrial septal defect underwent surgery in adults (>18 years), from January 2003 to June 2015, assessing the surgical benefit in the short and medium term, and evaluating improvement, deterioration or maintenance of functional class, determination of residual shunt, size and function of the right ventricle, tricuspid regurgitation and pulmonary artery pressure by transthoracic echocardiography and assessment of arrhythmias known or background.

Results and Discussion: A total of 163 patients were collected from all cardiac surgeries performed in the period described, of which the most representative group was the women (n = 114) compared to males (n = 49). Surgical Benefit: it was 100% in all operated without mortality data; Functional Class: 14 patients returned to functional class II to I (28% improvement in functional class II), 3 patients underwent functional class III to II (100% improvement in NYHA functional class III), and 17 patients joined functional class I, from the previous 110 patients who had; Right Ventricular Function (TAPSE): improved in 17 cases after surgery, with 9 patients within the first three months and 8 patients at 6 months; whereas Systolic Pulmonary Artery Pressure (SPAP): improved in 26 cases. Documented 4 types of Arrhythmias

Conclusions: Surgical repair of an ASD in adults in our institution has a zero mortality and good results with normal life expectancy and low morbidity in the short, medium and long term.

P2913 - THE RISK OF CHRONIC DISEASE IN ADULTS WITH CONGENITAL HEART DISEASE A NATIONWIDE POPULATION BASED WITH CASE CONTROL STUDY IN TAIWAN

Hsiao-ling Yang
National Taiwan University, School of Nursing, Taipei-Taiwan

Background: The relationship between congenital heart disease (CHD) and chronic disease has not been determined. The purpose of this study was to examine the prevalence of major chronic diseases in adult CHD patients and to compare it with healthy adult in Taiwan.

Materials and Methods: Adult CHD patients (> = 18 years) and healthy adults were identified from the Taiwan National Health Insurance Research database between 2010 and 2013. Outcome measures were the prevalence of 22 selected chronic diseases and the log-rank test was used to evaluate the survival curves of recorded chronic diseases.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: A total of 1746 adult CHD patients and 6984 healthy controls matched by age, gender and region of residence were identified and included in current study. The overall crude prevalence of adult CHD was 0.523 to 0.918 per 1000 adults with a mean age of 37.8 years (58.7% female). Top four common chronic diseases in adult CHD patients were hypertension (24.7%), cardiac dysrhythmias (20.5%), angina and coronary heart disease (18.0%), hyperlipidemia (15.5%), and chronic obstructive pulmonary disease (15.3%). Cases were significantly more likely than controls to have all selected chronic diseases ($p < 0.05$).
Conclusions: Adults with CHD have significantly increased chronic disease risk, especially cardiac and lung disease. Health care professionals should develop long term care guideline for adult with CHD to prevent chronic disease.

P2921 - SINGLE ANOMALOUS PULMONARY VEIN CAUSING SIGNIFICANT EXERTIONAL DYSPNEA IN A 60 YEAR OLD MAN

Julie Biller, Md[1], Stuart Berger, Md[2], Scott Cohen, Md[3]
Medical College of Wisonsin, Pulmonary and Critical Care Medicine, Milwaukee-United States[1]; Lurie Children, Pediatric Cardiology, Chicago-United States[2]; Medical College of Wisconsin, Cardiology, Milwaukee-United States[3]

Anomalous drainage of single pulmonary vein rarely causes symptoms. We present 60 year-old with improvement in dyspnea on exertion after surgical repair. He is a 40 pack year ex-smoker with history of treated CAD, obesity and hypertension. Additional history of inhalational farm injury treated with a nebulizer, and oral steroids with complete resolution. Presented to an ED with complaints of acute onset of dyspnea on exertion. Chest CT revealed anomalous drainage of the left upper lobe pulmonary vein to the brachiocephalic vein, no PE, and minimal centrilobular emphysema in the upper lobes. A complete set of pulmonary function tests were normal except for minimal reduction in DLCO (75%). Echocardiogram revealed mild right heart dilatation and moderate LV diastolic dysfunction. 18 months before this episode he was diagnosed with CAD treated with 3 RCA stents. Nuclear stress test showed no evidence of cardiac ischemia. After unsuccessful trial of newer medications for COPD he had repeat cardiac catheterization. Coronary angiography was normal with widely patent coronary arteries including the previous RCA stents. The LUPV drained to the lateral innominate vein without obstruction and was quite large angiographically. Innominate vein and SVC were dilated. Qp:Qs 1.2 to 1, mean PA pressure 26-28, PCWP 14. Surgical correction was undertaken with successful reimplantation of LUPV to LA appendage and closure of PFO. The surgeon noted a very large LUPV. Post-op he had complete resolution of his debilitating exertional dyspnea. Despite the fact that a single anomalous pulmonary vein usually results in no symptoms, occasionally it can lead to symptomatic pulmonary overcirculation requiring corrective surgical intervention. Perhaps co-morbidities such as coronary artery disease, primary lung disease and/or diastolic LV dysfunction could be contributing factors in such a circumstance. Patients with clinical symptoms and single anomalous pulmonary vein should be considered for surgical correction.

P2934 - CANADIAN MUSTARD AND SENNING POPULATION DEMOGRAPHICS AND MANAGEMENT

Nancy Poirier[1], Camille Hancock-frieson[2], Pierre-Luc Bernier[3], Andrew Campbell[4], Mohammed Al Aklabi[5], Fred Jacques[6], Gyaandeo Maharajh[7], William Williams[8], Jacques Lacroix[9]
Montreal Heart Institute, Cardiac Surgery, Montreal-Canada[1]; Dalhousie University, Cardiac Surgery, Halifax-Canada[2]; Mcgill University, Cardiac Surgery, Montreal-Canada[3]; University of British Columbia, Cardiac Surgery, Vancouver-Canada[4]; University of Alberta, Cardiac Surgery, Edmonton-Canada[5]; University of Laval, Cardiac Surgery, Quebec City-Canada[6]; University of Ottawa, Cardiac Surgery, Ottawa-Canada[7]; University of Toronto, Cardiac Surgery, Toronto-Canada[8]; University of Montreal, Cardiac Surgery, Montreal-Canada[9]

Background: There exists no national data on the demographics, follow-up and management of patients that have underwent a Mustard or Senning procedure in Canada. Furthermore, little is know on the growing number of patients in heart failure and pulmonary hypertension.
Methods and Results: A scenario-based, self-administered survey was completed by a congenital cardiac surgeon from each of the 8 congenital cardiac surgery programs across Canada with the collaboration of their multi-disciplinary team. Half of programs followed more than 50 Mustard patients (Range: <20-280 patients) and less than 20 patients who underwent a Senning (Range: 0-100 patients). Less than 5 Mustard and Senning patients have cardiac surgery per year. Respondents reported that a total of 28201 adult congenital cardiac patients are actively followed across Canada (mean: 3512 + /- 356 patients/program). A first scenario was: "A 35 year-old male patient who underwent a Mustard procedure is deemed clinically stable." Respondents (5/8) would evaluate the Systemic Right Ventricle (sRV) yearly: TTE (7/8), MRI (6/8), TEE (1/8). The second scenario was: Same patient however, last TTE showed a 40% sRV Ejection fraction with moderate systemic Tricuspid Regurgitation (sTR). Respondents (8/8) claimed they would evaluate sRV every 6-12 months using one or more imaging modalities: TTE (8/8), MRI (6/8), TEE (2/8). There was no consensus on optimal timing of cardiac catherization to measure pulmonary artery pressures (PAP), necessary in the decision-making with respect to intervention for sTR, cardiac transplantation and/or mechanical assistance.
Conclusion: Almost 30000 adult congenital heart disease patients are actively followed across Canada in specialized multidisciplinary clinics including over 520 Mustard and 90 Senning patients. There appears to be consensus amongst Canadian congenital cardiac surgeons on the modalities and follow up timing of Mustard and Senning adult patients but not on the

P2950 - TRANSPOSITION OF THE GREAT ARTERIES ARTERIAL SWITCH IN A 32 YEARS OLD FEMALE CASE REPORT

Martín Alfonso Saldaña Becerra, Alejandra Valeria Iturriaga Hernández, Bertin Ramírez González, Julia María Martínez Morales, Jorge Luis Cervantes Salazar, Antonio Benita Bordes, Edgar Samuel Ramírez Marroquin
Instituto Nacional De Cardiología Ignacio Chávez, Pediatric Cardiac and Congenital Heart Disease Surgery, Saltillo-Mexico

The transposition of the great arteries is a congenital heart malformation characterized for an atrioventricular concordance and a ventriculoarterial discordance. It has an incidence of 1 in 3500-5000 newborns. The association with other heart malformations, like a ventricular septal defect or a left ventricular outflow obstruction, determine the time and the form of clinical presentation. It is generally a lethal congenital malformation, with a life expectancy of approximately 9 months in non-operated patients. We present the case of a 32-year-old female patient with a diagnosis of D Transposition of the large arteries with pulmonary stenosis and atrial and ventricular septal defects, which was taken to surgical anatomical correction by performing an arterial switch (Jatene procedure) with an extension of the neaorta valvular

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

annulus (Nicks) and mechanical valvular prosthesis placement, as well as closure of the septal defects, with a favorable evolution.

P2984 - A CASE OF CONGENITAL LEFT CORONARY ARTERY ATRESIA AND MITRAL INSUFFICIENCY

Hirokuni Ono, Masahide Chikada, Syota Kita, Satoshi Kinebuchi, Takeshi Miyairi
St.Marianna University of Medicine, Cardiovascular Surgery, Kawasaki City-Japan

Left main coronary artery atresia is a rare coronary anomaly in which there is no left coronary ostium,blood flows from the right coronary artery to the left through small collateral arteries and retrogradely. Since published case reports are few and rather scattered. The case of a 44years-old men with atresia of the left main coronary ostium and mitral insufficiency is presented. The men underwent a left internal thoracic-left anterior descending coronary artery bypass and plasty of the mitral valve. A selective study of the left internal thoracic artery demonstrated excellent flow into the left coronary artery system. In view of the occurrence of sudden death and massive myocardial infarction in adult patients shown to have atresia of the left main coronary artery, it is suggested that adult patients with this condition, who require open-heart surgery for any other cardiac disorder, should undergo coronary artery bypass grafting concurrently.

P3047 - EXERCISE CAPACITY AFTER PERCUTANEOUS BALLOON VALVULOPLASTY FOR CONGENITAL PULMONARY STENOSIS IN LONG TERM FOLLOW UP

Jaroslaw Meyer-Szary, Joanna Kwiatkowska, Robert Sabiniewicz
Medical University of Gdańsk, Department of Paediatric Cardiology and Congenital Heart Diseases, Poland-Poland

Introduction: Early studies have shown congenital valvular pulmonary stenosis (PS) treated by percutaneous balloon pulmonary valvuloplasty (PBPV) to have excellent outcomes with respect to relief of PS and risk of pulmonary regurgitation (PR) provided proper balloon diameter was selected. However, more recent long-term studies have shown that patients may have suboptimal functional outcome, which may be related to residual changes, mainly PR. The aim of this study was to assess exercise capacity by Bruce protocol in long-term survivors of PBPV.
Methods: Fifty-six patients treated by PBPV underwent detailed medical and echocardiographic assessment. Those without contraindications underwent a treadmill stress-test in accordance with maximal exercise Bruce protocol. Exercise capacity index (ECI) was calculated as z-score based on age- and sex-relevant normative data. Data is presented as mean ± standard deviation or median (range) dependending on distribution.
Results: Median time of observation was 13,6 (5,7–24,2) years. Eleven patients were excluded from stress-test due to contraindications – handicap (n = 5), other cardiac disease not related to PS nor PBPV (n = 3), orthopaedic (n = 2), infection (n = 1). The remaining 45 patients were 56% female and 20,5 (6,8–48,4) years of age. The exercise time was 10,9 ± 2,2 minutes and METs was 11,4 ± 1,8 kcal/kg*h), ECI was 0,1 ± 0,9 (-2,2–3,1). All patients had normal HR and BP response and terminated exercise due to symptoms of exertion. Only 6% (n = 3) of patients had a significantly reduced ECI and in 11% (n = 5) ECI reduction was mild. Further analysis indicated that the reduction was correlated with comorbidities (e.g. asthma, obesity) rather than residual transvalvular gradient or pulmonary regurgitation.
Conclusion: There is no overt reduction in exercise tolerance related to outcome of PS treatment by PBPV at long-term follow-up. This pilot study is limited by a small number of patients and use of exercise time or METs as exercise capacity proxy.

AMBULATORY

P1080 - THE LONG TERM FOLLOW UP OF FUNCTIONAL HEALTH STATUS OF ADOLESCENTS WHO HAVE UNDERGONE CARDIOPULMONARY BYPASS IN INFANCY

Wotherspoon Jane[1], Eagleson Karen [2], Auld Ben[2], Johnson Susan[2], Stocker Christian[2], Heussler Honey[3], Ware Robert[4], Gilmore Linda[5], Justo Robert[2]
QUT, School of Psychology and Counselling, Brisbane-Australia[1]; Chq, Queensland Paediatric Cardiac Service, Brisbane-Australia[2]; CHQ, Child Development Program, Brisbane-Australia[3]; Griffith University, Menzies Health Institute Queensland, Brisbane-Australia[4]; QUT, Faculty of Education, School of Cultural and Professional Learning, Brisbane-Australia[5]

Background: Congenital heart surgery survivors are at risk of poorer functional health outcomes compared with healthy peers. 35 neurologically normal infants aged less than 6 months underwent cardiopulmonary bypass surgery for congenital heart disease between 1999 and 2001. Assessment at 1 and 5 years post procedure demonstrated impaired cognitive, behavioural and neuropsychological performance. This study describes the neuropsychological and functional health of adolescents with congenital heart disease followed since infancy.
Methods: This was a prospective cohort study. Participants underwent medical review, genetic screening, health-related quality of life (HRQoL) assessment and a comprehensive battery of neuropsychological tests. Parents also completed rating scales.
Results: 21 patients, 95% of whom had a biventricular circulation, were assessed at median age 15.4 years (range, 14–17 years). All patients were NYHA classification 1, reporting peak physical activity ranging from sedentary to competitive sport. A deletion was detected on 8q22.3 following SNP array analysis in one patient. While global intelligence was in the average range (94.3 + 12.7; p = 0.06), adolescents scored significantly lower than expected across various neurodevelopmental areas compared to the general population including cognitive domains of working memory and processing speed. Participants also performed below expected on a test of mathematical achievement. Deficits in attention, executive function and visual-spatial ability were found. In social-emotional and adaptive domains, participants reported more learning problems, poorer attitude to teachers, higher sense of inadequacy and poorer self-reliance. Parent scales indicated poorer home living abilities in their children. Adolescents described more positive family relations, while parents reported less aggression and fewer externalising problems. Adolescents and parents reported significantly lower HRQoL across all domains.
Conclusions: These results are consistent with previously described outcomes for this cohort, and with patterns of impairment reported in international studies. The importance of early intervention is emphasised, as early deficits extend into young adulthood.

P1120 - CHARACTERISTICS OF ADMISSIONS FOR KAWASAKI DISEASE FROM 1997 TO 2012 LESSONS FROM A NATIONAL DATABASE

Rohit Loomba, Alexander Raskin
Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-United States

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Kawasaki Disease (KD) is one of the most common causes of acquired heart disease in children. While countries like Japan have characterized national characteristics of KD, such data has not yet been presented for cases in the United States. The aim of this study was to characterize Kawasaki Disease admission using data from a national database.
Materials and Methods: Data from the Kids' Inpatient Database from 1997 to 2012 was used for this cross-sectional study. Characteristics of KD admissions as well as those without KD were collected/ Multivariate analysis was done to identify risk factors associated with KD. Multivariate analysis was also conducted to determine whether KD is an independent risk factor for cardiogenic shock or coronary artery aneurysm.
Results: A total of 15,962,403 admissions were included in this analysis. Of these, 17,918 (0.11%) were for KD. For those with KD, the median age of admission was 2 years with a (range 1 month to 20 years). The median length of admission was 3 days (range 1 to 76 days). Median cost of hospitalization was 15,186 US dollars. Of those with KD admission, 485 (2.7%) were found to have coronary artery aneurysms, 19 (0.1%) suffered from cardiogenic shock, and 5 (0.1%) required extracorporeal membrane oxygenation. Only 4 patients (0.01%) experienced inpatient mortality. KD was not an independent risk factor for cardiogenic shock or need for extracorporeal membrane oxygenation. KD was an independent risk factor for coronary artery aneurysm (odds ratio 2,882.381, 95% confidence interval 1,848.024 to 3,395.679).
Conclusion: KD accounts for a small percent of total pediatric inpatient admissons but is associated with high cost of hospitalization. Certain races are associated with an increased risk of KD as is younger age. KD is an independent risk factor for coronary artery aneurysms bot not cardiogenic shock.

P1127 - RISK FACTORS ASSOCIATED WITH RECURRENCE OF KAWASAKI DISEASE IN MEXICAN CHILDREN

Giovanni Sorcia-Ramirez[1], Gabriela Morales-Garnica[2], Luis Martín Garrido-Garcia[3]
Instituto Nacional De Pediatría, Immunology, Mexico City-Mexico[1]; Instituto Nacional De Pediatría, Pediatrics, Mexico City-Mexico[2]; Instituto Nacional De Pediatría, Cardiology, Mexico City-Mexico[3]

Background: Kawasaki disease (KD) is an acute febrile illness characterized by systemic vasculitis. Recurrences of KD (defined as at least three clinical signs of KD in addition to fever ≥ 5 days), presenting ≥ 14 days after the return to baseline from the index episode is reported in approximately 3-4% of all cases in Japan.
Objective: To assess the frequency and determined the risk factors associated with recurrences of KD in patients treated at the Instituto Nacional de Pediatría in Mexico City.
Material and Methods: An observational, comparative, retrospective and case-control study of all patients diagnosed with recurrent KD in our Institution from August 1st, 1995 to August 31st, 2016 was performed. The clinical presentation, laboratory results, treatment used and coronary artery abnormalities in the recurrent-KD and non-recurrent KD groups were analyzed and compared.
Results: We included 525 patients with KD diagnosed at our institution; we had 21 recurrences of KD (4.0%), 17 patients had one recurrence, 1 patient had 2 recurrences and 1 patient had 3 recurrences of KD. 19 cases or our cases were male (90.4%) with mean age at diagnosis of the first episode of 29.81 ± 35.10 months and with a mean of 15.42 months of the new event after the initial episode (1 to 60 mo.) In bivariate analysis, male gender ($p < 0.037$), central nervous system manifestations in the acute phase of KD ($p < 0.053$) and coronary aneurysms at diagnosis ($p < 0.05$) showed statistical significance. There were no factors associated with recurrence in a multivariate analysis.
Conclusions: This is a very small series of KD with a slightly increased rate of recurrence compared with the rate of recurrences reported in the literature. But to allow an early recognition of a new event, a previous history of KD should be considered to initiate.

P1141 - MANAGEMENT DIFFICULTY OF LATE DIAGNOSED TRANSPOSITIONS OF THE GREAT VESSELS IN A DEVELOPING COUNTRY

Houda Ajmi[1], Zeineb Ellafi[1], Sameh Mabrouk[2], Mehdi Slim[1], Minyar Tfifha[1], Saida Hassayoun[1], Jalel Chemli[1], Noura Zouari[1], Essia Boughzela[2], Saoussen Abroug[1]
Sahloul University Hospital, Pediatric Department, Sousse-Tunisia[1]; Sahloul University Hospital, Cardiology Department, Sousse-Tunisia[2]

Background: Transposition of the great vessels (TGV) is a relatively frequent congenital cyanotic heart disease. The diagnosis is made in the antenatal or neonatal period and surgical correction should be rapid, usually at the age of 15 days. However, in our country, this heart disease is belatedly diagnosed and thus belatedly operated. Objective: Describe the clinical features and the management difficulties of late-diagnosed TGVs.
Methods: We conducted a retrospective observationnel study in the department of Pediatrics of Sahloul hospital-Sousse. All children with late-diagnosed TGV were included. The study period went from 2000 until 2015.
Results: We collected 10 cases of TGV (4 girls, 6 boys). The average age of diagnosis was 22 days. The clinical features at admission were a cyanosis in 100% of cases associated with heart failure signs at 50% of patients with hemodynamic instability requiring mechanical ventilation. TGV was isolated in 2 cases, associated with CIV in 7 cases; and in one case, it was associated with pulmonary stenosis, aortic coarctation and hypoplasia of the aorta. A Rashkind was done in 6 cases within 6 days. The arterial Switch was performed in 5 cases after 31 days on average. Only one patient was placed on ECMO after surgery and no child had pulmonary banding before doing the Switch. The outcome of these patients was favorable in 4 cases; 1 patient died secondary to Septic shock, 2 months after surgery. Patients who not underwent surgery (5 cases), died within 30 days on average.
Conclusion: Children with TGV require urgent diagnosis and management. High rates of morbidity and perioperative mortality of late-diagnosed TGV result of the inability of the right ventricle to ensure systemic circulation. This situation may begin even before the age of 1 month as illustrated by our study.

P1158 - CLINICAL IMPORTANCE OF SCHOOL CARDIAC SCREENING WITH UNIVERSAL ELECTROCARIOGRAPHIC SCREENING IN THE DIAGNOSIS OF ASYMPTOMATIC YOUNG PATIENTS WITH ATRIAL SEPTAL DEFECT

Kenji Suda, Yasuto Maeda, Masanori Kuwahara, Hironaga Yoshimoto, Yozo Teramachi, Yusuke Koteda, Shintaro Kishimoto, Yoshiyuki Kudo, Motofumi Lemura
Kurume University School of Medicine, Departmet of Pediatrics & Child Health, Kurume-Japan

Background: Japanese government has enforced a law of regular school cardiac screening (SCS) with universal electrocardiographic (ECG) screening at 1st, 7th, and 10th grader in 1995. The aim of

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

this study was to determine impact of SCS in the management of patients with atrial septal defect (ASD).
Methods: Subjects were 253 patients with ASD aged between 6.5 and 35 years old that had documented reasons why patients were sent to cardiologists. Based on the retrospective chart review including demographics, past history, physical examination and ECG findings at SCS, we determined the role of SCS in the diagnosis of ASD.
Results: About half of patients (48%) were detected at SCS and the remaining patients were diagnosed at younger age mainly because of cardiac murmur (87%). In patients detected at SCS, three fourths (75%) of patients were identified by ECG screening due to incomplete RBBB with right axis deviation or incomplete RBBB with rR' pattern and the remaining one fourth patients were mainly identified by cardiac murmur. Notably, 60% of these patients identified by ECG abnormality at SCS did not have significant cardiac murmur, >= 2/6 in Levine grading. There was no significant difference in age (13.8 ± 2.5 vs. 14.5 ± 2.9 years old), Qp/Qs (2.5 ± 1.0 vs. 2.4 ± 0.9), and mean PAP 14 ± 3 vs. 15 ± 3 mmHg) between patients with and without significant cardiac murmur. As summary, 22% of patients with asymptomatic ASD in this age group might not be diagnosed if there is no ECG screening in Japan.
Conclusions: SCS, especially combined with universal ECG screening, has significant role to identify asymptomatic patients with ASD in Japan though cost effectiveness must be determined.

P1164 - KAWASAKI DISEASE IN CHILDREN YOUNGER THAN 1 YEAR OF AGE IN A MEXICAN POPULATION

Samia Gaffare-Aranda[1], Luis Martin Garrido-Garcia[2], Patricia Cravioto-Quintana[3], Fernando Galvan-Castillo[4]
Instituto Nacional De Pediatra, Neonatology, Mexico City-Mexico[1]; Instituto Nacional De Pediatria, Cardiology, Mexico City-Mexico[2]; Instituto Nacional De Pediatria, Teaching Department, Mexico City-Mexico[3]; Instituto Nacional De Pedaitria, Teaching Department, Mexico City-Mexico[4]

Background: Kawasaki disease (KD) is an acute febrile vasculitis of unknown origin. KD represents the most common cause of acquired heart disease in children in developed countries. KD is uncommon in patients younger than 1 year of age and in Mexico there are few reports of KD in this group of age.
Objective: To describe the clinical features, laboratory parameters, treatment employed and outcome of patients with KD younger than 1 year of age in a third level facility in Mexico City.
Methods: A cross-sectional study was conducted at the Instituto Nacional de Pediatria in Mexico City, Mexico From August 1995 to August 2016. Children with KD younger than 12 months of age were used as the case group and patients older than 12 months of age as a control group. P < 005 was considered to be statistically significant.
Results: During the study period, 519 patients were diagnosed with KD at our Institution; 116 patients (22.3%) were younger than 1 year of age. The mean age at diagnosis was 8.16 ± 2.95 months. Seventy-nine patients were male (68.10%). Mean time from the onset of fever to diagnosis of KD was 10.15 ± 6.852 days (range 3 to 41 days). An incomplete form of KD was present in 34 patients (29.31%). Fifty-three of our patients developed coronary aneurysms (z-score >2.5), and seventeen of them were categorized as giant aneurysms; two of these patients died of cardiogenic shock in the acute phase of the disease.
Conclusions: In Latin American countries are few reports of KD in patients younger than 1 year of age. In our experience, more patients had coronary artery aneurysms than the reported in the literature.

P1166 - KAWASAKI DISEASE IN PATIENTS OLDER THAN 8 YEARS OLD IN A CHILDREN'S HOSPITAL IN MEXICO CITY. IS THERE REALLY A DIFFERENCE IN PRESENTATION AND OUTCOME

Itzel Rios-Olivares[1], Luis Martin Garrido-Garcia[2], Patricia Cravioto-Quintana[3], Fernando Galvan-Castillo[3]
Instituto Nacional De Pediatra, Pediatrics, Mexico City-Mexico[1]; Instituto Nacional De Pediatria, Cardiology, Mexico City-Mexico[2]; Instituto Nacional De Pediatria, Teaching Department, Mexico City-Mexico[3]

Background: Kawasaki Disease (KD) is an acute febrile illness characterized by systemic vasculitis of unknown etiology. Cardiac sequelae, such as coronary artery aneurysms (CAA), are one of the most important aspects of this disease. KD is rarely diagnosed in older children.
Objective: To describe the clinical and laboratory features, cardiac sequelae and outcome in children older than 8-years old with KD in a third-level facility in Mexico City.
Methods: A cross-sectional and comparative study was conducted at the Instituto Nacional de Pediatria in Mexico City, Mexico From August 1995 to August 2016. Children with KD older than 8 years were used as the case group and patients younger than 8 years were used as the control group. $p < 0.05$ was considered to be statistically significant.
Results: 519 cases of KD were diagnosed during the study period, 37 cases of them were older than 8-years old, (7.12%), with a mean age of 137.92 ± 31.24 months (range 96 to 200 months). There were no statistically difference in the classical KD signs, but older children more often had arthralgias ($p < 0.015$) congestive heart failure ($p < 0.020$) and an incomplete form of KD ($p < 0.034$). We found no difference in the development of coronary artery aneurysms in both groups. Almost all patients in both groups received IVIG but patients in the older group required a second IVIG dose ($p < 0.01$)
Conclusions: KD in patients older than 8-years old represent a clinical challenge because in most of the cases they presented with an atypical clinical picture, which contribute to a delayed diagnosis.

P1175 - GRADUAL DETERIORATION OF VITAMIN D STATUS AND BONE MASS DENSITY IN CHILDREN AND ADOLESCENTS WITH FONTAN CIRCULATION

Simone Goa Diab[1], Kristin Godang[2], Anne Grethe Myhre[3], Ingrid Sparr[4], Runar Almaas[4], Gaute Døhlen[1], Jens Bollerslev[2], Thomas Möller[1]
Oslo University Hospital, Pediatric Cardiology, Oslo-Norway[1]; Oslo University Hospital, Endocrinology, Oslo-Norway[2]; Norwegian National Advisory Unit on Rare Diseases, Frambu Resource Centre For Rare Disorders, Oslo-Norway[3]; Oslo University Hospital, Pediatric Medicine, Oslo-Norway[4]

Background: Our group has shown high prevalence of vitamin D deficiency and low bone mass density in adolescents with Fontan circulation. The study aim was to investigate vitamin D status and bone mass density in children with Fontan circulation at different ages.
Material and Methods: Patients were recruited from our national Fontan clinic and divided in two cohorts aged 5 to 9 years and 10 to 15 years respectively. We prospectively measured serum levels of 25-OH-vitamin D and total body bone mass density by narrow

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

fan-beam dual energy x-ray absorptiometry (DXA) scan. The DXA results were compared to age and gender matched reference data and expressed as Z-scores. Vitamin D and DXA results of the two cohorts were compared to the previous cohort of 17 patients aged 16 to 18 years. Current recommendations for patients with chronic illness suggest an optimal serum level of 75 – 125 nmol/L.
Results: We included 15 patients aged 5 to 9 years and 19 patients aged 10 to 15 years. Vitamin D levels in the two cohorts were 77.5 ± 31.0 nmol/L (mean ± SD) and 61.6 ± 30.2 nmol/L respectively, while the level in the adolescent cohort was 34.6 ± 18.3 nmol/L. The DXA scans for the two youngest cohorts showed z-scores of 0.7 ± 0.9 and -0.7 ± 1.4, while the oldest cohort had a z-score of -0.8 ± 1.1. Apart from BMD in age group 2 and 3 ($p = 0.74$), all group differences were statistically significant.
Conclusion: Both vitamin D status and bone mass density show age-related differences in Fontan patients and a significant decrease through childhood and adolescence. Whether this is due to life style factors (i.e. sun exposure, dietary intake of vitamin D and physical activity) or due to a pathophysiological effect of the Fontan circulation is unknown.

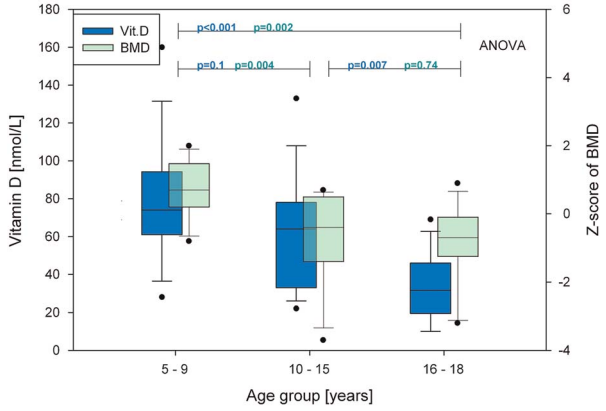

Figure.

P1191 - RISK FACTORS FOR DEVELOPMENT OF CORONARY ARTERY ANEURYSMS IN KAWASAKI DISEASE IN MEXICAN CHILDREN

Gabriela Morales-Garnica[1], Luis Martín Garrido-Garcia[2], Patricia Cravioto-Quintana[3], Fernando Galvan-Castillo[4]
Instituto Nacional De Pediatria, Pediatrics, Mexico City-Mexico[1]; Instituto Nacional De Pediatria, Cardiology, Mexico City-Mexico[2]; Instituto Nacional De Pediatria, Teaching Departmenth, Mexico City-Mexico[3]; Instituto Nacional De Pediatría, Teaching Department, Mexico City-Mexico[4]

Background: Kawasaki Disease (KD) is an acute febrile illness characterized by systemic vasculitis of unknown etiology. Coronary artery aneurysms (CAA), are one of the most important complications of the disease. Actually, it is the major cause of acquired heart disease in developed countries but its frequency in Mexico is still unknown.
Objective: To establish the risk factors for development of coronary artery lesions in children with KD who were treated at the Instituto Nacional de Pediatria in Mexico City.
Material and Methods: An observational, comparative, retrospective case-control study of all patients diagnosed with KD in our Institution from August 1995 to August 2016. We reviewed the medical records and analyzed gender, age, weight, height, clinical manifestations, time from the onset of the symptoms to diagnosis, hemoglobin, leucocyte count, platelet count, ESR, C-RP, albumin, sodium, AST ASL, treatment used and the development of coronary artery aneurysms.
Results: We studied 499 cases of KD, 65.9% were male with a mean age at diagnosis of 37.87 ± 35.81 months. The mean duration of fever from the onset of the symptoms to diagnosis was 9.1 ± 548. An incomplete form of KD was diagnosed in 103 patients (20.64%). 165 patients developed CAA (33%). Multivariate analysis for CAA showed that younger age ($p < 0.004$) prolonged time to diagnosis ($p < 0.001$), central nervous system manifestations ($p < 0.008$) anemia ($p < 0.001$) leukocytosis ($p < 0.005$), thrombocytosis ($p < 0.041$) were the most important risk factors for development of CAA in our patients.
Conclusions: This is the largest series of KD in Mexico, with most cases diagnosed in recent years, so it appear that the disease is more common than initially thought. Also, the frequency of CAA is greater than the reported in the literature, but it appears to be related to a delayed

P1196 - CONTROVERSIES IN ASSOCIATION OF CARDIORESPIRATORY FITNESS AND ARTERIAL STIFFNESS IN CHILDREN AND ADOLESCENTS

Jan Müller, Julia Elmenhorst, Tobias Giegerich, Renate Oberhoffer
Technische Universität München, Institute of Preventive Pediatrics, Munich-Germany

Objective: The relationship of cardiorespiratory fitness and arterial compliance in children and adolescents remains controversial. The aim of this study was to assess this association with a quantitative approach.
Patients and Methods: 646 healthy school children and adolescents (316 female, age 13.9 ± 2.1 years) were cross-sectionally investigated in seven school settings in and around Munich for their cardiorespiratory fitness, demographic, anthropometric and hemodynamic parameters. Surrogates of arterial stiffness like pulse wave velocity (PWV), augmentation index normalized to a heart rate of 75 (AI@75), peripheral and central systolic blood pressures were measured in a supine position using the oscilliometric Mobil-O-Graph®. Cardiopulmonary fitness was measured with a six minute indoor run tests.
Results: After correction for age, sex, body mass, body height, heart rate and mean arterial pressure controversial findings occurred. PWV increased with higher cardiorespiratory fitness (Beta = .173; $p < .001$) which means an unfavorable relation, whereas AI@75 declined with higher cardiorespiratory fitness (Beta = -.106; $p = .025$). Higher cardiorespiratory fitness seems therefore, in contrast to PWV, beneficial for AI@75. The third surrogate of arterial stiffness, central systolic blood pressure, showed no association to cardiorespiratory fitness (Beta = .066; $p = .052$).
Conclusions: Different surrogates of arterial stiffness provide different associations to cardiorespiratory fitness in children and adolescents still after correction for multiple confounder. More research is needed in this field to understand functioning of the juvenile vessels and also measurements and methodological approaches should be reconsidered.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

P1203 - SHORT STATURE PREVALENCE BEFORE CARDIAC SURGERY IN CHILDREN WITH CONGENITAL HEART DISEASE

Guillermo Larios[1], Catalina Le Roy[2], Daniel Springmuller[3], Cristian Claveria[3]
P.Universidad Catolica and The Hospital For Sick Children, Pediatric Cardiology, Toronto-Canada[1]; P.Universidad Catolica, Gastroenterology and Nutrition, Santiago-Chile[2]; P.Universidad Catolica, Pediatric Cardiology, Santiago-Chile[3]

Background: Children with congenital heart disease (CHD) frequently present malnutrition, being a possible long-term consequence short stature (SS). The aim of this study was to compare the nutritional status and prevalence of SS in children according to CHD prior to surgical intervention.
Methods: Retrospective study in a South American cardio-surgical center. We studied children with CHD undergoing surgery with extracorporeal circulation between 2009 and 2013. Patients with previous history of prematurity, genotype or other illness with possible nutritional compromise were excluded. An anthropometric evaluation was performed per Z-score and World Health Organization standards. A comparison of SS prevalence according to CHD was conducted.
Results: Six hundred and forty-three cardiac surgeries with cardiopulmonary bypass were performed during the period in 549 patients, 55.7% men (median age: 9.7, interquartile range 3.3-39.2 months). The mean height-for-age Z-score (HAZ) was -1.0 ± 1.3 and 21.5% of the patients presented SS (HAZ < -2). The mean weight-for-height Z-score (WHZ) was -0.3 ± 1.5, 11.7% of the patients presented wasting (WHZ < -2) and 5.8% obesity (WHZ $> +2$). Patients with ventricular septal defect (VSD), and tetralogy of Fallot (TOF) presented the highest SS prevalence (30.3% and 31.3%, respectively) versus in atrial septal defect with the lowest SS prevalence, 17% ($p < 0.01$). In patients with univentricular physiology undergoing to Fontan circulation, 4 of 44 patients (9.1%) presented SS before the first stage (mean HAZ -0.7 ± 1.3), 14 of 47 (29.8%) prior to the second stage (HAZ -1.5 ± 1.1) and 3 of 23 (13%) prior to the Fontan (HAZ -0.4 ± 1.0, $p < 0.01$ between stages). No correlation was found between the age of surgery and HAZ.
Conclusions: There is a high prevalence of SS in patients prior to CHD surgery, especially in patients with VSD, TOF and prior to the second stage. As SS is an indicator of chronic malnutrition, it is relevant to optimize nutritional support in these patients.

P1204 - COMPARISON OF THE EFFECTIVENESS OF FOUR(4) SESSION PLAY MODULE VERSUS THE CONVENTIONAL CARDIOVASCULAR REHABILITATION THERAPY AMONG POST OPERATIVE CONGENITAL HEART DISEASE PEDIATRIC PATIENTS AGES 5 12 YEARS OLD

Mary Antoniette Lozada[1], Jhuliet Balderas[1], Maria Ina Bunyi[1], Consuela Suarez[2]
Philippine Heart Center, Pediatric Cardiology, Quezon City-Philippines[1]; Philippine Heart Center, Rehabilitation Medicine, Quezon City-Philippines[2]

Background: Play is primarily a way for a child to communicate, especially when under stress. However, the efficacy of therapeutic play is not widely accepted by the scientific community due to lack of evidence-based studies. The objective of this study was to determine the effectiveness of the four-session play module as cardiovascular post-operative rehabilitation therapy.
Methodology: A randomized controlled clinical trial among pediatric patients ages 5-12 years old diagnosed of Congenital Heart Disease, who underwent elective open heart surgery. The patients were divided into two groups: play module or conventional rehabilitation therapy. Quality of life (QoL) was assessed through PedsQL cardiac module.
Result: There was a total of 56 subjects, with a mean age of 7.3 years. On the 2nd post-operative day, there was a significant difference on the QoL of patients who had the play module with regards to heart problem (2.4 ± 0.77 vs 1.4 ± 0.74, $p < 0.001$), treatment problem (1.2 ± 1.12 vs 0.5 ± 0.74, $p = 0.019$), perceived physical appearance (2.2 ± 1.09 vs 1.4 ± 1.1, $p = 0.007$), treatment anxiety (2.6 ± 0.99 vs 1.4 ± 1.14, $p < 0.001$), cognitive (1.7 ± 0.94 vs 0.8 ± 0.69, $p < 0.001$), and communication (2.4 ± 1.15 vs 1.3 ± 1.1, $p < 0.001$). The QoL was also significant on the 5th post-operative day, except for treatment problem. Comparing the treatment group, there was a significant improvement on the QoL as the sessions progressed.
Conclusion: The structured play module is an effective therapeutic tool for cardiovascular rehabilitation of post-operative pediatric patients. It helped improved the quality of their lives post-operatively.

P1218 - MUSCULAR ENDURANCE AND AGILITY LIMIT THE PHYSICAL ACTIVITY CAPACITY OF CHILDREN WITH CONGENITAL HEART DEFECTS COMPARED TO CANADIAN SCHOOLCHILDREN

Anastasia Alpous[1], Jane Lougheed[2], Patricia Longmuir[1]
Cheo Research Institute, Halo, Ottawa-Canada[1]; Children's Hospital of Eastern Ontario, Cardiology, Ottawa-Canada[2]

Background/Hypothesis: Physical literacy is the motivation, confidence, knowledge and physical competence to pursue physical activity for life. Children with congenital heart defects (CHD) are more sedentary than peers, suggesting a physical literacy deficit. It was hypothesized that children with CHD would demonstrate physical competence and daily behavior deficits.
Materials and Methods: Cross-sectional study of children, 8 to 12 years of age, with CHD ($n = 37$, 35% female) or attending local schools ($n = 963$, 55% female). The Canadian Assessment of Physical Literacy assessed total physical literacy and four subdomains (daily behaviour, physical competence, motivation and confidence, and knowledge and understanding).
Results: Children with CHD walked more steps each day ($13{,}750 \pm 3457$; $p < 0.001$) and tended to report more sedentary behaviour ($p = 0.02$), as shown in Table 1. Their muscular endurance was only 60% of that achieved by school children of similar age (CHD: 3.6 ± 2.4; School: 6.0 ± 4.4; $p < 0.001$). CHD children also tended to have lower agility scores ($p = 0.02$). In multi-variable regression models accounting for age, sex, and season of assessment, higher physical competence scores occurred among school children, older children, males, and those tested during the summer (model $R2 = 0.13$). Age, sex, season and study group explained very little of the variance in physical literacy scores (model $R^2 \leq 0.03$).
Conclusions: Children with CHD have motivation for, and knowledge about physical activity that is similar to peers. However, muscular endurance and agility were decreased even among our highly active sample of CHD patients. The impact of interventions to enhance muscular endurance and agility and the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

physical literacy of a randomly selected sample of children with CHD should be pursued.

Similar Knowledge and Understanding	11.8 ± 2.7	11.5 ± 2.6	-1.57,0.91	0.48

[1] For all measures a higher score represents a healthier behavior (e.g., higher sedentary score = less sedentary time).
[2] CHD = congenital heart defect; School = children tested in local schools.
[3] Conf. Int. = confidence interval; significance set at $p < 0.01$ to account for multiple outcomes ($p = 0.05$ / 5 primary outcomes (total + 4 domain scores)); significant differences shown in bold; *trends shown in italics*.

P1255 - BICUSPID AORTIC VALVE IN CHILDREN WITH MARFAN SYNDROME HIGH APPEARANCE WITHOUT CORRELATION TO SEVERITY OF CLINICAL SYMPTOMS

Veronika C. Stark, Thomas S. Mir, Florian Arndt, Jakob Olfe, Friederike S. Seggewies, Goetz C. Mueller, Rainer Kozlik-Feldmann
University Heart Center, Pediatric Cardiology, Hamburg-Germany

Background: Due to age dependent development of most pathologies in Marfan syndrome (MFS) estimation of clinical outcome in childhood is difficult. Bicuspid aortic valve (BAV) is correlated with MFS and prevalence is up to 4.7% in adult Marfan patients. Data in childhood about appearance and correlation with severity of phenotype is missing. Subsequently it may be a predictor for onset of pathologies and helpful to determine individual patient care. We hereby evaluated correlation of present BAV with Marfan pathologies in childhood.
Material and Methods: Since 2008 we investigated 395 patients (11.4 ± 5.5 y) with suspected MFS. In 145 patients MFS was diagnosed, thereby 16 patients showed BAV. We retrospectively analyzed correlation of prevalence and age of onset of cardiovascular pathologies (Dilatation sinus of valsalvae (SV), Mitral valve prolaps (MVP)), systemic manifestation of Ghent Criteria and FBN1 mutation with appearance of BAV.
Results: Prevalence of BAV in pediatric Marfan patients was 11.0%. Age of patients with and without BAV did not differ significantly. There is no correlation of BAV with prevalence or age of onset of marfan pathologies (SV, MVP, systemic manifestation, ectopia lentis, FBN1 mutation) of MFS ($p > 0.05$).
Conclusions: In our large collective prevalence of BAV in MFS was surprisingly higher compared to adult. The reason is unknown, but can possibly be an effect of selection. Indeed, occurrence of BAV did not correlate with severity of clinical phenotype. Especially SV dilatation did not appear earlier or more often in BAV patients. Thus BAV is present frequently in MFS but is no predictor for clinical outcome and estimation of need for therapy. Development of pathologies in those patients in adulthood is unknown but may be relevant for course of disease. Good predictors for severity of phenotype in childhood are unfortunately still missing.

P1273 - EARLY FUNCTIONAL HEALTH OUTCOMES FOR INFANTS AND THEIR FAMILIES WHO HAVE UNDERGONE ARTERIAL SWITCH OR NORWOOD PROCEDURES

Naychi Lwin[1], Karen Eagleson[1], Susan Johnson[2], Honey Heussler[3], Nelson Alphonso[1], Robert Justo[1]
Lady Cilento Children's Hospital, Queensland Paediatric Cardiac Service, Brisbane-Australia[1]; Lady Cilento Children's Hospital, Department of Psychology, Brisbane-Australia[2]; Lady Cilento Children's Hospital, Child Development Program, Brisbane-Australia[3]

Background: This Program assessed the impact on functional health, in the current era, of cardiac bypass surgery on a cohort of neonates at risk of neurodevelopmental disability.
Methods: Infants undergoing Arterial Switch Operation (ASO) or Norwood procedure from January 2013 were enrolled prospectively into the Neurodevelopmental Program. Demographic and clinical data were analysed. Bayley Scales of Development Third Edition, Health-Related Quality of Life (HRQoL) and Parenting Stress assessments were performed at 6, 12 and 24 months.
Results: ASO patients had median Comprehensive Aristotle Complexity Scores (CACS) of 12 (IQR 10 – 14) and intensive care (PICU) stay of 8.8 days (IQR 6.0-11.9). Norwood infants had median CACS of 17 (IQR 14 – 20) and PICU stay of 21.4 days (IQR 16.1-27.1). Infants were assessed at 6 (ASO: n = 25, Norwood: n = 13), 12 (ASO: n = 20, Norwood: n = 8) and 24 months (ASO: n = 7, Norwood: n = 3). ASO infants scored in low average range in adaptive behaviour at 12 months (86.9 ± 24.5), and at least average range across other domains at 6, 12 and 24 months. Norwood infants scored in low average range in adaptive behaviour but average range across all domains at 6 months. Subsequently they scored in low average-borderline range; in language (12 month: 83.6 ± 35.9, 24 month: 85.3 ± 33.2), motor (12 month: 71.9 ±29.8, 24 month: 86.3 ± 21.5) and adaptive behaviour (6 month: 88.64 ± 30.4, 12 month: 85.9 ± 12.4, 24 month: 77.7 ± 23.0) domains. Parent-reported total HRQoL was significantly lower in ASO group at 6 months only. Lower total HRQoL in the Norwood group was persistent at 12 months. Parenting stress was in the normal range for both groups at all time point.
Conclusion: Study findings suggest that infants undergoing the Norwood procedure have reduced functional health when followed beyond 12 months.

P1293 - THE MENTAL HEALTH OF ADOLESCENTS LIVING WITH POTENTIALLY FATAL ARRHYTHMIA A SYSTEMATIC REVIEW OF THE LITERATURE

Patricia Longmuir[1], Margaret Sampson[2], Jennifer Ham[1], Makenzie Weekes[1], Bhavika Patel[1], Robert Gow[3]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Cheo Research Institute, Halo Research Group, Ottawa-Canada[1]; Children, Media and Library Services, Ottawa-Canada[2]; Children, Cardiovascular Surgery, Ottawa-Canada[3]

Background/Hypothesis: Potentially fatal arrhythmia diagnoses add to the mental health challenges of adolescence. This systematic review sought to summarise current knowledge regarding the mental health of adolescents diagnosed with a life-threatening cardiac arrhythmia.
Materials and Methods: Search terms using psychological problems of environmental origin and inherited cardiac arrhythmia diagnoses identified studies among those 9 to 18 years. Multiple authors screened 3238 titles/abstracts and reviewed citations to identify 233 potentially relevant articles. Full text review identified 15 articles meeting inclusion criteria.
Results: All 15 studies (see table) were cross-sectional; 8/15 required an implantable cardioverter defibrillator (ICD). Methods were quantitative (n = 10), qualitative (n = 4) or mixed (n = 1), with 16% to 100% of participants having an inherited cardiac diagnosis. Patients and parents reported lower quality of life, particularly in relation to physical function, social relationship difficulties, being restricted from peer activities, bodily pain and mental and emotional health. Mental health studies (n = 8) suggest that mental and emotional health issues are not extensive among patients with ICDs assessed 2 + years after implant. Children's self-perceptions and behaviour were similar to healthy populations and rates of anxiety and depression were not increased. However, psychosocial stresses may be more significant in the months immediately after diagnosis. Anxiety, depression or aggressive behaviour is reported by 15-33% of these patients, with higher risk among patients who also have a diagnosed sibling, those with cardiomyopathy, and those who report decreased quality of life.
Conclusions: Mental health research among adolescents with inherited arrhythmias is extremely limited and of low quality. Data, primarily from patients 2-4 years post ICD implant or diagnosis, indicate quality of life may be decreased and 15-33% experience mental health issues. The mental health of adolescents with inherited arrhythmias, whether or not they have an ICD and from time of diagnosis, and the impact of clinical interventions remain unknown.

P1312 - ECHOCARDIOGRAPHY AND CORONARY ANGIOTOMOGRAPHY AS A NON INVASIVE METHOD FOR DIAGNOSIS OF CORONARY ANEURYSMS IN KAWASAKI DISEASE

Lucia M. V. O. Salerno[1], Carolina V. O. Salerno [2], Juliana V. O. Salerno[3], Pedro Rafael Salerno[4], Karina T.M. Nobrega[5]
HC-UFPE, Cardiology, Recife-Brazil[1]; UFPE, Student, Recife-Brazil[2]; FCMPB, Student, Joao Pessoa-Brazil[3]; UPE, Cardiovascular Surgery, Recife-Brazil[4]; IMIP, Radiologist, Recife-Brazil[5]

Background: Kawasaki disease (KD) is a systemic vasculitis that mainly occurs in children under 5 years. Coronary artery aneurysms (CAA) occur in 20% of cases untreated with intravenous immunoglobulin (IVIG), and in 5-7% of treated patients, which can lead to ischemic heart disease and death.
Case 1: MG, 2y7m old male, presented a 6-day fever, followed by oropharynx hyperemia, maculopapular rash in trunk and members, bilateral conjunctivitis and hyperemia in hands and feet. The echocardiogram (ECHO) was normal. He was treated with IVIG (2 g/kg) and acetylsalicylic acid (AAS) 100 mg/kg/day until being

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

afebrile for 72 h and was discharged with AAS (5 mg/kg/day). A month later, a new ECHO showed a 7mm aneurysm in the right coronary artery (RCA) and 6mm one in the left coronary artery (LCA). A coronary angiotomography (CAG) confirmed the ECHO findings.
Case 2: RDS, 3 year-old male, presented complete symptomatology for KD. On the 7th day of onset disease, he received IVIG (2 g/kg) and AAS (100 mg/kg/day). His fever persisted, so prednisone (2 mg/kg/day) was administered for 14 days. The first ECHO and EKG were normal. He was discharged with AAS (5 mg/kg/day). The follow-up ECHO and CT scan showed a 5mm aneurysm in the RCA and multiple CAA like rosary beads in the LCA. The CAG showed further aneurysms in the RCA and left circumflex artery. Infliximab was administered (5 mg/kg), in an attempt to reduce cardiac sequelae.
Conclusion: KD surpassed rheumatic fever as leading cause of acquired cardiac disease in children of the developed world. Despite the use of IVIG, 10% of patients develop cardiac alterations. CAG complements the evaluation detecting aneurysms, thrombus, and stenosis in the distal regions of the coronaries which the ECHO is unable to identify.

P1315 - OBSERVATIONAL STUDY OF CARDIAC ALTERATIONS IN PATIENTS WITH MUCOPOLYSACCHARIDOSIS

Lucia M. V. O. Salerno[1], Carolina V. O. Salerno [2], Raiza Souza Landim[3], Natália De Souto Leite[3], Juliana V. O. Salerno[4], Pedro Rafael Salerno[5]
UFPE, Cardiology, Recife-Brazil[1]; UFPE, Student, Recife-Brazil[2]; UNICAP, Student, Recife-Brazil[3]; FCMPB, Student, Joao Pessoa-Brazil[4]; UNICAP, Cardiovascular Surgery, Recife-Brazil[5]

Background: Mucopolysaccharidosis (MPS) are inherited lysosomal storage disorders caused by the deficiency of enzymes responsible for the degradation of glycosaminoglycans (GAGS). The systemic deposition of GAGS results in progressive organic dysfunction. Cardiovascular involvement is variable but contributes towards the morbidity/ mortality of the patients.
Materials and Methods: A prospective observational study was conducted with 27 MPS patients aged 3-21 years. Two patients were type I, seven type II, three type IV and fifteen type VI. Twenty-three patients underwent enzyme replacement therapy (ERT). Their clinical alterations, electrocardiographs (ECG) and echocardiograms (ECHO) were analyzed. Cardiac findings, time of ERT and severity of valvular lesions were compared between the different types of MPS.
Results: Although ECHO alterations were present in all patients, 74,1% referred dyspnea or palpitations, only 55,6% presented murmurs and 7,4% showed ventricular overload in the ECG. All patients were in sinus rhythm, and 22,2% had incomplete right bundle branch block. Systolic function was overall normal, although 30,8% presented left diastolic dysfunction. Pulmonary hypertension was found in 33,3% and systemic hypertension in 25.9%. One patient had a biologic mitral valve prosthesis. Mitral valve thickening was seen in 26 patients (92.3%), of which 29.1% had no dysfunction, 75% had discrete or moderate regurgitation, and 3.7% had double lesion. The aortic valve was affected in 70.4% of patients (11.1% had double lesion and 59.3% had regurgitation). Mild or moderate tricuspid regurgitation was present in 33.3% and left ventricle hypertrophy in 44% of the patients. The type IV patients manifested less mitral valve lesions ($p = 0{,}035$).
Conclusion: Valvular lesions are frequent in MPS patients particularly in those with type I, II and VI. These patients presented a higher prevalence of mitral and aortic valvulopathy with a predominance of regurgitation.

P1364 - "DOCTOR WHAT WOULD YOU DO IF IT WAS YOUR CHILD – IS THAT THE CORRECT QUESTION TO ANSWER IN PRENATAL CARDIAC COUNSELLING "

Samuel Menahem
Monash Health, Fetal Cardiac Unit, Melbourne-Australia

Background: The prenatal diagnosis of a complex cardiac abnormality generates considerable stress for the affected parents. Counselling strategies have been described with limited documentation of their efficacy.
Methods and Materials: Against the background of an accurate fetal diagnosis parents were informed in simple lay terms, aided by diagrams and the attending obstetrician ultrasonologist, of the nature of the abnormality, it's likely consequences and potential interventions. Explanations included the immediate and long term functional outcomes rather than the detailed anatomy. At times multiple visits were required being cognizant of the parental emotional distress and their difficulties to "hear" and assimilate what is said.
Results: Using a self report scale, 70% of mothers of a cohort of 39 affected pregnancies felt that the above approach allowed for a clear or very clear explanation of the cardiac abnormality, 85% felt that the details were just right while 60% rising to 80% following subsequent scans, described their understanding to be good to excellent. These results were especially meaningful when 70% acknowledged being distressed or very distressed at the time. At no stage even if asked, was it necessary for the clinicians to give their own views as if it was their child.
Conclusion: Simple explanations emphasising function and outcome and taking into account the emotional distress of the parents, allowed for a good understanding of the cardiac abnormality and its consequences. Such an approach may have facilitated informed consent if termination was an option. It did away with the clinicians expressing their personal views allowing the parents to reach their own decision taking into account their life experiences, needs and responsibilities.

P1365 - LIPID ABNORMALITIES IN CHILDREN ONE YEAR AFTER KAWASAKI DISEASE

Pei-Ni Jone[1], Michal Schafer[1], Meredith Wilson[1], Heather Heizer[2], Marsha S. Anderson[2], Mary P. Glode[2], Samuel R. Dominguez[2]
University of Colorado, School of Medicine, Pediatric Cardiology, Aurora-United States[1]; University of Colorado, School of Medicine, Pediatric Infectious Disease, Aurora-United States[2]

Background: Kawasaki Disease (KD) patients have abnormal lipid profiles at presentation. Because coronary artery lesions (CAL) develop in 25% of untreated KD patients, lipid profile screening has been recommended by the American Heart Association guideline in KD patients after recovery. High density lipoprotein (HDL) has been shown in adults to be protective of atherosclerosis and coronary artery disease; however, we do not know the role of HDL in KD patients with CAL. In this study, we evaluated the lipid profiles of KD patients 1 year after disease onset and compared lipid profiles of KD patients with and without CAL.
Methods: Patients medical charts were retrospectively reviewed from 2014-2016. CALs were defined as left anterior descending artery and right coronary artery z-scores ≥ 2.5. Lipid profiles were obtained in KD patients (fasting state) 1 year after disease onset. Demographic and biomarkers were compared with HDL $\geq$ 45 mg/dl and $<$ 45 mg/dl and between patients with and without CAL using a student s t-test for normally distributed continuous

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

variables, Wilcoxon ranked sum test for non-uniform distributed variables, and $\chi 2$ for categorical variables.
Results: 53% of KD patients had HDL <45 mg/dl. There were no significant differences in clinical and initial laboratory values between the two groups (Table 1) with the exception of hemoglobin ($p < 0.007$) and albumin ($p < 0.01$). There were no significant differences in lipid profiles in KD patients with and without CAL (Figure 1). There were no significant differences between the body mass indexes between the two groups when the lipids were drawn at 1 year after disease onset.
Conclusions: Half of KD patients had HDL <45 mg/dl one year after disease onset. Preventative counseling to KD patients diet and exercise are important in KD patients with abnormal HDL. Future studies are are needed to elucidate the pathophysiology of this lipid abnormality in KD patients.

Table 1. Clinical and Laboratory Characteristics of KD patients at time of diagnosis with low and normal HDL.

	HDL < 45 (n = 39)	HDL ≥ 45 (n = 34)	P-value
Age (years)	4.3 ± 3.1	4.3 ± 3.5	0.9688

P1395 - QUEENSLAND FAMILIAL HYPERCHOLESTEROLAEMIA CLINIC OUTCOMES ANALYSIS

Ari Horton, Rachel Tarte, Theresa Crouch, Robert Justo
Children's Health Queensland, Queensland Paediatric Cardiac Service, Brisbane-Australia

Background: Consensus guidelines exist for the diagnosis, treatment and management of Familial Hypercholesterolaemia (FH) in childhood. We review the practical outcomes of preventative intervention from a state-wide paediatric FH clinic.
Methods: Prospective assessments included response to treatment, review of side-effects, carotid intima-media thickness (CIMT) and echocardiography at appropriate intervals. Of the 26 clinic patients, 24 had full datasets for lipid profiles including initial response and late follow-up. 14 had CIMT measurements early and at late follow-up.
Results: Presentation was predominantly in asymptomatic children from cascade screening. All patients had phenotypically confirmed FH with elevated low-density lipoprotein (LDL-C) levels (>4.0 mmol/L) and a significant family history. The cohort was 63% male with diagnosis occurring at median age of 12.7 years (range 4.8-16.8). 4 patients had concurrent type 1 diabetes mellitus. Statin treatment was commenced at median age of 13.0 years (range 8.0-16.8) and followed guidelines. At diagnosis mean total cholesterol (TC) was 8.2 mmol/L (CI 0.6) and mean LDL-C was 6.1 mmol/L (CI 0.5). Initial post-therapy levels were TC 5.6 mmol/L (CI 0.3) (=31% reduction, CI 4%) and LDL-C of 3.7 mmol/L (CI 0.4) (=39% reduction, CI 4%). These reductions were maintained at median follow-up of 3.5 years (range 1.1-9.2) with TC 5.7 mmol/L (CI 0.5) (=29% reduction, CI 6%) and LDL-C 3.9 mmol/L (CI 0.5) (=35% reduction, CI 6%). Targeted dose escalation was required in 45% of patients. 8 children changed medications with 6 due to documented mild side-effects, which all resolved. During follow-up Left-CIMT (n=14) was reduced from 0.52mm (CI 0.04) to 0.48mm (CI 0.02). (All reported results $p < 0.05$).
Conclusion: We demonstrated that early intervention has the potential to improve lipid levels and CIMT, both of which are associated with cumulative lifetime risk-reduction. A large proportion of unrecognised and untreated paediatric patients must exist based on known incidence of FH of >1:500.

P1415 - CHARACTERIZATION OF PULMONARY HYPERTENSION IN CHILDREN IN ALTITUDE (2.640 METERS OVER SEA LEVEL) IN LAST YEAR

Gabriel Fernando Diaz Gongora[1], Alicia Marquez[2], Roy Sanguino[3], Manuel Huertas[1], Santiago Ucroz[4], Miguel Ronderos[5], Sandra Matiz[6]
Universidad Nacional De Colombia, Pediatrics, Bogota-Colombia[1]; Clinica De La Mujer, Pediatrics, Bogotá-Colombia[2]; Homi, Pediatrics, Bogotá-Colombia[3]; Fundación Santafe, Pediatrics, Bogotá-Colombia[4]; Fundación Cardioinfantil, Pediatrics, Bogotá-Colombia[5]; Universidad Del Bosque, Pediatrics, Bogotá-Colombia[6]

Introduction: The effect of altitude is significant over 2.500 MOSL. Bogotá, where we made the study, is at 2.640 MOSL.
Objective: To show the effect of Hypobaric Hypoxia on PH in Children.
Patients: We include only new patients studied the last 12 months. All had Clinical evaluation, BNP, prolonged Hyperoxia Test and Catheterism, except one patient that didn´t have catheterism because he died before the procedure. Necropsy study showed Idiopathic Pulmonary Hypertension with severe Pulmonary Vascular Disease. In the Cath. Lav. all patients had Vascular Reactivity Test with NO and Oxygen. Living at low altitude is recommended.
Results: We had 20 new patients; 16 females (80%); 8 were 3 years old or less (40%); 12 had IPH (60%), 4 CHD (3 developed PH after surgery); 2 CPD, 1 HAPE and 1 group 5. Majority of patients had severe PH: MPP >60 mm Hg; PR >20WU.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Discusion: Altitude gives special characteristics to PH by hypobaric hypoxia, affecting epidemiology, pathogenesis, diagnostic approach and treatment. Epidemiology: PH is frequent, begins and could be severe at an early age, and IPH is the main cause. Pathogenesis: Hyperreactivity of Pulmonary Vasculature is important and remodeling could be severe very early. Diagnosis and treatment: Oxygen plays important role.
Conclusion: At altitude, Hypobaric Hypoxia gives special characterstics to PH. Because Hypobaric Hypoxia influences not only other pathologies of group 3 but also pathologies of groups 1 and 5 of Nice Classification, maybe PH of altitude deserve to be considered as a subgroup of group 3.

P1421 - EARLY DETECTION OF SEVERE PULMONARY HYPERTENSION IN CHLDREN AT ALTITUDE 2.640 METERS OVER SEA LEVEL

Gabriel Fernando Diaz Gongora[1], Alicia Marquez Garia[2], Roy Sanguino[3], Manuel Huertas[1], Miguel Ronderos[4]
Universidad Nacional De Colombia, Pediatrics, Bogota-Colombia[1]; Clínica De La Mujer, Pediatrics, Bogota-Colombia[2]; Fundacion Homi, Pediatrics, Bogota-Colombia[3]; Fundación Cardioinfantil, Pediatrics, Bogota-Colombia[4]

New advances in knowledge of PH, have allowed longer and better quality of life of patients. It is important early detection for avoid the remodeling of pulmonary vasculature.
Objective: To show a serie of cases with severe PH in children diagnosed in early childhood in Bogota, Colombia (2.640 MOSL), analyzing the outcome and the answer to early diagnosis.
Material and Method: We analyzed clinical and laboratory records of children with severe PH. Diagnosis was made considering clinical findings, EKG, Thorax X Ray, echocardiogram and catheterism. Oxygen and vasodilators were used.
Results: 31 patients had severe PH: media PSP: 102 mm Hg. (68-170). Pathologies: IPH: 23; ES: 2; Talasemia: 1; With CHD: 5; Age at diagnosis: Media: 3.85 years (0.4-12 Years). Time of follow up: 5.3 years; (0.5-33 years). One child (22 months old at diagnosis), had a BMPR2 mutation. Today after 14 years of Follow up, is asymptomatic. 8 patients died, 10 stable, 9 very well, 2 asymptomatic and 2 bad. 18 went to live at low altitude; 13 are well or stable.
Discussion: Initially PH is a "silent" disease, but can be detected early, considering clinical aspects. In altitude, the therapeutic approach is different; it is important to live at low altitude. The early detection of PH correlate with better outcome although by hypobaric hypoxia, PH could be agressive and 8 patients died in spite of live at low altitude
Conclusion: PH is a disease with poor prognosis and early mortality. There isn't cure; with early diagnosis we can get better prognosis, avoiding pulmonary vascular disease. In 31 children we have got a mean follow up of 6.3 years (0.5-33) including a patient with a BMPR2 mutation (initial PSP: 153 mm Hg) with Follow up of 14 years. The patient is asymptomatic with PSP of 48-50 mm Hg.

P1476 - PULMONARY ARTERIAL HYPERTENSION AS A LATE COMPLICATION OF CONGENITAL HEART DISEASE

Andréa Consuelo De Oliveira Teles, Candice Torres De Melo Bezerra Cavalcante, Klebia Magalhães Pereira Castello Branco, Ronald Guedes Pompeu, Isabel Cristina Leite Maia, Jeanne Araújo Bandeira, Kiarelle Penaforte, Anna Karina Martins Brito, Marília Ramalho, Márcia Souza Degobi
Messejana's Hospital, Pediatric Cardiology, Fortaleza-Brazil

Background: Despite advances in diagnosis and treatment of congenital heart disease (CHD), there are many patients with undiagnosed or un-operated CHD in the developing countries, mainly because of late referral to specialized centers. Pulmonary arterial hypertension (PAH) associated with CHD (PAH-CHD) is usually the result of a large systemic-to-pulmonary shunt and it is a heterogeneous condition, depending on the type of the underlying defect and previous repair strategies. The presence of PAH increases morbidity and reduces survival in patients with CHD. The prevalence of PAH-CHD has been estimated to range between 1.6 and 12.5 cases per million adults. Despite of recent evidence of the benefits of PAH-specific therapy in the PAH-CHD population, the mortality rates remain relatively high.
Objectives: determinate the epidemiologic characteristics and outcomes of patients with diagnosis of HAP in a regional referral center in Brazil.
Methods: all patients with PAH-CHD were included. Data about gender, age, underlying diagnosis, previous cardiac surgery, medications in use and mortality were recorded.
Results: from a total of 113 patients in the registry, 70 were female (61,9%). Average age of these patients was 24,13 ± 14,40 years (range from 4 to 76 years) and 18,8% had Down Syndrome diagnosis. The average time of follow up was 6,12 ± 4,09 years. The most frequent underlying defects were ventricular septal defects (20,4%), complete atrio-ventricular septal defect (20,4%) and atrial septal defects (15,9%). Thirty two patients (28,3%) have undergone previous surgical procedures. The majority of patients were using sildenafila (89,1%), furosemide (67,3%) and digoxine (61,9%). Only 10,6% of patients were receiving treatment with bosentana. The overall mortality was 6,2%.
Conclusion: The HAP-CHD is a common complication of late treatment of CHD with high mortality.

P1513 - LIPOPROTEIN (A) DOES NOT ADVERSELY IMPACT VASCULAR HEALTH IN CHILDREN WITH DYSLIPIDEMIA

Omar Qayum, Chizitam Ibezim, Geetha Raghuveer
University of Missouri-Kansas City, School of Medicine, Kansas City-United States

Background/Hypothesis: Lipoprotein (a) [Lp(a)] accelerates atherosclerosis and is strongly heritable. Elevation of Lp(a) is an independent risk factor for premature cardiovascular disease in adults, but its role in atherosclerotic progression in children is unclear. We conducted a cross-sectional pilot study to determine whether Lp(a) contributes to altered vasculature in children with dyslipidemia.
Materials & Methods: Children and adolescents aged 9-18 years with dyslipidemia were prospectively recruited from a pediatric preventive cardiology clinic. Each completed a lipid panel and Lp (a) measurement. Participants were separated into either a study group (Lp(a) ≥30 mg/dL) or control group (Lp(a) <30 mg/dL). Pulse wave velocity [PWV], a measure of vascular stiffness, was calculated using a combined oscillometric and tonometric device. Carotid artery intima-media thickness [cIMT] was measured along the far wall of the right and left common carotid arteries using semi-automated edge detection software.
Results: 64 children (32 per group) were recruited: study group (37.5% males, age 15.43 ± 2.35 years) and control group (40.6% males, age 13.42 ± 1.84 years). Number of vascular risk factors was 3.7 ± 1.6 in the study group and 3.4 ± 1.3 in the control group. Family history of premature cardiac death was present in 21.9% of the study group and 15.6% of the control group. Lp(a) was 99.8 ± 55.4 mg/dL (median 93.0 mg/dL) in the study group and

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

10.1 ± 4.4 mg/dL (median 10.0 mg/dL) in the control group. Between groups, there was no difference in PWV (study 4.7 ± 0.8 meters/second [median 4.8 meters/second]; control 4.8 ± 1.7 meters/second [median 4.6 meters/second]; p = 0.83) or cIMT (study 0.47 ± 0.05mm [median 0.45mm]; control 0.47 ± 0.04mm [median 0.47mm]; p = 0.61).
Conclusions: Despite the presence of elevated Lp(a) and other atherosclerosis-promoting risk factors in this young, cross-sectional study population, there was no evidence of adverse change in the vasculature when compared to those with normal Lp (a). However, continued follow-up of this high-risk group is recommended in view of their known risk for premature cardiovascular disease.

P1517 - RIGHT ATRIUM ANEURYSM IN A 14 YEAR OLD BOY DIAGNOSED SINCE INTRAUTERINE LIFE

Maria Cristina Ventura Ribeiro[1], *Fabiana Aragão Feitosa*[1], *Tereza Arraes Pinheiro*[1], *Flavia Jeronimo Da Silva*[1], *Fernando Moraes Neto*[2], *Aline Borges Maciel*[1], *Cleusa Lapa Santos*[1]
IMIP, Pediatric Cardiology, Recife-Brazil[1]; *IMIP, Pediatric Surgery, Recife-Brazil*[2]

Background: Right atrial (RA) aneurysm is a rare cardiac abnormality of unknown origin with few cases described in the literature, especially in intrauterine life. This defect is usually diagnosed incidentally and many patients are asymptomatic. Others present arrhythmia, chest pain and shortness of breath. The best approach to asymptomatic patients has been controversial and the natural evolution of these malformations remains uncertain.
Case Report: The authors describe a 14-year-old-boy who was referred with palpitations and shortness of breath during mild efforts. He was using no medication. He had had an intrauterine diagnosis of right atrium aneurysm, with no other malformations and was accompanied in another city. On physical examination he was eupneic and acyanotic. In the thoracic auscultation, the heart sounds were rhythmic with a systolic murmur at tricuspid area with a positive Rivero-Carvallo's sign. Chest radiography disclosed considerable cardiomegaly due to RA dilatation. On electrocardiogram, he presented sinus rhythm with signs of right atrium enlargement. Echocardiogram revealed a normal positioned tricuspid valve, a huge right atrium and right atrium appendage. Right atrium volume was 413 mL. There was moderate to severe tricuspid regurgitation. He underwent surgery with extracorporeal circulation. The right atrium was opened with resection of a large aneurysm and a tricuspid valvuloplasty was performed. Postoperative echocardiogram revealed discrete increased right atrium with a 49 mL volume and mild to moderate tricuspid regurgitation. He was discharged on the tenth postoperative day in good conditions.
Conclusions: For the little experience accumulated with RA aneurysm diagnosed in intrauterine life, the wiser conduct seems to be expectant. Fetal echocardiography plays an important role in diagnosis of congenital cardiopathies and in the event of finding atrial dilatation on obstetric ultrasound examination, fetal echocardiogram should be performed.

P1519 - FOUR NEUROLOGICALLY INTACT SURVIVING PATIENTS AFTER COLLAPSE DUE TO HYPERTROPHIC CARDIOMYOPATHY OUTCOMES OF MANAGEMENT BASED ON HEART SCREENING FOR SCHOOLCHILDREN

Chie Aota, Masaru Yamakawa, Chitose Miyakoshi
Kobe City Medical Center General Hospital, Pediatrics, Kobe-Japan

Background: The system of electrocardiogram screening for all schoolchildren was initiated in 1997 in Japan. Since the use of automated external defibrillators (AEDs) by the general public was approved in 2004, many AEDs have been supplied to public schools. More children with hypertrophic cardiomyopathy (HCM) are being successfully resuscitated after collapse owing to the increased availability and accessibility of basic life support systems. Our hospital conducts screening of schoolchildren in Kobe City, and provides emergency and critical care. Four patients with HCM who survived after being resuscitated were sent to our hospital since 2005.
Cases: All the patients were diagnosed with HCM while in primary or junior-high school and they had been restricted from performing exercise. They had no subjective symptoms, and no arrhythmia was detected before the cardiac event. Only case 3 had a family history of sudden death.
Case 1: A 16-years-old boy collapsed while practicing judo during. The teachers immediately requested for a rescue team, and the ambulance crew used an AED.
Case 2: A 14-years-old boy collapsed while running on the school ground. The teachers immediately used an AED.
Case 3: A 21-years-old woman collapsed during her internship work. The attending supervisor immediately used an AED.
Case 4: A13-years-old boy collapsed when he was about to leave school. Bystanders and teachers performed emergency cardiopulmonary resuscitation, and the rescue team used an AED.
After being defibrillated, the patients were sent to our hospital and received low-temperature therapy and implantation of an implantable cardiovascular defibrillator. All of them recovered without any neurological sequelae.
Conclusion: We teach about emergency cardiopulmonary resuscitation in junior high schools and high schools, and spend more educational time at schools with more registered high -risk patients. We hope to reduce the total number of sudden deaths under school supervision through the screening system and activities after diagnosis.

P1542 - BEYOND THE SINUS OF VALSALVA POSITIVE EFFECT OF ANGIOTENSIN II RECEPTOR BLOCKERS ON MITRAL VALVE PROLAPSE IN A RETROSPECTIVE ANALYSIS OF PEDIATRIC PATIENTS WITH MARFAN SYNDROME

Jakob Olfe, Jannis Pesch, Goetz Mueller, Friederike Seggewies, Veronika Stark, Rainer Kozlik-feldmann, Thomas Mir
University Heart Center Hamburg, Dept. For Pediatric Cardiology, Hamburg-Germany

Objectives: Treatment with Angiotensin-II-receptor-blockers (ARB) in patients with Marfan syndrome (MFS) has been well established. Most studies, so far, focused on the the aortic root dilatation. No study has focused on the effect on the regularly appearing mitral valve prolapse (MVP) in MFS. The aim of our study was to analyse the treatment effect of ARB on the degree of MVP in pediatric patients with MFS.
Methods: Since 2008 we investigated 398 patients (11.4 ± 5.5 y) with suspected MFS. 140 patients were diagnosed with MFS. 62 patients showed MVP. We retrospectively analysed database data and 2D-echocardiograms. Because of the high error measuring the actual MVP in millimeter, mitral anular diameter (MAD) was used as a surrogate parameter for MVP in MFS (Pini R, 1989, Circulation). Patients in the treatment group received oral Valsartan, control patients had no treatment. Patients taking beta-blockers or having being operated on the aorta were excluded to clearly indicate group allocation.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: Prevalence of MVP in pediatric Marfan patients was 43,8%. In the control group the z-score of the MAD did not change significantly during the observation period. In patients treated with an ARB the z-score of the MAD was significantly reduced. Detailed data is shown in table 1.
Conclusion: Prevalence of MVP in children with MFS is 40 times higher than in a healthy population (Sattur S, 2010, Exp Clin Cardiol). In our study, treatment with an ARB in pediatric patients with MFS leads to a significant reduction of the MAD as a surrogate parameter for MVP. This first data suggests another positive effect of ARB treatment in MFS beyond the growth restrictive effect on the aorta. Future studies have to analyse greater numbers of patients, the long term effect and develop better imaging methods for the detailed analysis of MVP e.g. MRI.

Table 1. Demographic and mitral valve date before therapy initiation or at first visit (t0) and at last follow up (t1) in patients with MFS without treatment (control) or treated with an angiotensin receptor blocker (ARB).

Demographic data	control group n = 12 (3 female)			ARB group n = 8 (4 female)		p value
Age (years) at treatment initiation /first visit	8,2 ± 4,75			12,3 ± 3,61		ns
Follow up period in years	2,4 ± 1,93			3,4 ± 2,08		ns
Mitral valve prolapse	t0	t1	p value	t0	t1	p value
z-score of mitral anular diameter	2,23	2,04	0,5121	2,59	2,21	0,0336

ARB, angiotensin II receptor blocker

P1557 - ANOMALOUS CORONARY ARTERIES CONNECTED TO PULMONARY ARTERY IN COMBINATION WITH OTHER CONGENITAL HEART DEFECTS AND EXTRACARDIAC ANOMALIES – OVERVIEW OF 98 PATIENTS

Franziska Ziermann[1], Juergen Hoerer[2], Ruediger Lange[3], Peter Ewert[1], Alfred Hager[1]
Deutsches Herzzentrum München, Technical University of Munich, Department of Paediatric Cardiology and Congenital Heart Defects, Munich-Germany[1]; Centre Chirurgical Marie Lannelongue, Department of Congenital Heart Disease, Paris-France[2]; Deutsches Herzzentrum München, Technical University of Munich, Department of Cardiovascular Surgery, Munich-Germany[3]

Background: Anomalous coronary arteries connected to the pulmonary artery are rarely associated with other congenital heart defects.
Materials and Methods: From 1974 to 2016, 98 patients with anomalous coronary arteries connected to the pulmonary artery were retrospectively analyzed. Anomalous left coronary artery connected to the pulmonary artery (ALCAPA) was present in 84 patients, anomalous right coronary artery connected to the pulmonary artery (ARCAPA) in 4, anomalous circumflex coronary artery connected to the pulmonary artery (ACXPA) in 6, anomalous left anterior descending coronary artery connected to the pulmonary artery (ALADPA) in 2, and anomalous single coronary artery connected to the pulmonary artery (ASCAPA) in 2 patients. Surgery and angiography protocols as well as medical reports were screened for any type of other cardiac and extracardiac defects and the connecting part of the pulmonary artery.
Results: Abnormal origin of the coronary arteries from the pulmonary arteries is associated in 12% of the patients with other congenital heart defects; the combination of left heart obstructions and ACXPA was observed particularly often. Extracardiac anomalies were found in 2 ALCAPA (Rubinstein-Taybi, pelvic kidney); one ARCAPA had fetal alcohol syndrome and another one VACTERL association; one ACXPA had cystic kidney disease with vertebral anomaly, another ACXPA segmental lung hypoplasia; one ASCAPA had congenital diaphragmatic hernia. In ACXPA patients the anomalous coronary artery connected in 5 of 6 patients from the right pulmonary artery.
Conclusions: Especially in patients with left heart obstructions and heart failure, the possible presence of an abnormal origin of the coronary artery from a pulmonary artery should be taken into account.

Table.

Group	Number of Cases	Combination with other CHD	Associated CHD	Connecting part of pulmonary artery
ALCAPA	84	2	1: CoA + VSD, 2: Left carotic artery from Truncus brachiocephalicus, LPSVC	81 from PA, 1 RPA, 2 LPA
ARCAPA	4	3	1: HLHS, 2: VSD, + ASD, + LPVCS, 3: APW + VSD + LPSVC	3 PA, 1 RPA
ACXPA	6	6	1: CoA + VSD + ASD, 2: CoA + BAV, 3: CoA, 4: HLHS, 5: BAV + AS, 6: CoA + VSD	1 PA, 5 RPA
ALADPA	2	0	-	2 PA
ASCAPA	2	1	1: Shone Complex	1 PA, 1 RPA

P1563 - ASSESSMENT OF QUALITY OF LIFE IN TURKISH CHILDREN WITH CONGENITAL HEART DISEASE

Hatice Kubra Konca[1], Ercan Tutar [2], Mehmet Ramoglu[3], Semra Atalay[2], Tayfun Ucar[2]
Ankara University Faculty of Medicine, Department of Pediatrics, Ankara-Turkey[1]; Ankara University Faculty of Medicine, Department of Pediatric Cardiology, Ankara-Turkey[2]; Van Regional Education and Research Hospital, Department of Pediatric Cardiology, Van-Turkey[3]

Objectives: Due to the recently improved survival rates of children and adolescents with congenital heart disease (CHD) greate attention should be focused on outcomes of treatment than survival– such as the patients' quality of life (QoL). The main aim of this study was to assess and compare the self-reported and parent-reported QoL of children with CHD with the healthy controls. We also aimed to determine whether there is any relationship between the QoL and the severity of CHD and patients' sociodemographic characteristics.
Methods: The patient group consisted of 181 children between 5-18 years of age with a diagnosis of CHD and their families. The control group included 200 healthy children between 5-18 years of age and their families. PEDsQL scores and sociodemographic characteristics were compaired between groups.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: The patient group had poorer levels of monthly income and lower parental education levels compared to controls. The highest impact on QoL was noted in the 5-7 years age group in CHD patients and their families, who had lower total score, physical health, psychosocial health, social functioning and school functioning compared to healthy controls and their families. In the 13-18 years age group, there was no difference in QoL scores between the patients and the controls. A regression analysis revealed that the patient's education level, medical treatments and sex were independently associated with QoL.
Conclusions: We found that children with CHD had lower QoL compared to healthy children of the same age and that gap in QoL scores between these two groups closes as child grows up. Higher QoL scores of male patients is an interesting finding and deserves further discussion. We believe that clinicians play a key role in improving QoL in those patients, with a focus on identifying QoL-lowering risk factors and providing the family with the necessary support.

P1566 - SUDDEN CARDIAC DEATH (SCD) IN CHILDREN AND ADOLESCENTS IS SELECTIVE ELECTROCARDIOGRAM (ECG) SCREENING JUSTIFIED

Erika Rezola Arcelus[1], Maria Angeles Izquierdo Riezu[1], Francisco García Urra[2], Jose Manuel Porres Aracama[2], Nagore González Gómez[2]
Osakidetza, Pediatrics, Donostia-Spain[1]; Osakidetza, Intensive Care Unit, Donostia-Spain[2]

Background: SCD in otherwise healthy children is a rare but devasting event. Merits of universal ECG screening programs at a specific age versus selective screening in high-risk individuals (young athletes, Metilfenidate treatment and family history of SCD) have been debated. This study compares results in SCD screening in 2 Spanish different young athlete and adolescent cohorts.
Matherial and Methods: Cross-sectional study at Irun's athletes' football team cohort and San Sebastian's High School adolescents' cohort. Screening included a standardized history, physical examination (PE) and 12-lead electrocardiogram (ECG) as recommended by the American Heart Association. Student's t-test was used to compare continuous variables and Chi-square test for categorical changes. Association was assessed by Odds Ratio (OR) estimation and Spearman's rho (r) was used in correlation analyses.
Results: A total of 265 adolescents (mean age: 12,3 ± 0,9 years, 132 males) and 53 athletes (mean age: 14,5 ± 1,7 years; all males) participated in this study. 12 (3,8%) individuals were under Metilfenidate treatment and 26 (8,2%) had family history of SCD. In adolescents group, 4 (1,3%) had abnormal PE and 7 (2,2%) had abnormal ECG (2 Long QT syndrome, 1 Wolff-Parkinson-White pre-excitation, 2 left ventricular hypertrophy and 2 right ventricular hypertrophy). Athletes had longer QRS interval than adolescents regardless Metilfenidate intake or family SCD history confounders (88,1 ms versus 84,2 ms; p = 0,001). No other significant differences were seen in ECG or PE between both groups. Risk of abnormal ECG was 1,9 times (OR confidence interval: 0,2-16,5) higher for SCD family history individuals. There was a good correlation between PE and ECG screening results for cardiac abnormalities (r 0,56; p < 0,001).
Conclusion: No pathological significant differences were found between both groups. This results do not justify selective ECG screening programs. Extensives studies and cost-effectiveness analysis of universal screening programs are required.

P1568 - OUTCOME OF PATIENTS WITH CONNECTIVE TISSUE DISORDERS PRESENTING WITH CARDIOPULMONARY SYMPTOMS AT LESS THAN 6 MONTHS OF AGE

Anji Yetman[1], Lois Starr[2], James Hammel[3]
CHMC, Cardiology, Omaha-United States[1]; CHMC, Genetics, Omaha-United States[2]; CHMC, CT Surgery, Omaha-United States[3]

Background: Children with Marfan syndrome and other aortopathies are rarely symptomatic during early infancy. Early onset of symptoms is thought to confer an adverse prognosis. We sought to evaluate the natural history of patients with a genetically confirmed connective tissue disorder who presented with cardiopulmonary symptoms at <6 months of age.
Methods & Results: Database review was performed and age, genetic mutation and symptoms at diagnoses were recorded. Age at, type of, and indication for surgical interventions were noted. Thirteen patients were identified. Etiology of symptoms included severe mitral insufficiency in 5, concurrent congenital heart defects in 3, airway obstruction in 2 and aneurysmal PDA in 3. Genetic diagnosis included neonatal Marfan syndrome in 5, vascular Ehlers Danlos in 1, Loeys-Dietz in 1, neonatal ACTA2 vasculopathy in 3, familial Marfan syndrome in 1, smad3 aortopathy in 1, and MYH11 aortopathy in 1. Eleven (92%) patients required surgery with an age at initial surgery of 4.5 + /- 4.0 months. Surgical intervention in infancy included tracheostomy in 4, ductus ligation in 2, mitral valve repair in 3, mitral and aortic replacement in 1, pulmonary valvuloplasty in 1, right ventricular outflow patch in 1, and VSD closure in 1. Of the 11 patients who survived beyond infancy, 9 had progressive aortic dilation with 6 (60%) undergoing aortic root replacement at 14.3 + /- 6.7 years. There were 5 (38%) deaths overall secondary to aortic dissection in 1, arrhythmia in 1, heart failure in 1, and multisystem organ dysfunction in 2. There were no childhood cardiac deaths in those who underwent cardiac intervention.
Conclusion: Timely surgical intervention in infants with heart failure secondary to connective tissue disease allows for long term survival.

P1593 - THERMAL MONITORING OF A FOOT SURFACE WITH A NON CONTACT INFRARED THERMOMETER IN PEDIATRIC PATIENTS AFTER CARDIAC CATHETERIZATION

Timur Mese[1], Murat Muhtar Yilmazer[1], Yiğithan Güzin[2], Rahmi Özdemir[3], Barış Güven[4]
Izmir Dr.Behçet Uz Children's Hospital, Pediatric Cardiology, Izmir-Turkey[1]; Izmir Dr.Behçet Uz Children's Hospital, Pediatrics, Izmir-Turkey[2]; Dumlupinar University, Evliya Çelebi Training and Research Hospital, Pediatric Cardiology, Kütahya-Turkey[3]; Tepecik Training and Research Hospital, Pediatric Cardiology, Izmir-Turkey[4]

Introduction: One of the most important complication is arterial thrombosis in lower extremity arteries associated with cardiac catheterization procedure. We sought to evaluate the thermal changes in lower extremity after femoral arterial puncture more quantitative with non-contact infrared thermometer .
Methods: This prospective study consists of 32 patients who underwent femoral arterial puncture for cardiac catheterization. Surface temperature measurements were done in a stable room temperature (22-24 °C), just before ,immediately after, at 1st, 3rd, 6th, 12th and 24th hours of cardiac catheterization procedure with non-contact infrared thermometer . Measurement were done from left or right foot surface in order to catheterization site. Three consequent measurements were detected and the mean of these

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

measurements was taken. No signs of arterial thrombosis was detected in any patient.
Results: Mean foot surface temperature decreased significantly ($p = 0.00$) immediately after the procedure. After one hour the procedure, foot surface temperature reached the pre-procedural level and continued to rise. During follow up temperature was detected to rise gradually at 2., 3 and 12. hours after completion of procedure ($p = 0.00$). The last measurement was done after 24 hours and the mean temperature value was declined and closed to the initial pre-procedural value ($p = 0.915$).
Discussion: Our results demonstrate that skin temperature was significantly decrease immediately after the arterial puncture. In the following monitoring it was found that the surface temperature increased gradually and reached the highest value at 12 hours after the procedure. Finally it was found that it returned to the initial value measured before the procedure. This temperature changes suggested that reactive hyperthermia occurs in the affected extremity shortly after the procedure and it returns to normal values after 24 hours.

P1611 - LEOPARD SYNDROME ASSOCIATED WITH HYPERTROPHIC CARDIOMYOPATHY

Alexander Jurko[1], Tomas Jurko[2], Jana Krsiakova[3], Alexander Jurko[1], Vargoncikova Lucia[1]
LTVSRO, Pediatric Cardiology, Martin-Slovakia[1]; Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Neonatology Clinic, Martin-Slovakia[2]; Jessenius Faculty of Medicine in Martin, Department of Genetic Medicine, Martin-Slovakia[3]

Backround: LEOPARD syndrome is a rare genetic disorder that affects multiple organs. Characteristic symptoms include: lentigines, electrocardiographic conduction abnormalities, ocular hypertelorism, pulmonary stenosis, abnormal genitalia, retardation of growth and deafness (sensorineural). Cardiac involvement may have a significant impact on the prognosis.
Case Presentation: We report two cases of LEOPARD syndrome in an 18-year-old boy and a 10-year-old girl. In both cases multiple lentigines, ocular hypertelorism and growth retardation were present together with obstructive hypertrophic cardiomyopathy. Both patients met the criteria for LEOPARD syndrome. The second case was caused by a mutation in the PTPN11 gene. The first patient underwent surgery for a moderate obstruction of the left ventricular outflow tract with uneventful postoperative follow up. The presented cases fulfill the criteria for a typical LEOPARD syndrome with predominant left ventricular outflow tract obstruction.
Conclusions: The diagnosis of hypertophic cardiomyopathy in children and adolescents is important because there is a risk of sudden death. Besides traditional clinical findings, hypertrophic cardiomyopathy with left ventricular outflow track obstruction may be an improtant diagnostic and prognostic parameter in patients with LEOPARD syndrome.

P1614 - ARTERIAL STIFFNESS IN CHILDREN WITH WHITE COAT AND ESSENTIAL HYPERTENSION

Alexander Jurko[1], Tomas Jurko[2], Michal Mestanik[3], Andrea Mestanikova[3], Lucia Vargoncikova[1], Ingrid Tonhajzerova[3]

Introduction: The term "arterial stiffness" denotes alterations in the mechanical properties of arteries, which may represent higher cardiovascular risk in middle-aged and older adults. Recently, the question regarding the arterial stiffness in patients with risk factors for the early progression of systemic atherosclerosis in vulnerable adolescent age-period are rare. Thus, the aim of this study was to evaluate the carotid stiffness and early atherosclerotic changes in adolescents suffering from essential and white coat hypertension using noninvasive markers.
Methods: One hundred thirty eight children – 46 (23 boys) children suffering from WCH, 46 (23 boys) patients with essential hypertension (EH) and 46 age/gender-matched healthy controls – were examined under standard conditions. The age-period of all children ranged from 14 to 18 years. Ultrasonography combined with echo-tracking system (Prosound F75 Aloka) on common carotid artery (CCA) was used to analyse of local arterial stiffness. In the study five physiological parameters of the CCA were analysed – mean stiffness index (β), elastic modulus (Ep), arterial compliance (AC), augmentation index (AI) and pulse wave velocity (PWV β).
Results: Statistical analysis revealed significant differences in parameters β, Ep, AC and PWV β between the both hypertensive groups (WCH, EH) and control group (Tab 1). Significant differences were not found in the index AI between EH, WCH and control groups. No significant differences were found between WCH and essential hypertensive groups.
Conclusions: Study revealed significantly increased carotid stiffness in children suffering from white coat and essential hypertension. This finding could help to understand hypertension atherosclerosis interaction. We suggest that further research regarding the potential atherosclerotic changes using the sensitive noninvasive parameters in pediatric hypertension is important. Support: VEGA 1/0087/14, project "Biomedical Center Martin" ITMS code [26220220187] co-financed from EU sources.

Table 1. Parameters of carotid stiffness in children with white coat hypertension (WCH), essential hypertension (EH) and control group (C group).

	WCH n = 46	EH n = 46	C group n = 46
β	6,14 ± 0,9***	6,01 ± 1,01***	4,8 ± 0,9
Ep (kPa)	85,4 ± 14,4***	85,2 ± 16,4***	56,1 ± 9,7
AC (mm^2/kPa)	0,84 ± 0,2***	0,84 ± 0,18***	1,10 ± 0,24
AI	5,06 ± 37^{NS}	6,7 ± 32^{NS}	-6,1 ± 6,7
PWV β (m/s)	5,3 ± 0,5***	5,3 ± 0,6***	4,4 ± 0,4

β, mean stiffness index; Ep, elastic modulus; AC, arterial compliance; AI, augmentation index; PWV β, pulse wave velocity ***, $p < 0,001$ compared to control group.

P1620 - ADOLESCENT HYPERTENSION IS ASSOCIATED WITH DIMINISHED SYMPATHETIC REACTIVITY TO STRESS ASSESSED BY NONLINEAR ANALYSIS OF HEART RATE VARIABILITY

Michal Mestanik[1], Alexander Jurko[2], Tomas Jurko[3], Andrea Mestanikova[1], Zuzana Visnovcova[4], Peter Langer[5], Ingrid Tonhajzerova[1]

Background: Excessive sympathetic activity is a well-known mechanism involved in pathophysiology of hypertension and related cardiovascular complications. Importantly, both dysregulation of basal autonomic outputs and the altered reactivity to stress increases the risk of cardiovascular diseases. Therefore, we aimed to assess the complex cardiac sympathetic regulation under stress conditions using novel method of non-linear heart rate variability (HRV) analysis – symbolic dynamics - in adolescents with newly diagnosed essential and white-coat hypertension.
Materials and Methods: Thirty adolescent boys with newly diagnosed essential hypertension (16.9 ± 0.2 years, body mass index (BMI) 22.9 ± 0.4 kg/m2), thirty patients with newly diagnosed white-coat hypertension (16.8 ± 0.3 years, BMI 22.6 ± 0.5 kg/m2) and thirty healthy controls (16.2 ± 0.4 years, BMI 22.1 ± 0.4 kg/m2) were examined. Electrocardiogram was continuously recorded in supine position and during active orthostatic test (phase duration6 minutes). Sympathetic cardiac regulation was assessed using nonlinear analysis of HRV complexity - symbolic dynamics index 0 V% (zero variation of HRV).
Results: The beta-adrenergic cardiac activity indexed by 0 V% was significantly increased during supine position in both white-coat and essential hypertension groups compared to control group ($p < 0.05$ for both). The reactivity (percentual increase) of sympathetic index 0 V% to orthostatic test was significantly lower in white-coat and essential hypertension compared to control group ($p < 0.05$ both). No significant between-groups differences were found in absolute values of 0 V% during orthostatic test.
Conclusions: The novel sympathetic marker- symbolic dynamics HRV index 0 V% - was sensitive to assess greater sympathetic cardiac activity at rest, and lower reactivity to orthostatic stressin both white-coat and essential hypertension. Our findings could help to elucidate the role of diminished physiological reactivity to stress in the pathophysiology of hypertension and possible negative health outcomes.
Support: This work was supported by grant VEGA 1/0087/14, APVV-15-0075, andthe project „Biomedical Center Martin"ITMS code: 26220220187, co-financed from EU sources.

P1625 - THE CLINICAL FEASIBILITY OF PRE OPERATIVE NEUROLOGICAL AND NEUROMOTOR ASSESSMENT IN INFANTS UNDERGOING OPEN HEART SURGERY

Miranda Campbell[1], *Bridgette Rabbidge[2], Leanne Sakzewski[3], Jenny Ziviani[1]*
Children's Health Queensland and University of Queensland, School of Health & Rehabilitation Science, Brisbane-Australia[1]; University of Queensland, School of Health & Rehabilitation Science, Brisbane-Australia[2]; University of Queensland, School of Medicine and Queensland Cerebral Palsy and Rehabilitation Research Centre, Brisbane-Australia[3]

Introduction: Infants with congenital heart disease (CHD) who undergo open-heart surgery are at high risk for long-term neurodevelopmental delay. Neurodevelopmental impairments can lead to an increased burden on families, health care systems and educational facilities. Conducting pre-operative assessment allows for early identification of at risk infants and implementation of early intervention. Challenges undertaking pre-operative neurodevelopmental assessments have been reported, limiting the extent to which the impact of surgery can be estimated. This study aims to investigate factors impacting the clinical feasibility of pre-operative assessment in infants undergoing open-heart surgery before four months of age.
Methods: Infants with CHD who underwent open-heart surgery before four months of age participated in this prospective cohort study. The Test of Infant Motor Performance (TIMP) and Prechtl's Assessment of General Movements (GMs) were undertaken pre- and post-operatively. When assessments could not be undertaken, reasons were ascribed to either infant or environmental circumstances. Demographic data and Aristotle scores, which measure complexity of surgical procedures, were compared between groups of infants who did or did not undergo assessment. Associations were explored using binary logistic regression.
Results: Sixty infants were recruited to the study. Median gestational age was 38.78 weeks (IQR 36.93–39.72). Of these infants, 37 (62%) were unable to undergo preoperative assessment due to infant (40%) and environmental (22%) related factors. For every point increase in the Aristotle Patient Adjusted Complexity (APAC) score, the infants likelihood of being able to undergo pre-operative assessment decreased by 35% (OR: 0.35; 95% CI: 1.03-1.77, $p = 0.03$).
Discussion: Over half the participants were unable to undergo pre-operative assessment, primarily due to infant related medical instability. This study highlights the fragility of this cohort and the limitations associated with administering neurodevelopmental assessments pre-operatively. Further research investigating the APAC score as a potential indicator of children requiring developmental surveillance is warranted.

P1645 - WEIGHT TRAJECTORIES ARE ASSOCIATED WITH EXERCISE CAPACITY AMONG CHILDREN WITH COMPLEX CONGENITAL HEART DEFECTS DOES LIMITED GROWTH INDICATE LIMITED ENERGY FOR EXERCISE

Patricia Longmuir[1], *Tyler Kung[1], Kenneth Tang[2], Warsame Yusuf[1], Jane Lougheed[3]*
CHEO Research Institute, Halo Research Group, Ottawa-Canada[1]; CHEO Research Institute, Clinical Research Unit, Ottawa-Canada[2]; Children, Cardiology, Ottawa-Canada[3]

Background/Hypothesis: Children with congenital heart defects (CHD) are often short and lightweight relative to healthy peers, requiring supplementary feeding to meet energy demands. It was hypothesized that CHD patients with limited growth would also have decreased energy for exercise.
Materials and Methods: A retrospective review of Bruce protocol treadmill exercise test results identified CHD patients 8 to 14 years of age. Weight at each clinic visit was extracted from medical charts. Latent class analysis grouped children by growth trajectory: WC 1 = normal weight, WC 2 = underweight, WC 3 = overweight. Extrapolation of energy consumption (ml O2/kg/min) as a function of heart rate standardized energy consumption at a heart rate of 170 bpm for each child. ANOVA examined standardized exercise capacity by weight class, age, and sex.
Results: The growth trajectories of 51 children with CHD (39% female) were classified as normal (n = 10), underweight (n = 19) or over weight (n = 22). Exercise capacity differed significantly by growth trajectory ($p = .003$), but not age ($p = .10$) or sex ($p = .84$). Normal weight children had the highest exercise capacity (estimated marginal mean ± SE: 42.8 + /-2.0 ml O2/kg/min). Overweight children had significantly lower exercise capacity (37.8 + /-1.5, $p = .04$), but underweight children had the lowest exercise capacity (33.8 + /-1.5, $p = .003$), a decrease of 21%.
Conclusion: Children with CHD whose growth trajectory is underweight have much lower capacity for exercise than CHD

patients whose growth is normal or overweight. Insufficient energy for normal growth may increase the risk of sedentary lifestyles, and the associated negative health outcomes. Future research should evaluate whether underweight growth trajectories are associated with decreased daily physical activity and could be used to identify children in need of kinesiology referral.

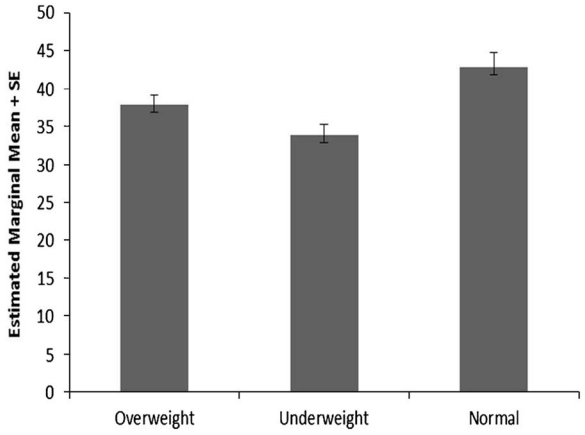

Figure 1.

P1648 - ANATOMICAL AND FUNCTIONAL ASSESSMENT OF CORONARY ARTERIES AFTER ARTERIAL SWITCH OPERATION

Paulo Manso[1], Mariana Ferreira[1], Tarcisio Silva Jr[1], Leonardo Zancaner[2], Henrique Trad[3], Julio Crescencio[2], Pedro Schwartzmann[2]
Ribeirao Preto Medical School, Pediatrics, Ribeirao Preto-Brazil[1];
Ribeirao Preto Medical School, Cardiology, Ribeirao Preto-Brazil[2];
Ribeirao Preto Medical School, Radiology, Ribeirao Preto-Brazil[3]

Background: Arterial switch operation (ASO) is the treatment of choice for transposition of great arteries (TGA). However, late complications, such as aortic regurgitation, pulmonar supravalvar stenosis and coronary obstruction may arise in up to 30% of patients. The true incidence and clinical significance of coronary obstruction in these patients is unknown.
Hypothesis: This research aims to correlate anatomical alterations in patients submitted to ASO with rest echocardiography and cardiorespiratory test.
Methods: Sixty-one patients aged five years or above (9.7 ± 3.1 years) were submitted to cardiopulmonary test (treadmill protocol), electrocardiography, rest echocardiography, and coronary artery computerized tomography (CT).
Results: Only two patients (3.3%) presented with severe obstruction of one coronary artery (1 main left; 1 right coronary) although cardiopulmonary test, ECG (both at rest and at effort), and rest echocardiography were normal. Both patients were asymptomatic.
Conclusions: Coronary artery obstruction does not correlate with cardiopulmonary test or rest echocardiography in this population. Coronary artery CT scan is a sensitive and safe method to diagnose coronary artery obstruction in children after ASO.

P1684 - RELATION BETWEEN HEART RATE VARIABILITY AND EXERCISE HEART RATE IN CHILDREN WITH CONGENITAL HEART DIESASE AND HEALTHY CONTROLS

Ashok Kakadekar[1], Natasha Boyes[2], Stephanie Funsnik[2], Mark Haykowsky[3], Shonah Runnalls[1], Marta Erlandson[2], Scott Pharis[1], Charissa Pockett[1], Timothy Bradley[1], Corey Tomczak[2]
University of Saskatchewan, College of Medicine, Saskatoon-Canada[1];
University of Saskatchewan, Kinesiology, Saskatoon-Canada[2];
University of Saskatchewan, Nursing & Health Innovation, Saskatoon-United States[3]

Background & Hypothesis: Children with congenital heart disease (CHD) display resting autonomic dysfunction as shown by a reduction in heart rate variability (HRV) compared to healthy control children. Children with CHD also display exercise intolerance compared to healthy children that may be due, in part, to a lower exercise heart rate response. We tested the hypothesis that the power spectral HRV ratio would be negatively correlated with 6-min walk test exercise heart rate in children with CHD and healthy control children.
Materials & Methods: Twenty-two children with CHD (11 ± 2 years; females = 9) and 21 healthy controls (11 ± 3 years; females = 11) were studied. CHD diagnoses included simple and complex lesions. HRV was determined following 10 min supine rest using a 5 min surface ECG recorded epoch. 6-min walk test heart rate by telemetry was determined as the average exercise value. Analyses were completed using unpaired t-tests and correlation-regression with $P < 0.05$ being significant. Data are mean ± SD.
Results: 6-min walk test distance was lower (513 ± 75 versus 599 ± 81 m; $P < 0.001$) and 6-min walk test heart rate was lower (122 ± 15 versus 139 ± 18 beats/min; $P = 0.001$) in children with CHD versus healthy controls, respectively. Power spectral HRV analyses revealed no difference in low frequency (LF) power (30 ± 16 vs. 25 ± 16%; $P > 0.05$), but significant differences in high frequency (HF) power (34 ± 19 vs. 49 ± 14%) and the LF/HF ratio (1.4 ± 1.5 vs. 0.6 ± 0.3%) in children with CHD versus healthy controls, respectively (all $P < 0.05$). The LF/HF ratio was significantly correlated with 6-min walk test heart rate for the study group ($r = -0.328$, $P = 0.032$).
Conclusions: Resting autonomic function in children with CHD and healthy controls significantly predicts exercise heart rate. Autonomic heart rate control may be important in the pathophysiology of exercise intolerance in children with CHD.

P1701 - ATHEROSCLEROSIS RISK AND CAROTID INTIMA MEDIA THICKNESS AFTER KAWASAKI DISEASE IN MEXICAN CHILDREN

Luis Martin Garrido-García[1], Andres González-Ortíz [2], Sara Solorzano-Morales[3], Francisco Espinosa-Rosales[4], Silvestre García De La Puente[5]
Instituto Nacional De Pediatra, Cardiology, Mexico City-Mexico[1];
Instituto Nacional De Pediatría, Cardiology, Mexico City-Mexico[2];
Instituto Nacional De Pediatria, Radiology, Mexico City-Mexico[3];
Instituto Nacional De Pediatría, Immunology, Mexico City-Mexico[4];
Instituto Nacional De Pediatría, Methodology and Statistics, Mexico City-[5]

Background: Kawasaki disease (KD) is an febrile illness characterized by systemic vasculitis of unknown etiology. Recent studies have shown that endothelial dysfunction persists and may progress to premature atherosclerosis. Carotid intima-media thickness (cIMT) is a well-established marker for atherosclerosis in both pediatric an adult patients.
Objective: To assess whether patients after Kawasaki disease (KD) have increased risk factors and abnormalities suggestive of premature atherosclerosis by measuring the cIMT compared with healthy control subjects
Material and Methods: 153 patients with KD aged 101.05 ± 42.78 months (67.64 ± 39.89 after the acute episode) and 162

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

age-matched healthy control subjects were examined for family, medical and dietary history, serum markers of atherosclerotic risk and inflammation and carotid intimal-medial thickness (CIMT) with vascular ultrasound scanning.
Results: Patients and control subjects were similar in age, gender, family and dietary history, body mass index and blood pressure. The levels of total cholesterol (159.37 ± 28.3 vs 147.4 ± 18.3), LDL cholesterol (95.33 ± 25.75 vs 89.63 ± 10.52), and HDL cholesterol (49.88 ± 13.37 vs 39.70 ± 9.28) were slightly higher in patients after KD with no statistical significance. The cIMT was also higher in the KD group (0.48 ± 0.1 vs 0.45 ± 0.15) We did found higher levels in the lipid profile and in the cIMT in children after KD with or without regression of coronary aneurysms compared with children with KD without coronary aneurysms.
Conclusions: There is no clear evidence of increased atherosclerosis in Mexican children with KD, but there is evidence of an altered lipid profile and in the cIMT in patients with KD with coronary lesions compared with children with KD without coronary lesions the warrant further study.

P1710 - DOES ECHOCARDIOGRAPHY HAVE A ROLE IN THE MANAGEMENT OF CONGENITAL HEART DISEASE

Fiona Hiu Ip[1], Margaret Hay[2], Samuel Menahem[3]
Ballarat Health Services, Sunshine West-Australia[1]; Monash University, Health And Clinical Education, Melbourne-Australia[2]; Monash Health, Paediatric Cardiology, Melbourne-Australia[3]

Background: Innocent murmurs are not uncommon in well children. While echocardiography is able to diagnose almost all congenital cardiac abnormalities, previous studies have shown that it may be unnecessary when the clinical diagnosis of an innocent murmur is made by an experienced cardiologist. This study was undertaken to determine if echocardiography had a role in the diagnosis of innocent murmurs in childhood and whether it reduced parental anxiety.
Materials and Methods: Parents of children referred for evaluation of a murmur completed State- Trait Anxiety Inventory questionnaires after the cardiologist's clinical diagnosis of an innocent murmur. The questionnaires were repeated after echocardiography to assess if there was a change in the parental understanding regarding their child's murmur, and to review their level of anxiety. The paediatric cardiologist also completed a questionnaire before echocardiography to determine the reasons for ordering investigation(s), level of confidence regarding his clinical diagnosis, and whether the diagnosis was correct.
Results: 50 mothers have been recruited. 30 of them completed the questionnaires. All 50 echocardiograms were normal except for three. The abnormal changes include congenitally corrected transposition of great arteries and another partial anomalous left upper lobe pulmonary vein both of whom had innocent murmurs. The third revealed a small muscular ventricular septal defect (VSD). Parental and the referring doctor's expectations were found to be the leading reason compelling the specialist to order further investigations. There was a reduction in the anxiety level after completion of the echocardiogram. Enhancement in parental understanding of the diagnosis was also demonstrated.
Conclusions: While the sample size to date is small, the trend shown in this study suggests that echocardiography may be useful not only to clarify the diagnosis but also to supplement parental education and reduce parental anxiety. It also unexpectedly detected three abnormal findings that would otherwise have been missed without echocardiography.

P1718 - PATIENT AND REFERRAL CHARACTERISTICS FOR CLINICAL CARDIOPULMONARY EXERCISE TESTING IN A PEDIATRIC HOSPITAL IN SINGAPORE

Micheal Lim[1], Ching Kit Chen[2]
KK Women, Sports Medicine Programme, Singapore-Singapore[1]; KK Women, Cardiology Service, Singapore-Singapore[2]

Background: Cardiopulmonary exercise testing (CPET) is a well-established procedure for the evaluation of functional capacity in pediatric clinical settings. It is a tool that can provide useful information to assist pediatricians with diagnosis and management of common pediatric medical conditions. KK Women's and Children's hospital started CPET service in 2009. Till date, there has been limited information on how the CPET service has been utilized in the hospital. The aim of this paper is to describe the characteristics of patients referred for cardiopulmonary exercise testing.
Methods: A retrospective review of patients referred for cardiopulmonary exercise testing, from the year 2009, were conducted.
Results: A total of 37 patients (29 males, 8 females) were referred for CPET since year 2009 and their average age, height and weight were 14.6 ± 2.3 years, 163.5 ± 10.9 cm and 59.5 ± 14.9 kg respectively. Majority of the patients have an underlying congenital heart condition such as tetralogy of fallot (TOF), and dilated cardiomyopathy. Common referral reasons were to evaluate functional capacity, reasons for chest pain, shortness of breath and presyncope. Majority of the test were conducted on treadmill (n = 31), cycle (n = 5), and one patient did not complete the test. Average test duration were 11 mins and 13 secs (range 6 to 16 mins). A summary of the results from the CPET is shown in Table 1.
Conclusion: The aim of this study was to describe the characteristics of patients referred for CPET. Majority of the patients were referred from cardiology service, with majority having congenital heart conditions and a varied range of referral indications.

Table 1. Physiological results from cardiopulmonary exercise test.

Variables	Results
Peak VO^2 (L/min)	2.12 ± 0.8
Peak VO^2 (ml/kg/min)	39.20 ± 10.8
Peak VCO^2 (L/min)	2.51 ± 1.0
RER	1.19 ± 0.1
VE (L/min)	75.95 ± 28.9
VE/VO^2(slope)	39.49 ± 11.1
VE/VCO^2 (slope)	30.88 ± 4.7
Peak HR (bpm)	162 ± 30

P1728 - CHARACTERISTICS OF CARDIOVASCULAR DISEASE IN CHILDREN EXAMINED IN THE CARDIOLOGY OUTPATIENT SERVICE IN A TERRITORIAL HOSPITAL FROM ROMANIA PROSPECTIVE CLINICAL TRIAL

Delia Mercea[1], Raluca Ianos[2], Bogdan Lucian[3], Calin Pop[4]
Emergency County Hospital Dr Constantin Opris, Cardiology, Baia Mare-Romania[1]; Heart Institute Niculae Stancioiu, Cardiology, Cluj Napoca-Romania[2]; Emergency County Hospital Dr Constantin Opris, Pediatry, Baia Mare-Romania[3]; West University, Cardiology, Arad-Romania[4]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Introduction: Pediatric cardiology is a relatively new specialty in Romania and there are a small number of pediatric cardiologists, therefore children's with heart disease are being followed up by cardiologists. PURPOSE: The aim of this clinical study was to describe the characteristics of cardiovascular disease in children who were examined in the cardiology ambulatory between 2012 and 2015.
Methods: A number of 422 children from an outpatient cardiology service were enrolled in a prospective study. We recorded demographic characteristics and pathological findings in echocardiography, EKG and Holter EKG evaluation.
Results: Our population consisted of 220 males (52%) and 202 females (48%), with ages between 1 month and 17 years, mean age 5.69. We divided them in age categories and we obtained a number of 53 infants, 118 toddlers, 87 preschool children, 107 school children and 57 in the early adolescence. The most common cardiovascular entities were: mitral valve prolapse in 38 patients(8.9%), patent foramen ovale in 25 patients(5.9%), ventricular septal defect in 28 patients(6.6%),moderate mitral insufficiency in 7 patients(1.65%), moderate aortic valve insufficiency in 2 patients(0.47%), aortic bicuspidy in 4 patients(0.94%), persistent arterial duct in 7 patients(1.65%), atrial septal defect in 14 patients, Fallot's Tetralogy in 2 patients and atrioventricular canal in 2 patients. There was 1 patient with situs inversus and 1 patient with interatrial septum aneurysm. The EKG findings revealed 1 patient with ventricular extrasystole, 1 patient with WPW syndrome and 4 with RBBB.
Conclusions: A complete overview of cardiovascular diseases in children from Maramures County isn't possible because access to pediatric cardiology care is still limited. VSD, ASD and TOF were the most common congenital heart desease in our survey. This study highlights that the development of pediatric cardiology in the region is mandatory.

P1742 - EKG KEY FOR LATE ALCAPA DIGNOSIS

Alaa Aldajani
King Fahd Hospital of University, Pediatric Cardiology, Dammam-Saudi Arabia

13 years old presented to clinic of unspecified symptoms easily tiredness , her exam revealed soft systolic murmur at the apex EKG showed q wave in aVL and posterior leads when suspicion of ALCAPA appeared ECHOCARDIOGRAM done with report of mild mitral regurgitation LVd at upper normal Coronary angiogram done shoed evidance of ALCAPA After that patient transferred to a cardiac center for the surgical which done with no cmplication By concentrated reading of the EKG , the diagnosis made and prevent patient from sudden cardiac arrest

P1748 - VALUE OF THE OXYGEN DEFICIT AND THE EXCESS POST EXERCISE OXYGEN CONSUMPTION TO EVALUATE EXERCISE PERFORMANCE IN CHILDREN AND ADOLESCENTS WITH CONGENITAL HEART DISEASE

Jorge Bleiz, Victoria Corradi, Analia Pardo, Andrea Cueli, Paula Campana, Sabina Garobbio, Rodrigo Egues, Eugenia Sabbione, Soledad Manciola, Ximena Suarez
Children's Hospital, Cardiology, La Plata-Argentina

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background/Hypothesis: during the first minutes of a physical activity there is a delay in the respiratory and circulatory systems to provide oxygen to the active muscles (Oxygen Deficit;OD) and to reach an steady-state. At the end of the exercise there is a high oxygen consumption (Excess Post-exercise Oxygen Consumption;EPOC) to restore the disturbance of homeostasis produced. We hypothesize that physical training in children and adolescents with congenital heart disease (CHD) has a positive impact on OD and EPOC.
Objetive: To determine the usefulness of OD and EPOC measurement to evaluate physical performance in children and adolescents with CHD.
Material and Methods: We analyzed the cardiopulmonary tests (CPT) of our database of the pediatric cardiovascular rehabilitation program, of 25 patients (P) with CHD (15 male – 10 female), aged 5 to 19 years (mean 13). CPT was performed before and after the program (24 session/12 weeks of aerobic exercises) and then the Oxygen Consumption (VO2), the production of carbon dioxide (VCO2) and Minute Ventilation (VE) were analyzed to determine the OD and EPOC in each of the CPT. Lasting of the exercise testing (minutes), heart rate at rest (bpm) and VO2 peak (ml/min/Kg), were used to determine the improvement in aerobic capacity after the program. Matched variables were analyzed with McNemar's test.
Results: the magnitude of OD and EPOC post program was 21% and 24% less than the pre program respectively ($p < 0.05$), and the time elapsed in both was 25% and 30% less than the pre program respectively ($p < 0.05$). Lasting of the exercise testing and VO2 peak increased 70% and 24% respectively ($p < 0.05$), and heart rate at rest decreased 16% ($p < 0.05$) post program.
Conclusions: OD and EPOC can be important surrogates for other more complex measurements and have value to evaluate exercise performance in children and adolescents with CHD.

P1761 - TRANSITION OF PEDIATRIC PATIENTS WITH MARFAN SYNDROME TO ADULT CARE AN IMPORTANT FACTOR TO PREVENT EXACERBATION

Friederike Seggewies[1], Veronika Stark[1], Jakob Olfe[1], Götz C. Müller[1], Yskert Von Kodolitsch[2], Kozlik-Feldmann Rainer Gerhard[1], Thomas Mir[1]
University Heart Center, Department of Pediatric Cardiology, Hamburg-Germany[1]; University Heart Center, Department of Cardiology, Hamburg-Germany[2]

Objectives: Marfan-Syndrome (MFS) is a genetic disorder with a variable clinical presentation. One of the main causes of mortality is the transformation of the cardiovascular system. Aim of this study is the validation of the clinical presentation and status of patients with MFS at date of transition to adult care.
Methods: Since 2008 we investigated 381 patients (11.4 ± 5.5y) with suspected MFS, 51 patients of that group have a diagnosed MFS and are about or have already transited to adult care (age 16-26y; middle age 19.6 ± 2.6y; male:female 28:23). We included most serious manifestations: dilatation of sinus valsalvae (SV), atrioventricular valve prolapse (AVVP), ectopia lentis (EL), skeletal abnormalities (SK, minimum 3 positive signs of revised ghent nosology) ($n = 51$). We also included the incidence of dural ectasia (DE) ($n = 45$), as well as medical and surgical treatment.
Results: All patients show a high percentage of clinical manifestations (SV66.7%, AVVP56.9%, EL13.7%, DE47.1%, SK74.5%). There is a noticeable difference in the level of percentage of patients <18y and >18y (SV75 and 64%, AVVP50/59%, EL8/15%. DE33/51%, SK83/72%). In both groups cardiovascular and skeletal system are more likely affected than lenses and dura. 55% recieve beta blockers and/or AT1 antagonists. 10% have already undergone valve-sparing aortic root replacement. 49% of the >18y old MFS patients are still in pediatric care, 41% have already transited. Amount of lost follow-up examinations was 10% (5/51) only.
Conclusions: It became clear that disease specific pathologies are very dynamic during the period of transition to adult care. The majority of our patients with MFS between 16-26 years of age already show a high percentage of abnormalities of the cardiovascular and skeletal system, irrespective of whether they are over or under 18 years of age. This proves once again how important it is to closely monitor the transition of these patients during this critical episode.

P1762 - CORONARY ARTERY ANEURYSM REGRESSION AFTER KAWASAKI DISEASE IN A MEXICAN POPULATION

Luis Martín Garrido-García[1], Eduardo Bustillo-Del Cueto[1], Silvestre García De La Puente[2], Patricia Cravioto-Quintana[3], Fernando Galvan-Castillo[3]
Instituto Nacional De Pediatria, Cardiology, Mexico City-Mexico[1]; Instituto Nacional De Pediatria, Methodology, Mexico City-Mexico[2]; Instituto Nacional De Pediatría, Teaching Department, Mexico City-Mexico[3]

Background: Coronary artery aneurysms (CAA) in Kawasaki disease (KD) developed in 30% of untreated patients and in 3% of patients treated with intravenous gamma globulin. Regression of the CAA has been reported to occur in about 50% of the cases.
Objective: To evaluate regression rate of CAA in Mexican children with KD and evaluate factors associated with regression.
Material and Methods: We evaluated all KD patients with CAA at the Instituto Nacional de Pediatria in Mexico City, Mexico from August 1995 to December 31st, 2015. Regression rate and regression factors were analyzed.
Results: A total of 472 patients with KD were diagnosed at our Hospital during the study period. 154 of them developed CAA (32%). Only 132 of them have been evaluated at follow-up. CAA regression occurred in 91 patients (68.93%). Regression occurred at 11.2 ± 17.35 months after the acute event of KD. Age less than 12 months of age ($p < 0.010$), diagnosis before 10 days after the onset of fever ($p < 0.000$) and small coronary aneurysms based in z-score classification ($p < 0.001$) were the only factors associated with regression of the CAA.
Conclusion: In our study, regression occurs in a slightly higher rate than reported in the literature. Smaller age at diagnosis of KD and small CAA were favorable factors associated with regression.

P1785 - GENETIC VARIABILITY AS A POSSIBLE EXPLANATION OF THE WIDE ANATOMICAL SPECTRUM ASSOCIATED TO OBSTRUCTIVE LEFT HEART DISEASES

Simona Anna Marcora[1], Giacomo Amelio[2], Lorenzo Galletti[3], Duccio Federici[4], Daniela Marchetti[5], Maria Elena Sana[5], Francesco Consonni[6], Maria Iascone[5]
Papa Giovanni XXIII, Pediatric Cardiology, Bergamo-Italy[1]; University of Milan, Pediatric, Milano-Italy[2]; Papa Giovanni XXIII, Pediatric Cardiac Surgery, Bergamo-Italy[3]; Papa Giovanni XXII, Pediatric Cardiac Surgery, Bergamo-Italy[4]; Papa Giovanni XXIII, Genetic, Bergamo-Italy[5]; Papa Giovanni XXIII, Anesthesiology, Bergamo-Italy[6]

Background: Obstructive left heart diseases (OLHD) encompass a spectrum of various degrees of underdevelopment of left side

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

structures. The genetic background of this spectrum has not yet completely known. We aim to identify significant genetic variants and find a possible correlation with different anatomic features in patients with OLHD.
Matherial and Methods: The genomic DNA of 96 patients with OLHD and available parents were studied by TruSeq Custom Amplicon and MiSeq platform (Illumina, San Diego,CA) targeting all the exonic regions of 6 genes associated to the development of valves and ventricles: NOTCH1, LRP6, KIA00182, ZNF236, ZNF423, JARID2.The Exome Sequencing Project (ESP) database was used as normal population. To evaluate a correlation with different phenotypes patients,according to universally recognized echocardiographic criteria ,were divided in hypoplastic left heart syndrome (HLHS), hypoplastic left heart complex (HLHC) and aortic valve stenosis (AVS) group.
Results: 66 single nucleotide variants (SNV) were identified in OHLD. The number of SNVs in OLHD was greater than in ESP population and JARID2 was the more frequently mutated gene (21,9% OLHD versus 1,1% ESP; $p < 0{,}001$). The analysis of variants with a minor allele frequency (MAF) <1% indicated that all 6 genes in OLHD are characterized by very rare variants not reported in any databases (MAF = 0). Moreover the low MAF of these SNVs in ESP population (range 0.029 to 0.043) confirmed that these mutational events are not well tollerated in normal population. A minor number of SNVs was found in patients with hypoplastic left heart valves (HLHC) compared to atresic or stenotic valves (HLHS and AVS) $p = 0{,}023$.
Conclusion: OLHD spectrum could be caused by a cumulative effect of rare low-penetrance alleles superesposed on an unfavorable environment (multi-factorial inheritance model). Preliminary data would suggest a correlation between genetic and anatomical heterogeneity. Further analysis will investigate prognostic and therapeutic implications of our results.

P1792 - LONG TERM FOLLOW UP OF GIANT CORONARY ARTERY ANEURYSMS AFTER KAWASAKI DISEASE IN A MEXICAN POPULATION

Luis Martín Garrido-García[1], Alfredo Bobadilla-Aguirre[2], Jose Luis Colín-Ortíz[2], Carlos Corona-Villalobos[1], Alexis Palacios Macedo-Quenot[3], Patricia Cravioto-Quintana[4], Fernando Galvan-Castillo[4]
Instituto Nacional De Pediatría, Cardiology, Mexico City-Mexico[1]; Instituto Nacional De Pediatria, Cardiology, Mexico City-Mexico[2]; Instituto Nacional De Pediatría, Cardiovascular Surgery, Mexico City-Mexico[3]; Instituto Nacional De Pediatría, Teaching Department, Mexico City-Mexico[4]

Background: Giant coronary artery aneurysms (GCAA) are a rare but severe complication after Kawasaki disease. The clinical course in these patients often is complicated with ischemic changes either in the acute or chronic phase of the disease.
Objective: Evaluate the long-term follow-up of giant coronary artery aneurysms after Kawasaki disease in a Third-Level Pediatric Hospital in Mexico City, Mexico.
Material and Methods: From the Institutional database of KD, we analyzed all patients who developed GCAA (z-score >10) from August 1995 to December 2016. Information on patient demographics, catheter and surgical interventions, and most recent status was collected from medical records.
Results: 38 patients developed GCAA in the acute phase of KD. Median age at diagnosis was 12.5 months (2 to 66 months). One patient died at diagnosis and one patient was lost to follow-up. Therefore, we analyzed 36 patients. Median time from diagnosis to the most recent medical evaluation was 92 months (5 to 192 months). At follow-up 14 patients (38.8%) developed regression of the coronary aneurysms, median time to regression was 26.5 months. 18 patients (50%) persist with coronary aneurysms, (2 with GCAA). Seven patients developed coronary stenosis in one or more coronary arteries, but only 3 developed myocardial ischemia. CABPG was performed in these patients with a median time from the onset of KD to time of surgery of 105 months (12 to 156 months). One patient developed dilated cardiomyopathy and died 1 year after coronary surgery. The overall survival rate in our series is 94.6%
Conclusions: Despite being a small series, the long-term survival of patients with KD complicated by giant coronary aneurysms in our center is relatively good. Further research, should focus on long-term complications and the indications of coronary interventions.

P1793 - KNOWLEDGE BASE OF ADOLESCENTS WITH CONGENITAL HEART DISEASE

Mark Gelatt, Pam Finn, Julie Martin, Jennifer Marshall, Jennfier Pancuo, Jenea Schmidt
Children, Cardiology, Kansas City, MO-United States

Introduction: Most congenital heart disease [CHD] is diagnosed in early childhood with parents as decision-makers and recipients of information. Adolescents gradually assume this role. We performed an observational study to evaluate adolescent and parental recognition of their CHD.
Methods: Established clinic patients, >11 y.o. and parents were independently surveyed. Electrophysiology, cardiomyopathy and cardiac transplant patients were excluded. Results were scored as full, partial or incomplete recognition.
Results: Most (98% parents; 83% adolescents) reported that their cardiologist had provided education. Summary results are noted in Table I. Older adolescents performed better. Parents performed better than all patients. History of prior surgery/intervention had no significance. Patients undergoing last surgery >11 y.o. scored better than those with surgery at younger age or without surgery ($p < 0.05$). Patients with complex lesions (single ventricle, tetralogy of Fallot, transposition of the great arteries) were better at naming their defect ($p < 0.05$) but similar in ability to describe the anatomy compared to those with minor lesions. Those with more complex disease were better at providing the full name of the defect (81/134; 60%) than in fully describing it (43/134; 32%; $p < 0.005$).
Conclusions: Unlike their parents, only 1/2 of adolescents can name their cardiac defect and 1/3 can adequately describe the anatomy. Older adolescents and those with more complex defects are more knowledgeable. A stronger emphasis should be made on educating this population.

Table 1.

	Name defect (n = 522)		Describe defect (n = 521)	
	Full	**Partial**	**Full**	**Partial**
11-14 y.o	40% (n = 102)*	13% (n = 34)	23% (n = 58)*	35% (n = 89)
15-17 y.o.	51% (n = 87)*	17% (n = 29)	35% (n = 56)*	37% (n = 63)
> 18 y.o	68% (n = 65)*	16% (n = 15)	54% (n = 51)*	31% (n = 29)
TOTAL	**49% (n = 254)***	**15% (n = 78)**	**32 %(n = 165)***	**35% (n = 181)**
Parent	78% (402/512)*	11% (n = 56)	61% (312/512)*	29% (n = 151)

P1794 - PERCEIVED EFFECT OF CARDIAC DEFECT ON EXERCISE ABILITY AND QUALITY OF LIFE IN ADOLESCENTS

Mark Gelatt, Pam Finn, Julie Martin, Jennifer Marshall, Jennfier Pancuo, Jenea Schmidt
Children's Mercy Hospital, Cardiology, Kansas City, MO-United States

Introduction: Exercise ability and quality of life (QOL) vary widely in patients with congenital heart disease (CHD), depending on the type of defect. It is expected that those with more severe CHD would be more adversely affected.
Methods: Adolescents with CHD were asked to describe how their CHD affected their exercise ability and how it would "affect your life as an adult?" Answers were scored as 'None,' 'Mild', 'Moderate' and 'Severe' restriction.
Results: The vast majority of patients expect no (63%) or minimal (28%) effect on long-term QOL. Single ventricle (SV) patients were most severely affected, followed by those with repaired tetralogy of Fallot (Table I). These findings correspond with perception of current exercise ability (Table II).
Conclusions: The vast majority of adolescents with CHD do not perceive that it significantly adversely affects their exercise ability or QOL. Patients with more severe lesions report more significant effect.

Table I. Perceived effect of CHD on QOL.

	Shunt (n = 131)	Left-sided (n = 168)	Tetralogy (n = 59)	TGA (n = 23)	SV (n = 37)	Total (n = 418)
None	80% (106)	60% (101)	41% (24)	70 % (16)	30% (11)	63% (258)
Mild	18% (23)	32% (53)	49% (29)	13% (3)	32% (12)	28% (120)
Moderate	2% (2)	6% (12)	10% (6)	17% (4)	32% (12)	8% (36)
Severe	0	1% (2)	0	0	5% (2)	1% (4)

Table II. Perceived effect of CHD on exercise ability.

	Shunt n = 136	Left heart n = 164	TOF n = 58	TGA, TAPVR n = 24	SV n = 40	Total n = 422
None	79% (n = 108)	66% (n = 109)	41% (n = 24)	54% (n = 13)	20% (n = 8)	62% (n = 262)
Mild	17% (n = 23)	25% (n = 41)	41% (n = 24)	17% (n = 4)	30% (n = 12)	25% (n = 104)
Moderate	3% (n = 4)	8% (n = 13)	16% (n = 9)	25% (n = 6)	45% (n = 18)	12% (n = 50)
Severe	1% (n = 1)	1% (n = 1)	2% (n = 1)	4% (n = 1)	5% (n = 2)	1% (n = 6)

P1797 - CLASSIFICATION OF CORONARY ARTERY ANEURYSMS IN KAWASAKI DISEASE BASED ON Z SCORE IN A MEXICAN POPULATION

Mario Rubio-Neria[1], Alejandra Peña-Juárez[2], Silvestre Garcia De La Puente[3], Luis Martín Garrido-García[2]
Instituto Nacional De Peditría, Cardiology, Mexico City-Mexico[1]; Instituto Nacional De Pediatría, Cardiology, Mexico City-Mexico[2]; Instituto Nacional De Pediatria, Methodology, Mexico City-Mexico[3]

Background: Kawasaki Disease is the most common acquired heart disease in developed countries. Classification of coronary artery abnormalities (CAA) has been changed across the years. Recently the use of z-score based on body-surface-area has increased the accuracy of definition or coronary abnormalities.
Objective: Compare the definition of coronary artery abnormalities in KD using the classification based on coronary intraluminal diameter proposed by the American Heart Association with the z-score classification based on body-surface-area.
Material and Methods: All patients in the acute phase of KD diagnosed at the Instituto Nacional de Pediatría in Mexico City, Mexico from August 1995 to of August 31st, 2015 were included. Coronary artery luminal dimensions were converted to body-surface-area adjusted z-scores and compared with the classification proposed by Manlhiot. The Kappa correlation test was used to evaluate the accuracy of both classifications.
Results: A total of 384 patients with KD were reviewed. When we used the AHA classification based on coronary artery luminal dimensions, 141 cases were diagnosed with coronary artery abnormalities in the acute phase of KD (36%). When we adjust the classification of CAA using the body-surface-area 146 cases were diagnosed with CAA (37.6%). The main differences between these classifications were present in small children and in large coronary artery aneurysms. The AHA classification overestimated the severity of small CAA, but underestimated significantly in giant coronary aneurysms. (85.7%)
Conclusions: Classification of CCA based in body-surface z-score improves the correct classification of CAA in KD patients. This improvement is important for defining management especially in small children.

P1802 - FIRST DATA OF CLINICAL PRESENTATION OF SIBLINGS WITH DIAGNOSED MARFAN SYNDROME MANY BUT NOT ALL

Friederike Seggewies, Veronika Stark, Jakob Olfe, Götz C. Müller, Florian Arndt, Rainer Gerhard Kozlik-Feldmann, Thomas Mir
University Heart Center, Department of Pediatric Cardiology, Hamburg-Germany

Objectives: Marfan syndrome(MFS) is a genetic disorder with a variable clinical presentation. Most serious manifestations may affect heart, aorta, skeleton and eyes. The aim of our study is the external validation of the clinical presentation of siblings with an identical evidence of MFS.
Methods: Since 2008 we investigated 381 patients (11.4 ± 5.5y) with suspected MFS, whereas 30 patients are siblings with a genetic (n = 21) or clinical evidence(n = 9) for MFS (13.0 ± 5.8 y; age difference of siblings: 3.7 ± 3.1 y; 18 male: 12 female). We analyzed most serious manifestations: dilation of sinus valsalvae (SV), atrio-ventricular-valve prolapse (AVP), ectopia lentis (EL) and skeleton indices (SK, ≥3), (n = 30). Manifestation of dural ectasia (DE) was included for patients who were suitable for MRI.
Results: In all manifestations except DE, siblings showed a high percentage of identical clinical presentation (SV 71%, AVP 86%, EL 86%, SK 71%, DE 50%). The impact of SV and SK was higher in the group with genetic evidence of MFS (56% vs 25% and 44% vs 25%) but was not influenced by any other parameter. EL was found in 50% of siblings with genetic evidence (clinical evidence 13%). In all siblings without genetic evidence an AVP in at least one sibling was found. The data of the 30 patients shows no influence of gender, age difference and period of observation.
Conclusion: We can conclude that siblings with diagnosed MFS showed a high percentage of identical clinical manifestation. There is an obvious different impact of clinical manifestation between siblings with or without a genetic evidence of MFS. The reason why some siblings with the same evidence for MFS showed a different clinical presentation is still unknown. Further investigations with a larger collective are needed to amplify the results. These findings may be relevant for the clinical guidance of affected families by allowing a better estimation of prognosis and individual therapy.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

P1818 - PAEDIATRIC PREVENTION OF ADULT CARDIOVASCULAR DISEASES IN THE UAE

Elhadi Aburawi
CMHS, UAE University, Pediatric Cardiology, Al Ain-United Arab Emirates

Background/Hypothesis: Atherosclerosis or cardiovascular disease (CVD) starts early in life. In children the disease is asymptomatic and characterized by a progressive initial phase that is hastened by serious health problems such as obesity, hypertension, diabetes and dyslipidemia. Early recognition and prompt intervention halt the progression of atherosclerosis in children with increased risk factors for developing CVD as adults.
Aims: To determine the prevalence and risk factors of obesity, hypertension, diabetes and dyslipidemia in Emirati children. These aims are purposed by identifying obese, hypertensive, pre diabetic diabetic and dyslipidemic students in the study cohort. Children with increased CVD risk will be followed for risk reduction and counselling.
Methodology: The study population n = 523 included school-age children at grades 2 elementary school, 6 middle schools and 10 high school of ?200 student's grade. Parents will complete the study questionnaire which addresses consanguinity and risk factors for cardiovascular disease. Participants had the following determinations: Height, weight body mass index, waist circumference, blood pressure, and pulse rate. Venous blood samples will be collected for measuring the lipid profile total cholesterol high density lipoprotein low-density lipoprotein, and triglycerides random blood glucose, hemoglobin A1c, adiponectin and inflammatory biomarkers interleukin6, high sensitivity C reactive protein and tumor necrosis factor-α.
Results: The results will identify prevalence and risk factors of cardiovascular disease in our young Emirati students. Recognized health problems will be amenable to treatment counseling and risk prevention.
Conclusions.

P1826 - ASSESSMENT OF SERUM VITAMIN D LEVELS IN CHILDREN WITH CONGENITAL HEART DISEASE

Saeed Abtahi[1], Zahra Mostafavian[2]
Department of Pediatric Cardiology, Mashhad Branch, Islamic Azad University, Mashhad, Iran, Pediatric Cardiology, Mashhad-Iran[1]; Department of Community Medicine, Mashhad Branch, Islamic Azad University, Mashhad, Iran, Community Medicine, Mashhad-Iran[2]

Background: Congenital heart disease (CHD) is a relatively common problem with an estimated prevalence of 1 per 100 in the general population. A significant number of these patients will require corrective surgeries over their lifetime. Emerging literature suggests vitamin D deficiency to be a highly prevalent problem in the immediate post-operative CHD population. Also many studies have shown that vitamin D deficiency contributes to secondary organ pathophysiology and worsens outcome in critically ill populations. In this study we aimed to compare serum vitamin D levels in children with CHD who were candidate for corrective surgery with children without CHD.
Materials and Methods: In a case-control study that was conducted in 2015 in Mashhad /Iran, serum levels of vitamin D in 44 children with CHD was compared to 44 controls. Cases of congenital heart disease diagnosed by echocardiography and were recruited by convenience sampling. The control group was selected from healthy less than 2 year's old children who referred to health centers for routine care. Exclusion criteria for both groups were concurrent systemic diseases, irregular consumption of multivitamin drops and malnutrition. Data analysis was done in SPSS V 20 software and descriptive statistics, t-test and analysis of covariance were used.
Results: The mean age in cases was 10.5 ± 1.7months and in controls was 14.5 ± 3.6 months. In cases, 24 patients (54.5%) and in controls 22 cases (50%) were male. The mean serum vitamin D values in subjects 38.2 ± 30 ng/dl and controls 42.6 ± 18 ng/dl was significantly different ($P < 0.05$). Age and sex had no significant effect on vitamin D values.
Conclusions: There was a significant difference in serum vitamin D values in subjects and controls. Therefore, we suggest that the serum levels of vitamin D in children with CHD should be checked especially before corrective surgery of congenital heart disease.

P1836 - CARDIAC HEMANGIOMA IN INFANCY. A CASE OF SUCCESSFUL TREATMENT WITH PROPRANOLOL

Valeria Acevedo[1], Patricia Alvarez[1], Carla Garcia[1], Ricardo Eltit[2], Rodrigo Nehgme[3]
Hospital Roberto Del Rio, Pediatric Cardiology, Santiago-Chile[1]; Hospital Carlos Van Buren, Pediatric Cardiology, Valparaiso-Chile[2]; Arnold Palmer For Children, Pediatric Cardiology, Orlando-United States[3]

Hemangiomas are a type of vascular tumors that could be associated with morbidity and mortality in infants and children. Propranolol has been used successfully in treating patients with hemangiomas in different organs but its effectiveness has not been reported in cardiac hemangiomas. We present a case of an infant with a right atrial cardiac hemangioma treated with propranolol.
Case Report: 16 days old male newborn infant, born at term referred for cardiac evaluation of a holosystolic heart murmur with normal vital signs. Echocardiography showed a large, 33 by 16 mm, multiloculated mass, centrally heterogenous with well-defined edges extending from the roof of the right atrium to the tricuspid valve. Color Doppler demonstrated flow in the central lacunae. Obstruction of the SVC or IVC drainage into the right atrium was not seen and there was no interference with tricuspid valve function. Additionally, 2 apical VSD's 2 × 3 mm each were seen. Cardiac MRI confirmed the diagnosis. Treatment with oral propranolol was initiated at progressive doses up to 2.5 mg/kg/day. This was well tolerated without adverse effects. Follow up echocardiography showed a gradual decrease in tumor size and blood flow starting peripherally as early as 2 weeks after initiation of therapy. There was complete resolution of the tumor by echocardiography and MRI at the age of 1 year. The VSD's closed spontaneously at 18 months.
Conclusion: Propranolol was effective in treating this infant with a rare cardiac hemangioma. A quick favorable response was observed and, in the absence of significant hemodynamic consequences requiring surgical intervention, propranolol should be the first line of therapy in cardiac hemangiomas as well.

P1847 - PEDOMETER ACCURACY FOR MEASURING PHYSICAL ACTIVITY BEHAVIOUR DECREASES WITH AGE AMONG PAEDIATRIC CARDIOLOGY PATIENTS

Angelica Blais[1], Patricia Longmuir[1], Jane Lougheed[2]
University of Ottawa, Human Kinetics, Ottawa-Canada[1]; Children's Hospital of Eastern Ontario, Cardiology, Ottawa-Canada[2]

Background: Physical activity (PA) counselling is recommended at every clinical encounter for those with congenital heart defects.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Clinicians recognize that self- or parent-proxy reports of patients' PA can be highly inaccurate. Pedometers are simple, inexpensive tools to objectively and reliably measure PA levels in adolescents and adults. This study evaluated whether pedometer accuracy varies by age, as PA patterns differ significantly between young children and adolescents.
Methods: A convenience sample of eligible participants (n = 22) between 3 and 14 years of age wore a belt with an attached pedometer and accelerometer for one week. Step counts and time spent in moderate to vigorous physical activity (MVPA) were compared between devices, accounting for age, sex and diagnosis.
Results: Accelerometer and pedometer step counts ($r = 0.76$) and MVPA ($r = 0.53$) were moderately correlated, with significant agreement (Kappa = 0.66), but pedometers overestimated activity relative to accelerometer results. The devices were most strongly correlated for steps ($r = 0.98$) and MVPA ($r = 0.97$) among adolescents (12 to 14 years old). The discrepancy in steps between devices was significantly greater for young children (3 to 5 years) compared to older children (6 to 11 years, $p = 0.02$) and adolescents (12 to 14 years, $p = 0.05$). Differences in time spent in MVPA were similar (greater discrepancy in younger children compared to older children [$p < 0.01$] and adolescents [$p < 0.01$]). Diagnosis and gender did not contribute to device differences ($p > 0.35$).
Conclusion: Pedometers are easy to use, inexpensive tools which can provide clinicians with reliable, objective information on the PA of adolescent patients. The large discrepancy between pedometer and accelerometer measures among younger children suggests that pedometers may not be as suitable for assessing their more diverse PA movement patterns.

P1862 - ORALLY ACQUIRED AND TREATED CHAGAS DISEASE AFTER 9 YEARS. IS IT ALL OVER

Cielo Rojas[1], *Reina Zerpa*[1], *Ivan Machado*[1], *Belkisyolé Alarcón De Noya*[2], *Claudia Scanzoni*[3]
Hospital Universitario De Caracas, Cardiac Congenital Section, Caracas-Venezuela[1]; *Instituto De Medicina Topical, Parasitology, Caracas-Venezuela*[2]; *Fundación De Todo Corazón Richard Gibson, Pediatric Cardiology, Caracas-Venezuela*[3]

Introduction: in Latin America a sparse number of orally acquired Chagas disease outbreaks have been reported. The largest urban outbreak occurred in a school in Caracas- Venezuela in 2007. In this event 103 people were infected by ingestion of guava juice prepared under inadequate sanitary conditions.
Objective: The aim of this study is to describe nine years of cardiovascular follow up in a group of patients with Chagas disease by oral transmission.
Methods: Since 2007 we followed 22 pediatric patients from an outbreak of oral acquired Chagas disease. The annual evaluation consists in a clinical exam, 12-lead electrocardiogram, Doppler echocardiogram, 24 hour Holter monitoring and serologic tests.
Results: Of the 103 patients, 22 had been in cardiovascular control (59% males, 41% females) with a mean age of 16,22 ± 3,81, weight of 57,07Kg ± 16,77 and size of 164,45 cm ± 12,59. 100% of the patients received treatment with Nitro derivates compounds, 50% required a second cycle between 2010-2011 and 4,5% required a third cycle in 2012. Among the electrocardiographic findings, 50% of the patients had early repolarization disorders, 18% intraventricular conduction disorders, 18% sinus bradycardia, and 4,5% incomplete right bundle branch block. Echocardiographic findings indicate that 45% of patients had a restrictive diastolic filling pattern of LV, 36% of RV and 9% already show an increase in the final diastolic diameter of LV. In the Holter monitoring, < 3,5 sec sinus pauses were found (18%), low atrial rhythm (13,5%), 1st degree AVB (4,5%), premature supraventricular beats (13,5%) and premature ventricular beats (4,5%)
Conclusion: Persistent serological changes in patients with acute oral Chagas with adequate treatment suggest a progression of the disease. Despite of it, we strongly suggest lifetime follow up ptotocol including electrocardiographic and echocardiographic evaluations as a prognostic tool of chronic cardiomyopathy development.

P1916 - ISOLATED AORTIC DILATION WITHOUT OSTEOARTHRITIS A CASE OF SMAD3 MUTATION

Jose Arroyave Sagastume[1], *Joan Sanches De Toledo*[2], *Juan Manuel Carretero Bellon*[2], *Domenico Gruosso*[3]
Hospital San Joan De Deu, Pediatric Cardiologypediatric Cardiology, Barcelona-Spain[1]; *Hospital San Joan De Deu, Pediatric Cardiology, Barcelona-Spain*[2]; *Hospital Vall´d´hebron, Cardiology, Barcelona-Spain*[3]

Introduction: Thoracic aortic aneurysms and dissections (TAADs) are often found in the context of genetic syndromes. Aneurysms-osteoarthritis syndrome (AOS) is a recently discovered inherited autosomal dominant connective tissue caused by SMAD3 mutations. AOS responsible for 2% of familial TAADs and characterized by aneurysms, dissections and tortuosity throughout the arterial tree in combination with osteoarthritis. Early-onset osteoarthritis is present in almost all patients. We present a patient with aortic root dilation caused by pathogenic mutation in SMAD3 gene with atypical clinical presentation.
Case Report: Asymptomatic 11 years old male, referred to our department with dilation of the aortic root diagnosed. Neither craniofacial abnormalities such as hypertelorisim and bifid uvula, nor chest deformities were found. Echocardiography revealed dilation of the aortic root and ascending aorta that rapidly progressed in subsequent follow-up echocardiograms. Imaging assessment was completed with MRI. Surgical repaired was deemed necessary and patient underwent a Bentall procedure with good outcome. Genetic study showed pathogenic mutation on SMAD3 (Alteration c.733 G > C (p. Gly245Arg)). Neither joint abnormalities nor cerebrovascular tortuosities were found on complimentary examinations.
Discussion: We describe a patient with AOS with typical cardiovascular findings but without joint abnormalities. Identification of the underlying genetic defect in TAADs is crucial, considering the variability in prognosis, treatment strategy, and risk assessment in family members. Cardiologists should suspect AOS in all patients with aneurysmal dilation of the aorta of unknown cause. Early

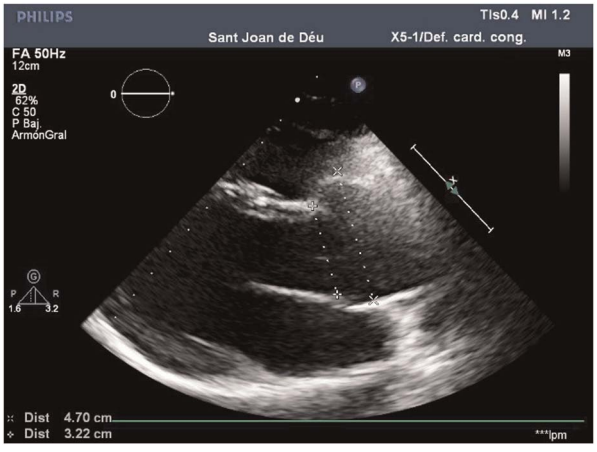

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

elective surgical intervention is indicated in AOS patient's because dissections can occur in relatively small aortic diameters. A multidisciplinary approach including clinical geneticists, cardiologists, orthopedic surgeons, radiologists, neurologists, and vascular or cardiothoracic surgeons when necessary is key to manage the multisystem involvement of these patients

Figure 2.

P1942 - THE EFFECT OF PHYSICAL ACTIVITY BOUT PATTERNS ON BLOOD LIPIDS IN YOUTH NHANES 2003 2006

David A. White[1], Erik A. Willis[2]
Children's Mercy Hospital, Cardiology, Kansas City-United States[1]; National Cancer Institute, Division of Cancer Prevention, Bethesda-United States[2]

Background/Hypothesis: Some evidence suggests that moderate to vigorous physical activity (MVPA) accumulated in bouts of 10 continuous minutes or longer have an independent effect on body composition, cardiorespiratory fitness, bone density, and weight loss. Although the effects of physical activity (PA) bout patterns in adults is well documented, the effects of PA bout patterns on cardiometabolic risk in youth needs further study. The purpose of this study is to determine the effects of PA bout patterns on blood lipids and body composition in youth.
Materials/Methods: Data from children and adolescents (2-17 years of age; N = 1066) with a minimum of four valid days of accelerometer wear time participating in the National Health and Nutrition Examination Survey 2003-2006 were used. Accelerometers were assessed for time spent in sporadic bouts (<5 minutes) of MVPA, short bouts (5-10 minutes) of MVPA, and medium-long bouts (≥10 minutes) of MVPA. Cluster analysis grouped subjects into three distinct exercise patterns. Covariate adjusted general linear models were used to compare blood lipid and body composition outcomes of individuals of different exercise patterns.
Results: PA pattern characteristics are as follows: Cluster 1 (96.6% sporadic, 2.5% short, 1.0% medium-long bouts, n = 718); Cluster 2 (89.1% sporadic, 8.8% short, 2.0% medium-long bouts, n = 232); and Cluster 3 (82.7% sporadic, 10.9% short, 6.3% medium-long bouts, n = 115). After controlling for age, sex, BMI percentile, and total MVPA minutes, there were no differences between clusters for total ($p = 0.877$), HDL ($p = 0.410$), or LDL ($p = 0.753$) cholesterol, triglycerides ($p = 0.295$), systolic ($p = 0.287$) or diastolic ($p = 0.108$) blood pressure, waist circumference percentile ($p = 0.145$), waist to height ratio ($p = 0.793$), or body composition ($p = 0.631$).
Conclusions: MVPA bout patterns, independent of total MVPA minutes, have no effect on blood lipids or body composition in children. Youth should be encouraged to accumulate the recommended minutes per day of MVPA without regulation for pattern or bout duration.

P1945 - HYPERTRIGLYCERIDEMIC WAIST PHENOTYPE PREDICTS VASCULAR HEALTH IN YOUTH WITH DYSLIPIDEMIA

David A. White[1], Omar Qayum[2], Chizitam F. Ibezim[2], Gautam M. Anand[3], Geetha Raghuveer[1]
Children's Mercy Hospital, Cardiology, Kansas City-United States[1]; University of Missouri-kansas City, School of Medicine, Kansas City-United States[2]; Lenox Hill Hospital, Vascular Surgery, New York-United States[3]

Background/Hypothesis: The hypertriglyceridemic waist phenotype (HTWP) is defined by the presence of elevated waist circumference (WC) (≥90th percentile) combined with elevated triglycerides (≥1.1mmoL). Linking WC with triglyceride concentrations allows clinicians to stratify presence of metabolically active visceral fat opposed to less metabolically active subcutaneous fat. In youth, the HTWP is associated with low fitness, elevated total cholesterol, low HDL cholesterol, impaired fasting glucose, and high diastolic blood pressure. However, the effects of the HTWP and this clustering of risks on vascular health in children is unknown. The purpose of this study is to determine the effect of the HTWP on vascular health in youth with dyslipidemia.
Materials/Methods: Children and adolescents aged 8-15 years were recruited from a pediatric preventive cardiology clinic. All participants completed a full blood lipid panel. WC was measured 2 cm above the iliac crest by a single observer. Pulse wave velocity (PWV) and augmentation index (Aix) were measured using a combined oscillometric and tonometric device. Carotid artery intima-media thickness (CIMT) was measured on the far wall of the left and right common carotid arteries using a semi-automated edge detection software.
Results: Of the 115 youth (males = 58; mean age = 13.05 ± 1.86 years), 65 met criteria for HTWP. After controlling for blood pressure, LDL and HDL cholesterol, children with HTWP had an elevated Aix (standard) (HTWP 14.43% ±1.74; normal 7.96% ±2.04; $p = 0.025$), Aix (heart rate controlled at 75bpm) (HTWP 11.91% ±1.77; normal 5.41% ±2.08; $p = 0.027$), and CIMT (HTWP 0.466mm ±0.004; normal 0.468mm ±0.005; $p = 0.821$). There were no differences in PWV (meter/sec) (HTWP 5.19 ±0.114; normal 5.01 ±0.128; $p = 0.327$).
Conclusions: Presence of the HTWP is associated with vascular damage characterized by increased Aix in children with dyslipidemia. HTWP can be used to stratify children who are at increased risk for premature vascular disease.

P1948 - IMPACT OF INTRAUTERINE GROWTH RESTRICTION ON CARDIOPULMONARY EXERCISE DURATION

Andrew Spearman, Rohit Loomba, Sara Creighton, Michael Danduran, Joshua Kovach
Children, Pediatrics, Milwaukee-United States

Background: Infants subjected to impaired delivery of nutrients and oxygen are at risk for impaired fetal growth, commonly termed

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

intrauterine growth restriction (IUGR). Multiple studies have demonstrated association of IUGR with early and late-onset cardiovascular pathologies, including systolic and diastolic dysfunction, altered sarcomere structure, decreased cardiomyocyte endowment, increased cardiac fibrosis, hypertension, and adult-onset ischemic heart disease. The effects of these changes on exercise capacity in children and adolescents are unknown.
Methods: We performed a retrospective chart review of a single-institution's cardiopulmonary exercise stress lab database on patients born after 1/1/1990 with cardiopulmonary exercise testing (CPET) prior to 7/1/2016. We cross-referenced documented birth weight and gestational age to obtain a weight-for-gestational age percentile. Individuals with birth weight <10th percentile for gestational age were defined as IUGR. We excluded patients with a known history of congenital heart disease or cardiomyopathy. Normal controls were obtained from a previously defined cohort of healthy patients at Children's Hospital of Wisconsin. Controls were matched 2:1 with IUGR cases by gender and age at CPET.
Results: A total of 126 patients were included with 42 IUGR cases and 84 controls. IUGR patients had mildly decreased exercise duration that did not reach significance (11:54 versus controls 12:34, $p = 0.14$). There was no significant difference in heart rate response (IUGR 114.5 ± 17.2 bpm; controls 119.7 ± 17.0, $p = 0.12$). Regression analysis confirmed that IUGR was not an independent predictor of exercise duration but age, gender, and BMI were predictors.
Conclusions: IUGR is not associated with significant differences in measurements of exercise capacity in children, though there was a mild difference in exercise time. This study was limited by patient numbers. Further research is needed to study the effects of the pathophysiology of growth restriction on cardiovascular and exercise physiology.

P1964 - NEURODEVELOPMENTAL OUTCOMES IN CHILDREN WITH SINGLE VENTRICLE CIRCULATION UNDER THE AGE OF FIVE YEARS RECRUITED IN THE LONDON AREA

Suzan Kakat[1], Aparna Hoskote[1], Deborah Ridout[2], Victoria Banks[1], Rodney Franklin[3], Thomas Witter[4], Rhian Lakhani[4], Victor Tsang[1], Jo Wray[1], Katherine Brown[1]
Great Ormond Street Hospital NHS Foundation Trust, Charles West Division, London-United Kingdom[1]; UCL Great Ormond Street Institute of Child Health, Population, Policy and Practice Programme, London-United Kingdom[2]; Royal Brompton and Harefield NHS Foundation Trust, Paediatric Cardiology Department, London-United Kingdom[3]; Evelina London Children's Hospital, Department Paediatric Cardiology and Cardiac Surgery, London-United Kingdom[4]

Background: Neurodevelopmental abnormalities are common in children with heart disease, with the greatest risk in children with single ventricle (SV) circulation. There is no current process for routinely monitoring this patient group in the UK, resulting in late detection and referral.
Methods: Children with SV circulation under the age of 5 years were recruited from three children's heart centres in London between January 2014 and July 2015 as part of a wider cross sectional study. Neurodevelopment was evaluated with the Mullen Scales of Early Learning (MSEL) cognitive score (all children) and MSEL motor score in children aged <33 months. Parents completed the Ages and Stages questionnaire (ASQ-3).
Results: Ninety patients with SV circulation with a median age of 15 months were evaluated, 52 (58%) were male, 44 (49%) had HLHS, 46 (51%) other single ventricle lesions. Fifty-five patients (61%) had undergone more than 1 congenital heart operation and 18 (20%) had a non cardiac diagnosis linked to developmental delay. Of 90 children assessed with MSEL for cognitive function, 18 (20%) had scores 1-2 SD below and 10 (11%) had scores >2 SD below the normative mean. Of 61 children assessed with MSEL for gross motor function, 12 (20%) had scores 1-2 SD below and 8 (13%) had scores >2 SD below the normative mean. Parents of 80 children completed the ASQ, with 19 (24%) obtaining borderline and 45 (56%) abnormal results.
Conclusions: A higher proportion of children with SV circulation assessed by the MSEL have impaired neurodevelopmental outcomes compared to the normal population. The ASQ flagged up a much higher proportion as abnormal than the MSEL, and may be picking up a wider range of health related issues. There is a need for improvement in the quality of neurodevelopmental assessment for children with SV circulation in the UK.

P1993 - CARDIOPULMONARY EXERCISE TESTING IN BOYS WITH ATTENTION DEFICIT HYPERACTIVITY DISORDER

Miroslawa Sielska-Wojtaszek[1], Tomasz Mikulski[2], Bozena Werner[1]
Medical University of Warsaw, Department of Pediatric Cardiology And General Pediatric, Warsaw-Poland[1]; Polish Academy of Sciences, Department of Applied Physiology Mossakowski Medical Research Centre, Warsaw-Poland[2]

Background: Exercise capacity is one of the most important indicators of health, in children with attention hyperactivity deficit disorder (ADHD) physical activity increases their concentration, cognition, improves motor behavior and exercise tolerance. The aim of the study was to evaluate the exercise capacity of boys with ADHD.
Methods: Cardiopulmonary exercise test (CPET) was conducted in 37 boys with ADHD, (7-17 years, mean 11.3 ± 2.6) who were divided into 3 age subgroups: I – 7-10 years, mean 9.0 ± 0.3 years, II – 11-13 years, mean 12.1 ± 0.2 years , III – 14-17 years, mean 15.5 ± 0.4 years. Their results were compared with two age-matched reference groups REF1 ($n = 68$, 8-19 years, mean 14.2 ± 2.9) and REF2 ($n = 69$, 6-17 years, mean 11.5 ± 3.5) of healthy boys.
Results: ADHD boys achieved significantly lower workloads (116 ± 7 W) than the healthy boys (REF1-150 ± 8 W, $p < 0.01$) in the whole group, as well as in the age subgroups (I – 81 ± 6 W vs. REF1 118 ± 9 W; II – 114 ± 5 W vs. REF1 140 ± 7 W, both $p < 0.01$ and III – 175 ± 10 W vs. REF1 220 ± 12 W, $p < 0.05$). Peak VO2 in ADHD (1.56 ± 0.09 l/min) boys was similar to the REF1 values (1.62 ± 0.08 l/min), but significantly lower than in REF2 (1.92 ± 0.11 l/min, $p < 0.05$). Differential analysis in subgroups showed statistically significant difference only in subgroup II (1.41 ± 0.08 l/min vs 1.81 ± 0.09 l/min in REF2, $p < 0.01$). Anaerobic threshold was achieved at significantly lower workloads (subgroup I 50 ± 3 W vs. REF1 86 ± 5 W, $p < 0.001$; subgroup II 72 ± 7 W vs. REF1 91 ± 8 W, $p < 0.001$). No significant difference in subgroup III was found.
Conclusions: Decreased exercise tolerance was observed in boys with ADHD before their puberty. They reached the anaerobic threshold earlier than their healthy peers, thus the effort is performed less efficiently and associated with greater physiological strain. Cardiopulmonary exercise testing is a safe and valuable diagnostic tool in boys with ADHD.

P2047 - CHROMOSOME 22Q11.2 DELETION SYNDROME ANALYSIS OF ASSOCIATIONS BETWEEN CARDIAC AND EXTRACARDIAC MALFORMATIONS IN A COHORT OF 276 PATIENTS

Patricia Alvarez[1], Valeria Acevedo[1], Francisco Navarro[2], Patricia Rios[3], Analia Cuiza[2], Helena Poggi[2], Gabriela Repetto[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Clinica Alemana-UDD, Cardiology, Santiago-Chile[1]; Clinica Alemana-UDD, Center For Genetics and Genomic, Santiago-Chile[2]; Universidad De Chile, Cardiology, Santiago-Chile[3]

Cardiac malformations in 22q11.2 microdeletion syndrome (22q11DS) are frequent. The most common congenital heart disease (CHD) involve conotruncus and aortic arch. Extracardiac anomalies are also common. CHD, in association with other malformations may help suspect the diagnosis.
Objectives: Describe CHD in a cohort of Chilean patients with 22q11DS. Analyze their frequency and compare them with non-syndromic CHD population reported in literature. Assess the association between cardiac and non-cardiac malformations to search those suggestive of the syndrome.
Materials and Methods: review of clinical and demographic database of patients with 22q11DS diagnosed between 1998 and 2016.
Results: 276 patients; 148 (52.9%) were female. CHD was present in 50.4%. The most frequent were: VSD in 23.6%, ASD 14.3% , Tetralogy of Fallot (TF) in 18.9%; truncus arteriosus (TA) 3.2%; double outlet RV 1.8% and interruption of the aortic arch type B (IAA-B) 5.4%. With respect to extracardiac malformations, palate anomalies were present in 63.6%; CNS in 11.1%, renal 6.1%; skeletal 24.6%. According to Hoffman et al (2002), the frequency of CHD in the general population is 0.9%, with a frequency of VSD of 0.35%; ASD 0.09%; TF 0.04%; TA, 0.01%; DSVD 0.01% and IAA-b of 0.001%. No association of intracardiac malformations with aortic arch anomalies or between CHD and other malformations was observed in our cohort.
Conclusions: In this large, unselected cohort of patients with 22q11.2DS, the frequency of CHD was 50 times greater than that described for general population. It was 5,400 times more common for IAA-b B, 470 for TF and 60 for VSD. These results show the high risk of CHD in 22q11DS, and suggest that the deletion should be suspected in interruption of arch aortic and conotruncal heart disease per se, even in the absence of other anomalies. Fondecyt grant 1130392

P2117 - LATE EVALUATION OF PATIENTS UNDERGOING TOTAL CAVOPULMONARY BYPASS CLINICAL ASPECTS REINTERVENTIONS AND COMPLICATIONS THAT INTERFERE WITH MORBIDITY AND MORTALITY

Paula Rodrigues S. M. Costa, *Natália Freitas Jatene Baranauskas, Thalyta Madeira Correa, Cristiane Felix Ximenes, Ieda Biscegli Jatene Hospital For The Heart (Hospital Do Coração), Pediatrics and Congenital Heart Disease, São Paulo-Brazil*

Introduction: The single ventricular hearts (SVH) correspond to a group of congenital heart diseases with several anatomical combinations. The treatment is performed through surgical staging culminating in the realization of Total Cavopulmonary Shunt Operation (TCSO) as final stage.
Objective: To evaluate the delayed evolution of patients submitted to TCSO in relation to complications thrombosis, protein-losing enteropathy, ventricular dysfunction and hepatic cirrhosis) and the need for reintervention, relating possible factors that may interfere in morbidity and mortality. Material and method: a cross-sectional study of patients submitted to TCSO with an extracardiac conduit (EC), from Jun/2003 to Jan/2016, in outpatient follow-up. Data obtained by survey of medical records. Descriptive analysis was performed and retrospective analysis of age at the time of surgery, presence of fenestration in the EC, perioperative thrombosis and previous pulmonary pressure.
Results: A total of 59 patients were analyzed, (70.2% males). Mean age at surgery: 4.45 ± 2.69 years. Left single ventricular heart performed 54.4%. Average follow-up time approximately 49 months. 68.4% had a mean pulmonary artery pressure (PAP) lower than 15 mmHg. 61.4% did not undergo EC fenestration. 35.1% had thromboembolic complication. When comparing the presence of thrombus 50% use of ASA. There was no statistical significance in the relation of the presence of fenestration, Left Heart Hypoplasia Syndrome and PAP > 15 mmHg with the appearance of protein-losing enteropathy. 15% had ventricular dysfunction, and 77% of then were Right Single Ventricle (RSV). 50% had some degree of hepatic congestion/hepatomegaly. 21% required re-interventions. No patient presented with plastic bronchitis or arrhythmias.
Conclusion: There was no statistical significance between patients who used ASA or oral anticoagulant for antithrombotic prophylaxis. The only preoperative factor that interfered with late evolution was RSV.

P2182 - PALIVIZUMAB IN INFANTS LESS THAN 1 YEAR WITH HEMODYNAMICALLY SIGNIFICANT CONGENITAL HEART DISEASE IN ARGENTINA A COMPARATIVE STUDY WITH HISTORICAL CONTROL GROUP

Maria Guillermina Soraiz[1], *Silvia Beatriz Andrés[2], Silvia Beatriz Castro[2], María Fernanda Alvarez[2], Diego Claudio Micheli[3], Gabriela Bauer[1]*
Hospital Nacional De Pediatría Garrahan, Follow-up Clinics, Buenos Aires-Argentina[1]; Hospital Nacional De Pediatría Garrahan, Neonatology, Buenos Aires-Argentina[2]; Hospital Nacional De Pediatría Garrahan, Cardiology, Buenos Aires-Argentina[3]

Background: In 2009, Argentina launched a national program to assist children with congenital heart disease (CHD) and, since 2014, Health Ministry provides palivizumab (PVZ) to all infants with CHD. The Hospital Nacional de Pediatría Garrahan is a tertiary center with a Follow-up Clinic for children with chronic medical conditions (CMC). The study main objective was to analyze the impact of immunoprophylaxis with PVZ, comparing a cohort of infants with hemodynamically significant CHD (HS-CHD) that received PVZ vs. a historical cohort of HS-CHD infants not receiving PVZ.
Subjects and Methods: Prospective cohort study with historical control. HS-CHD patients <1 year of age, followed up at the CMC clinics between 2014 and 2016 were included. All patients received PVZ according to local guidelines. HS-CHD was defined with usual criteria. Historical control group comprised HS-CHD patients <1 year of age, followed up between 2007 and 2009, not receiveing PVZ. Data corresponding to respiratory syncytial virus (RSV) high circulation months (May to September) were analyzed. Demographic and clinical data, global hospitalization rates, RSV-specific hospitalization rates, length of hospitalization and need for mechanical ventilation were compared. Descriptive statistics, t-test, Wilcoxon test and chi-square test were used as appropriate. Differences are expressed as Relative Risk (RR), RR reduction, CI95% and Number Needed to Treat (NNT). A $p < 0.05$ was considered statistically significant.
Results: Fifty-three patients were included in PVZ group and 50 patients in control group. Table 1 shows groups characteristics. There were 10 respiratory tract infection hospitalizations (19%) in PVZ group vs. 15 (30%) in control group. Forty per cent of all hospitalizations were in June. There were no respiratory deaths. Table 2 shows differences between groups.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: RSV-related hospitalization rate was significatively lower in PVZ group. PVZ impact was high, even though patients with severe HS-CHD were more frequent in PVZ group.

Table 1. Groups characteristics.

	PVZ Group (n = 53)	Control Group (n = 50)	P
Follow-up period	2014-2016	2007-2009	
Sex (M/F)	27/26	33/17	0.08
Birth weight (g) (x ± DS)	3,240 ± 460	3,077 ±590	0.29
Gestational age (w) (x ± DS)	39.0 ± 1.3	39.0 ± 1.7	0.89
HS-CHD classification:			
Gl*	14 (26%)	17(34%)	0.27
G2*	31 (59%)	16(32%)	0.006
G3***	8 (15%)	17 (34%)	0.02
Single Ventricle/LVH	27 (51%)	11(22%)	0.001
Pulmonary hypertension	18 (34%)	9 (18%)	0.02

PVZ: Palivizumab. **HS-CHD**: Hemodynamically significant congenital heart disease. ***Gl**: Left-to-right shunt with congestive heart failure. ****G2**: Cyanotic CHD uncorrected or palliated (including single ventricle lesions). *****G3**: Corrected **CHD** with residual defects. **LVH**: Left ventricular hypoplasia.

Table 2. Outcomes.

P2228 - IMPACT OF REAL TIME TELECONSULTATIONS IN PEDIATRIC CARDIOLOGY ELEVEN YEARS OF EXPERIENCE

Dimpna Albert[1], *Rosa Collell*[2], *Marc Figueras*[3], *Cristina Marimón*[2], *Susana Uriel*[3], *Ferran Roses*[1], *Angels Puigdevall*[3], *Josep Girona*[1]
University Valle De Hebron Hospital, Pediatric Cardiology, Barcelona-Spain[1]; *University Sant Joan Hospital, Pediatric Cardiology, Reus-Spain*[2]; *University Josep Trueta Hospital, Pediatric Cardiology, Girona-Spain*[3]

Background: A telemedicine program was initiated between the Pediatric Cardiology Department of a tertiary care hospital in Barcelona and pediatric cardiologists from 2 remote hospitals (around 100 km distance) in 2006 and 2008 respectively. The Project consists of real-time teleconsultation with direct connection of the echocardiogram images in real-time and in presence of the family (seeing people face to face), using a videoconference system with internet protocol (IP) connectivity with encrypted information.
Methods: We performed a retrospective review of all teleconsultations from 2006 to 2016 and analyzed the population, indications for teleconsultation, diagnoses, impact and satisfaction of the families (obtained through a satisfaction survey carried out in the first 118 teleconsultants).
Results: Over ten years, a total of 515 real-time videoconference were carried out, 388 with the first Hospital and 127 with the second, corresponding to structural congenital heart disease (97,2%) or arrhythmia disorders (2,8%); 220 (42,7%) females and 295 (57,3%) males; 9,9% were neonates. The most frequent reason of connections was cases for surgery 157 (30,5%), followed by the evaluation of children and follow-up 148 (28,7%), patients to plan an interventional catheterization or electrophysiology study 146 (28,4%) or second opinion (12,4%) (see Figure). The satisfaction of parents (118 patients) was very high in the survey (9.5 over 10) and a tele-consultation was preferred more than traditional consultation in 99,2% of cases. There were minor discrepancies between pediatrics cardiologists in 9,7% of the cases.
Conclusions: In our experience, real-time telemedicine is an important tool in the diagnosis and follow-up of children with cardiovascular diseases. It plays an important role in continuous medical training for the staff of hospitals in remote areas of a tertiary hospital and has significant medical, economic and social benefits for patients and their families.

P2238 - KAWASAKI DISEASE MARRAKECH UNIVERSITY HOSPITAL EXPERIENCE

Nadia El Idrissi Slitine, Mariam Makkaoui Alaoui, Fatiha Bennaoui, Ghizlane Draiss, Noureddine Rada, Mohamed Bouskraoui, Fadel Maoulainine
Neonatal Intensive Care Unit , Mother and Child Hospital, Mohammed Vi Marrakech University Hospital, Morocco., Childhood Health and Development Re, Pediatrics, Marrakesh-Morocco

Introduction: Kawasaki disease (KD) is the leading cause of acquired heart disease among children which affects the coronary arteries. We aimed to evaluate the clinical manifestations, laboratory parameters, echocardiographic findings at diagnostic and assess the follow-up of KD in children.
Patients and Methods: In this retrospective study, we studied the clinical data, of all children with KD who had been admitted in the infectious pediatric department at Mohamed VI University Hospital Marrakech, from January 2011 to November 2016.
Results: The study enrolled 50 patients. Sex ratio was 1.5. The age at the disease onset ranged from 4 months to 12 years. All patients had a persistent fever, followed by oral mucosal lesions. 45 patients had typical KD, 5 had atypical KD. All patients had elevated CRP, 95% had elevated ESR. Elevated leukocyte count was observed in 60% and thrombocytosis in 40% of the patients. 42% of the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

echocardiography was performed during the acute stage of the disease. There were 16 cases , with lesion of coronary artery; pericarditis in two patients and an aneurysm of the left humeral artery in one child. During the follow-up, cardiac involvement was documented in 32 cases; coronary artery dilatation resolved in 2 children, the patients that were not found with arterial coronary at the acute stage had no abnormality in the follow-up. 44 patients received intravenous immunoglobulin (IVIG). One patient was complicated by pleuresia and only one patient relapsed and died with sepsis and intestinal necrosis.
Conclusion: Different facts play a role in the diagnostic and management of KD in our context. There is a shortage of pediatric cardiologists in our university hospital, which drains all the cardiac children of the southern regions of Morocco. The expensive cost of IVIG is an obstacle for patients to access therapy.

P2240 - HOSPITAL PREVALENCE OF CONGENITAL HEART DISEASE IN A MOROCCAN CITY MARRAKESH

Abdellatif Daoudi[1], Nadia El Idrissi Slitine[1], Soufiane Moussaoui[1], Fatiha Bennaoui[1], Ghizlane Draiss[2], Noureddine Rada[2], Fadel Maoulainine[1], El Idrissi Slitine Nadia Idrissi Slitine Nadia[8]
Nicu, Mother and Child Hospital, Med Vi Hospital, FMPM, Cadi Ayyad University, Pediatrics, Marrakesh-Morocco[1]; Pediatrics A, Mother and Child Hospital, Med Vi Hospital, FMPM, Cadi Ayyad University, Pediatrics, Marrakesh-Morocco[2]

Background: Congenital heart disease englobes all cardiac and vascular malformations. It is a major health problem, especially in developing countries. The aim of this work is to assess the prevalence of congenital heart disease.
Methods: It is a retrospective, descriptive and analytical study, including all children aged 1 to 18 years hospitalized in the pediatric department of Mohammed VI university hospital in Marrakech, with diagnosis of congenital heart disease, between January 2011 and November 2016.
Results: Out of 7627 patients admitted, 247 had a congenital heart disease, corresponding to a hospital prevalence of 3.2%. Mean age was 15.2 months. Boys represented 55.8% of cases. Children with Down Syndrome represented f25.9%, parental consanguinity represented 15.38%. concerning the diagnosis, VSD was the most frequent with 108 cases (43.7%), followed by ASD in 97 patients (39.2%), the PDA in 34 cases (13.7%), tetralogy of Fallot in 20 patients (8%), pulmonary stenosis in 16 cases (6, 4%), transposition of great arteries in 12 cases (4.8%). In children with trisomy 21, the most common malformation was AV canal, found in 25 patients (39%).
Conclusion : The prevalence of congenital heart disease is variable, could be underestimated in this study. The prevalence is constantly increasing, which could be explained by the development of investigation techniques but also lifestyle modification with more exposure to teratogenic risks. The high rate of consanguinity in Morocco exposes to even more congenital heart disease. The lack of resources is the major problem of management in our context. Knowledge of the prevalence of congenital heart disease could allow for good organization and planning of care, from diagnosis to treatment.

P2256 - CLINICAL CHARACTERISTICS COMPARISON BETWEEN CLASSICAL AND ATYPICAL KAWASAKI DISEASE IN UNIVERSITY MALAYA MEDICAL CENTRE

Norazah Zahari[1], Joyce Darshinee Ddm Sirisani[1], Mohamad Rodi Isa[2]
University Malaya Medical Centre, Paediatric, Kuala Lumpur-Malaysia[1]; Univeristy Technology Mara, Preventive Medicine, Selangor-Malaysia[2]

Introduction: Kawasaki disease (KD) is a self limiting vasculitis commonly affecting children less than 5 years old. We aimed to study the clinical characteristics between classical and atypical KD by examining the coronary artery (CA) status and systemic inflammatory markers.
Methods: A single centre, retrospective review of children with KD during 4 years. All children had an echocardiography at diagnosis, and at 1,3 and 6 months after diagnosis. Patients received intravenous immunoglobulin (IVIG) and antiplatelet therapy after confirmed to have KD.
Results: A total of 43 children with mean age 23.9 ± 18.2 months, 23 male and 20 female were included. KD were of classical type in 33, 8 atypical and 2 incomplete type. Clinical characteristics includes fever duration of 6.65 ±2.09 days, cervical lymphadenopathy in 37(86%), polymorphous rash in 36(83.7%), non purulent conjunctivitis in 34(79.1%), erythematous lips in 37(86%), extremities changes in 22(51.2%)and BCG scar flare in 16(37.2%). IVIG administered at 7.18 ± 2.18 days of illness. Atypical KD are more likely in children less than 6 months. Parameters includes hemoglobin, erythrocyte sedimentation rate and serum albumin is significantly elevated in classical compared to atypical KD with p value of 0.011,0.034,0.004 respectively. Coronary artery aneursyms commonly involve left main coronary artery(LMCA). At diagnosis, 10 patients had z score >2.50 for LMCA, 4 patients had z score >2.50 for right coronary artery (RCA) and 4 patients had involvement of both LMCA and RCA.6 patients had an increase in z score of LMCA at 1 month after diagnosis compared to at diagnosis.
Conclusion: Inflammatory markers are a useful surveillance markers in classical KD. Coronary artery aneurysm are less severe in classical KD.

P2364 - INCIDENCE OF CONGENITAL HEART DEFECTS IN CHILDREN WITH CHROMOSOME ABNORMALITIES IN SOUTH EASTERN EUROPEAN COUNTRY A POST WAR PERIOD

Tomica Bozic[1], Maja Batinica[2], Jure Pupic Bakrac[3], Darinka Sumanovic Glamuzina[4], Antonija Mustapic[4], Marijana Raguz[4], Marija Bosnjak[4]
University Clinical Hospital, Department of Pediatrics,cardiology Unit, Mostar-Bosnia and Herzegovina[1]; Children's Hospital, Department of Pediatrics,Cardiology Unit, Zagreb-Croatia[2]; University Clinical Hospital, Department of Pediatrics, Mostar-Bosnia and Herzegovina[3]; University Clinical Hospital, Neonatology Unit, Mostar-Bosnia and Herzegovina[4]

Background: Congenital heart defects (CHD) etiologically are result of genetic aberrations and environmental factors. Chromosome abnormalities are one of genetic factors that come with a significant risk of CHD. Additionally, it is already known that maternal stressful life can increase prevalence of CHD in offspring.
Aim: Analysis of incidence and pattern of CHD in children with chromosome abnormalities syndromes.
Patients and Methods: Study has been conducted in post-war period 2007-2015 yr, in the University Clinical Hospital Mostar, Bosnia and Herzegovina. Altogether 62 children were diagnosed with numerical or structural chromosome abnormalities - syndromes, majority with Down (50), and rest with Edwards (4), Turner (2), Patau (2), DiGeorge (2), Wolf-Hirschhorn (1), Kleefstra (1). From the medical documentation two main findings were analyzed - cytogenetic and echocardiographic, and four additional parameters - gender, birth weight, birth term and outcome. Children were followed-up to 1 year old.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: Of all patients, 51.6% (32/62) had CHD. The most frequent defects were as follows: AVSD (37.5%), VSD (21.9%), clinically significant ASD/PDA (15.6%), valvular defects (9.4%). Incidence of CHD in patients with certain syndromes were: in Down 46% (23/50), in Edwards 100% (4/4), in Turner 50% (1/2), and in other rare syndromes pulled together 66.7% (4/6). In Down syndrome the most common CHD was AVSD (12/23), in Edwards VSD (1/4), in Turner valvular defect, and in group of patients with other rare syndromes VSD and aortic coarctation/stenosis (1 and 1 out from 4, respectively). CHD incidence was higher in hypothrophic patients (87.5%) and generally led frequently to fatal outcome (7/32).
Conclusion: Knowing the incidence of CHD in specific syndromes has practical implications and is important in diagnostic chain. Our results of CHD incidence in patients with Down and Edwards syndromes are in accordance with the literature data, as well as the mortality rate.

P2375 - LRP2 AN ENDOCYTIC VESICLE TRAFFICKING PROTEIN ASSOCIATED WITH CONGENITAL HEART DISEASES

Jiuann-Juey, Ivy Lin[1], Anupma Jha[2], Jacob Mccleary[2], Cecilia W Lo[2]
University of Pittsburgh/children, Critical Care, Pittsburgh-United States[1]; University of Pittsburgh, Developmental Biology, Pittsburgh-United States[2]

Objectives: Congenital heart diseases affect nearly 1% of neonates per year in the United States and are the leading cause of neonatal death. Despite a strong indication of genetic contribution to congenital heart diseases, the developmental processes and genetic components are poorly understood. From the large-scale forward genetic screen using inbred mice chemically mutagenized with ethyl-nitrosourea (ENU), a finding of endocytic trafficking gene mutations, including Lrp2, were recovered as causing congenital heart disease phenotypes. Endocytosis plays an important role in modulating cell signaling by regulating the internalization, recycling and degradation of receptor-ligand complexes. This involves the regulation in trafficking of the internalized endocytic vesicles to different endosomal compartments, some destined for fusion with lysosomes and degradation while others are recycled to the surface by recycling endosomes. Mutations in LRP2 causes a spectrum of congenital heart disease comprising of outflow tract abnormalities and alignment defects including truncus arteriosus with/without aortic arch anomalies.
Methods and Results: Here we report the LRP2 [line 1625(MGI 5489925)] mutant mouse models recovered from a forward genetic screen. Exome sequencing identified line1625 (MGI5489925) results in an A to G substitution at nucleotide -3 of an intron before nucleotide 8456 (c.8456-3 A > G, NM_001081088), a presumed splicing mutation. The mutants exhibit a spectrum of septation and outflow tract defects including truncus arteriosus type II with or without aortic arch anomalies. we use a series of tissue-specific genetic manipulations to define the crucial role of the LRP2 pathway in these three fields of cells (endocardial cushion, secondary heart field and cardiac neural crest) during outflow tract development and septation. LRP2-Mef2C and LRP2-Nkx2.5 recapitulate LRP2m/m cardiac phenotype (truncus arterious with or without arch anomalies).
Conclusions: We provide the evidence of endocytic vesicle trafficking pathway associated with the development of congenital heart diseases with malalignment/sepetation and outflow tract defects

P2393 - HOME AED PREVENT SUDDEN DEATH IN CHILDREN !

Takashi Higaki, Toyohisa Miyata, Shoji Takahashi, Toshiyuki Ito, Hiroaki Urata, Ryo Tashiro, Toshifumi Yamauchi, Tomozo Moritani, Toshiyuki Chisaka, Hidemi Takata, Masaaki Ohta, Nurzed Bayarmaa, Eiichi Ishii
Ehime University Graduate School of Medicine, Regional Pediatrics and Perinatology, Toon-Japan

Introduction: Sudden death of children may occur at any time. Once the accident happens, it influences the life of family members, and also affects all concerned in the school and in the community. Automated external defibrillator (AED) was initially installed for general citizens in 2004 in Japan, resulting in an increased number of live people rescued by non-medical workers. Recently, it has been proven that sudden death in children is often caused by ventricular fibrillation, which is an indication of AED. However, providing the Home AED is still not common. Here, we report a case that has been life-saving by Home AED and the effectiveness and necessity of installation are discussed.
Case Report: A 13-year-old boy who has been emergency admitted to our hospital due to ventricular tachycardia.10 years ago, he was suffering from fulminant myocarditis complicated with refractory ventricular tachycardia. As a result, remained ventricular aneurysm as sequelae. Although recent clinical course is stable and the arrhythmia was not observed, this time when he was down the stairs of his house, palpitations happened suddenly, and was deteriorating rapidly. His mother noticed tachycardia, attached AED to him in great haste. AED instructed to shock of electrical cardioversion, she press the shock button without hesitation.
Discussion and Conclusion: The analysis results of the recording of AED demonstrated heart rate of 260 beets/min of ventricular tachycardia, if appropriate management is not performed by the mother, there is a high possibility that had led to death. Home AED is one of the effective methods in order to protect the children from sudden death. Especially having an underlying disease, it is necessary to consider aggressively introduced.

P2409 - CLINICAL SIGNIFICANCE OF CARDIAC BIOMARKERS IN CHILDREN WITH HEART PROBLEMS

Tomica Bozic[1], Maja Batinica[2], Ivan Malcic[3]
University Clinical Hospital, Department of Pediatrics Cardiology Unit, Mostar-Bosnia and Herzegovina[1]; Children's Hospital, Department of Pediatrics Cardiology Unit, Zagreb-Croatia[2]; Clinical Hospital Center, Department of Pediatrics Cardiology Unit, Zagreb-Croatia[3]

Background: Cardiac biomarkers are indicators of heart disease severity. B-type natriuretic peptide (BNP) or N-terminal pro B-type natriuretic peptide (NT-proBNP) are produced in the cardiac ventricles and are primarily used to evaluate the severity of heart failure. Cardiac troponin T (cTnT) is a specific marker of acute heart damage. Creatine kinase (CK) is relatively low specific for myocardial injury.
Aim: Aim of the study was to determine the level of NT-proBNP, cTnT and CK in children with various cardiac diseases.
Patients and Methods: Prospective analysis included 65 children with heart problem (30 male and 35 female) from 1 month to 17 years of age (mean 4 years and 7 months). They were divided into three groups: 1. native CHD before surgery; 2. condition of CHD after surgery; 3. conditions of cardiomyopathies and arrhythmias, without morphological signs of CHD. The control group consisted of 20 patients, matched by sex and age. For analysis 2 ml peripheral vein blood was used in the morning.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: The values of NT-proBNP, cTnT and CK were elevated in children with heart failure, early after CHD surgery, and in the active phase of cardiac arrhythmias. The highest NT-proBNP levels were found in children with HLHS and DORV. After CHD surgery, a significant drop in the value of proBNP was noticed (20.4%). The mean NT-proBNP value in children with cardiomyopathies and arrhythmias was higher than in the control group (25.2%). The highest values were recorded in patients with dilatative cardiomyopathy and SVT. In patients with PDA cardiac biomarkers level was under normal limits. Cardiac troponin T values were significantly elevated early postoperatively.
Conclusion: Cardiac biomarkers in children are valuable indicators of heart condition upon which we can assess the severity of the child's clinical condition and course of the disease, in the terms of recovery.

P2415 - OUES CUT OFF VALUES FOR CHILDREN AND ADOLECENTS COMPARING CONGENITAL HEART DISEASE VERSUS GROUP CONTROL

Carlos Alberto Cordeiro Hossri[1], Isabela Pilar Moraes A De Souza[2], Joana Sena T De Oliveira[2], Paula Rodrigues Silva Machado Costa[3], Elaine Cristina Gorobets Furquim [3], Ieda Biscegli Jatene[3]
Hospital For The Heart And Dante Pazzanese Institute, Cardiopulmonary Rehabilitation, São Paulo-Brazil[1]; Dante Pazzanese Institute, Ergometry, São Paulo-Brazil[2]; Hospital For The Heart, Pediatric Cardiology, São Paulo-Brazil[3]

Background: Cardiopulmonary testing is an important tool if evaluated by its myriad variables. Among them, the efficiency of the peripheral oxygen uptake represented by the Oxygen Capture Efficiency Scale - OUES (logarithmic regression curve between oxygen consumption and ventilation. This ratio increases in importance due to its reliability even for submaximal tests or with standards of Erratic ventilators, reflecting the muscular work, extraction and use of peripheral oxygen.
Objective: The objective of this study is to estimate cut off values for oues per kg in children healthy versus congenital heart disease and distinguish between the normal or deficit response.
Methods: Cardiopulmonary test in 305 healthy children and 371 with heart disease, divided into groups by age group. Certain OUES and other indices. The efficiency of VO2 (OUES) was analyzed for the presence or absence of cardiac change and correlated with functional capacity.
Results: The median of OUES between heart disease and the control group presented a significant difference (1217 vs 2354, p <0.05). TThe median O2 saturation at the peak of exercise was equal between the groups, but the additional finding of values lower than 70% reinforced the severity of the children with the test. The cutoff value of the OUES for the classification of subjects with heart disease was 36.6 (sensitivity 72% and specificity 62%, p <0.05). The cut of OUES for classification of individuals with normal functional capacity (>80% of predicted maximum VO2) was 35.27 (sensitivity 75% and specificity 83%, p <0.05). While the cut of OUES for individuals with values greater than 85% of the predicted maximum VO2 was 35.69 (sensitivity 78% and specificity 78%, p <0.05).
Conclusions: The results suggest that oues was able to provide an objective assessment of functional capacity in healthy and cardiac patients.

P2421 - ECHOCARDIOGRAPHIC FINDINGS AND CLINICAL OUTCOME OF FETAL CARDIOMYOPATHIES

Takako Toda, Yousuke Kouno, Hiroaki Kise, Keiichi Koizum, Kanji Sugita, Minako Hoshiai
Yamanashi University, Department of Pediatrics, Chuo-Japan

Background: Recently, there have been few reports of fetal cardiomyopaties (CMs). However, there is a paucity of information about assessment and outcome of the disease.
Methods: We retrospectively reviewed our experience with CMs diagnosed in fetal life, from 2008 to 2016. We investigated fetal echocardiographic findings, postnatal laboratory findings, acute phase treatment course and clinical outcome.
Results: Five cases (4 boys and 1 girl) were diagnosed fetal CMs at 28 weeks to 35 weeks (median 31 weeks 6 days). All patients were diagnosed dilated cardiomyopathy. Associated left ventricular noncompaction (LVNC) were noted in 4 patients. All patients required mechanical ventilation and continued catecholamine

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

infusion in the neonatal period. After postnatal treatment, all cases showed a tendency to improve symptoms of heart failure, but 3 cases worsened thereafter and died in infancy (5 months, 6 months, 9 months). Two patients survived and discharged. Cardiovascular profile score (CVPS) in fetal echocardiography was 7 to 8 points in two survivors, 4 to 6 points in three nonsurvivors. BNP levels at birth were 42 to 378 pg/ml in survivors, 1231 to 3620 pg/ml in non-survivors. LVEF was 30-35% in survivors, 18-23% in nonsurvivors. Neonatal intubation period and continuous administration period of catecholamine were shorter in survivors than in nonsurvivors (3 to 7 days vs 13 to 41 days, 7 to 10 days vs 22 to 58 days).
Conclusion: More than half cases died in infancy. Fetuses with CMs have a poor prognosis. However, it was possible that patient of higher CVPS survive and discharge after undergoing intensive care in neonatal period.

P2424 - PREDICTIVE VALUE OF CRYPTOGENIC SEROSANGUINOUS PERICARDIAL EFFUSION FOR HISTOPLASMOSIS IN AN ENDEMIC REGION

Marc Lee, Michael Perez, Emily Hayes, Rush Waller, Shyam Sathanandam
Lebonheur Children, Pediatrics, Memphis-United States

Background: Histoplasmosis is a mycosis that is endemic to the Mississippi River valley. It's presentation ranges from asymptomatic infections to disseminated histoplasmosis. Pericarditis and pericardial effusions have been reported with varying prevalence rates; but its diagnostic value is unknown.
Methods: A retrospective review was performed at a single tertiary care children's hospital including all immunocompetent children up to 18 years of age presenting with clinically significant pericardial effusions of unknown etiology requiring pericardiocentesis or pericardial window from Oct 2012 – May 2016. The prevalence, sensitivity, specificity, and positive predictive value (PPV) of the initial presentation of histoplasmosis as a serosanguinous effusion was determined. The diagnosis of histoplasmosis was based on either positive serology or clinical diagnosis by an infectious disease specialist.
Results: There were 54, immunocompetent children that underwent therapy during the study period; of which 38 were cryptogenic. Of the 22 serosanguinous pericardial effusions, 16 were eventually diagnosed to have histoplasmosis (PPV = 72.7%). Only 4 of the 16 non-serosanguinous effusions (serous or purulent) were diagnosed as histoplasmosis. The sensitivity and specificity of serosanguinous pericardial effusion as a presentation of histoplasmosis were 80% and 66.7% respectively. The other etiologies included new onset malignancy, viral, autoimmune, or unknown. Eight of the 20 patients (40%) with histoplasmosis that presented as pericardial effusions went on to develop either pulmonary artery or pulmonary vein stenosis within 8 + 6 months; all of whose effusions were serosanguinous in character at presentation.
Conclusions: Histoplasmosis was diagnosed in a majority of immunocopetent children who presented with hemodynamically significant serosanguinous pericardial effusion of unknown etiology in an endemic region. Long term follow-up due to risk of developing additional sequelae resulting from fibrosing mediastinitis is required.

P2431 - PREEMPTIVE LIVER TRANSPLANTATION FOR HOMOZYGOUS FAMILIAL HYPERCHOLESTEROLEMIA IN CHILDREN CASE SERIES

Mohammad Alnoor[1], Arpan Doshi[2], J. Steve Bynon[3], Essam Imseis[4], Gurur Biliciler-denktas [5], Duraisamy Balaguru[2]
University of Texas Houston Mcgovern Medical School, Pediatrics, Houston-United States[1]; University of Texas Houston Mcgovern Medical School, Pediatric Cardiology, Houston-United States[2]; University of Texas Houston Mcgovern Medical School, Surgery - Immunology and Transplantation, Houston-United States[3]; University of Texas Houston Mcgovern Medical School, Pediatric Gastroenterology, Houston-United States[4]; University of Texas Houston Mcgovern Medical Center, Pediatric Cardiology, Houston-United States[5]

Background: Familial hypercholesterolemia (FH) is characterized by high serum cholesterol levels and premature atherosclerosis. Heterozygous FH common (1 in 200-500 population), but homozygous FH is rare (1 in 1 million). Normally, liver contains 50-75% of LDL receptors in the body. In homozygous FH, there is severe deficiency of LDL receptors (2-25%) causing failure to uptake LDL for metabolism and elevation of serum LDL cholesterol level in 1000 mg% range. Atherosclerosis develops early and coronary stenosis, aortic valve disease and other complications occur in second decade. Manifestations include cutaneous xanthomas, arcus in the eye, vascular plaques, atherosclerosis aortic valve disease and carotid occlusion leading to stroke. Aggressive traditional therapies (medications, plasmapheresis and bowel bypass surgeries) have been applied which only slow down the progression. Eventually, heart surgery, heart transplant and/or liver transplant is required at an early age is needed in several homozygous FH patients. Therefore, preemptive liver transplant before onset of cardiovascular manifestations of atherosclerosis has been proposed.
Methods: Retrospective review of 5 cases.
Result: Five children who showed early signs of atherosclerosis (xanthoma, carotid bruit and early plaques in carotid and or coronary arteries), failure of response to medications and underwent preemptive liver transplant were included. Preoperative total cholesterol (813-2316 mg%) and LDL cholesterol (733-1029 mg%)(Table 1). Age range at liver transplant was 2-7 years. Lipid profile normalized during immediate postoperative period and maintained during follow-up. After liver transplant, total cholesterol range was 130-201 mg% and LDL cholesterol 74-133 mg%. All patients had xanthomas which resolved after transplant (Figure 1). Follow up duration range is 3 months to 3 years. All patients were doing well at last follow-up
Conclusion: Preemptive liver transplant is an effective therapy for homozygous FH. Further follow-up is needed to establish such approach as primary therapeutic approach.

Table 1. Patient characteristics

Patient number	Preoperative Total/LDL cholesterol (mg%)	Age at liver transplant (years)	Posoperative Total/LDL cholesterol (mg%)	Length of follow-up
1	2316/733	7	161/106	2 years
2	887/772	5	183/133	3 years
3	813/791	5	130/74	1 year
4	867/804	2	154/77	6 months
5	1092/1029	3	201/114	3 months

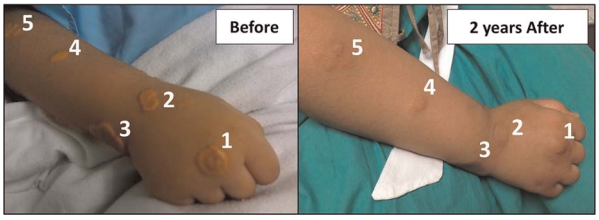

Figure 1.
Xanthomas before and after liver transplant.

P2444 - THE NEW MODIFIED BLOOD PRESSURE TO HEIGHT RATIO SIMPLIFIES THE SCREENING OF HIGH BLOOD PRESSURE IN AMERICAN CHILDREN

Felipe Mourato[1], Wilson Nadruz Junior[2], Thamine Hatem[3], Sandra Mattos[4]
Círculo Do Coração De Pernambuco, Científico, Recife-Brazil[1]; Universidade De Campinas, Clínica Médica, Campinas-Brazil[2]; Círculo Do Coração De Pernambuco, Assistência, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[4]

Background: High blood pressure is often underdiagnosed among children and adolescents. Many friendly tools have been described to overcome these problems. One of them, the modified blood pressure-to-height ratio (MBPHR) was tested in children between 8 and 12 years old. However, a variation of this formula (MBPHR3) showed better sensitivity and specificity in Chinese children. Therefore, confirmation on other populations is mandatory.
Material and Methods: We utilized data from the National Health and Nutrition Examination Survey (NHANES) 1999-2014. Only patients with one Systolic blood pressure (SBP) and Diastolic Blood Pressure (DBP) measurements and complete data for height, weight, gender and age between 8-12 years were included in the present study. The MBPHR were calculated as: SBP (mmHg)/ (Height(cm) + 7x(13-age(in years)) to SBP and DBP (mmHg)/(Height(cm) + 7x(13-age(in years)) to DBP. The MBPHR3 were calculated as: SBP (mmHg)/ (Height(cm) + 3x (13-age(in years)) to SBP and DBP (mmHg)/(Height(cm) + 3x (13-age(in years)) to DBP. Receiver Operator Characteristics curves (ROC) were drawn to identify optimal thresholds for each method. Afterwards, the sensitivity, specificity and positive predictive value (PPV) of each method were calculated with the respective confidence intervals. The software used was MedCalc 16.8.4 (Software bvba, Ostend, Belgium).
Results: A total of 6587 cases were analyzed. Exactly 3.92% of the participants were pre-hypertensive and 2.84% hypertensive. MBPHR3 showed higher specificity and PPV than MBPHR and BPHT, with similar sensitivity, for pre-hypertension or hypertension (MBPHR3: 93.12%, 92.66% and 99.47% for males and 96.04%, 89.94% and 40.98% for females. MBPHR: 96.79%, 86.23% and 33.44% for males and 95.15%, 90.33% and 41.94% for females).
Conclusion: MBPHR3 showed better results in American children aged 8-12 years with a low number of cut-off points.

P2447 - GENDER DIFFERENCE IN THE PREVALENCE OF CONGENITAL HEART DISEASE IN DOWN'S SYNDROME A BRIEF META ANALYSIS

Felipe Mourato[1], Tereza Diogenes[2], Sandra Mattos[3]
Círculo Do Coração De Pernambuco, Científico, Recife-Brazil[1]; Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[2]; Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[3]

Background: Down's syndrome (DS) affects one per 700 live births and congenital heart disease (CHD) occurs in 40-60% of these patients. Many factors contributes to the origin of CHD in DS and gender could be one of them. The purpose of this study was to compare the prevalence of CHD and DS between genders through a meta-analysis and systematic review.
Material and Methods: Studies that described the prevalence of CHD in DS and included gender information for each defect were included. The search for articles was performed in the following data sources: Medline (accessed via Pubmed), Scopus and Scielo. Terms utilized were those used by Mesh for Medline and Scopus, and the descriptors of Health Sciences (Decs) for Scielo. The terms included: "prevalence", "Down syndrome" and "congenital heart disease". A combined data analysis was performed to identify the Odds Ratio between genders, being the female gender considered a risk factor. The confidence intervals and the size of the pondered effect were calculated and the meta-analysis graphs built using the MedCalc v 16.8 software. Random effects model was utilized.
Results: 595 abstracts were selected for analysis, but only four filled the eligibility criteria and were included in the meta-analysis totaling 8580 patients with DS (4726 from the male gender and 3854 from the female gender). It is observed that female gender is a risk factor for the presence of CHD in Down's syndrome (OR: 1.398; 1.143 to 1.709). The same occurs if we consider AVSD alone (OR: 1.421; CI: 1,252 to 1.613). However, when VSD and ASD are considered, there is no difference among groups.
Conclusion: this meta-analysis showed a clear trend towards a higher prevalence of CHD in the female population with Down syndrome.

P2448 - COMPARISON OF CAPTOPRIL AND VALSARTAN IN CHILDREN L TO R SHUNT WITH HEART FAILURE

Alit Utamayasa[1], Taufiq Hidayat[2], Mahrus A Rahman[2], Teddy Ontoseno[2]
Cardiology Division Pediatric Department, Airlangga University-Soetomo Hospital, Surabaya-Indonesia[1]; Cardiology Division Pediatric Department, Airlangga Univerity-Soetomo Hospital, Surabaya-Indonesia[2]

Background: In children, heart failure is most often caused by L to R shunt which the management has largely evolved based on clinical experience and the application of adult data, supported by the more limited paediatric literature. Valsartan are increasingly used in heart failure in adults, especially where there is intolerance to captopril. There is no published evidence supporting their use in children with the condition in Indonesia.
Objectives: The aim of this study was to compare the effects of captopril and valsartan in children L to R shunt with heart failure.
Methods: Randomized controlled trial was conducted on 1-16 year-old L to R shunt with heart failure.Thirty two patients were randomized into 2 groups to received captopril either valsartan. We performed examinations including PHFS, echocardiography, electrocardiography, and chest x-ray before and 4 weeks after treatment. Both group had also received diuretic spironolacton. Statistical analysis was carried out using paired t-test, t-test, Mann-Whitney test, and independent t-test.
Results: Treatment with captopril resulted in significant improvement of PHFS from 7.06 ± 2.04 to 4.75 ± 2.43 ($p < 0.0001$; 95% CI -2.98 to -1.65); reduction of heart rate from $117,75 \pm 14,67$ times/minute to $109,63 \pm 17,59$ times/minute ($p < 0.05$; 95% CI -15.78 to -0.46). While valsartan resulted in significant improvement of PHFS from $6,81 \pm 2,25$ to 3.94 ± 1.98 ($p < 0.0001$; 95% CI -3.76 to -1.98); reduction of heart rate from 117.1 ± 21.86 times/minute to 108.6 ± 20.66 times/minute ($p < 0.05$; 95% CI -14.17 to -2.83), decrement of S Amplitude in lead V1 from 10.06 ± 6.78 to 7.31 ± 5.99 mm ($p < 0.05$; 95% CI -4.69 to -0.81), decrement of CTR from 59.74 ± 4.72% to 57.19 ± 5.14% ($p < 0.001$; 95% CI -3.87 to -1.23). In our study, RR 0.85, ARR

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

0.125, RRR 0.143. Valsartan have lower rates of cough than captopril (NNH = 8).
Conclusion: Valsartan had better effect than captopril and could be one of choice beside captopril in treating heart failure.

P2450 - NEW EQUATIONS CAN IMPROVE THE DIAGNOSIS OF HIGH BLOOD PRESSURE

Felipe Mourato[1], Wilson Nadruz Junior[2], Sandra Mattos[3], Thamine Hatem[4]
Círculo Do Coração De Pernambuco, Científico, Recife-Brazil[1]; Universidade De Campinas, Clínica Médica, Campinas-Brazil[2]; Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[4]

Background: high blood pressure is usually underdiagnosed in children and adolescents. One of the factors that determine this is the complicated diagnosis process. Several screening methods were developed to circumvent those problems, and each has advantages and disadvantages. A method that combines simplicity and the non-use of additional tools can change this context.
Methods: linear regressions correlating height with the 90th percentile of systolic and diastolic blood pressure for each year of age and sex were calculated (?). The values of the constants obtained were rounded to the closer integer value to make it easier to remember. Then, the equations were tested and the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for high blood pressure identification were calculated. We utilized data from the National Health and Nutrition Examination Survey (NHANES) 1999-2014. Only patients with one Systolic blood pressure (SBP) and Diastolic Blood Pressure (DBP) measurements and complete data for height, weight, gender and age between 8-17 years were included in the present study. A total of 14167 patients was analyzed. The utilized software was MedCalc 16.8.4 (Software bvba, Ostend, Belgium).
Results: the obtained formulae were: 70 + height/3 for SBP and 40 + height/4 for DBP for both genders. Formulae presented high sensitivity (92.75%; CI: 90,97% to 94,28%), specificity (98,66%; CI: 98,45% to 98,85%), NPV (99,44%; CI: 99,30% to 99,56%) and PPV (84,14%; CI: 81,86% to 86,25%). The frequency of pre-hypertension and hypertension in this population was 7.1%.
Conclusion: the use of the described equations can aid in the identification of children and adolescents with high blood pressure. Among its advantages are the possibility of its use in different populations, the need of no additional tools and accuracy of results for both genders.

P2455 - POTASSIUM INTAKE AND HIGH BLOOD PRESSURE IN CHILDHOOD

Amanda Da Silva[1], Felipe Mourato[2], Thiago Tavares[3], Carolina Freitas[4], Sandra Mattos[5]
Círculo Do Coração De Pernambuco, Nutrição, Recife-Brazil[1]; Círculo Do Coração De Pernambuco, Científico, Recife-Brazil[2]; Círculo Do Coraçãode Pernambuco, Informática, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Enfermagem, Recife-Brazil[4]; De Pernambuco, Geral, Recife-Brazil[5]

Background: Hypertension is a worldwide public health problem, because of its intimal correlation with conditions of high mortality like stroke. Its prevalence is increasing among children, as a consequence of the obesity epidemics. Additionally, different patterns of consumption of micronutrients can lead to or protect from hypertension. This study aimed to compare the food intake of sodium and potassium between children with and without high blood pressure.
Material and Methods: parents of children participating in an active search for congenital heart disease in 13 different cities from Paraíba – a state form northeast Brazil – in July 2016 were included in this study. They answered a food intake questionnaire for their children, from the previous day. Then, the intake of sodium and potassium were calculated from tables of Instituto Brasileiro de Geografia e Estatística (Brazilian Institute of Geography and Statistics). Non-parametric tests were performed to search for correlation between the presence of high blood pressure and the intake of such nutrients. Only preschool and school children were included.
Results: A total of 225 children (54.12% male) were analyzed. Exactly 115 were preschool children and 47 had obesity. According to the measured blood pressure, 20 children had high blood pressure (prehypertension or hypertension). A significant correlation between obesity and high blood pressure was encountered ($p < 0.01$). The intake of potassium was higher in children without high blood pressure ($p = 0.0254$), but no correlation was seen between sodium intake and high blood pressure ($p = 0.7762$). A lower sodium to potassium ratio correlated with normal blood pressure ($p = 0.4488$).
Conclusion: a poor potassium intake from childhood may lead to high blood pressure. Nutrition counseling from early ages may contribute not only to the health of the child but throughout an individual's life course.

P2462 - PHYSICAL ACTIVITY MODULATES ARTERIAL STIFFNESS IN CHILDREN WITH CONGENITAL HEART DISESASE

Charissa Pockett[1], Natasha Boyes[2], Marta Erlandson[2], Stephanie Fusnik[2], Mark Haykowsky[3], Shonah Runnalls[4], Scott Pharis[1], Ashok Kakadekar[1], Timothy Bradley[1], Corey Tomczak[2]
University of Saskatchewan, Pediatrics, Saskatoon-Canada[1]; University of Saskatchewan, College of Kinesiology, Saskatoon-Canada[2]; University of Texas At Arlington, College of Nursing And Health Innovation, Arlington-United States[3]; University of Saskatchewan, College of Medicine, Saskatoon-Canada[4]

Background & Hypothesis: Children with congenital heart disease (CHD) are often less physically active compared to healthy children. Children with CHD are also at risk for developing greater arterial stiffness and physical inactivity can potentiate this risk. We tested the hypothesis that less physically active children with CHD would have greater arterial stiffness compared to more physically children with CHD.
Materials & Methods: Nineteen children with CHD (11 ± 3 years; males = 9) and 20 age- and sex-matched controls (11 ± 3 years; males = 11) were studied. Carotid-radial pulse-wave velocity (PWV) was assessed with applanation tonometry to determine arterial stiffness. A 6-minute walk test (6MWT) was performed to estimate aerobic fitness. Average daily step count was assessed by accelerometry over a 7-day period. The median step count score for each group was used to determine high-step (high physical activity) and low-step (low physical activity) groups. Data were analyzed with t-tests and significance accepted at $P < 0.05$.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: 6MWT distance was lower in CHD (521 ± 50 vs. 605 ± 79 m; $P < 0.001$). PWV was similar between CHD (8.78 ± 1.24 m/s) and controls (8.67 ± 1.28 m/s; $P > 0.05$). However, when considering physical activity as a modulating factor for PWV (by comparing high-step and low-step groups), PWV was significantly lower in the high-step CHD group (7.89 ± 0.68 m/s) compared to the low-step CHD group (9.78 ± 0.91 m/s; $P < 0.001$), but not between the high-step (8.70 ± 1.35 m/s) and low-step control group (8.64 ± 1.28 m/s; $P > 0.05$).
Conclusion: Physically activity in children with CHD may be an especially important modulating factor for arterial stiffness.

P2464 - PRESENCE OF CONGENITAL HEART DISEASE IN NEONATES WITH AND WITHOUT MICROCEPHALY AFTER ZIKA OUTBREAK A COMPARATIVE STUDY IN NORTHEAST BRAZIL

Felipe Mourato[1], Juliana Araújo[2], Renata Gomes[3], Lucia Moser[2], Sandra Mattos[4]
Círculo Do Coração De Pernambuco, Científico, Recife-Brazil[1]; Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[2]; Círculo Do Coração De Pernambuco, Estatística, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[4]

Background: Brazil faced an increase in number of microcephaly cases last year. Until now, the ZIKA virus is being considered the main responsible for the phenomenon. Besides microcephaly, other malformations can occurred in infected neonates. Congenital heart disease (CHD) could be one of them. Therefore, the objective of this work was to compare the presence of CHD between neonates with and without microcephaly after ZIKA outbreak.
Material and Methods: Comparative study, based on a retrospective data analysis. The data were obtained from Rede de Cardiologia Pediátrica Pernambuco-Paraíba (Pediatric Cardiology network Pernambuco-Paraíba). The Network uses pulse oximetry and screening echocardiograms to diagnosis neonates with CHD. Neonates born after the first semester of 2014 with informed head circumference, gestational age above 37 weeks and echocardiographic results were included. A head circumference smaller than 32 cm was considered microcephaly. The chi-square test was utilized to compare categorical variables. $P < 0.05$ were considered significant.
Results: A total of 788 patients were analyzed. Only 39 (4.9%) had microcephaly. In relation to gender, 438 were female (55.6%). CHD was diagnosed in 334 cases. No statistical correlation between microcephaly and CHD was observed ($p = 0.8601$). The main diagnoses were septal defects (223), patent ductus arteriosus (199), and pulmonary stenosis (25). Complex lesions were present in 16 had complex lesions. No statistical significance was obtained between each type of CHD and the presence of microcephaly.
Conclusion: There seems to be no relation between microcephaly and CHD. However, it is still necessary to exclude the association between microcephaly and functional anomalies or arrhythmias.

P2480 - RISK OF RESPIRATORY SYNCYTIAL VIRUS INFECTION IN CONGENITAL HEART DISEASE IN A TROPICAL COUNTRY

Syed Mohammed Saiful Islam[1], Wai Lin Ang[1], Alyssa Xin Hui Lin[2], Yu Xian Pang[2], Ching Kit Chen[1]
KK Women, Cardiology Service, Department of Paediatric Subspecialties, Singapore-Singapore[1]; National University of Singapore, Yong Loo Lin, School of Medicine, Singapore-Singapore[2]

Background: The impact of respiratory syncytial virus (RSV) infection in infants and children with congenital heart disease is relatively understudied in Southeast Asian tropical countries. In temperate countries, seasonal activity of RSV has been reported, particularly in association with temperature, while variable trend of RSV activity has been found in tropical countries.
Objective: To compare the risk of RSV-associated hospitalization and analyze the epidemiology of RSV infection in patients with cyanotic and acyanotic congenital heart disease (CHD) in tropical Singapore, where RSV immunoprophylaxis is not routine practice.
Method: This was a single-centre, retrospective study, including patients diagnosed with CHD from 2005-2010. The study cohort included 75 patients with cyanotic CHD and 225 patients with acyanotic CHD. Patients with acyanotic CHD were further classified into hemodynamically significant (hs)-acyanotic and non-hs-acyanotic groups according to whether they underwent surgery or took at least 2 anticongestive medications.
Results: RSV-associated hospitalization rate was similar in all 3 groups. However, intensive care admission (15% vs 9% vs 8%, $p = 0.01$) and high-dependency admission rates (23% vs 19% vs 4%, $p = 0.03$) were higher in the cyanotic group than in the other 2 groups. Logistic regression revealed that cyanotic CHD was the most significant risk factor for the ventilator support and RSV-associated morbidities. In both patients with cyanotic and acyanotic CHD, RSV-associated hospitalization rate was higher in patients aged younger than 1 year, and in the middle of the year (May – Aug) in Singapore, a tropical country.
Conclusions: The results show that patients with cyanotic CHD have a higher risk of severe RSV infection than do those with acyanotic CHD. RSV prophylaxis is more important and may reduce costs more for patients with cyanotic CHD.

P2486 - THE IMPROVEMENT CLINICAL MANIFESTATION AND CHEST X RAY AFTER CARVEDILOL THERAPHY IN HEART FAILURE DUE TO CONGENITAL HEART DISEASE LEFT TO RIGHT SHUNT

Mahrus A Rahman[1], Taufiq Hidayat[2], Alit Utamayasa[2], Teddy Ontoseno[2]
Cardiology Division Pediatric Department, Airlangga University-soetomo Hospital, Surabaya-Indonesia[1]; Cardiology Division Pediatric Department, Airlangga Univerity-Soetomo Hospital, Surabaya-Indonesia[2]

Background: Heart failure due to congenital heart defect (CHD) left to right shunt are increased pulmonary blood flow and caused volume overload. Conventional therapy has not blocked the sympathetic system yet. Carvedilol, a novel non selective β-blocker, reduces mortality and hospitalization in adults with heart failure. Limited information is available about its use in children.
Objective: To evaluate the effect of carvedilol for changes of pulse rate, respiratory rate, hepatomegaly, and chest x-ray in children with heart failure due to CHD left to right shunt.
Methods: A randomized, double-blind, placebo-controlled study was done. In addition to conventional therapy (ACE inhibitors and diuretics), patients were assigned to receive placebo or carvedilol. Carvedilol was initiated at a dose of 0.05 mg/kg/day, with a target dose of 0.2 mg/kg/day. The outcomes of pulse rate, respiratory rate, and hepatomegaly presence were evaluated before-after treatment. Chest x-ray was done before-after treatment and evaluating for cardio-thoracic ratio (CTR) and pulmonary vascularity. The data was analyzed using independent sample t-test and Chi-square test, with confidence interval 95%.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: Of 30 patients, 15 in each groups. The mean age was 57.6 (SD 43.57) months, 19(63.3%)were boys. There were 21(70%) children with VSD and 9(30%) children with PDA. Compared to control group, there were greater reductions of pulse rate (-19.2 ± 7.5) and respiratory rate (-7.2 ± .8) in carvedilol group with p value <0.0001. No hepatomegaly. The carvedilol group had a significant decreasing of CTR(-2.94 ± 2.34% versus -0.48 ± 3.19%, p = 0.023, CI 95%:-4.556 to-0.360). However, there was no significant change of pulmonary vascularity (p = 0.153).
Conclusion: Carvedilol decreases the pulse rate, respiratory rate, and the CTR on chest x-ray, but does not decrease hepatomegaly, and the pulmonary vascularity.

P2492 - THE INCIDENCE AND OUTCOMES OF ASYMPTOMATIC VENTRICULAR SETPAL DEFECTS DETECTED BY NEONATAL SCREENING ECHOCARDIOGRAPHY

Betau Hwang[1], Chung-Chih Kao[2], I-Hsin Lu[3], Chun-Hsiang Ko[3], Hua Guo[4]
Tungs, Cardiovascular Center, Taichung-Taiwan[1]; Tungs, Pediatric Cardiology, Taichung-Taiwan[2]; Tungs, Radiology, Taichung-Taiwan[3]; Meiho University, Nursing, Pingtung-Taiwan[4]

Background: Ventricular septal defect is the most common type of congenital heart disease. Echocardiography can easily provide an accurate diagnosis of these cardiac defect.This study focuses on the incidence & short-term outcomes of VSD which were diagnosed by using screening echocardiography in asymptomatic neonates.
Methods: From January 2009 to June 2015, a total of 10150 full-term newborn babies were delivered in our hospital. Of them, 3125 received screening echocardiographic study. The echocardiography was performed within 3 days of life by two well-trained technicians. Besides the other 135 neonates with complex CHD, the various subtypes of simple VSD were picked up on 61 neonates (1.95%). Forty-five neonates who had complete perinatal data and regular follow-up studies were enrolled for analysis. The gender, birth body weight, parity, family history of CHD, methods of delivery, & subtypes of VSD were analyzed by using statistical software SPSS. The spontaneous closure rate & outcomes of various subtypes of VSD were also analyzed
Results: Of the 45 neonates with VSDs, there were subpulmonic in 1 case, perimembranous type in 14 cases, atrioventricular type in 0 cases & muscular type in 30 cases. The p valve of relationship between the occurrence of VSD with the gender, birth body weight , family history of CHD, and method of delivery are 0.745,0.763,0.872 and 0.436 respectively. Spontaneous closure of VSD was noted 72.41% in perimembanous type 43.48% and 86.49% in muscular type during the 3 months to 6 years (7.28months ± 5.18 months) follow-up There are no patients developed the symptoms and signs of congestive heart failure needed medical therapy. 2 patients underwent surgical closure . 31 cases are followed-up in out-patients clinic regularly.In addition, the p value the spontaneous closure is 0.041(p < 0.05).
Conclusions: The incidence of VSD in asymptomatic neonates is 1.95% which is much higher

P2501 - CONGENITAL UNILATERAL ABSENCE OF PULMONARY ARTERY SINGLE INSTITUTIONAL EXPERIENCE IN A LOW MEDIUM INCOME COUNTRY

Gcina Dumani, Paul Adams, Hopewell Ntsinjana, Antoinette Cilliers
Chris Hani Baragwanath Academic Hospital, Paediatric Cardiology, Johannesburg-South Africa

Background: Unilateral absence of pulmonary artery (UAPA) is a rare congenital cardiac malformation characterized by complete absence of the intrapericardial segment of one of the main pulmonary arteries.It can present as an isolated lesion (40%) or may be associated with other congenital heart defects (CHD) in approximately 60%. Isolated UAPA is associated with increased morbidity and mortality related to pulmonary hypertension (PHT) and recurrent haemoptysis. Surgery is limited to the intracardiac anomalies if no identifiable PA in the hilum.
Methods: Retrospective review of 35 cases of UAPA seen at the Chris Hani Baragwanath Academic Hospital, a tertiary care institution between 1980-2016.
Results: Twenty infants(57,1%) and fifteen children were reviewed.Median age at presentation was 10 months (1day-11years). UAPA was isolated in 15 patients(42,9%) and associated with CHD in 20 patients(57,1%). Thirty three patients (94,3%) were symptomatic. Common presenting feature was respiratory distress in isolated UAPA(73.3%) and cyanosis in associated UAPA (47.9%). Chest X-ray was suggestive of UAPA in all patients with isolated UAPA and nine patients(45%) with associated UAPA. The diagnosis of UAPA was confirmed on computerized tomography (CT) scan, angiography and at surgery in thirty one patients(88.6%). Unilateral absence of right pulmonary artery (UARPA) was identified in 80% of the isolated UAPA as compared to the UALPA identified in 75% OF associated UAPA. Pulmnary hypertensio(PHT) was common in patients with isolated UAPA(53.3%) and the majority were infants(75%). Collateralls were identified on angiography in twelve patients (34,3%). Congenital heart defects with UAPA were as follows: Ventricular septal defect(VSD) = 3; Patent ductus arteriosus (PDA) = 3; Common atrium = 1;Double inlet left ventricle (DILV) = 1; Tetralogy of Fallot(TOF) = 9; Double outlet right ventricle(DORV) with pulmonary stenosis(PS) = 3. Surgical anastomosis was performed in one patient with TOF associated with UALPA.Surgery for other associated congenital cardiac defects was performed in eighteen patients(51.4%). Overall mortality was 34,3%.
Conclusion: Mortality is high in association with UAPA. Isolated UAPA and associated UAPA with increased PBF (pulmonary blood flow) were associated with PHT. Isolated UAPA was commonly associated with UARPA while UALPA was found in majority of associated UAPA.

P2539 - ARTERIAL ISCHEMIC STROKE IN CHILDREN WITH CONGENITAL HEART DEFECT

Beatriz Salamanca Zarzuela[1], Fernando Centeno Malfaz[1], Antonio Hedrera Fernández[2], Elena Perez Santaolalla[3], Carlos Alcalde Martín[1], David Conejo Moreno[4], Ramon Cancho Candela[2]
Hospital Universitario Rio Hortega, Pediatric Cardiology, Valladolid-Spain[1]; Hospital Universitario Rio Hortega, Pediatric Neurology, Valladolid-Spain[2]; Complejo Asistencial, Pediatric Cardiology, Burgos-Spain[3]; Complejo Asistenicla, Pediatric Neurology, Burgos-Spain[4]

Introduction and Objectives: A third of paediatric arterial ischemic stroke (AIS) is related to procedures in patients with congenital heart defects (CHD). An incidence of AIS with motor deficit is estimated in 2-6% of these patients, with higher rates in surgeries requiring extracorporeal circulation. Our objective is to describe the characteristics of AIS in children with CHD.
Methods: retrospective descriptive study of patients with CHD who suffered an AIS followed in 2 visits to outpatient clinics of

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Child Cardiology during 8 years. We analysed: heart disease, previous procedures, clotting test, clinical and diagnostic delay, prophylaxis, and neurological sequelae.
Results: 10 cases of AIS in CHD were collected (see chart below). In all cases, the neurological disease was noticed in the first 6 months after surgery, except in one case that was delayed up to 5 years. In 4 patients, the procedure prior to AIS was a catheterization, in the other 6 was major surgery, two of them with postoperative extracorporeal membrane oxygenation (ECMO). Clotting test was performed in 6 of the cases, being positive for the same mutation in two of them, not related. The neurological consequences were in 7 of the cases cerebral palsy(CP) type Spastic Hemiparesis (SH), that one of the cases was transient. Intellectual disability occurs in 5 of our patients, in one case in isolation, and in others, associated with focal epilepsy or developmental delay. Two patients are under tests due to suspicion of metabolic pathology.
Conclusions: In a child with CHD, it is a priority to think about AIS in the presence of any neurological symptom, especially focal, and if there is a history of recent invasive procedures. In these cases, clotting tests should be considered as a cause of comorbidity. a multidisciplinary management of these patients is basic in order to minimize the sequelae.

Table.

	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Patient 6	Patient 7	Patient 8	Patient 9	Patient 10
Age at diagnosis of AIS	10 m.o.	12 m.o.	6 m.o.	5 y.o.	2 y.o.	1 m.o.	7 m.o.	26 m.o.	3 m.o.	8 m.o.
CHD type	VSD	VSD + pulmonary atresia	VSD + pulmonary stenosis	ToF	Hypoplastic left heart syndrome	CoA & Taussig–Bing syndrome	Scimitar syndrome and pulmonary hypoplasia	ASD & Primary Pulmonay Hypertension	ToF	Pulmonary atresia
Procedure prior to AIS	Major surgery	Catheterization	Major surgery	Major surgery + ECMO	Catheterization	Major surgery + ECMO	Major surgery	Catheterization	Major surgery + ECMO+ sepsis+ endocarditis	Catheterization
Genetic Clotting test	Normal	F2 20210G>A mutation	Normal	Normal	No	No	No	F220210G>A mutation	Normal	No
Primary prophylaxis	Antiaggregation	No	Antiaggregation	No	Anticoagulation	No	No	No	No	Anticoagulation
Motor focal manifestations	CP, left SH	Transient left SH	CP, right SH	Left SH	CP, left SH	No	No	Left SH	No	CP, Right SH
Other neurological manifestations	Focal epilepsy	No	No	No	Intellectual disability	Focal epilepsy, Mild developmental retardation.	Intellectual disability	Intellectual disability	Developmental retardation.	No

VSD: Ventricular septal defect; ToF: tetralogy of Fallot; CoA: Coarctation of the aorta; ASD: atrial septal defect.

P2541 - DIAGNOSES AND OUTCOMES OF THE PATIENTS EVALUATED IN A CONSULTATION OF FETAL ECHOCARDIOGRAPHY IN THE PAST 10 YEARS

Fernando Centeno Malfaz[1], Beatriz Salamanca Zarzuela[1], Marta Arribas Arceredillo[2], Paula Marbella Polanco Zea[2], Ana Isabel Beltrán Pérez[3], Carlos Alcalde Martin[1]
Hospital Universitario Rio Hortega, Pediatrics Cardiology, Valladolid-Spain[1]; Hospital Universitario Rio Hortega, Pediatrics, Valladolid-Spain[2]; CS Parque Alameda-Covaresa, Pediatrics, Valladolid-Spain[3]

Introduction and Objectives: Congenital heart disease affects approximately 1% of live births. Our objective was to describe the clinical characteristics and the fetal evolution of pregnant women referred to the Perinatal Cardiology Clinic in our hospital.
Material and Methods: A descriptive, retrospective study that included the pregnant women referred to the Perinatal Cardiology Clinic at our hospital from its implementation in 2006 until December 2015.
Results: A total of 481 ultrasound scans where performed in 220 different gestations, with an average of 2.18 ultrasounds per gestation. Pregnant women from several provinces of the Community were seen. 35% of gestations were in the second trimester, 65% in the third. 47% were referred for suspicion of structural heart disease, 7% for suspected arrhythmia, 3% for anomalous cardiac echogenicity, 33% for family history of heart disease, 3% for maternal disease and 5.4% for pregnant women without risk factors The suspicion of structural heart disease was confirmed in 64.7% of fetuses, with ventricular septal defects being the most frequent pathology (32%), followed by aortic anomalies (8.8%), tetralogy of Fallot and transposition of large arteries . After the diagnosis of heart disease, 22 patients voluntarily terminated their pregnancy and 47 pregnancies followed their natural evolution, with an intrauterine death fetus at 38w of gestacional age. Of the complex heart diseases, one patient required heart transplantation at birth, the others received corrective surgery with good evolution, except for 4 deaths in the first two years of life due to complications of their heart disease.
Conclusions: Fetal echocardiography is an essential tool in the diagnosis of congenital heart disease, which allows planning the right place and time for delivery and provides an early treatment for newborn affection, especially relevant in communities without Congenital Heart Surgery such as ours.

P2545 - ADOLESCENTS IN THE CARDIOLOGY CONSULTATION

Beatriz Salamanca Zarzuela[1], Marta Arribas Arceredillo[2], Paula Marbella Polanco Zea[2], Garazi Fraile Astorga[3], Carlos Alcalde Martin[1], Fernando Centeno Malfaz[2]
Hospital Universitario Rio Hortega, Pediatrics Cardiology, Valladolid-Spain[1]; Hospital Universitario Rio Hortega, Pediatrics, Valladolid-Spain[2]; Corporació Sanitària Parc Taulí, Pediatrician, Sabadell (Barcelona)-Spain[3]

Introduction and Objectives: The reason for consultation in Pediatric Cardiology varies according to age. The objective of the study was to describe the characteristics of the consultations performed in the Cardiology Clinic by adolescents.
Material and Methods: A retrospective descriptive study of the clinical evolution of patients between 10 and 14 years of age, derived from our Clinic, in a 1 year period.
Results: 134 adolescents came to a first consultation inthis period. The causes of referrals where: 3% family history of heart disease, 5% personal cardiac history, 10% suspected arrhythmia on routine electrocardiogram, 12% cardiologic study due to another disease, 15% murmur in clinical examination and 55% presence of Cardiovascular symptoms (35% palpitations, 23% chest pain, 27% presyncope and 15% dyspnea). All patients with a personal history had normal complementary tests. Only one case with family history presented positive tests. 3 of the patients with systemic pathology presented cardiac involvement. Among patients who consulted because of a murmur, 2 coronary fistulas and 4 minor structural heart defects were diagnosed. 8 arrhythmias were confirmed, 2 of them where severe. Regarding symptom consultations, palpitations were equally present in both sexes. Presyncope was more frequent in women, and only one of them presented complementary positive tests. Chest pain did not show differences between sexes, and only one case showed cardiac disease . Dyspnea was more frequent in men with 78% of them showing abnormal spirometries.
Conclusions: In our study, the most frequent cause of consultation in adolescent patients was the presence of cardiovascular symptomatology, which causes great distress in the patients and their families, being the complementary tests in the majority of them negative, with the exception of the ones who presented alarm symptoms in the anamnesis.

P2547 - AORTIC STIFFNESS ECHOCARDIOGRAPHIC ASSESSMENT IN DIABETES MELLITUS TYPE 1 PEDIATRIC PATIENTS

Beatriz Salamanca Zarzuela[1], Ines Mulero Collantes[2], Andres Alvarez Hodel[3], Garazi Fraile Astorga[4], Carlos Alcalde Martin[1], Fernando Centeno Malfaz[1]
Hospital Universitario Rio Hortega, Pediatrics Cardiology, Valladolid-Spain[1]; Hospital Universitario Rio Hortega, Pediatrics Endocrinology, Valladolid-Spain[2]; Hospital Medina Del Campo, Emergency Service, Medina Del Campo (valladolid)-Spain[3]; Corporació Sanitària Parc Taulí, Pediatrics, Sabadell (barcelona)-Spain[4]

Introduction: Among vascular complications of diabetes mellitus, pediatric arterial stiffness has shown to be a cardiovascular disease predicting factor in adult age. Our objective was to use echocardiography for the assessment of aortic stiffness in a group of patients and its association with metabolic control and physical activity.
Material and Methods: Case-control descriptive cross-sectional study. 44 cases: DM1, under 18 years old and without cardiovascular symptoms. 51 controls, healthy, with same age and anthropometric measurements. Aortic function was assessed calculating aortic diameter change (mm) = aortic systolic diameter (SD)– aortic diastolic diameter (DD). Aortic strain = (SD-DD)/DD. Elastic modulus E(p) = (Systolic Blood Pressure (SBP) – Diastolic Blood Pressure (DBP))/Aortic tension. Aortic Stiffness (βindex) = In (SBP/DBP). Aortic Distensibility = (2 x strain)/(SBP-DBP).
Results and Discussion: Healthy patients showed a more elastic aorta (t(48): -1.748, $p < 0,05$) than cases (t(38): -1.748, $p < 0,05$).

- DM1 patients had greater aortic stiffness while decreased distensibility, elasticity and strain than healthy controls.
- Aortic systolic and diastolic diameters and aortic velocity were similar in both cases and controls.
Linear Regression:
Aortic Distensibility: -0.004 + 0.05. weekly METs -0.001. HbA1C – 0.005. Non HDL cholesterol -0.001 current age.
Aortic Strain: 0.06-0.001. Non HDL cholesterol +0.001 weekly METs.
Our work, as found in available bibliography, but assessed by a simpler technique, concluded that DM1 patients have significantly decreased elasticity and distensibility indexes while greater aortic stiffness, even in preadolescent patients

P2550 - CARDIOVASCULAR FUNCTION EVALUATION BY ECHOCARDIOGRAPHY IN DIABETES MELLITUS TYPE 1 PEDIATRIC PATIENTS

Beatriz Salamanca Zarzuela[1], Ines Mulero Collantes[2], Carla Escribano García[3], Andres Alvarez Hodel[4], Sara Marin Urueña[3], Ramon Cancho Candela[5], Carlos Alcalde Martin[1], Fernando Centeno Malfaz[1]
Hospital Universitario Rio Hortega, Pediatrics Cardiology, Valladolid-Spain[1]; Hospital Universitario Rio Hortega, Pediatrics Endocrinology, Valladolid-Spain[2]; Hospital Universitario Rio Hortega, Pediatrics Neonatology, Valladolid-Spain[3]; Hospital Comarcal Medina Del Campo, Emergency Service, Medina Del Campo (valladolid)-Spain[4]; Hospital Universitario Rio Hortega, Pediatrics, Valladolid-Spain[5]

Introduction: Vascular complications are the most important cause of morbidity and mortality in Type 1 diabetes mellitus (DM1) patients. Our objective was to use echocardiography to evaluate cardiovascular repercussions in these patients and its association with physical activity and metabolic control.
Material and Methods: Case-control descriptive cross-sectional study. 44 cases: DM1, under 18 years old and without cardiovascular symptoms. 51 controls, healthy, with comparable anthropometric features and age. MAPSE, E' and S' waves were used to measure systolic function; TAPSE, E/A ratio, insovolumetric relaxation time (IRT), E'/A' and E/E' ratio for diastolic function and Tei index for global function.
Results and Discussion:
SYSTOLIC FUNCTION:
- A higher E/E' ratio was found in diabetic patients, a persistent difference in the evaluated groups.
- E/A, E'/A', TAPSE and IRT were similar in both cases and controls. DIASTOLIC FUNCTION: Healthy, sports inclined patients had higher S' waves than sedentary ones. - E' and MAPSE were comparable in all groups. - S' was similar in both groups. Tie Index: Results were higher in cases than in controls, but similar between subgroups. LINEAL REGRESSION: E/E' ratio: 4.194 + 0.23. Non HDL cholesterol – 0,044. Weekly METs. Our findings concur with previous bibliography on the subject, for we found diastolic dysfunction with normal systolic function in pediatric and preadolescent diabetic patients. We found E/E' ratio to be the most useful for diastolic function evaluation, showing in addition a direct association with non HDL cholesterol levels and indirectly with active lifestyle. Tei index, which evaluates global cardiovascular function, was higher in cases than in controls, probably at the expense of diastolic function. Furthermore, we found an association between this index and HbA1C levels.

P2552 - ELECTROCARDIOGRAPHY APPLICABILITY ON CARDIOVASCULAR EVALUATION OF DIABETES MELLITUS TYPE 1 PEDIATRIC PATIENTS

Beatriz Salamanca Zarzuela[1], Garazi Fraile Astorga[2], Antonio Hedrera Fernandez[3], Andres Alvarez Hodel[4], Rebeca Mozun Torrico[3], Carlos Alcalde Martin[1], Fernando Centeno Malfaz[5]
Hospital Universitario Rio Hortega, Pediatrics Cardiology, Valladolid-Spain[1]; Corporació Sanitària Parc Taulí, Pediatrician, Sabadell (barcelona)-Spain[2]; Hospital Universitario Rio Hortega, Pediatrics, Valladolid-Spain[3]; Hospital Comarcal Medina Del Campo, Emergency Service, Medina Del Campo (Valladolid)-Spain[4]; Hospital Universitario Rio Hortega, Chief of Pediatrics Service, Valladolid-Spain[5]

Introduction: Type 1 diabetes mellitus (DM1) is one of the most common chronic diseases in infants, having great public health impact globally nowadays. Besides acute complications, vascular complications are the most significant cause of morbidity and mortality in these patients. Routine follow-up has included microvascular diseases screening for a long time. Our objective was to evaluate cardiovascular status in DM1 pediatric patients using electrocardiography.
Material and Methods: Case-control descriptive cross-sectional study. 44 cases: DM1, under 18 years old and without cardiovascular symptoms. 51 controls, healthy, with similar age and anthropometric characteristics.
Results and Discussion: Regarding electrocardiographic intervals, the only statistically significant difference ($p < 00,5$) were shorter ST intervals found in DM1 patients, compared with controls. QRS and P waves were similar in both groups. T wave axis did show a statistically significant difference ($p < 00,5$), being smaller in DM1 cases; it was between 0° and 90° in all subjects. QRS-T didn't display any significant differences. Sokolow index measurement revealed statistically significant differences ($p < 00,5$) among both groups, with only one DM1 patient in pathological range. The previously described statistically significant differences found in the electrocardiographic records have no clinical significance, therefore we do not consider this an appropriate cardiovascular screening technique in DM1 patients.

P2585 - DIAGNOSIS AND MANAGEMENT OF CONGENITAL RIGHT CORONARY ARTERY ANOMALIES A SINGLE CENTER EXPERIENCE

Hideki Motomura[1], Yoshinori Kuwahara[1], Mari Yokokawa[2], Hirofumi Fukunaga[2], Mari Nakagaki[2], Tomoyuki Hasuwa[2], Hiroyuki Moriuchi[2]
National Hospital Nagasaki Medical Center, Pediatrics, Omura-Japan[1]; Nagasaki University Hospital, Pediatrics, Nagasaki-Japan[2]

Background: Anomalous origin of the right coronary artery (ARCA) is a rare congenital heart disease that may cause sudden death. Since most patients are asymptomatic and its detailed natural history remains obscure, diagnosis is challenging and clinical management is controversial.
Objective: To investigate clinical course and short-term prognosis of ARCA cases at a single center covering approximately 70,000 children population during the last 10 years.
Design/Methods: Patients referred to Nagasaki University Hospital between 2005 and 2015 were recruited and underwent echocardiography, multi-detector computed tomography (MDCT), exercise ECG and myocardial scintigraphy. Medical charts of ARCA cases without any other cardiovascular complication were reviewed retrospectively for clues to make diagnosis, athletic activities, symptoms, evidence of ischemic condition, and therapeutic interventions.
Results: Six ARCA cases (4 males and 2 females), aged 6-17 years, were identified and followed up for 4-15 years. They were demonstrated by echocardiography and confirmed by MDCT. Two were siblings. Three were referred for chest pain. Two were referred for a complete right bundle branch block on a regular ECG examination at school. Although minimal abnormal findings were detected by exercise ECG in one and by myocardial scintigraphy in two, they were transient and poorly reproducible. All patients are permitted to take moderate exercise, if they feel no chest discomfort. None of them underwent surgical procedures since there was no apparent evidence of ischemia. None has developed myocardial infarct or died so far.
Conclusions: Siblings need the screening, since there sometimes exist familial cases of ARCA. Chest pain provided diagnostic clues most commonly in this study; however, neither exercise ECG nor myocardial scintigraphy evidently showed ischemic change. Although short-term prognosis appears good, it is difficult to determine whether surgical intervention is required for ARCA cases without apparent ischemic change. Further studies are needed to set up better clinical management.

P2595 - PREVENTION OF ADULT CARDIOVASCULAR DISEASES IN EMIRATI CHILDREN – A PRELIMINARY REPORT

Elhadi Aburawi[1], Hassib Narchi[2], Lolowa Al Mukhini[1], Sania Al Hamad[1], Abdul-Kader Souid[1]
CMHS, UAE University, Pediatrics, Al Ain-United Arab Emirates[1]; CMHS, UAEU, Pediatrics, Al Ain-United Arab Emirates[2]

Background/Hypothesis: Atherosclerosis starts early in life and remains asymptomatic in children. Its progression is hastened by obesity, hypertension, diabetes, and dyslipidemia. Early recognition and prompt intervention of these adverse events would halt the development of cardiovascular diseases (CVD) in adults.
Aims: (1) Determine the prevalence of obesity and hypertension in Emirati children; and (2) Engage students with increased susceptibility to CVD in risk-reduction and counselling programs.
Methods: Study subjects were children in grade 2 (elementary school), 6 (middle school) and 10 (high school). Parents completed the study questionnaire, which addressed consanguinity and CVD risk factors. Students had height, weight, body-mass-index (BMI), waist circumference and blood pressure (BP) determinations. The International Obesity Task Force (IOTEF) criteria were used for BMI classification.
Results: Five-hundred-thirty-five students were included in this study; their mean [SD] age was 10.7 [11] years (M:F = 1:1). Risk factors identified in their fathers were smoking (21%), hypertension (14%), dyslipidemia (12%), heart attacks (3%), diabetes (16%), and obesity (9%). Risk factors identified in their mothers were hypertension (4%), dyslipidemia (5%), diabetes (6%), and obesity (3%). The prevalence of consanguinity was 38%. For male students, the prevalence of thinness was 31%, overweight 14%, obesity 6%, and extremely-obesity 3%. For female students, the prevalence of thinness was 40%, overweight 9%, obesity 5%, and extremely-obesity 3% (Fig. 1). The z-scores of systolic and diastolic BP increased with increased excess body fat (Fig. 2). Fig. 3 represents the waist circumference percentiles in function of age.
Conclusions: Hypertension and obesity were common among the studied children. Affected students require counseling and effective interventions.

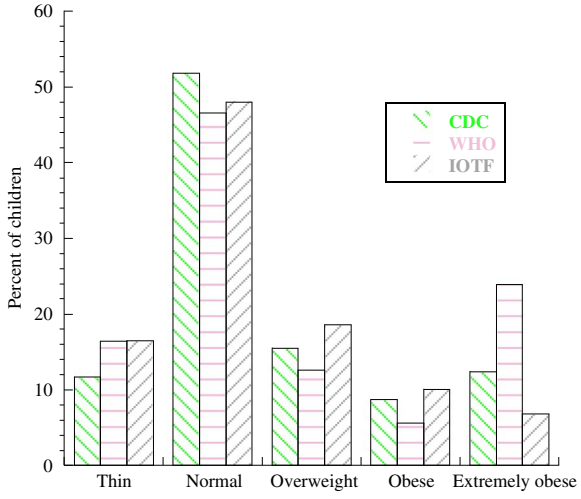

Figure 1.
IOTEF classification of the BMI of the studied students.

P2599 - DEVELOPMENT AND VALIDATION OF THE BRIEF DEVELOPMENTAL ASSESSMENT IN PRE SCHOOL CHILDREN WITH HEART DISEASE

Aparna Hoskote[1], Deborah Ridout[2], Christina Pagel[3], Suzan Kakat[1], Victoria Banks[1], Rodney Franklin[4], Thomas Witter[5], Rhian Lakhani[5], Monica Lakhanpaul[6], Victor Tsang[1], Katherine Brown[1], Jo Wray[1]
Great Ormond Street Hospital For Children Nhs Foundation Trust, Critical Care and Cardiorespiratory Division, London-United Kingdom[1]; UCL Great Ormond Street Institute of Child Health, Population, Policy and Practice Programme, London-United Kingdom[2]; University College London, Clinical Operational Research Unit, London-United Kingdom[3]; Royal Brompton and Harefield NHS Foundation Trust, Paediatric Cardiology Department, London-United Kingdom[4]; Evelina London Children's Hospital, Department of Paediatric Cardiology and Cardiac Surgery, London-United Kingdom[5]; UCL Great Ormond Street Institute of Child Health, Community Child Health, London-United Kingdom[6]

Background: Despite awareness of neurodevelopmental abnormalities in children with congenital heart disease (CHD), there is no routine monitoring in the United Kingdom, with a potential for delayed detection and intervention. To address this, we developed an easy to administer early recognition tool – the Brief Developmental Assessment (BDA) - targeted for children with CHD. The BDA covers 5 age bands (0-4 months, 5-8 months, 9-14 months, 15 months-2.9 years, 3-4.9 years), and allows categorisation as green (appropriate for age), red (delayed) or amber (equivocal), can be administered by non-developmental specialists, and without specialised equipment.
Methods: A convenience sample of 960 pre-school children with CHD from each of the five age bands was recruited from three UK tertiary cardiac centres. The BDA was prospectively validated using Mullen Scales of Early Learning (MSEL). Internal reliability was explored using Cronbach's alpha. Construct validity was based on BDA detection of children with known neurodevelopmental abnormalities, and sensitivity and specificity of BDA was evaluated against MSEL.
Results: The BDA was successfully validated in the older four age bands (not those <4 months) as pre-set validation thresholds were met (lower 95% confidence limit for the correlation coefficient above 0.75) between two raters and with MSEL. Based on American Association of Pediatrics Guidelines, which state that the sensitivity and specificity of a developmental screening tool should fall between 70 and 80%, the BDA outcome of 'red' met threshold for detection of MSEL scores >2 standard deviations below the mean.
Conclusions: The BDA, along with a user-training package and an action guide, may be used to improve the quality of neurodevelopmental assessment of children with CHD, facilitating early detection and increased access to services. Further research is needed to determine the best approach in infants <4 months of age and assess progression over time in children with CHD.

P2605 - LOW INCIDENCE OF "TYPICAL" ECG FINDINGS IN 70 ALCAPA PATIENTS

Franziska Ziermann, Peter Ewert, Alfred Hager
Deutsches Herzzentrum München, Technical University of Munich, Department of Pediatric Cardiology and Congenital Heart Defects, Munich-Germany

Background: Usually, the electrocardiogram of an infant with anomalous left coronary artery from pulmonary artery (ALCAPA) shows signs of anterolateral myocardial infarction like Q waves in I, aVL, V5 and V6 as well as ST changes and T wave inversions in the same leads, and possibly an abnormal R wave progression in the chest leads.
Material and Method: From 1974 to 2016, 84 patients with ALCAPA were seen at our center. We analyzed all 70 existing preoperative ECGs of these patients.
Results: The heart rate was normal in most patients, while some showed tachycardia. The corrected QT time was longer than 440ms in 24 of 70 patients. We found 3 patients with a left bundle branch block and 1 patient with an incomplete block. Q waves were pathologic just in 57% or 73% of the cases in aVL depending on which threshold was considered as pathologic (Table). Remarkably, we found a delayed R wave progression in 22 patients and no R/S ratio >1 in any lead in 22 patients. ST changes were rarely seen. A T wave inversion was present in 74% of the patients in lead aVL.
Conclusion: Even if there are no or very few typical ECG signs for ALCAPA in infants with heart failure, ALCAPA cannot be ruled out. We did not observe the typical ECG findings in all our patients. Therefore we suggest to use echocardiography or angiography to confirm or disprove any suspicion of the diagnosis ALCAPA.

P2609 - INCORPORATING PATIENT REPORTED EXPERIENCE MEASURES AND PATIENT REPORTED OUTCOME MEASURES INTO ROUTINE FOLLOW UP OF CHILDREN AFTER NEONATAL REPAIR OF TRANSPOSITION OF THE GREAT ARTERIES

Jo Wray, Annette Mcquillan, Victoria Banks, Allan Goldman, Shankar Sridharan, Sachin Khambadkone
Great Ormond Street Hospital For Children Nhs Foundation Trust, Critical Care and Cardiorespiratory Division, London-United Kingdom

Background: With decreasing mortality and morbidity after repair of congenital heart disease, there is increasing emphasis on the use of patient reported experience measures (PREMs) and patient reported outcome measures (PROMs) as key indicators of improvement and quality. Our aim was to integrate PROMs and PREMs into the routine follow-up pathway for infants who had undergone repair of transposition of the great arteries (TGA) and to collect some preliminary data.
Methods: Parents of neonates were asked to complete a PREM about their hospital experience on discharge after their surgery. At their 12 month follow-up outpatient appointment parents completed a PROM about their infant – the infant PedsQL, a generic measure of quality of life assessing aspects of physical and psychosocial health. Comparisons were made with published norms for healthy children.
Results: Over a 45 month period 102 infants were discharged after TGA repair and 93 infants were eligible for 12 month follow-up. Parents of 98 infants completed the PREM at discharge (96% response rate), with 53% reporting that they felt moderately or severely anxious and not feeling adequately prepared for going home. PedsQL scores were available for 64 infants (69% response rate) at 12 months and were not different from those of healthy norms (TGA Total score: 83.31; S.D. 11.93; healthy total score: 82.47; S.D. 9.95).
Conclusions: Incorporating PREMs and PROMs collection into routine follow-up of babies who have undergone TGA repair is feasible. Parents valued the opportunity to provide feedback about their experience and importantly, previously unavailable data were collected about quality of life in the first year after surgery indicating excellent outcomes. Areas for improvement in the hospital experience were also identified. However, collecting such data was resource intensive, with specific challenges identified for data collection in outreach clinics, and alternative methods need to be explored.

P2655 - HEART RATE PRESSOR RESPONSE DURING ISOMETRIC HANDGRIP EXERCISE IN CHILDREN WITH CONGENITAL HEART DIESASE AND HEALTHY CONTROLS

Christopher Scott Pharis[1], Stephanie Fusnik[2], Natasha Boyes[2], Mark Haykowsky[3], Shonah Runalls[4], Marta Erlandson[2], Charissa Pockett[1], Ashok Kakadekar[1], Timothy Bradley[1], Corey R Tomczak[2]
University of Saskatchewan, Pediatric Cardiology, Saskatoon-Canada[1]; University of Saskatchewan, College of Kinesiology, Saskatoon-Canada[2]; University of Texas, College of Nursing And Health Innovation, Arlington-United States[3]; University of Saskatchewan, College of Medicine, Saskatoon-Canada[4]

Background & Hypothesis: The exercise pressor reflex activates an increase in heart rate (HR) via mechanically and metabolically sensitive afferents in contracting skeletal muscle. Children with congenital heart disease (CHD) display exercise intolerance compared to healthy control children, but whether an abnormal exercise pressor reflex contributes to the observed exercise intolerance in children with CHD is not known. We tested the hypothesis that the early HR response to isometric handgrip exercise would be blunted in children with CHD versus healthy control children.
Materials & Methods: Twenty-one children with CHD (11 ± 2 years; females = 9) and 20 healthy controls (11 ± 2 years; females = 11) were studied. CHD diagnoses included simple and complex lesions. Children with a pacemaker or heart transplantation were not included in the study. Children performed isometric handgrip exercise for 2 minutes at 30% of maximal voluntary contraction. The early (first minute) and late (second minute) of the HR response was recorded by surface ECG. Children performed the protocol twice and responses were averaged. A 6-minute walk test was performed to assess exercise capacity. Analyses were completed using unpaired t-tests with $P < 0.05$ being significant. Data are mean ± SD.
Results: 6-minute walk test distance was lower in CHD than controls (523 ± 56 versus 605 ± 79 metres; $P < 0.001$). The early HR response from rest to isometric handgrip exercise at 1 minute was lower in CHD than controls (5 ± 5 versus 10 ± 9 beats/minute; $P = 0.029$). There was no difference in the late HR response from rest to isometric handgrip exercise at 2 minutes between groups (CHD: 10 ± 7 versus controls: 11 ± 8 beats/minute; $P > 0.05$).
Conclusions: A blunted exercise pressor reflex during early exercise may contribute to the pathophysiology of exercise intolerance in children with CHD and low exercise capacity.

P2696 - CONGENITAL HEART BLOCK AND SINGLE INSTITUTIONAL EXPERIENCE WITH EPICARDIAL PACING IN CHILDREN IN A LOW MEDIUM INCOME COUNTRY

Gcina Dumani, Paul Adams, Hopewell Ntsinjana, Antoinette Cilliers
Chris Hani Baragwanath Academic Hospital and University of Witwatersrand, Paediatric Cardiology, Johannesburg-South Africa

Introduction: Epicardial pacemaker systems are still preferred in many centers than the endocardial pacemaker systems for the young children and infants <10 kilograms because of the increased risk of venous occlusion, associated complex congenital structural cardiac anomalies with limited access, right to left shunts and increased risk of thromboembolism, small size and somatic growth.On the other hand, the epicardial approach is invasive and the epicardial leads are associated with high rate of fractures, increased pacing threshold and reduced generator longevity.
Methods: A retrospective review of cases requiring permanent epicardial pacing presenting to the Division of Paediatric Cardiology at the Chris Hani Baragwanath Academic Hospital between 1992 and 2015. There are no dedicated pacemaker follow up facilities for the children and onsite surgical cardiothoracic services. Data related to demographics, indications, diagnosis, associated structural heart anomalies, pacemaker system, surgical approach, lead and generator longevity, mortality and follow up was collected.
Results: Forty five patients (females,61.1%)underwent insertion of permanent epicardial pacemaker and the majority(55.6%)were diagnosed with congenital complete heart block. Median age at first implant in patients with congenital complete heart block was 3 months (0.099-144 months,IQR = 0.67-69). The median weight was 8.1 kilograms (2.5-36 kilograms,IQR = 3.3-17.2). The other indications were postoperative complete heart block in thirteen cases (28.8%)and sinus node dysfunction in seven cases (15.6%). Associated structural congenital heart anomalies were

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

found in twenty patients(44.4%). Fifty nine pacemaker generators were placed either in the pleural cavity or rectus sheath via the antero-lateral thoracotomy or median sternotomy and seventeen pacemaker generators (37.8%) were revised due to battery depletion (mean = 7.16 ± 2.85 years;3.0-14.75 years. Twenty one epicardial leads were replaced (mean = 5.13 ±2.53 years;0.008-9.83 years). Overall mortality was 26.7% and related to the pacemaker in one patient.Mean follow up was 6.89 ±5.09 years (0.5-17.33 years).
Conclusion: Congenital complete heart block is the commonest indication for epicardial pacemaker insertion in children .Lead malfunction and battery depletion were common reasons for revision of the pacemaker system.

P2704 - EVALUATION OF THE RESPONSE TO THE CARDIOPULMONARY TEST OF EFFORT IN UNIVENTRICULAR PATIENTS

Rogerio Souza[1], Elaine Cristina Gorobets Furquim [2], Paula Rodrigues Silva Machado Costa[2], Camila Lino Rodrigues[2], Alinne Christina Pinheiro Pereira[2], Patricia Figueiredo Elias[2], Cristiane Felix Ximenes Pessotti[2], Carlos Alberto C. Hossri[3], Ieda Biscegli Jatene[2]
Hospital For The Heart and Incor, Pneumology, São Paulo-Brazil[1]; Hospital For The Heart, Pediatric Cardiology, São Paulo-Brazil[2]; Hospital For The Heart, Cardiopulmonary Rehabilitation, São Paulo-Brazil[3]

Introduction: It is known that patients with complex cardiac structural alterations have reduced exercise capacity in relation to simple heart diseases. This fact can be explained both by residual hemodynamic defects and by the lack of physical conditioning.
Goals: The objective of this study was to analyze the exercise capacity of children and adolescents who were submitted to Glenn or Fontan procedure and to compare with no heart diseases controls.
Methods: Were included all univentricular patients submitted to cardiopulmonary testing between March 2005 and July 2014. The controls were selected from a sample of children submitted to the same test to assess physical activity during the same period, matching for gender and age. Demographic data and variables of the cardiopulmonary exercise test were compared between the two groups.
Results: There was no statistical difference between the two groups regarding age, height, BMI, heart rate and resting systemic blood pressure, as well as vital capacity. The group of univentricular patients presented a significant reduction of the maximum VO2 (77.9%) in relation to the controls (101.7%) ($p < 0.001$). There was no difference between the respiratory reserve and the maximum oxygen pulse. However, the univentricular group presented lower PET CO2 and higher CO2 equivalent (VE/CO2) at peak exercise ($p = 0.001$), as well as lower initial and final oxygen saturations in relation to control ($p < 0.01$).
Conclusion: Univentricular patients present decreased exercise capacity, which is related to cardiocirculatory limitation. This decreased exercise capacity is not determined by the pulse of O2

P2707 - THE PREDICTIVE VALUE OF PHENOTYPIC FEATURES OF CARDIAC PATIENTS FOR FISH TESTING FOR THE 22Q11.2 DELETION SYNDROME AT RED CROSS WAR MEMORIAL CHILDREN'S HOSPITAL CAPE TOWN SOUTH AFRICA

Rik De Decker[1], Lesley Hendricks[2]
University of Cape Town and Red Cross Children, Division of Cardiology, Cape Town-South Africa[1]; University of Cape Town and Red Cross Children, Department of Paediatrics and Child Health, Cape Town-South Africa[2]

Background: Chromosome 22q11.2 deletion syndrome (22qDS), an autosomal dominant disorder, is the most common microdeletion syndrome. More than 180 phenotypic features are associated with 22qDS and this wide phenotypic variability may make it difficult to know when to confirm 22qDS by FISH (fluorescent-in-situ-hybridisation) testing. Its diagnosis is important, since it may have serious implications for the patient's management and prognosis. Óskarsdottir's score is commonly used to suggest the need for FISH testing for 22qDS, but a recent study done at our hospital found its criteria to have a positive predictive value of only 14%! This may be due to the fact that Óskarsdottir's study was based on the phenotypic features of a Caucasian study population, in Sweden, while our population is largely non-Caucasian. We sought to describe which phenotypic features in our patient population would best suggest the need for FISH testing for 22qDS.
Methods: A retrospective review of the clinical case notes for the phenotypic features of patients, who had had FISH tests done after the clinical suspicion of 22qDS, was performed. The clinical triggers to suggest FISH testing of 144 patients (72 FISH-positive 22qDS vs 72 FISH-negative patients) were reviewed.
Results: The four most common phenotypic triggers for testing FISH-positive patients were congenital heart disease (CHD), failure to thrive, "soft" dysmorphic features and developmental delay. Younger children presented frequently with CHD, while older children presented with developmental delay and dysmorphic features. The (combined) positive predictive value (PPV) for these 4 most common triggers was 76.4%, far better than the 14% attained by the Óskarsdottir score in our population.
Conclusion: It is clear that non-Caucasian populations have some unique phenotypic expressions of 22qDS that require different, population-specific diagnostic criteria to suggest performing FISH testing for a confirmation of a diagnosis of 22q11.2 deletion syndrome.

P2743 - CARDIAC SCREENING PROGRAM FOR HIGH SCHOOL ATHLETES IN BERGEN COUNTY A FEASIBILITY AND UTILITY STUDY

Subhashini Subramanian, Robert Tozzi
Hackensack University Medical Center, Pediatrics, Hackensack-United States

Background: Sudden cardiac death during intense physical activity is a rare but devastating event in children and young adults. Various studies have evaluated the utility and predictive value of cardiac screening programs in high school athletes. We report the results of a cardiac screening program for high school athletes in Bergen County.
Material and Methods: The study population consisted of high school athletes aged 13 to 16 years from local high schools in Bergen County. Study participants filled out a questionnaire based on existing guidelines for sports participation. Salient points included cardiac symptoms, growth and development, past medical history and family history. Informed consent was obtained for exam and screening tests. Limited physical exam included vital signs and calculation of a BMI. Students then underwent a 12-lead electrocardiogram and complete echocardiogram. Study results were interpreted by a pediatric cardiologist, who recommended appropriate follow up. This study analyzes the results of the complete cardiology evaluation on follow up and looks at the predictive value of the screening program.
Results: A total of 450 students between the ages of 13 and 16 participated in the screening program. 104 were flagged as abnormal on the screening based on electrocardiogram or

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

echocardiogram, and were advised a complete evaluation by a pediatric cardiologist. Common diagnoses included bicuspid aortic valve, mitral valve prolapse, patent foramen ovale and sinus bradycardia. Our study is ongoing, and will compare the results of the complete cardiology evaluation with the screening results.
Conclusion: Although routine cardiac screening of high school athletes is not recommended, our study aims to look at the feasibility and predictive value of a local cardiac screening program because of the devastating effects of sudden cardiac death on families of young athletes, and potential benefits of prevention.

P2782 - EPIDEMIOLOGICAL AND CLINICAL PROFILE OF CONGENITAL HEART DISEASE IN A REGIONAL MATERNITY CENTER OF TUNISIA

Fatma Ezzahra Chioukh[1], Houda Ajmi [2], Hayet Ben Hamida[1], Karim Ben Ameur[1], Sonia Hamdi[3], Besma Seket[1], Amina Ben Salem[4], Chiraz Hafsa[4], Faouzi Maatoug[3], Kamel Monastiri[1]
Maternity Center, Department of Neonatal Intensive Care Unit, Monastir-Tunisia[1]; Teaching Sahloul Hospital, Department of Pediatrics, Sousse-Tunisia[2]; Teaching Fattouma Bourguiba Hospital, Department of Cardiology B, Monastir-Tunisia[3]; Maternity Center, Department of Radiology B, Monastir-Tunisia[4]

Background: Congenital heart defects have an estimated worldwide incidence of 6-8 per 1000 live births. Given the frequence of consanguinity in our country, this incidence should be higher in Tunisia.
Objective: The aim of this work was to analyse the epidemiological and clinical characteristics of congenital heart disease among hospitalized newborns in the regional maternity center of Monastir city.
Materials and Methods: This is a retrospective study of patients with cardiac conditions seen at the maternity center over 5 years 8 months realized in our service (from 1 January 2010 to 31 December 2014).
Results: During the study period, 150 cases were analyzed among which 79 summers were selected. The sex ratio of 1.25. Consanguinity was found for 12 couples and congenital heart disease history was found in 4 cases. Prenatal diagnosis was made in 17 cases at an average term of 29 weeks [GA 16-37]. The average age at admission of those with postnatal diagnosis was 16h30 minutes [1 h - 330 h]. After birth, the discovery of congenital heart disease was accidental in 31 cases. In the remaining cases, the most frequent reasons for hospitalization were cyanosis (18 cases) and neonatal respiratory distress (17 cases). Most of children had congenital heart disease involving the right ventricular outflow tract and association with a malformation syndrome was found in 19 newborns with a predominance of down syndrome (6 cases). The Prostine® was indicated for 22 infants and 8 newborns underwent surgery. The overall mortality rate was 38% (30 cases) with an average death age of 13-day [1-75 days].
Conclusion: To improve the management of congenital heart disease we must ameliorate the antenatal diagnosis, which still insufficient in our country, and planning of delivery at risk in a center equipped with appropriate materials and human skills.

P2794 - THE QUOTIENT OF SINUS VALSALVAE AND SINOTUBULAR JUNCTION – AN ADDITIONAL AND INDEPENDENT PARAMETER TO CLASSIFY THE AORTIC AFFECTION OF PEDIATRIC PATIENTS WITH MARFAN SYNDROME

Friederike Seggewies, Veronika Stark, Jakob Olfe, Götz C. Müller, Florian Arndt, Jannis Pesch, Rainer Kozlik-Feldmann, Thomas Mir
University Heart Center, Department of Pediatric Cardiology, Hamburg-Germany

Objectives: Marfan-syndrome (MFS) is an autosomal dominant connective tissue disorder with a variable clinical presentation. One of the main causes of mortality is transformation of the cardiovascular system. The measurement of sinus valsalvae aortae (SV) in relation to body surface and age (Roman et al) is the common marker to classify the risk for subsequent aortic complications over time. An independent tool for the evaluation of aortic dilation could be the measurement of the quotient of sinutubular junction (SJ) and SV. This additional criteria could be very suitable for a possible therapeutic decision irrespective of age and percentiles. In a first step we compared the SJ/SV quotient of children with and without MFS.
Methods: We investigated 381 pediatric patients (11.4 ± 5.5y) with suspected MFS, 141 patients of this group have diagnosed MFS (11 ± 5.6y). The quotient of SJ and SV was analyzed at first consultation of patients with diagnosed MFS (115patients) and suspected MFS (204patients). Patients with MFS younger than one year and patients without confirmation of MFS and enlargement of the SV (z-score: + 2) were not included in the study.
Results: The mean ± standard deviation was 0.78 ± 0.1 in the group of patients with diagnosed MFS and 0.83 ± 0.09 in the group of patients without MFS. This is a significant difference ($p \leq 0.005$).
Conclusions: There is a significant difference between the quotient of SJ/SV in patients with and without MFS, therefore this new parameter could be an additional tool to facilitate therapeutic decisions. In this first evaluation the new quotient appears to be an age and body surface independent parameter, but more investigations with a larger sample size and over time are needed to analyze whether the parameter is influenced by any other factors, for example whether it changes during adolescence.

P2811 - FOETAL ECHOCARDIOGRAPHY REASONS FOR REFERRAL AND PREVALENCE OF CONGENITAL HEART DISEASE

Ana Jacomé[1], Glory Gomes[1], Raimundo Amorim Junior[1], Camilla Ferreira[1], Natalia Moser[1], Renata Gomes[2], Sandra Mattos[3]
Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[1]; Círculo Do Coração De Pernambuco, Estatistica, Recife-Brazil[2]; Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[3]

Introduction: The prevalence of childhood congenital heart disease is estimated at 8 per 1000 live births. With the advent of foetal echocardiography (FE), early diagnosis of congenital heart diseases became possible, allowing adequate maternal follow-up and planning of birth in reference centres in paediatric cardiology. However, there is still no clear evidence of criteria for foetal echocardiography in the literature, with many exams performed without precise indications. This study aims evaluate relationship between the foetal diagnoses of congenital heart disease and the indications of the examination.
Material and Methods: Retrospective analysis of database of 11702 FE performed in 10921 patients at referral service from January 2004 to August 2016. The first examination of each patient was selected according to the reasons for referral and diagnostic findings.
Results: The main reasons for foetal echocardiography were: check-up (78.0%), a suspected CHD on US (%) maternal risk factor (16.0%), foetal risk factor (6.4%). A normal FE was 96.1%. Among the patients with alterations, arrhythmias (9.7%), complex heart disease (23.9%) and simple heart disease (65.9%) were found. Among the diagnosed heart diseases, the main were: ventricular septal defect (46.4%), coarctation of Aorta (6.9%), atrioventricular septal defects (6.2%). The reasons for referral that presented the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

highest frequency of positive diagnosis for congenital heart disease were: suspected heart disease (60%), fetal risk factor (9%). The variable maternal age didn't change the prevalence of positive diagnoses for congenital heart disease.
Conclusion: The main referral reason for a FE was a check-up. This indication, however, yield only 2,2% of positive diagnosis. Conversely, 60.4% of patients referred due to an abnormal obstetric ultrasound presented with some abnormality And the fetal referrals, particularly due to new indications are leading to detection rates close to 10%. This highlight, the need to reinforce the indications for FE based on more specific criteria.

P2838 - A RARE CAUSE OF HYPERTENSION IN A 7 YEAR OLD BOY

Halszka Kaminska[1], Anna Kostera-Pruszczyk[2], Anna Potulska-Chromik[2], Bozena Werner[1]
Medical University of Warsaw, Dept. of Pediatric Cardiology And General Pediatrics, Warszawa-Poland[1]; Medical University of Warsaw, Dept.of Neurology, Warszawa-Poland[2]

Background: Arterial hypertension in childhood is more likely to be secondary, but a differential diagnosis may be a challenge.
Case report: A previously healthy 7-year-old boy was referred to a pediatrician due to burning pain in palms and feet lasting for a week. The pediatrician detected high values of blood pressure up to 160/120 mm Hg and sent the boy to the hospital. On admission high blood pressure and tachycardia were found, the skin over the affected area was unchanged, no abnormalities in neurological examination were detected. During the observation in cardiology department he was irritable, suffering of severe pain non-responsive to analgesics, his blood pressure and heart rate were consistently high, temperature normal. Laboratory data did not revealed any abnormalities. Blood pressure and heart rate were constantly elevated, mean values 165/125 mm Hg and sinus rhythm 160 bpm respectively, without a variability during 24-hour monitoring. Shortly after admission he presented first in his life seizures attack without the blood pressure rise and a good response to midazolam. The blood and urine test showed elevated catecholamine metabolites, elevated aldosterone concentration and renin plasma activity. Imaging (ultrasound, CT, MRI) of brain, spine and abdomen showed no pathological masses. Samples of blood, urine and hair were negative for mercury poisoning. The acute autonomic neuropathy was confirmed by negative sympathetic skin response test. Nerve conduction studies were normal. The treatment with intravenous immunoglobulin, calcium blocker, beta-blocker and ACEI was introduced with gradual normalization of blood pressure and heart rate. Gabapentin was used for control of neuropathic pain with good result. All symptoms released during 3 months follow-up.
Conclusions: The described case reiterates the need for careful and open-minded approach to the patients with hypertension. Acute autonomic neuropathy should be considered as a cause of hypertension.

P2841 - REDUCING INTERESTAGE HOME MORTALITY IN A DEVELOPING COUNTRY A HIGH RISK AMBULATORY APPROACH

Gabriel Carmona Fernandes, Carolina Vieira De Campos, Ana Cristina Sayuri Tanaka, Nana Miura, Gustavo Foronda
HCFMUSP, Incor, Sao Paulo-Brazil

Background: During the inter-stage period there is controversy about the possibility of outpatient follow-up, due to high risk of death at home. However, keeping a patient hospitalized for months is also not a good solution. The literature has shown a reduction in home mortality using Home-Care or telemedicine, but this resources are unavailable for many patients from developing country due to cost issues. We developed an option of closely following these patients through a specialized ambulatory service.
Materials and Methods: The goal of our study was to evaluate the impact of a specialized ambulatory follow-up in home mortality of children in inter-stage period. We retrospectively analyzed charts from patients who underwent a palliative procedure in the neonatal period or had a complex cardiopathy that required close follow-up before the first procedure. These patients were discharged from the neonatal admission between jannuary 2015 and December 2016 and followed up in our specialized ambulatory. They were evaluated with close returns between 7 and 15 days, serial echocardiograms, oximetry, adjustment of medications and feeding.
Results: A total of 134 patients were followed in the period. Four patients died at home (0.03%). Currently, 76 patients have already undergone the definitive surgical procedure, 14 of whom remain hospitalized. Twelve patients died in the post-operative period and 50 patients no longer require closely follow-up and were switched to a conventional ambulatory. In addition, 54 patients are still being followed up in our ambulatory.
Conclusions: Inter-stage is a critical period in the management of this patients. Currently in Brazil we do not have enough resources to follow these children with Home-Care or telemedicine, so the proposal of specialized ambulatory follow-up with close returns and serial echocardiograms presents as an alternative to lower the mortality rate in this period.

P2842 - FUNCTIONAL CAPACITY IN POSTOPERATED TETRALOGY OF FALLOT PATIENTS ERGOSPIROMETRIC RESULTS ACCORDING TO THEIR PATHOPHYSIOLOGY

Angeles Fuertes Moure[1], Luisa García-cuenllas Álvarez [2], Miriam Centeno Jiménez[3], Reyes Álvarez García-Rovés[3], Enrique Maroto Álvaro[3], Constancio Medrano López[3], Juan Ignacio Castillo Martín[4]
Hospital Materno-infantil Teresa Herrera, Pediatric Cardiology, A Coruña-Spain[1]; Hospital Universitario De Salamanca, Pediatric Cardiology, Salamanca-Spain[2]; Hospital Universitario Gregorio Marañón, Pediatric Cardiology, Madrid-Spain[3]; Hospital Universitario 12 De Octubre, Pediatric Cardiology, Madrid-Spain[4]

Background: Postoperated Tetralogy of Fallot patients (PTF) show decreased exercise capacity (ExC) (represented by VO2) and increased VE/VO2 slope. Both parameters are factors of morbidity and predictors of death and hospitalitation. Right ventricular dysfunction and residual pulmonary stenosis or regurgitation severity play a significant role in the evolution of these patients.
Objectives: To correlate the pathophysiology and anatomy in pediatric PTF population with its ergospirometric parameters.
Methods: Retrospective observational study of 25 PTF (mean age 12 ± 3.2 years, weight 43.2 ± 14.55 kg, height 146.7 ± 14.4 cm, 58% male). Inclusion criteria admitted pulmonary atresia with VSD. Ramp treadmill ergometry (Bruce protocol) was performed with expired gas in all cases.
Results: Submaximal exercise tests limited by symptoms were performed, clinically and electrically negative in all cases, with no significant arrhythmias. 56% showed a normal spirometric pattern and 20% restrictive. 32% reached 85% predicted HR ($79,6 \pm 9,3$%. Rest HR 89 ± 14 bpm, maximal HR 170 ± 17 bpm (HRR 81 ± 22 bpm). SBP/DBP at rest was $97 \pm 10/57 \pm 8$ mmHg,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

maximum of 125 ± 10/71 ± 8 mmHg. DP was 20938 ± 2817. CPET showed decreased maximal VO2 (79,5 ± 10,2% predicted), with normal O2 pulse(101 ± 18,5% predicted). The rise in Vslope and CO2Eq at VAT (33,4 ± 8,3 and 34,9 ± 6,8 respectively) botht at the high limit of normality could translated ventilatory inefficiency. Respiratory reserve 42 ± 14,6 (normal).
Conclusions: CPET provides prognostic information in these patients, and can determine risk factors. Certain values of VO2 and V slope are associated with specific pathophysiological situations: greater V slope is found in pulmonary stenosis, lower VO2 when right ventricular dysfunction and greater pulmonary regurgitation occur. These data are relevant in the complex ergospirometric interpretation in congenital heart disease, within the limitations of a small sample size.

P2844 - ANDERSEN TAWIL SYNDROME A TOO LATE DIAGNOSIS

Jorge Palacios Argueta[1], *Elisabeth Gabau*[2], *Carmen Massons Capdevilla*[3], *Jordi Punti Sala*[4]
Parc Tauli-Universitat Autonoma De Barcelona, Pediatrics. Pediatriccardiology, Sabadell-Spain[1]; *Parc Tauli-Universitat Autonoma De Barcelona, Pediatrics.Genetics, Sabadell-Spain*[2]; *Parc-Tauli-Universitat Autonoma De Barcelona, Psychiatry, Sabadell-Spain*[3]; *Parc Tauli-Universitat Autónomo De Barcelona, Cardiology, Sabadell-Spain*[4]

Background: Andersen-Tawil syndrome (ATS) is an autosomal-dominant disorder characterized by ventricular arrhythmias, periodic paralysis, distinctive facial-skeletal anomalies and developmental abnormalities. The affected genes is KCNJ2. Cardiac manifestations include Premature Ventricular Contraction (PVC),Q-U prolongation, prominent U waves,ventricular tachycardia. Family history of sudden cardiac death sometimes is not known.
Case: We present a 42 year old woman with history of Psychological negligence abuse in childhood and eating disorder. Father died 2 years ago. Mother is alive. First of 3 sisters. No past medical history. Problems during childhood, poor social relationships. During first hospitalization episode in Psychiatric ward it was documented a BMI under 15, Mixed personality disorder with autolytic threats; a consultation to clinical genetics unit was done, due of dysmorphic phenotype. Physical exam with small stature, small lower jaw, low-set ears, widely spaced eyes, clinodactyly were demonstrated. Cardiovascular exam,no murmurs were found. An ECG with a slightly prominent U wave in V3-V4 leads with a QUc of 660 mseg was found. 24 Hours Holter documented frequent PVC without any VT episode. An Echocardiogram was perfomed without any abnormal founds. The Comparative Genomic Hibridization (CGH) array demonstrated a Delection 17q24.3 in KCNJ2 gen. No antiarrhytmic medication was prescribed. Quetiapine, Paroxetine and Diazepam were prescribed.
Conclussion: ATS is a rare channelopathy, this type of patient present with a wide clinical spectrum from distinctive facial-skeletal anomalies, ventricular arrhythmias, neurocognitive anomalies and periodic paralysis, our patient fullfil most of clinical criteria confirmed by a genetic test. ATS patient has a very high arrhythmia burden, but most frequently asymptomatic, the optimal pharmacological therapy has to be identified.Despite the late timeframe to diagnosis, the management and treatment of this type of patient require a high degree of clinical suspicion and remember to us the importance of a multidisciplinary approach.

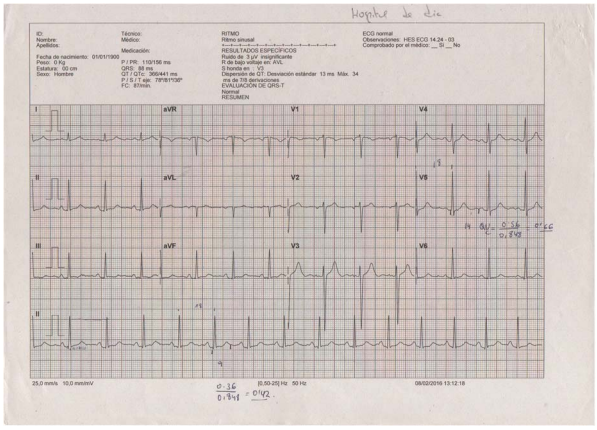

Figure 1.

P2976 - CHALLENGES OF SURVEILLANCE IN CLINIC FOLLOWING COARCTATION OF THE AORTA REPAIR

Ioana Dumitrascu-Biris, *Nanda Prabhu, Paraskevi Theocharis, John M. Simpson*
Evelina Children Hospital, Paediatric Cardiology, London-United Kingdom

Objectives: Identify the monitoring challenges in outpatient department setting post repair of Coarctation of the Aorta.
Methods: 1 year retrospective review of all children seen in clinic with status post Coarctation of the aorta repair. 136 paediatric patients were seen in our clinics at The Evelina Children Hospital from 15th January 2016 to 15th January 2017.We enrolled patients with isolated Coarctation of the aorta, associated atrial or ventricular septal defect and any aortic valve malformation.
Results: For all the 136 patients we recorded weight, height, casual systolic and diastolic blood pressure, descending aortic arch gradient post operative and in clinic, interventricular septum and posterior wall dimensions, anatomy of the aortic valve, timing of diagnosis and age at surgery. For a random subset of this group (n = 69 patients) reliable SBP was available in 62 patients of whom 36.6% had SBP > 95th centile and 16% of them are already under treatment for systemic arterial hypertension. The median age at operation was 13 days and an antenatal suspicion of coarctation was raised in 35%. The systolic blood pressure was significantly associated with the Doppler velocity in the descending aortic arch (r = 0.319, p = 0.012)There was poor correlation between LVPW z scores and SBP z scores (r = -0.104, p = 0.476). Age at operation and hypertension has also positive correlation with statistically significance (r = 0.301 , p = 0.016).
Conclusion: In our subset of repaired coarctation we noticed strong association between SBP and Doppler arch velocity. The prevalence of hypertension following coarctation repair is worryingly high and further evaluation with a control group is warranted.

P3034 - A NEWBORN WITH NOONAN SYNDROME PRESENTED AS RESPIRATORY DISTRESS BY H CMP AND CYSTIC HYGROMA

Eun Joo Kim, *Hong Ryang Kil, Jin Sun Lee*
Chungnam National University, Pediatrics, Daejeon-Korea, South

Noonan syndrome (NS) is Autosomal dominant (1/1,000-2,500 live birth) characterized by the hypertelorism, ptosis, short neck, low-set-ears, short stature, CHD, and multiple skeletal and

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

hematologic et al. Most patient (94%) with positive genotype had known CHD. PTPN11 mutation was noted in 79% of pulmonic stenosis and RAF1 & specific PTPN11 mutation in 12% h-CMP. Children with NS diagnosed with h-CMP before 6month(51%), but rare neonatal presentation.
Case: GA 38wks, 3560 g, NSVD was presented with Cyanosis & tachypnea, which was Not improved with Oxygen therapy by hood tent. Prenatal USG showed the short femur Vital sign : HR 148 /min, RR 68/min, BT :36.5°C, BP : Arm 57/31 mmHg Leg 61/35 mmHg WT 3500gm(50-90pecentile) Ht 47.3 cm(10-50percentile) HC 39.5 cm (>97 percentile) A characteristic configurations of patient were cystic hygroma in neck, flat nose bridge, low set ear and hairline. Mild chest retraction, inspiratory stridor, midsystolic ejection murmur along left sternal border were noted. Cardiac hypertrophy of left ventricle and diastolic dysfunction without left ventricular outflow obstruction was noted on echocardiograhphy. Mechanical Ventilation for severe respiratory distress and then replaced to N-CPAP, continued until 7th day due to CO2 retentions and tachypnea. Oxygen was stopped on the 18th day. Upper airway was not obstructive, and spontaneous resolution of cystic hygroma without surgery. Gene study : negative for PTPN11 gene c.770c > T (p.Ser257Leu) of RAF1 gene. In Neonatal Noonan syndrome, respiratory distress may be appear due to cystic hygroma and h-CMP. Hypertrophic CMP in NS is over represented in RAF1 rather than PTPN11 association, common mutation in patient with PS.The infant require regular detailed follow up for heart and respiratory complication due to hypertrophic CMP and cystic hygroma

ANESTHESIA

P1092 - INCIDENCE OF COMPLICATIONS AND ANESTHETIC MANAGEMENT OF PATIENTS UNDERGOING PULMONARY ARTERY REHABILITATION IN THE CATHETERIZATION SUITE A RETROSPECTIVE REVIEW

Alexander Froyshteter[1], Jeffrey Moore[5], Samantha Vizzini[5], Darren Berman[2], Aymen Naguib[3]
Nationwide Childrens, Anesthesia and Pain Medicine, Columbus-United States[1]; Nationwide Childrens, The Heart Center, Columbus-United States[2]; Nationwide Childrens, The Heart Center/ Anesthesia, Columbus-United States[3]

Introduction: Patients with complex pulmonary artery (PA) stenosis often undergo multiple procedures involving balloon angioplasty, cutting balloon angioplasty and stent implantation collectively referred to as pulmonary rehabilitation. We sought to evaluate the anesthetic management and outcomes of PA rehabilitation cases, focusing on known complications.
Methods: Single center retrospective review of patients who underwent PA angioplasty with or without stent placement between October 1, 2010 and October 1, 2015. Data collected included diagnosis, procedure, anesthetic techniques, use of bronchial blockers, pulmonary bleeding, vascular injury detected on chest X- ray, and postoperative course. Additionally, we collected intraoperative hemodynamic data, including right ventricle/femoral artery (RV/FA) pressure ratios.
Results: Data were collected for 108 patients. All patients with single ventricle physiology were excluded. Table 1 compares perioperative data between tetralogy of Fallot (TOF) with pulmonary atresia and other patients. Table 2 illustrates perioperative outcomes and the rate of use of bronchial blockers.
Discussion: Patients with TOF with pulmonary atresia were more likely to experience complications related to PA angioplasty with or without stent placement. Higher RV/FA pressure ratio increased the risk for complications. While use of bronchial blockers in this cohort was infrequent, this may represent the evolution of our anesthetic management of these patients over the study period. Our current protocol is to place a bronchial blocker, either through the lumen of the endotracheal tube or outside, at the beginning of the procedure in patients deemed to be at high risk for pulmonary hemorrhage. The bronchial blocker can be advanced into either lung under fluoroscopic guidance in the event of significant pulmonary hemorrhage or reperfusion injury that interferes.

Chelyabinsk Federal Cardiac Center, Anesthesia, Chelyabinsk-Russia[1]; Chelyabinsk Federal Cardiac Center, Cardiac Surgery, Chelyabinsk-Russia[2]; Heart To Heart, Oakland-United States[3]; Nationwide Children, The Heart Center, Columbus-United States[4]; Nationwide Children, Anesthesia/ The Heart Center, Columbus-United States[5]

Introduction: Medical mission trips are a very rich environment to exchange experiences between the visiting and the home teams.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Assessing the success of a change in practice based on such experience can be a very practical tool in establishing the real impact of such experience. The concept of early tracheal extubation after repair of congenital heart disease utilizing cardiopulmonary bypass (CPB) has been adopted as a safe technique in many heart centers across North America. In this retrospective review, we evaluated the progress of early tracheal extubation in children undergoing surgery for congenital heart disease utilizing CPB in a Heart Center program in Russia after a multidisciplinary team visit from the United States.
Methods: A retrospective review of extubation data for children undergoing congenital cardiac surgery at a major heart center in eastern Russia between August 1st 2016 and September 30th 2016. As a control group, we collected data between January and December 2015. Data included age, weight, gender, type of lesion, CPB time, aortic cross clamp time, complications, cardiac intensive care unit (CTICU) length of stay (LOS) and hospital LOS.
Results: A total of 312 were included in the study cohort. We excluded 53 patients who had thoracic surgeries not requiring CPB. A total of 259 patients were included in the final cohort (221 prior and 38 after implementing the early extubation protocol). Table 1 illustrates the demographics and perioperative outcomes
Discussion: Our early results demonstrate that early extubation can be achieved safely at a rate (86.8%) that is very comparable to many centers in North America. This success has resulted in reduction of both the CTICU and hospital LOS. Validation of such results is necessary over a long term to illustrate the ability to reproduce such results with its potential clinical and economic impact.

Table 1. Demographic and perioperative differences.

	Early Extubation Group	Control (Prior to early extubation protocol)	P

P1693 - ANESTHESIOLOGIC MANAGEMENT FOR PERCUTANEOUS POTTS CREATION IN PEDIATRIC PATIENTS AFFECTED WITH SUPRASYSTEMIC PULMONARY HYPERTENSION

Mirabile Cristian[1], *Malekzadeh-Milani Sophie*[2], *Boudjemline Younes*[2], *Mazzola Alessandra*[3], *Biselli Camilla*[1], *Aboumerouane Nada*[1], *Gioia Enza*[1], *Sitefane Fidelio*[2], *Szezepanski Isabelle*[2]
Hopital Necker Enfants Malades, Anesthesia and Intensive Care For Pediatric Cardiac Surgery, Paris-France[1]; *Hopital Necker Enfants Malades, Centre De Référence Malformations Cardiaques Congénitales Complexes-m3c, Necker Hospital For Sick Children, Assistance Publique Des Hopitaux De Paris, Paris-France*[2]; *Hopital Necker Enfants Malades, Intensive Care For Pediatric Cardiac Surgery, Paris-France*[3]

Patients with suprasystemic PAH and NYHA class III –IV have poor prognosis, limited therapeutic options and are extremely fragile. We describe our modified anesthetic management for percutaneous Potts shunt creation in a pediatric population. Anesthesia has been modified to ensure safe induction, close monitoring of the patients during this challenging procedure (Creation of anastomosis between descending aorta and left pulmonary artery with covered stent after radiofrequency-guided vessel perforation) and weaning from anesthesia without rebound PH. We report our management for 8 patients. In case of venous access, arterial and second venous access were obtained after ketamine injection and local lignocaine administration, when no access was usable, sevoflurane was used to place peripheral IV and arterial lines. One access was used for epinephrine and norepinephrine administration. Once lines were secured, deep anesthesia was carried out with alfentanil and etomidate. In case of BIS index >50, propofol (Extremely titrated) was given if mean arterial pressure was >65 mmHg, ketamine was used otherwise. General anesthesia was maintained with sevoflurane, alfentanil and atracurium and patients were ventilated with 100% inspired fraction of oxygen and 20 ppm of nitric oxide. Perforation and stent placement were generally uneventful. 2 patients presented extremely low cardiac output after dilatation of the stent and effective Potts shunt creation due to acute off-loading of the left ventricle. VA ECMO was placed during resuscitation. Patients died because of brain damage. One patient has preventive VA ECMO after uneventful induction because of severe biventricular function; he died 1 month after the procedure because of ARDS. The remaining 5 patients are alive. Mean intubation duration and mean inotropic support were similar: 1.2 days; mean ICU stay was 2.4 days. Ventricular function and functional status improved in all patients. Our modified anesthetic management proved to be helpful in this challenging procedure in the vulnerable population.

Table 1. Patient's data and outcome.

P1754 - IMMEDIATE AND SHORT TERM OUTCOMES OF TOTAL ANOMALOUS PULMONARY VENOUS CONNECTION REPAIR AT A QUATERNARY CARE CENTRE IN INDIA

Khushboo Dharmani, Kamlesh Tailor, Shankar Kadam, Suresh Rao
Kokilaben Dhirubai Ambani Hospital, Paediatric Cardiac Anesthesia, Mumbai-India

Background: Strategic perioperative management of TAPVC in recent years has markedly improved the outcomes in developing countries like India. We share our retrospective short term outcome of TAPVC.
Methods: All TAPVC patients (n = 166) operated between June 2012 and September 2016 at our centre were included. Postoperative outcomes evaluated as 30 day mortality and morbidity were analysed amongst the various TAPVC subsets.
Results: Of 166 TAPVC patients, TAPVC was classified as Supracardiac in 91 patients (54.8%), cardiac in 18 patients (10.8%), Infracardiac in 45 patients (27.1%), and mixed in 12 patients (7.2%). Obstructed variants (n = 88) and unobstructed ones were (n = 78). 106:60 M:F, the mean age (month) was 2.75 ± 7.14 mean BSA calculated was 0.24 ± 0.07. No direct correlation of duration of CPB (148.87 ± 119.68) and ACC (68.65 ± 25.97) on any of the morbidity parameters. Duration of ventilation is significantly higher in Infracardiac (97.29 ± 82.67) and Mixed type (56.08 ± 38.39) TAPVC in comparison with Supracardiac (56.63 ± 73.18) ($p < 0.004$) and Cardiac type (42.93 ± 31.31) ($p < 0.009$) TAPVC. The mean duration of ionotrope in obstructed group (5.5 ± 2.15) was significantly higher as compare to unobstructed group (3.42 ± 1.84) ($p < 0.001$). We have also found statistically significant difference in the mean duration of ventilation (hrs) (85.17 ± 80.94 (66.92-103.42) in obstructed Vs 49.23 ± 60.70 (36.67-62.09) in unobstructed group) and duration of ICU stay (in obstructed (9.64 ± 5.96) with CI of (8.30-10.98) and 6.29 ± 5.12 (5.21-7.38) in unobstructed group p(<0.001)). There was a negative correlation between BSA of patient and duration of inotrope, ventilation time, length of ICU stay ($r = -0.313$, 2 tailed $p < 0.001$). Total mortality in our series was 9/166 which was 5.4% Risk factors for mortality in our study included lesser BSA (0.24 ± 0.07), type and Obstructed variant of TAPVC.
Conclusion: Prolonged use of ionotropes, longer ventilation time and ICU

P1755 - ONE AND HALF VENTRICLE REPAIR IN CASE OF ASD VSD AND HYPOPLASTIC RIGHT VENTRICLE PERIOPERATIVE PROBLEMS AND MANAGEMENT

Khushboo Dharmani, Kamlesh Tailor, Shankar Kadam, Suresh Rao
Kokilaben Dhirubai Ambani Hospital, Paediatric Cardiac Anesthesia, Mumbai-India

'One and a half ventricular repair' is a surgical option for congenital cardiac anomalies characterized by a hypoplastic but potentially or partially usable right ventricle which reduce early risk and late failure while still achieving separate pulmonary and systemic circulations. We describe successful outcome Managing a 7month old female with failure to thrive diagnosed of Large VSD and ASD with hypoplastic Right ventricle and small tricuspid z score -2.37. She was candidated for vsd closure but intraoperatively difficult weaning due to significant right to left shunting across ASD so plan was made to close ASD asd In an effort to reduce the volume load of the ventricle glenn shunt was also done. Postoperative management was challenging maintaining PA pressure surges with ventillatory strategies and pulmonary vasodilators. She had a complicated postoperative course of low cardiac output and maintaining hemodynamics was important key factor. Thus so called 'one and half ventricle repair' is to achieve a physiological correction by separating the pulmonary circulation from the systemic one, 'unloading' the insufficient RV at thetime of the correction,but most challenging is postoperative management of these subsets. We emphasize early anticipation and strategical postoperative management of such complicated repairs

P1882 - FEASIBILITY OF AUTOLOGOUS INTRAOPERATIVE BLOOD COLLECTION AND RETRANSFUSION IN SMALL CHILDREN WITH CONGENITAL HEART DEFECTS UNDERGOING CARDIOPULMONARY BYPASS

Ania Kaiser[1], Kati Miller [2], Tian Ganzhong[3], Renee Moore[3], Nina Guzzetta[1]
Emory University School of Medicine; Children, Anesthesiology, Atlanta-United States[1] Children, Clinical Research, Atlanta-United States[2] Emory University; Rollins School of Public Health, Biostatistics, Atlanta-United States[3]

Introduction: Transfusion of allogeneic blood products is common in infants undergoing cardiac surgery and cardiopulmonary bypass (CPB) although it is associated with an increased risk for adverse events. Autologous intraoperative blood collection and re-transfusion (AIBC) is a proven method of blood preservation, but has not been extensively practiced in smaller children. In this study we compare two groups of children weighing <10 kgs, one that received AIBC and one that did not, in terms of the efficacy and safety of this practice.
Methods: After IRB approval, we retrospectively reviewed the medical records of children weighing <10 kgs who underwent CPB between 1/1/2014 and 1/31/2016. Control patients were chosen in a 1:1 matched design based on three criteria: preoperative hematocrit (HCT), procedure, and patient body weight. For patients in both groups, we collected corresponding and pertinent demographic and surgical data, clinical outcomes and certain adverse events.
Results: Patient demographics (Table 1) and preoperative laboratory values (Table 2) were similar between the two groups. Study patients tended to require more inotropic support prior to CPB than control patients. Study patients also had a greater prolongation of immediate postoperative coagulation values when compared to the control patients. Despite this, outcome variables were either the same or improved in the study group (Table 3). Specifically, patients in the study group had significantly fewer donor exposures and a shorter ICU length of stay.

Table 1. Patient Demographics

	Study (n = 15)	Control (n = 15)	p-value

Discussion: AIBC is a viable option for children weighing <10 kgs. While the immediate postoperative coagulation values were more prolonged in the study group, they still fell within an acceptable range and did not result in greater chest tube output or extra transfusions. Importantly, fewer donor exposures could significantly benefit patients who need future surgery or cardiac transplantation. Our data support the concept that AIBC is an efficacious and safe practice in patients <10 kgs.

P1894 - RED BLOOD CELL TRANSFUSION AS A PREDICTOR OF OUTCOME AFTER CARDIAC SURGERY IN INFANTS LESS THAN SIX MONTHS OF AGE

Summer Niazi[1], Kati Miller[1], Traci Leong[2], Nina Guzzetta[3]
Children, Clinical Research, Atlanta-United States[1]; Emory University; Rollins School of Public Health, Biostatistics, Atlanta-United States[2]; Emory University; Children, Anesthesiology, Atlanta-United States[3]

Introduction: Red blood cell transfusion (RBCT) during pediatric cardiac surgery benefits patients when anemia becomes sufficiently severe to decrease oxygen delivery and when acute blood loss causes hemodynamic instability. Yet, RBCTs are not without risk and, in general, are associated with poorer postoperative clinical outcomes. In this study, we examine the incidence of RBCT and its association with postoperative clinical outcomes in infants ≤6 months of age undergoing cardiopulmonary bypass (CPB).

Methods: We retrospectively reviewed the medical records of 666 infants ≤6 months of age who underwent CPB at our institution over a 3 year period. Demographic and surgical data, intraoperative and postoperative RBCT volumes, and several postoperative clinical outcomes were collected. We analyzed the data for associations between RBCT volume and postoperative clinical outcomes after adjusting for disease severity.
Results: Of the 666 total infants, only 3 did not receive an intraoperative transfusion; 455 infants did not receive a postoperative transfusion. The median amount of RBCT intraoperatively was 74 (IQR: 51-125) mls/kg and postoperatively was 28 (IQR: 7-1256) mls/kg. Tables 1 and 2 show our results according to postoperative transfusion status. In our multivariate analysis, significant variables for intensive care unit (ICU) length of stay (LOS) were age ($p < 0.001$), CPB time ($p < 0.001$), intraoperative transfusion volume ($p = 0.01$) and postoperative transfusion as a yes/no variable ($p < 0.001$). For in-hospital mortality, significant variables were CPB time ($p < 0.001$), intraoperative transfusion volume ($p < 0.001$) and postoperative transfusion yes/no ($p = 0.005$).
Discussion: In infants ≤6 months of age undergoing CPB, RBCT is associated with poorer postoperative clinical outcomes. After adjusting for disease severity, the amount of intraoperative transfusion volume and the occurrence of a postoperative transfusion were associated with a longer ICU LOS and in-hospital mortality. Further study is needed to determine if a threshold exists below which the effects of RBCT are not as harmful.

Table 1. Clinical Outcomes.

P2001-10 DAY OLD WITH HYPOPLASTIC LEFT VENTRICLE SCHEDULED FOR A NORWOOD PROCEDURE AND BY THE WAY HAS EPIDERMOLYSIS BULLOSA (EB)

Michelle Dacosta, Laura Downey, Scott Kolesky
Emory University School of Medicine, Anesthesiology, Atlanta-United States

Introduction: Epidermolysis Bullosa (EB) is a rare disease characterized by extremely fragile skin and blister formations in response to friction, trauma, or pressure.1,2 Perioperative management in a cardiac patient with EB requires meticulous care to skin, adhesive dressings, monitors, intubation, and invasive procedures.1,3
Case Presentation: A 10 day old, 3 kg female, with history of heterotaxy, left atrial isomerism, right dominant unbalanced AV canal, hypoplastic left ventricle presented for the first-stage Norwood procedure. EB was diagnosed postnatally based on her father's history of EB and her physical presentation. After multidisciplinary discussions regarding the risks of proceeding with a multi-stage cardiac repair in the setting of EB, the surgery was scheduled. Dermatology was consulted to determine appropriate adhesives for securing critical monitors, invasive lines, endotracheal tube, and the risk of the transesophageal (TEE) probe placement. The patient was intubated preoperatively and duoderm® was placed on her face to protect her skin from the adhesive tape used to secure the endotracheal tube. A preoperative femoral arterial line and a left upper extremity PICC both were covered with a Sorbaview® occlusive dressing. Two additional PIVs were placed intraoperatively, one covered with a Tegaderm™, while the femoral PIV was sutured and covered by a Sorbaview®. An adhesive NIRS (Near-Infrared Spectroscopy) cerebral oximetry probe was placed preoperatively and electrocardiogram leads were trimmed so only adhesive gel remained for contact. One pulse oximetry probe was placed directly on her hand preoperatively and one was placed with a Tegaderm™ attached to the adhesive side so no adhesive material touched her. Lubricant eye ointment was applied followed by a petrolatum gauze cover and subsequent TEE probe placement. Upon completion of the surgery while dressing her open surgical site, removal of an Ioban™ film inadvertently exfoliated the patient's epidermis from her chest and abdomen. Mepilex® Lite and Mepilex® Transfer were applied based on wound care recommendation.
Discussion: There are more than 20 EB subtypes2 and the mouth, pharynx, upper airway, and esophagus may all be involved, resulting in esophageal strictures or increasingly difficult intubations. 3 Unfortunately, our patient has complex congenital heart disease that will require additional surgeries and diagnostic procedures that necessitate invasive monitoring. Therefore, a multidisciplinary approach is essential to reduce the risk of morbidity and mortality from EB or other disease states.1
Conclusion: Adequate perioperative evaluation and preparation are essential in managing congenital cardiac patients with EB2 who will require numerous surgical and catheter-based interventions.

P2028 - INCIDENTAL DIAGNOSIS OF CONGENITAL TRACHEAL STENOSIS IN PATIENTS WITH CONGENITAL HEART DISEASE

Emad Mossad, Ashraf Resheidat, Tamra Baker
Texas Childrens Hospital, Pediatric Anesthesia, Houston-United States

Congenital tracheal stenosis (CTS) is a rare anomaly that is difficult to diagnose. The anesthesiologist can be the first to diagnose CTS usually due to an unexpected difficult airway management either upon intubation or in the immediate post-operative period. We present a series of patients with previously unrecognized complete tracheal rings diagnosed in the perioperative and immediate postoperative period. See Table and Figures.
Discussion: Congenital tracheal stenosis is a rare anomaly (incidence of 1:64500)$_1$. It is a reduction of the tracheal diameter by more than 50% due to the formation of complete or near complete tracheal rings$_1$. It can be a neonatal life threatening respiratory anomaly. It is usually associated with congenital heart disease >50% which can make diagnosing these patients very challenging. Congenital tracheal rings are frequently associated with cardiac anomalies including ASD, VSD, CAVC, PDA, vascular anomalies (pulmonary sling) and non-cardiac anomalies like tracheaesophageal fistula, esophageal atresia, Trisomy 21, VATER/VACTERL syndrome, Pfeiffer's syndrome.$_2$ Patient's symptoms range from being asymptomatic to having biphasic stridor with respiratory compromise. Patients with CTS and congenital heart disease can develop pulmonary edema and respiratory distress that can lead to underdiagnosing CTS. Some of these patients present

early in their neonatal life to the OR for cardiac surgery prior to having developed respiratory symptoms caused by $CTS_{1, 2}$. In the Immediate postoperative period, difficulty ventilating the patient after recovery from the neuromuscular blockage or with attempting to advance the ETT should prompt the anesthesiologist to suspect tracheal narrowing. Diagnosis is confirmed with a bronchoscopic evaluation, cardiac CT and or cardiac MRI may be necessary to evaluate for vascular anomalies.

P2029 - PERIOPERATIVE MANAGEMENT OF HYPERTENSION FOLLOWING TEH ROSS PROCEDURE IN PEDIATRICS A RETROSPECTIVE ANALYSIS

Ashraf Resheidat, Emad Mossad, Marcie Meador
Texas Childrens Hospital, Pediatric Anesthesia, Houston-United States

Background: Perioperative hypertension following the Ross procedure is considered a potential complication that can lead to bleeding, autograft aneurysm and dilation. Tight blood pressure control can improve hemostasis; reduce the need for blood products and the need for reoperation.
Objectives and Methods: Study the correlation between blood pressure (BP) control in the immediate post cardiopulmonary bypass (CPB) period and postoperative bleeding, transfusion requirements and the length of ICU stay.

Results: See Tables 1–3 and Figures. This analysis includes 18 subjects. Demographic and clinical characteristics are presented in Table 1. There was no significant association between mean SBP and blood product exposure in the immediate post operative period. There was no significant association with the number of prior cardiac surgeries. In a linear regression analysis there was correlation between chest tube output and CPB duration ($r = 0.75$ for ages <2 years, $r = 0.55$ for ages > 2 years). In a univariate analysis there was no association between mean SBP at different time intervals in the postoperative period and chest tube output, but there was association between blood exposure and CPB duration ($P = 0.02$) Table 2, 3. The length of ICU stay was inversely related to the patient age ($p = 0.03$).
Conclusion: Our data demonstrated no significant association between bleeding and blood pressure control. There was correlation between CPB duration, CT output and transfusion requirements. Age was the only factor affecting the length of ICU stay

P2048 - REFRACTORY VENTRICULAR FIBRILLATION IN REDO CONGENITAL CARDIAC SURGERY KNOW THY PATIENT'S CORONARY

Sreekanthan Sundararaghavan[1], Jonathan Tlj Choo[1], Mark Nakao[2], Josephine Sk Tan[3], Monica Kotecha[1], Ching Kit Cheng[1], Teng Hong Tan[1]
KK Women And Children, Pediatric Cardiology, Singapore-Singapore[1]; KK Women And Children, Pediatric Cardiothoracic Surgery, Singapore-Singapore[2]; KK Women And Children, Pediatric Anesthesia, Singapore-Singapore[3]

Background: Ventricular Fibrillation (VF) in children with congenital heart disease is uncommon but could be an indicator of poor prognosis. VF during open heart surgeries is not uncommon but may be transient. However, refractory VF is rare even in the setting of open heart surgery. Survival to hospital discharge is still very low in "In hospital VF".
Methods: – Patients aged (–to–) underwent redo open heart surgery for repair of structural heart defects between year —— and – at KK women and children's hospital. 1 patient had refractory ventricular fibrillation that was not responding to conventional therapy including cardioversion.
Results: The right ventricle (RV) was lacerated while performing redo sternotomy and the patient was cannulated emergently via femoral route for CPB. After the repair was completed, the rhythm evolved into VF during rewarming but was recalcitrant and could not be corrected despite correction of metabolic parameters and multiple attempts at cardioversion. An on-table intracardiac hemodynamic assessment showed mild RV to pulmonary artery (PA) gradient across the conduit on low CPB flows. Review of the angiographic images to identify anatomical issues showed a small calibre left coronary system but normal anatomy. However, the left coronary artery patency could not be established beyond the bifurcation when probed. Hence, the RV –PA anastomosis was completely revised along with mobilization of the posterior adhesions,that resolved the VF, as the left coronary artery patency was re-established.
Conclusions: 1. Redo cardiac surgeries could compromise coronary circulation through adhesions even if the anatomical substrate does not have coronary anomalies.
2. Coronary hypo perfusion as an aetiology should always be sought in the context of prolonged refractory VF 3. Anatomical revision of the surgical repair may be required to mitigate refractory VF in some patients.

P2243 - CUSTODIOL FOR MYOCARDIAL PROTECTION FOR THE ARTERIAL SWITCH OPERATION RETROSPECTIVE ANALYSIS IN A SINGLE CENTER

Andrea Dolcino, Cristian Mirabile, Vanessa Lopez, Margaux Pontailler, Olivier Raisky, Mirella Bojan
Necker, PCICU, Paris-France

Background: Over 30% of the European pediatric cardiac surgery centers use cold Histidine-tryptophane-ketoglutarate (Custodiol) cardioplegia1. Neonatal procedures often imply aortic division, however repeated ostial canulation may cause intimal insult and affect long-term results. Custodiol cardioplegia is appealing since it has been suggested that a single-dose of cold Custodiol is safe for long aortic cross-clamping durations in infants2. Since cardiac troponins are specific markers of myocardial damage3, we thought investigate the association between myocardial no-flow duration and postoperative troponins in neonates undergoing the arterial switch operation with Custodiol cardioplegia.
Methods: 50 ml/kg Custodiol were administrated at 4 °C in the aortic root at cross-clamping, and repeated whenever judged necessary by the attending surgeon. High-sensitivity troponin was monitored postoperatively. The relationship between the longest myocardial no-flow duration per patient, i.e. the longest duration between two cardioplegia administrations and/or aortic unclamping, and the troponin concentration-time integral within 48 hours of surgery was analyzed using linear models stratified according to the coronary pattern.
Results: 101 patients were analyzed: age 6.0 ± 5.4 days, weight 3.7 ± 4.7 kg, cardiopulmonary bypass (CPB) duration 110.2 ± 53.2 min, cross clamping duration 75.3 ± 19.1 min, temperature during cross-clamping 31.2 ± 1.6 °C, duration of mechanical ventilation 5.9 ± 8.9 days, ICU stay 8.7 ± 9.5 days, 33

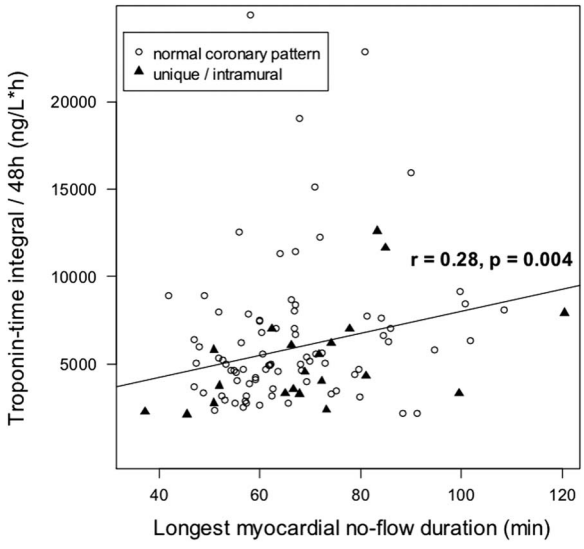

Figure.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

had delayed sternal closure, 1 required ECMO and died. The longest myocardial no-flow duration ranged 37-120 min, mean 67.2 ± 15.3 min, 26 patients had several cardioplegia administrations. Postoperative troponin peaked at 12565.3 ± 8994.8 ng/L. The longest myocardial no-flow duration was significantly associated with the troponin concentration-time integral ($R = 0.28$, $p = 0.004$), regardless of the coronary anatomy, the CPB duration and temperature, and with the need for delayed sternal closure ($p = 0.003$), but not with other outcome variables.
Conclusion: These results suggest that there is a risk of myocardial damage when single-dose Custodiol is used for long cross-clamping durations in neonates. 1.JECT 2012:186; 2.AFAR 2011: S17; 3.Eur Heart J 2000:1502.

P2400 - INCREASED LACTATE LOAD OF OLDER RED BLOOD CELL PREPARATIONS INCREASES BLOOD LACTATE CONCENTRATIONS IN INFANTS DURING CARDIAC SURGERY

Laetitia Desplanques[1], Cristian Mirabile[1], Paola Burgos[2], Tiffany Tourneur[2], Laurent Tourneur[2], Ilham Berkia[2], Souha Albinni[3], Mirela Bojan[1]
Necker-Enfants Malades University Hospital, Anesthesiology and Critical Care, Paris-France[1]; Necker-Enfants Malades University Hospital, Pediatric Cardiac Surgery, Paris-France[2]; Necker-Enfants Malades University Hospital, Blood Bank, Paris-France[3]

Background: The 2016 update of the red blood cell transfusion guidelines recommend the use of packed red blood cells (RRBC) selected at any point within their licensed dating period in all patients, including neonates1. Whereas the update included exclusively trials in premature neonates with reduced transfusion requirements, infants require massive transfusions during cardiopulmonary bypass (CPB). Older PRBCs contain high lactate concentrations, and there is evidence of slower lactate metabolism during CPB2. Since hyperlactatemia during CPB is considered to be an early and specific indicator of tissue hypoxia, it has become a major tool for hemodynamic monitoring and therapeutic guidance3. We thought investigate the relationship between PRBCs age and lactatemia during CPB in small infants.
Methods: During three month were explored the relationships between the PRBCs age, lactate concentration, and lactatemia on bypass in consecutive infants. Haematocrit was maintained >35% and venous saturation (SvO2) was maintained >70%. Data are shown as medians and interquartile ranges. Analyses used the Mann-Whitney test and linear regression.
Results: In 135 PRBCs, the PRBCs age (3-25days) correlated significantly with the lactate concentration (7.6-23 mmol/L), $r = 0.71$, $p < 0.01$. In 21 infants weighting <5 kg, aged 8 days [3-19], the prime volume was 218 mL [199-228], CPB duration was 169 min [128-274], CPB temperature was 32.8 °C [31.9-34.2], the duration of SvO2 excursions below 70% per patient was 0.5 min [0-3.4]. When compared with patients having received PRBCs <5days, patients having received PRBCs ≥5days had higher lactate concentrations in the prime 2.5 mmol/L [2-2.7] vs 1.6 mmol/L [1.5-1.7], $p = 0.04$ and at the end of CPB, 5.4 mmol/L [4.4-6.5] vs 2.7 mmol/L [1.8-2.8], $p < 0.001$, regardless of CPB duration, temperature, estimated patient blood volume or duration of SvO2 excursions below 70%.
Conclusion: When administered during CPB in small infants, PRBCs ≥5days represent a potential source of hyperlactatemia, and could lead to unnecessary and/or deleterious therapeutic interventions. 1. JAMA,2016:2025; 2. ICM,2003:1279; 3. ICM,2005:98

P2484 - CLINICAL OUTCOMES WITH THE USE OF LEVOSIMENDAN IN PATIENTS WITH HYPOPLASTIC LEFT HEART SYNDROME BROUGHT TO NORWOOD PROCEDURE

Maria Constanza Basto-Duarte[1], Claudia Ximena Flores-Rodriguez[2], Anderson Bermon[3], Sara E Mendoza-Crespo[4]
Fundación Cardiovascular De Colombia, Cardiac Surgery, Bucaramanga-Colombia[1]; Fundación Cardiovascular De Colombia, Cardiology, Bucaramanga-Colombia[2]; Fundación Cardiovascular De Colombia - Phd Student Ces, Research, Bucaramanga-Colombia[3]; Fundación Cardiovasular De Colombia, Cardiac Surgery, Bucaramanga-Colombia[4]

Introduction: Hypoplastic left heart syndrome (HLHS) can cause approximately 23% of all cardiac deaths in the first week of life and 15% in the first month, making it a strong morbidity and mortality indicator in specialized centers. Levosimendan, due to its inodilatory characteristics without increasing oxygen consumption, has been widely used in the adult population in high risk patients for cardiac surgery. Even though its use in children has been limited, given the physiological characteristics of HLHS, levosimendan arises as a possible inotropic alternative in the management of these patients.
Materials and Methods: Retrospective and descriptive study in a fourth level center in Colombia. Inotropic management (milrinone + adrenaline) was compared with (Levosimendan + adrenaline), initiated in the perioperative period. 30-day mortality and hospital discharge, as well as the clinical outcomes given by length of stay in the ICU, hospital stay, mechanical ventilation time, neurological compromise, need for ECMO, and renal failure were analyzed.
Results: Between January 2009 and December 2015, 55 patients diagnosed with HLHS were taken to Norwood procedure with pulmonary systemic shunt or RV-PA shunt, 17 (31%) patients received levosimendan and 38 (69%) received milrinone (Table 1). When comparing the two managements, the levosimendan group had an in-hospital mortality of 17.7% Vs 50% (p 0.036) and a decrease in the presence of postoperative renal failure 23.5% vs. 54.1% (p 0.036). No differences were found in 30-day mortality (p0.303) and in the clinical outcomes analyzed (Table 2).
Conclusions: In our study, levosimendan appears to be an alternative for inodilator management in the peri and postoperative period of HLHS patients undergoing Norwood procedure because it was found to significantly reduce the presence of postoperative renal failure and mortality.

P2509 - ROLE OF ROTEM IN BLOOD PRODUCT TRANSFUSION IN NEONATE ON ECMO UNDERGOING CONGENITAL DIAPHRAGMATIC HERNIA REPAIR

Satish Kumar Reddy Challa[1], Sudeep Saxena[2], Hee Hwan Ing[1]
KK Women's and Children's Hospital, Paediatric Anaesthesia, Singapore-Singapore[1]; Ministry of Health Holding, Anaesthesiology, Singapore-Singapore[2]

Congenital diaphragmatic hernia (CDH) is a rare congenital anomaly. Due to the hypoplastic lungs and severe pulmonary hypertension, frequent usage of extracorporeal membrane oxygenation (ECMO) is deemed essential for sustenance of the neonate. However, during surgical intervention, life threatening bleeding can occur in such patients. We present a case report of a neonate who underwent CDH repair with undergoing ECMO support, emphasizing the role of rotational thromboelastometry (ROTEM) in bed side checking coagulation profile and facilitating transfusion of blood products immediately.

Methods: The neonate was antenatally diagnosed having isolated CDH. He was delivered by normal vaginal delivery and was put on ECMO on day two after birth. Primary repair of CDH was planned in neonatal intensive care unit as no improvement was reported in physiological condition, with persistent poor lung to head ratio despite being on 100% oxygen.

Results: The neonate was on constant heparin infusion to maintain ECMO. Intraoperatively ROTEM system was used to check coagulation level effectively in rapidly changing haemodynamic status. Blood products were transfused according to the ROTEM result interpretation. The coagulation profile was monitored intermittently by the laboratory to validate ROTEM results. Total of more than seven hundred millilitre of blood products were transfused in a 2.96 kilogram neonate intraoperatively during 6 hours of operation.

Conclusion: This is the first neonatal non-cardiac surgery to the best of our knowledge where ROTEM was utilized to efficiently manage the coagulation profile in a neonate with so much amount of blood products transfused intraoperatively for CDH repair. The perioperative coagulation parameters remained in accordance with the laboratory results. Disclosure of Interest: None declared.

P2524 - EARLY SURGICAL OUTCOME OF PEDIATRIC TETROLOGY OF FALLOT SURGERY IN INDIAN POPULATION; A SINGLE CENTRE ANALYSIS

Srinath Damodaran, Rajarajan Ganesan, Ganesh Kumar Munirathinam, Goverdhan Dutt Puri
Pgimer, Cardiac Anaesthesia, Chandigarh-India

Background: Tetrology of fallot (TOF) is the most common cyanotic congenital heart disease. Management of total surgical correction of the tetrology patients remains challenging during the perioperative period in developing countries. Variability in early surgical outcome in tetrology patients in developing countries could be because of late presentation, surgical factors, associated anomalies, infections and economic factors. The aim of this study was to determine the early in-hospital mortality after TOF surgery and to identify the factors associated with adverse outcome in the early postoperative period.

Methods: This retrospective study involved 207 TOF patients who underwent surgery over a period of two years in a tertiary hospital in India.Age, sex, demographics, type of surgery, additional intraoperative echo findings, early postoperative mortality, duration of mechanical ventilation, duration of ICU stay and postoperative complicationswere recorded and analysed.

Results: In our centre, TOF surgical patients represented 21.75% of overall paediatric congenital heart surgery. Among the TOF patients who underwent surgery, two-third of patients were male. The mean age for shunt surgery and total intracardiac repair were 8 months and 7 years respectively. The overall surgical mortality in TOF patients was 10.6%. While mortality that occurred in shunt surgeries was 27.27%, total intracardiac repair patients had 7.4% early in-hospital mortality. Non-survivors in total intracardiac repair patients had higher aortic cross clamp time, bypass time and prolonged intensive care stay. Major aorto-pulmonary collaterals were present in 6% of patients. Junctional ectopic tachycardia (JET) remains the most common complication in the post operative period.

Conclusion: Late presentation for surgery, shunt surgeries in neonatal period, prolonged bypass time, prolonged cross clamp time and prolonged ICU stay were the factors associated with higher early surgical mortality in TOF patients in the Indian subcontinent.

P2536 - BENEFITS OF USING MICROCUFFED TRACHEAL TUBE IN PATIENTS UNDERGOING CONGENITAL CARDIAC SURGERIES EVIDENCE FROM A PROSPECTIVE RANDOMIZED STUDY

Chandan Kumar Mandal[1], Rakesh Chand[1], Saibal Roychowdhury[1], Pradeep Narayan[2], Emmanuel Rupert[1]
R.N.Tagore International Institute of Cardiac Sciences, Anaesthesia, Kolkata-India[1]; R.N.tagore International Institute of Cardiac Sciences, Cardiac Surgery, Kolkata-[2]

Background: It has been suggested that compared to conventional uncuffed tubes, high volume-low pressure microcuffed tracheal tubes in smaller children are beneficial. However, there is paucity of evidence of its usage in children undergoing congenital cardiac surgery. Aim of this study was to assess if microcuffed tracheal tubes in neonates and younger children undergoing congenital cardiac surgery is associated with better outcomes than uncuffed tubes.

Methods: We carried out this single centre, prospective, double blinded randomized study between June and November 2016. 80 patients were randomized into those receiving microcuffed tracheal tubes and conventional uncuffed tubes. Primary outcome

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

was post-extubation stridor. Secondary outcomes measured included number of tube changes, volume of anaesthetic gases required and cost incurred.
Results: The 2 groups were comparable in terms of baseline characteristics and duration of intubation.Incidence of stridor was significantly higher in conventional uncuffed tubes (12(30%) vs 4 (10%), $p = 0.04$) and so was the the number of tube changes required (17/40 (42.5%) vs. 2/40(5%); $p = < 0.001$). Tube change was associated with more than three-fold risk of stridor (odds ratio 3.92 (95% CI 1.23-12.43). Isoflurane (29.14 ± 7.01 ml vs 19.2 ± 4.81 ml; p value < 0.0001) and Oxygen flow requirement (p value <0.0001) and the resultant cost (p value <0.0001) were all significantly higher in the conventional uncuffed group.
Conclusion: Microcuffed paediatric tracheal tube is associated with significantly lower incidence of stridor, tube changes and anaesthetic gas requirement. This leads to significant cost-reduction that offsets the higher costs associated with usage of microcuffed tracheal tube.

P2750 - MULTIDISCIPLINARY IMPLEMENTATION OF EVIDENCED BASED GUIDELINES FOR EXTUBATION IN THE OPERATING ROOM FOLLOWING PEDIATRIC CARDIAC SURGERY

Riad Lutfi[1], Abbasi Rania K[2], Benneyworth Brian[1], Walker Scott[2], Kleiman Zachary[2], Mastropietro Christopher W[1]
Riley Hospital For Children at Indiana University Health, Department of Pediatrics, Indianapolis-United States[1]; Riley Hospital For Children at Indiana University Health, Department of Anesthesiology, Indianapolis-United States[2]

Background: Extubation in the operating room (OR) following pediatric cardiac surgery has become commonplace in contemporary practice. Its benefits however must be measured against its risks, most notably of which is extubation failure. We conducted an evidence-based quality improvement initiative at our institution aiming to minimize complications associated with extubation in the OR in this patient population.
Methods: A multidisciplinary team created the following guidelines for extubation in the OR after pediatric cardiac surgery (based on current literature): age >1 month; STAT mortality category ≤4; no known airway anomaly; cardiopulmonary bypass duration <150 minutes; non-emergent procedure; no significant intraoperative bleeding or respiratory complications; and postoperative beta-agonist therapy limited to dopamine infusion ≤5 mcg/kg/min (based on institutional preferences). A quality improvement initiative using these guidelines was conducted between 1/2015-12/2016, and data from this period were compared to historical data from 1/2011-12/2014.
Results: From 2011-2014, we extubated 953 of 1989 patients in the OR (48%), of which 13 failed extubation (1.4%). In 2015-2016, we extubated 317 of 960 patients in the OR (33%), of which 3 failed extubation (0.9%). The observed decrease in the proportion of patients extubated in OR occurred primarily in STAT category 1 and 2 procedures (Table). In this subset, median duration of postoperative mechanical ventilation increased slightly, from 0 hours (25%,75%: 0-7 hours) to 1.7 hours (25%,75%: 0-24 hours).
Conclusions: During our evidence-based quality improvement initiative in children undergoing cardiac surgery, we minimized the occurrence rate of extubation failure in the ICU following extubation in the OR. The clinical significance of the concomitant decrease in OR extubation rate and increase in duration of mechanical ventilation associated with this initiative is unclear. Further work is needed to optimize the practice of extubation in the OR after pediatric cardiac surgery.

Table. Proportion of Patients Extubated in the Operating Room.

STAT Mortality Categories	2011-2014	2015-2016
1	360/480 (75%)	122/208 (59%)
2	288/523 (55%)	80/241 (33%)
3	60/197 (30%)	27/99 (27%)
4	42/270 (16%)	15/153(10%)
5	2/59 (3.3%)	1/28 (4%)

P2768 - IMPACT OF ANESTHETIC MANAGEMENT DURING DIAGNOSTIC CATHETERIZATIONS PERFORMED IN SINGLE VENTRICLE PATIENTS PRIOR TO STAGE II PALLIATION

Issac Davidovich[1], Ryan Romans[2], Olubukola Nafiu[3], Jeffrey Zampi[2], Nicole Wilder[3]
Beaumont, Anesthesiology, Royal Oak-United States[1]; University of Michigan, Cardiology, Ann Arbor-United States[2]; University of Michigan, Anesthesiology, Ann Arbor-United States[3]

Background: Diagnostic cardiac catheterization plays a pivotal role in the assessment of a single ventricle (SV) infant's physiologic status prior to stage II palliation and wide variability in practice patterns exists. We sought to compare the safety and efficacy of sedation management strategies during the pre-stage II catheterization.
Methods: We performed a single center retrospective cohort study of SV infants undergoing pre-stage II catheterization between 2010-2015. Safe anesthesia was defined by absence of cardiac or respiratory events within 24 hours of the procedure and no need for post-catheterization ICU admission. Effective anesthesia was defined by stable hemodynamics (<2 episodes of heart rate increase requiring anesthetic boluses) and no need to convert from sedation to general anesthesia. Multivariate logistic regression models were utilized to compare results.
Results: Among 90 SV infants sedated for diagnostic pre-stage II catheterization, the anesthetic was safe in 72 (80%) and effective in 49 (54%), while 8 (89%) required conversion to general anesthesia. Demographics and perioperative variables are detailed in Table 1. All infants received dexmedetomidine infusions and 96% received midazolam. Fentanyl and ketamine were the next most commonly employed medications with less frequent boluses of propofol, morphine, and diphenhydramine. A safe anesthetic was independently associated with higher baseline weight and baseline Sa02, while negatively associated with cardiologist #2 (Table 2). An effective anesthetic was independently associated with higher weight (Table 3). There were no differences in remaining baseline demographics, procedural duration, cardiologists or anesthesiologist years of experience. Safe and effective anesthetic management was associated with a ketamine loading dose of >0.5 mg/kg and infusion, and independently associated with higher weight, while negatively associated with cardiologist #2 (Table 4).
Conclusions: Safe and effective sedation can be performed on SV infants undergoing pre-stage II catheterization with utilization of anesthetic medications that do not depress respiration.

P2831 - EFFECT OF AGE OF BLOOD AND PRIME LACTATE LEVEL ON THE PERIOPERATIVE OUTCOME IN CHILDREN UNDERGOING COMPLEX CONGENITAL HEART SURGERY

Muthukumar Sivasubramanian[1], *Periyasamy Thangavel*[1], *Ramkumar Shanmugasundaram*[1], *Ranjith Karthekeyan*[2], *Ramkumar Jeyavelan*[1]
Sri Ramachandra University, Cardiothoracic Surgery, Chennai-India[1]; *Sri Ramachandra University, Cardiac Anesthesia, Chennai-India*[2]

Aim: To Study The Effect of Age of Blood and Prime Lactate on the Perioperative Outcome in Children Undergoing Complex Congenital Cardiac Surgery.
Methods and Materials: Sri Ramachandra Medical Centre ethical committee permission was obtained before the study. Patients who were undergoing Complex Congenital Heart Disease From January 2012 to December 2013, 54 were retrospectively selected for this study. These 54 patients were divided into 2 groups depending upon the age of the blood they were subdivided into Group A(≤3 days) and Group B (>3 days) and depending upon the prime lactate values. Group I (≤10 mmol/l) and Group II (>10 mmol/l).
Inclusion Criteria: Patients of either sex, Patient age ≤10 years, patients with complex congenital cardiac disease.
Exclusion Criteria: Patients age >10 years and patients who had plasma as prime.
Conclusion: The storage time of RBCs deleteriously determine the postoperative morbidity of patients in terms of renal parameters. The increase in the prime lactate also significantly contributes to the elevated renal parameters and bilirubin with poor neurological outcome. This study has proven it significantly. Hence, the use of the freshest possible blood is suggested for CPB priming and maintaining the prime lactate as low as possible to avoid morbidity.

P2870 - SURGICAL OUTCOME OF THE VENTRICULAR SEPTAL DEFECT REPAIR WITH SEVERE PULMONARY HYPERTENSION IN TERTIARY CARE HOSPITAL IN INDIA

Srinath Damodaran[1], *Rajarajan Ganesan*[1], *Anjali V*[2], *Seshagiri Babu*[2], *Goverdhan Dutt Puri*[1]
Pgimer, Cardiac Anaesthesia, Chandigarh-India[1]; *Pgimer, Anaesthesia, Chandigarh-India*[2]

Background: Surgical closure of ventricular septal defect (VSD) is the most common acyanotic congenital heart surgery in pediatric patients. The nature of complications and outcomes in VSD patients with severe pulmonary hypertension (PH) undergoing surgery varies in developing and developed countries. The main purpose of this study was to determine the early outcome in VSD patients with severe PH during perioperative period.
Methods: This retrospective review included 35 pediatric patients of VSD with severe PH that were surgically treated for correction between January 2016 and December 2016. Age at time of surgery, sex, type of defect, pulmonary arterial pressure, shunt direction, ratio of blood flow in pulmonary circulation to systemic circulation (QP; QS), duration of mechanical ventilation, and duration of stay in the intensive care unit (ICU), complications and mortality during perioperative period were noted and analyzed.
Results: VSD patients with severe PH constituted 22.5% of overall VSD with equal gender distribution. The overall mortality occurred in cohort was 8.57%. The median age at which patients were operated was 3.5 years. The average mechanical ventilation and intensive care stay were 12 hours (IQR: 2–98) and 5 days (IQR: 1-18), respectively. Of the 35 patients, 3 patients had bidirectional shunt, which was incidentally diagnosed during

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

perioperative period with all three patients had QP:QS ratio more than two. Among the three patients with bidirectional shunt, one patient developed congestive cardiac failure in the immediate post operative period. Overall, 14.5% had CCF during perioperative period.
Conclusion: We concluded that VSD with severe PH continues to be a major cause of postoperative morbidity and have increased the duration of mechanical ventilation and ICU stay in these patients in developing countries. Advances in the management of PH during perioperative period drastically reduced the mortality in these patients over the past few years.

P2918 - THE USE OF SOMATOSENSORY EVOKED POTENTIAL (SSEP) AND ELECTROMYOGRAPHY (EMG) MONITORING TO DESCRIBE BRACHIAL PLEXUS AND FEMORAL NERVE CHANGES DURING CARDIAC CATHETERIZATION PROCEDURES IN CHILDREN

Mark Twite[1], *Richard Ing*[1], *Willy Boucharel*[2]
University of Colorado, Anesthesiology, Aurora-United States[1]; *University of Colorado, Neuromonitoring, Aurora-United States*[2]

Introduction: Children with congenital heart disease frequently require cardiac catheterization procedures and common to almost all procedures are the need for femoral vessel access and positioning the arms above the head. These procedures in children often last a long time, typically 4 to 6 hours, due to the complexity of their congenital heart disease and the difficulties in obtaining vascular access. Thus, many children undergoing cardiac catheterization require general anesthesia to tolerate the procedure and remain immobile, so optimal images and data can be obtained. Peripheral nerve injury may mar an otherwise successful cardiac catheterization and result in a potentially disabling injury for the patient and litigation involving the health care team. Examination of the American Society of Anesthesiologists Closed Claims Database showed that 16% of all claims in adults were related to nerve injury. The most frequent sites of injury were the ulnar nerve (28%) and brachial plexus (20%). Many patients with congenital heart disease now survive to adulthood and this patient population may be at particular risk of brachial plexus injury during cardiac catheterization procedures. There are several reports of brachial plexus injury during cardiac catheterization in children but no reports of using SSEP monitoring to detect brachial plexus changes or EMG to record inadvertent femoral nerve puncture during a cardiac catheterization procedure.
Study Aims: This single center prospective study aims to:

- Describe changes in the SSEPs in the brachial plexus during cardiac catheterization procedures
- Describe changes in EMG activity recorded over the quadriceps related to inadvertent femoral nerve puncture
- Determine if SSEP changes are clinically important for patients and if monitoring technology may be a useful tool to prevent nerve injury in patients.

Results: 42 children were successfully enrolled into the study and the data will be presented for the first time at WCPCCS.

P2930 - "ON THE TABLE" EXTUBATION IMMEDIATELY AFTER PEDIATRIC AND CONGENITAL HEART SURGERY

Vyas Kartha, Md[1], *Gerson Rodriguez, Md*[1], *Esteban Lugo, Md*[1], *Christopher Sutton, Md*[1], *James Quintessenza*[2], *Tom Karl, Md*[1], *Plato Alexander, Md Mba*[3], *Devendra Amre, Mbbs Phd*[4], *Jeffrey Jacobs, Md*[1]
John Hopkins All Children, Surgery, St. Petersburg-United States[1]; *Cchmc/Kentucky Children's Hospital, Surgery, Lexington-United States*[2]; *John Hopkins All Children, Critical Care, St. Petersburg-United States*[3]; *John Hopkins All Children, Pediatrics, St. Petersburg-United States*[4]

Background: "On the Table" extubation immediately after pediatric and congenital heart surgery ("immediate extubation" [IE]) has been described as safe and cost effective in adult patients undergoing open heart surgery. Early extubation (EE), or extubation within 6 hours after the operation, has shown a decrease in postoperative length of stay in patients having Tetralogy of Fallot repair and the Fontan operation. We reviewed our experience with IE after pediatric and congenital heart surgery, comparing our rates of IE to the national aggregate rates documented in the Society of Thoracic Surgeons Congenital Heart Database (STS CHD).
Method: We performed a retrospective review of all patients who underwent open heart surgery at a single institution between January 2010 and December 2016. Rates of IE were calculated for our patients stratified by age groups and STAT Mortality Categories, and these rates were compared to national aggregate data.
Results: Table 1 documents rates of IE stratified by age groups and STAT Mortality Categories, for our patients and for national aggregate data.
Conclusion: IE after pediatric and congenital heart surgery can be accomplished safely in selected patients across all ages, from neonates (sparingly) through adulthood (usually), and across all STAT Categories, although only sparingly for STAT Category 5. This strategy represents an opportunity for reducing postoperative length of stay and cost.

Table 1. Immediate extubation(IE) rates in the JHACH cohort (N = 1528) and comparison with the entire STS cohort (N = 60394).

Characteristic	JHACH	Entire STS
Extubation		
IE	1015/1528 (66.6%)	12099/60394 (20%)
IE according to age		
Neonates	47/294 (15.9%)	417/13918 (3.0%)
Infants	360/523 (68.8%)	2644/20378 (13.0%)
Children	510/584 (87.3%)	7758/22468 (34.5%)
Adults	98/122 (80.3%)	1280/3629 (35.2%)
IE according to STAT		
1	368/419 (87.8%)	5177/15296 (33.8%)
2	467/564 (82.8%)	4861/19236 (23.3%)
3	51/116 (43.9%)	780/6280 (12.4%)
4	97/296 (32.8%)	787/11706 (6.7%)
5	4/93 (4.3%)	97/2373 (4.1%)

P1020 - LATE POST OPERATIVE ARRYTHMIA AT TOTAL ANOMALOUS PULMONARY VENOUS CONNECTION

Danielle Lilia Dantas Tukamoto[1], *Moacir Fernandes De Godoy*[2], *Carlos Henrique De Marchi*[3], *Ulisses Alexandre Croti*[1], *Zilma Vercosa De Sá Ribeiro*[4], *Kenji Barbosa Tukamoto*[5]
HCM/FAMERP, Pediatrics, São Jose Do Rio Preto-Brazil[1]; *Famerp, Cardiology, São Jose Do Rio Preto-Brazil*[2]; *FAMERP, Pediatrics, São*

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Jose Do Rio Preto-Brazil[3]; Ufba, Pediatrics, Salvador-Brazil[4]; HB/ FAMERP, Cardiology, São Jose Do Rio Preto-Brazil[5]

Introduction: The frequency of events of anomalous pulmonary venous connection (APVC) varies in the different series from 5.9 to 7.1 / 100 000 live births, representing 1 to 5% of cases of congenital heart disease. Since the current care has develope, the need to approach possible late complications, such as arrhythmias, is important.
Objective: To evaluate the distribution of arrhythmias and possible related variables in patients in the late postoperative APVC.
Method: Medical record review and clinical and noninvasive arrhythmia evaluation were used for data analysis of 20 patients who underwent isolated APVC. Statistical analysis for the detection of related variables.
Results: Clinical and echocardiographic evaluations showed no significant changes. Of the 20 patients, 13 (65%) showed some abnormalities for age according to the 12-led EGC. By Holter, six patients (30%) presented atrial and/or ventricular ectopy with higher frequency than mild. Junctional rhythm and 2: 1 atrioventricular occurred in one patient (5%). Analyzing the criteria for sinus node dysfunction, bradycardia was observed by Holter in 30% of the patients. There were no pauses longer than two seconds. By Ergometric test, 82% of children had chronotropic deficit. Follow-up more than 60 months and abnormal ECG were related to the presence of arrhythmias.
Conclusion: The long term follow-up of patients undergoing anomalous pulmonary venous connection showed that regardless of the good clinical and echocardiographic results, the possibility of occurrence of atrial and/or ventricular arrhythmias highlight attention to the need for maintenance of regular clinical evaluations.

P1023 - A GIANT LEFT VENTRICLE ANEURYSM IN A 12 YEAR OLD MALE CHILD

Justine Iris Yap
University of the Philippines - Philippine General Hospital, Pediatric Cardiology, San Fernando-Philippines

Left ventricle aneurysm is a rare finding in children. We report a case of a 12 year old male who was brought to the emergency room for non-sustained ventricular tachycardia. He was previously diagnosed with Rheumatic Heart Disease but additional imaging studies (Transthoracic Echocardiogram and Chest CT scan) revealed a giant LV aneurysm. The patient was started on anticoagulation therapy due to the risk of thromboemboli and was given medication for left ventricular systolic dysfunction, in preparation for elective surgery. An endoventricular repair technique under cardiopulmonary bypass was done to repair the LV after removing the aneurysm. This was noted to be adherent to pericardium with neovascularization. An intraoperative transesophageal echocardiogram showed significant decrease in LV end diastolic dimension size from 6 cm to 4.8 cm, with moderate mitral regurgitation, sinus rhythm, with good LV contractility post repair. His post-operative rhythm was sinus, with no recurrence of VT. Histologic examination revealed a non-specific inflammatory process. Immediate postoperative course was uneventful and our patient was discharged after four days. On follow-up, a repeat TTE showed improved LV contractility with mild mitral regurgitation and remained sinus rhythm on ECG. Patients with a LV aneurysm are at potential risk for life-threatening ventricular tachyarrhythmias which may sometimes occur as the first clinical presentation. This can be reliably diagnosed with modern diagnostic imaging. The etiology of which is still mostly infectious in children. Successful surgical repair using standard operative techniques can be done which render excellent post-operative outcomes.
Key words: LV aneurysm, endoventricular repair, ventricular tachycardia

P1026 - RATE CONTROL BY TRANSOESOPHAGEAL ATRIAL QVERDRIVE PACING FOR REFRACTORY SUPRAVENTRICULAR TACHYCARDIA WITH SEVERE VENTRICULAR DYSFUNCTION – A BRIDGE TO RECOVERY

Christian Paech[1], Jan Janousek[2], Franziska Wagner[1], Roman Gebauer[1]
Helios Heart Center Leipzig, Pediatric Cardiology, Leipzig-Germany[1]; Charles University in Prague and Motol University Hospital, Pediatric Cardiology, Prague-Czech Republic[2]

Introduction: Tachyarrhythmia-induced cardiomyopathy (TIC) is a rare yet life-threatening phenomenon in children. TIC has been defined as myocardial dysfunction that is entirely or partially reversible after control of the responsible tachyarrhythmia and is typically caused by an incessant supraventricular tachycardia. In cases of unsuccessful termination of the tachycardia cardiogenic shock may occur. Several authors favour the use of mechanical circulatory support in such cases. In view of these partly severe cases the authors would like to present the option of transoesophageal overdrive pacing (TOP) as a tool for initial heart rate control and hemodynamic stabilization of patients with TIC refractory to conventional strategies of tachycardia termination.
Methods: Chart review for patients receiving TOP during the last 5 years in two centers was performed.
Results: A case series of successful TOP including technique and outcomes is depicted.
Conclusion: Rate control through TOP is a safe and effective option to restore acceptable hemodynamics in infants with refractory supraventricular tachycardia and severe impairment of ventricular function. It presents the possibility of immediate heart rate control and offers time for myocardial recovery and safe implementation of antiarrhythmic drug therapy.

P1088 - MEASURES OF HEART RATE VARIABILITY DEPEND ON AGE OF HEALTHY CHILDRENINTRODUCTION HEART RATE VARIABILITY (HRV) IS THE PHYSIOLOGICAL PHENOMENON CAUSED BY CHANGES OF DURATION BETWEEN CONSECUTIVE CARDIAC CYCLES OF SINUS ORIGIN. HRV HAS A PROVEN CLINICAL AND PHYSIOLOGICAL VALUE IN ADULTS FOR EXAMPLE FOR THE DIAGNOSIS OF DIABETIC AUTONOMIC NEUROPATHY SELECTION OF HIGH RISK POST INFARCTION PATIENTS OR PEOPLE UNDER INCREASED EMOTIONAL

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Heart rate variability (HRV) is the physiological phenomenon caused by changes of duration between consecutive cardiac cycles of sinus origin. HRV has a proven clinical and physiological value in adults, for example for the diagnosis of diabetic autonomic neuropathy, selection of high-risk post-infarction patients or people under increased emotional stress. In general, many HRV parameters become reduced with advancing age in adults, however data on the association between age and HRV are sparse in children. In this study we examined the correlation between the age of healthy children and selected measures of HRV in 24-hour ECG Holter recordings.
Material and methods: One hundred healthy children (51 girls), aged 3-18 years old, underwent 24-hour ECG Holter recording (Schiller Medilog Darwin, Switzeland) . After a detailed analysis, all cardiac cycles (RR intervals) with an annotations about the beat type were exported and analyzed with in-house software with the use of Lomb periodograms and the Poincaré plots analyses. The association between age and HRV parameters was analyzed with the nonparametric Spearman test.
Results: There were significant and positive correlations between children's age and the mean duration of RR interval ($r = 0.55$; $p < 0.0001$), the power of ultralow (ULF; $r = 0.42$; $p < 0.0001$), very low (VLF; $r = 0.35$; $p = 0.0004$) and low frequency (LF; $r = 0.3$; $p = 0.0028$), a measure of total HRV (SDNN; $r = 0.33$; $p = 0.0008$) and long-term HRV (SD2; $r = 0.37$; $p = 0.0002$). Neither the power of high frequency (HF) nor the measure of short-term HRV (SD1) were significantly correlated with age.
Conclusion: We show that most HRV measures derived from the 24-hour ECGs are significantly related to the age of healthy children. HRV indices which describe ultralow, very low and low frequency oscillations or total and long-term variability increase with age while HRV parameters related to either high frequency or short-term HRV are not dependent on age. The physiological and clinical value of our findings requires.

P1089 - HEART RATE ASYMMETRY IS PRESENT IN HEALTHY CHILDREN.INTRODUCTION HEART RATE ASYMMETRY (HRA) IS THE PHYSIOLOGICAL PHENOMENON CAUSED BY AN UNEQUAL CONTRIBUTION OF HEART RATE DECELERATIONS AND ACCELERATIONS TO DIFFERENT FEATURES OF HEART RATE VARIABILITY AND STRUCTURE. SO FAR HRA HAS BEEN DESCRIBED IN ECGS OF DIFFERENT LENGTH FROM 1 MINUTE TO 24 HOUR ONLY IN ADULTS BUT NOT IN CHILDREN. IN THIS

Magdalena Stefaniak[1], Waldemar Bobkowski[1], Katarzyna Gendera[1], Tomasz Krauze[2], Jaroslaw Piskorski[3], Przemyslaw Guzik[2]
Department of Pediatric Cardiology Poznan University of Medical Sciences, Poznań, Poland, Department of Pediatric Cardiology Poznan University of Medical Sciences, Poznań, Poland, Poznan-Poland[1]; Department of Cardiology- Intensive Therapy and Internal Diseases Poznan University of Medical Science, Poznań, Poland, Department of Cardiology- Intensive Therapy and Internal Diseases Poznan University of Medical Science, Poznań, Poland, Poznan-Poland[2]; Institute of Physics, University of Zielona Gora, Zielona Gora, Poland, Institute of Physics, University of Zielona Gora, Zielona Gora, Poland, Poznan-Poland[3]

Heart rate asymmetry (HRA) is the physiological phenomenon caused by an unequal contribution of heart rate decelerations and accelerations to different features of heart rate variability and structure. So far HRA has been described in ECGs of different length from 1-minute to 24-hour only in adults but not in children. In this study we examined whether HRA is present in healthy children in 24-hour ECG Holter recordings.
Material and Methods: One hundred healthy children (51 girls), aged 3-18 years old, underwent 24-hour ECG Holter recording (Schiller Medilog Darwin, Switzeland). After a detailed analysis, all cardiac cycles (RR intervals) with annotations about the beat type were exported and analyzed with in-house software to quantify the expression of various forms of HRA. To quantify the contribution of heart rate decelerations (d) the following parameters were applied: C1d for the short-term, C2d for the long-term, and CTd for the total HRA. Additionally, the departure of the proportions of different forms of HRA from 0.5 was analyzed with the binomial test. Expression of HRA is shown as mean + /- SD while proportions as a part of 1 and its 95% confidence interval (CI).
Results: Mean expression of C1d was 55.4 + /-4.1%, of C2d 47.2 + /-3.0% and CTd 47.7 + /-2.5% - these results show that heart rate decelerations have a larger contribution to the short-term (C1d) and smaller to the long-term (C2d) and total (CTd) heart rate variability. At the same time, the proportion of children with $C1d > 50\%$ was 0.94 (0.87-0.98; $p < 0.0001$), $C2d < 50\%$ was 0.86 (0.78-0.92; $p < 0.0001$) and CTd 0.86 (0.78-0.92; $p < 0.0001$) – these results show that different features of HRA are present in the majority of healthy children.
Conclusion: We show that short-term, long-term and total heart rate variability has asymmetrical features in 24-hour ECGs recorded in healthy children. This means that physiological phenomenon of heart rate asymmetry is present children.

P1119 - ARRHYTHMIAS IN ADULTS WITH CONGENITAL HEART DISEASE WHAT ARE RISK FACTORS FOR SPECIFIC ARRHYTHMIAS

Rohit Loomba, Matthew Buelow, Joshua Kovach, Salil Ginde
Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-United States

Background: An increasing number of patients with congenital heart disease are now surviving into adulthood. This has led to the emergence of complications from the underlying congenital heart disease, related surgical interventions, and associated combordities. While the prevalence of particular arrhythmias with specific congenital heart disease has been previously described, a detailed analysis of all lesions and a large number of comorbidities has not been previously published.
Materials and Methods: Admissions with congenital heart disease were identified in the National Inpatient Sample. Associated comorbidities were identified. Univariate analysis was done to compare those risk factors associated with specific arrhythmias in the setting of congenital heart disease. Next, regression analysis was done to identify what patient characteristics and comorbidities were associated with specific arrhythmias.
Results: A total of 52,725,227 admissions were included. Of these, 109,168 (0.21%) had congenital heart disease. Of those with congenital heart disease, 27,088 (25%) had an arrhythmia. The most common arrhythmia was atrial fibrillation which was noted in 86% of those with arrhythmia followed by atrial flutter which was noted in 20% with congenital heart disease. The largest burden of arrhythmia was found to be in those with tricuspid atresia with a 51% prevalence of arrhythmia, followed by Ebstein anomaly which had an arrhythmia prevalence of 39%. Increasing age, male gender, double outlet right ventricle, atrioventricular septal defect, heart failure, obstructive sleep apnea, transposition of the great arteries, congenitally corrected transposition, and tetralogy of Fallot were frequently noted to be independent risk factors for specific arrhythmias.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Approximately 25% of adult admissions with congenital heart disease are associated with arrhythmia. The burden of arrhythmia varies by the specific lesion and other risk factors as well. Understanding of these can help in risk stratification and can help devise strategies to lower this risk.

P1159 - PRENATAL DIAGNOSIS OF FETAL JUNCTIONAL ECTOPIC TACHYCARDIA USING MAGNETOCARDIOGRAPHY

S. Javed Zaidi[1], Saad Siddiqui[1], Janette F. Strasburger [2], Ronald T. Wakai[3]
Advocate Children, Pediatric Cardiology, Oak Lawn-United States[1]; Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-United States[2]; University of Wisconsin, Medical Physics, Milwaukee-United States[3]

Background: Fetal tachyarrhythmia, characterized by a sustained fetal heart rate (FHR) above 180 bpm may be poorly tolerated and cause ventricular dysfunction leading to heart failure and hydrops, and ultimately to fetal demise. We present the first case of fetal junctional ectopic tachycardia (JET) diagnosed in utero using fetal magnetocardiography (fMCG) and not associated with maternal SSA/SSB antibodies.
Methods: N/A
Results: The patient was first referred to us at 20 weeks gestation for non-variable fetal tachycardia (FHR 180 to 190 bpm) in an otherwise uncomplicated pregnancy. Extensive ascites, a small pericardial effusion, umbilical venous pulsations, and ductus venosus flow reversal were noted. The cardiovascular profile score was 6/10 (Huhta et al, 2006). The heart size and biventricular function were normal and no structural cardiac defects were noted. fMCG proved invaluable in our diagnosis as, despite suspicion, we were unable to document AV dissociation on fetal echocardiograms. There was primarily 1:1 retrograde VA conduction with rare complete VA dissociation. Fetal intervals from flat averages during JET were: RP 82 ms; QRS 34 ms; QTc 493 ms. During sinus rhythm on follow up, they were: PR 116 ms; QRS 60 ms; QTc 456 ms. Treatment (digoxin/sotalol, then amiodarone) was successful in completely reversing the fetal ascites prior to delivery with normalization of ascites, UV pulsations, and DV flow reversal which had been present since presentation.
Conclusion: Treatment of suspected JET at any rate associated with ascites or abnormal cardiovascular profile scores is advisable. Where available, fMCG can prove to be an invaluable resource in the diagnosis, assessment of medication cardiac effects in the fetus, and characterization during successful treatment of a variety of cardiac rhythm abnormalities, especially if the diagnosis remains unclear with standard imaging modalities.

P1176 - NITROUS OXIDE GENERAL ANESTHESIA IN PEDIATRIC ELECTROPHYSIOLOGY PROCEDURES IS SAFE AND EFFECTIVE FOR REVEALING THE CLINICAL ARRHYTHMIA

Bhavya Trivedi[1], Matthew Newbern[2], Danielle Blackham[1]
Florida Hospital For Children, Pediatric Cardiology, Orlando-United States[1]; Florida Hospital For Children, Anesthesia, Orlando-United States[2]

Background: During electrophysiology procedures, automatic atrial and ventricular arrhythmias, and sometimes AVNRT, can be suppressed by inhalation anesthetic agents such as sevoflurane. In pediatric patients, the option of moderate sedation is limited by patient acceptance and cooperation. In this study, we used nitrous oxide (N2O) in combination with versed and fentanyl (balanced technique) in cases where inhalation general anesthesia (GA) appeared to suppress clinical arrhythmia. N2O was chosen because of its sympathetic potentiation and absence of effect on cardiac conduction, and in most cases helped to reveal the clinical arrhythmia.
Methods: A retrospective review of 11 patients who underwent this GA technique was performed (May 2015 – July 2016). Patients were 11-19 years, with documented atrial tachycardia (AT), PVCs with high burden, AVNRT, or ventricular tachycardia (VT). In all cases anesthesia induction was with propofol, followed by conversion to balanced technique. Patients were monitored for anesthesia parameters and spontaneous occurrence of clinical arrhythmia, followed by standard EP testing and mapping/ablation.
Results: In 8 of 11 cases, N2O transition helped to reveal the clinical arrhythmia, which was initially suppressed (internal control). In six cases, the clinical arrhythmia was spontaneous after N2O transition, and inducible with stimulation protocols in the other cases. Arrhythmias included: AT (3), PVCs/VT (4), typical AVNRT (1). Ablation was successful in 6/8 cases, with arrhythmia mapping made possible by N2O transition in all cases. During the same time period, 6 patients underwent AT or VT/PVC ablation at our center where sevoflurane GA did not suppress the arrhythmia. The N2O technique provided stable hemodynamics and did not prolong emergence times. Post-op nausea and vomiting was seen in only 2 patients (16%).
Conclusions: In pediatric EP procedures where inhalational anesthetics suppress the arrhythmia, a balanced GA technique with N2O, fentanyl/versed is a safe and effective alternative to expose the clinical arrhythmia.

P1313 - CALMODULIN MUTATIONS CAUSE A SEVERE CLINICAL PHENOTYPE

Francesca Perin[1], Juan Jimenez Jaimez[2], Mercedes Cabrera Ramos[2], Maria Del Mar Rodríguez Vázquez Del Rey[1], Rosa Macías Ruiz[2], Miguel Álvarez López[2], Francisco J Bermudez Jimenez[2], Carmen Carreras Blesa[1], Concha Correa Vilches[3], Luis Tercedor Sánchez[2]
University Hospital Complex of Granada, Pediatric Cardiology Unit, Granada-Spain[1]; University Hospital Complex of Granada, Cardiac Arrhythmia Unit, Granada-Spain[2]; University Hospital Complex of Granada, Cardiology Service, Granada-Spain[3]

Background and Objectives: Cardiac channelopathies are inherited syndromes caused by mutations in genes encoding for ion channels, their subunits, or associated proteins that predispose the affected patient to arrhythmias, syncope and sudden death. Mutations in calmodulin, a ubiquitously expressed and essential calcium-signaling protein, have been recently associated with severe forms of Long QT Syndrome and Cathecolaminergic Polymorphic Ventricular Tachycardia, with life-threatening arrhythmias occurring at early age. Our aim here is to study the clinical behaviour of calmodulin mutations in a pediatric population with cardiac primary electrical disorders and compare it with channelopathies of a different genetic origin.
Methods: Children studied at our institution with a documented diagnosis of cardiac channelopathy that had been genetically tested were retrospectively included. For those without a previously identified genetic cause, CALM genes were sequenced. Clinical variables were collected and analyzed.
Results: 20 patients (mean age 11'5 ± 4'6 years) were included. 75% were male. Long QT Syndrome was the most prevalent diagnosis. 4 patients had an identified mutation in KCNQ1, 3 KCNH2, 2 SCN5A, 1 KCNJ2, 1 KCNQ1 + KCNH2, 3 in

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

ryanodine receptor RYR2, 2 in calsequestrin CSQ2. 3 patients had a mutations in CALM: in 2 cases N98S in CALM2, in 1 case a novel missense mutation E141K in CALM3 was identified. No genetic mutation could be found in 1 patient. Patients with CALM mutations had an earlier onset of the disease (3'6 ± 3'5 vs 7'6 ± 3'7, p = 0,013) with a poorer prognosis in terms of cardiac arrest (all 3 cases) and sudden death (2 of 3) compared to channelopathies of a different genetic origin. All the mutations in CALM were the novo, with both parents unaffected.
Conclusions: Our results confirm previous studies suggesting that calmoduline mutations can cause an unusually severe phenotype with high risk of sudden death and very early age of onset.

P1383 - REAL TIME THREE DIMENSIONAL ECHOCARDIOGRAPHY GUIDED ELECTROPHYSIOLOGICAL PROCEDURES IN PEDIATRIC PATIENTS

Christopher Ratnasamy[1], *Harikrishnan Kurup*[2], *Bennett Samuel*[1], *Joseph Vettukattil*[1]
Helen Devos Children's Hospital, Congenital Heart Center, Grand Rapids-United States[1]; *Sree Chitra Tirunal Institute For Medical Sciences and Technology, Cardiology, Trivandrum-India*[2]

Background/Hypothesis: Radiofrequency ablation of arrhythmogenic substrates is usually guided by three-dimensional (3D) electroanatomic mapping and fluoroscopy. Real-time 3D transesophageal echocardiography (RT3DTEE) has revolutionized interventional procedures by providing accurate visualization of various complex cardiac defects and intraprocedural guidance of catheters.
Materials and Methods: A 13-year-old female (Case 1) with Wolff-Parkinson-White syndrome and ventricle dysfunction due to right lateral accessory pathway; a 14 (Case 2) and 16-year-old male (Case 3) with incessant ectopic atrial tachycardia localized to the left atrial appendage (LAA); a 17-year-old male (Case 4) with atrial tachycardia arising from the aortic mitral continuity; and a 17-year-old male (Case 5) with ventricular tachycardia arising from the perimembranous septum underwent electrophysiological studies under RT3DTEE guidance. In another 17-year-old female presenting with intraatrial reentrant tachycardia status post Fontan procedure, RT3DTEE was used in conjunction with 3D electroanatomic mapping (Case 6).
Results: Visualization of the arrhythmogenic focus was enhanced by RT3DTEE and was useful in catheter positioning. The arrhythmogenic foci were successfully ablated in Case 1 and 3-6. Although the focus of the arrhythmia was accurately identified in Case 2, ablation was not successful due to its epicardial location. Real-time monitoring of cryoablation by demonstration of ice balling and evaluation of dyssynchrony was made possible by RT3DTEE in Case 1. Additional anatomic details like juxtaposition of atrial appendages were also easily observed in Case 1.
Conclusions: Arrhythmogenic substrates can be accurately identified on RT3DTEE, which provides enhanced visualization and serves to prevent complications by reducing radiation exposure. When combined with 3D electroanatomic mapping, RT3DTEE augments visualization of arrhythmogenic substrates and has a role for electrophysiological procedures in the setting of complex CHD.

P1460 - CLINICAL AND GENETIC PROFILE OF CONGENITAL LONG QT SYNDROME IN HONG KONG – 18 YEAR EXPERIENCE

Sit-Yee Kwok[1], *Anthony Py Liu*[2], *Kin-Shing Lun*[1], *Cindy Chan*[1], *Brian Hy Chung*[2], *Tak-Cheung Yung*[1]
Queen Mary Hospital, Department of Paediatric Cardiology, Hong Kong-Hong Kong[1]; *Queen Mary Hospital, Department of Paediatric and Adolescent Medicine, Hong Kong-Hong Kong*[2]

Background: Comprehensive review of all patients diagnosed with congenital long QT syndrome (LQTS) in a single tertiary paediatric cardiology centre is described.
Methods: All paediatric patients diagnosed at our centre with LQTS from January 1998 to December 2016 were included. LQTS was established with either a Schwartz score >= 3.5 or presence of pathogenic mutation.
Results: 59 subjects (33 boys) fulfilled the study inclusion criteria, with a mean age of 8.90 + /- 5.74 years at diagnosis. The mean follow-up duration was 5.33 + /- 4.65 years. 84.7% individuals were probands. 23 (39.0%) and 7 (11.9%) subjects presented with syncope and convulsion respectively. 7 subjects (11.9%) had cardiac arrest on presentation. Fetal bradycardia and neonatal 2:1 atrioventricular block were also the mode of presentation in 2 subjects. The mean corrected QT interval in our cohort was 504 + /- 47 ms. 42.4% individuals had a positive family history. 37 subjects (62.7%) confirmed to have pathogenic mutation for LQTS (LQT1-16.9%; LQT2-18.6%; LQT3-11.9%; LQT5-5.1%; LQT8-10.2%). No deaths were reported but 2 subjects had subsequent cardiac arrest despite on metoprolol. Pacemaker was implanted in 4 subjects, while implantable cardioverter-defibrillator was implanted in 14 subjects. 2 patients underwent left cardiac sympathectomy. 64.4% individuals were put on medical therapy, with metoprolol being the initial choice of beta-blocker therapy in half of our cohort.
Conclusions: 18-year experience in management of paediatric LQTS in a tertiary cardiology centre is described, with a significant proportion of probands. Syncope and convulsion were the main forms of presentation. Use of metoprolol was associated with breakthrough attacks in children with LQTS. Our cohort demonstarted relative good survival.

P1607 - CLINICAL COURSE AND ELECTROPHYSIOLOGICAL CHARACTERISTICS OF BINODAL DISEASE AT CHILDREN WITH IMPLANTED PACEMAKERS

Elena Vasichkina[1], *Tatyana Pervunina*[2], *Dmitry Lebedev*[3]
Federal North-west Medical Research Centre, Scientific Research Department of Cardiovascular Diseases in Children, Saint-Petersburg-Russia[1]; *Federal North-West Medical Research Centre, Institute of Perinatology and Pediatrics, Saint-Petersburg-Russia*[2]; *Federal North-West Medical Research Centre, Research Department of Arrhythmology, Saint-Petersburg-Russia*[3]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Purpose: This study is aimed to assess the results of the clinical course and electrophysiological characteristics of binodal disease (BB) at children with implanted pacemakers.
Methods: We enrolled 40 consecutive patients with BB who underwent pacemaker implantation, 24 (60%) male, 16 (40%) female. The average age for the moment of pacemaker implantation - 13,84 ± 0,621 (2,8-17,9) years. The longevity of persistence of BB before the pacemaker implantation had been 5,31 ± 4,36 years (several days - 14,29). BB included: combined sinus node dysfunction (SND): sinus bradycardia, sinoatrial block, sinus arrest with escape ectopic rhythm, and/or increasing the sinus node recovery time (SNRT) and/or corrected SNRT (cSNRT) and atrioventricular (AV) conduction disturbance as AV block of grade I or greater, and/or Wenckebach point (WP) below 500 msec. All children had carried out examination of the heart at least 2 times: ECG, Holter monitoring (HM), transesophageal electrophysiologic study (TEEPS) before pacemaker implantation and ECG, HM, noninvasive electrophysiologic study after pacemaker implantation.
Results: Long-term follow up of patients was 52,2 + 35,22 months (range 2,7 to 145,9). There was a statistically significant increase in the duration of SNRT 1617,7 ± 441,6 ms at the first examination to 1915,37 ± 655,7 ms at the end of follow-up ($p = 0.04$). In addition, there was a significant decrease in the Wenckebach point of 117 ± 35.52 pulses/min. to 102,2 ± 30,42 pulses/min. ($p < 0,05$).
Conclusions: Among children with binodal disease who underwent pacemaker implantation in monitoring there has been showed an improvement of clinical and hemodynamic picture of the disease during the follow-up, but in the whole the group experienced a worsening of electrophysiological parameters.

P1608 - ARRHYTMIAS AND CONDUCTION DISORDERS IN PATIENTS WITH SURGICAL CORRECTION OF ANOMALOUS TOTAL PULMONARY VENOUS CONNECTION AT THE NATIONAL INSTITUTE OF CARDIOLOGY "IGNACIO CHAVEZ"(2005 214)

Emilia Patino-Bahena[1], Arianna Covarrubias[1], Pablo Mendoza[2], Antonio Benita-Bordes[3], Samuel Ramírez-Marroquin[3], Alfonso Buendía-Hernandez[1]
National Institute of Cardiology, Paediatric-Cardiology, México-Mexico[1]; National Institute of Cardiology, Arrhythmias, México-Mexico[2]; National Institute of Cardiology, Surgery, México-Mexico[3]

Congenital heart defects are associated with arrhythmias, not only for the congenital anatomic component, there is also an increasingly acquired arrhythmogenic substrate associated with surgical repair. For the formation of new tachycardia circuits in the atriotomy, patches or prostheses and suture lines in approximately 10- 20 years of post-surgical evolution. A retrospective, descriptive, observational study of patients with anomalous total pulmonary venous connection who underwent total correction and subsequent arrhythmias after surgery at the National Institute of Cardiology "Ignacio Chavez" from January 2005 to December of 2014. We found 223 patients with this diagnosis after total correction. In 107 patients (48%) some type of rhythm or conduction disorder was documented. Conduction abnormalities were the most frequently found alteration, being nodal rhythm and complete atrioventricular block the predominant presentations in the short and medium term; and in the late period the most frequent abnormality was sinus node dysfunction. Ventricular fibrillation was the main tachyarrhythmia in the short and medium term, it should be mentioned that it is a poor prognosis that is associated with death; in the late period the atrial flutter. The main therapeutic intervention was the temporary pacemaker implantation. Eight patients required definitive pacemaker. Cardiac ablations were performed in 2 patients for atrial flutter.

P1631 - CLINICAL UTILITY WITH AN OBSERVATION OF ATRIAL KICK WAVE PATTERNS FOR DIFFERENTIAL DIAGNOSIS OF FETAL EXTRASYSTOLE

Kaori Hori, Masato Oguri, Tsuneyuki Nakamura
Kanazawa Medical University, Pediatric Cardiology, Ishikawa-Japan

Generally, obstetricians tend to have a feeling of being not good at fetal arrhythmia on ultrasound. If fetal electrocardiography becomes clinical widespread, we will be able to diagnose fetal arrhythmia accurately. However, at present we have to do diagnosis of fetal arrhythmia using echocardiography, M-mode method and superior vena cava/aorta Doppler flow method (SVC/AA Doppler method), because of no clinical widespread of fetal electrocardiography. This time, we hypothesize that the characteristic Doppler flow pattern exists in each extrasystole, premature atrial contraction (PAC) and premature ventricular contraction (PVC). We investigate how to better diagnose each extrasystole by those Doppler flow patterns. In this study, we enrolled 26 children (14 males and 12 females between 0 and 17 years old), who were already diagnosed with PVC or PAC using 12-lead ECG and Holter ECG. We grouped into 2 (19PVCs and 7PACs) and analyzed Doppler flow patterns using modified SVC/AA Doppler method. As the result, we find the following Doppler flow patterns; 1) in PVCs group, mostly similar reversal flow exists at midpoint of reversal flows (atrial kick wave) before and after extrasystole, 2) in PACs group, no exists at midpoint. In conclusion, observation of atrial kick wave patterns using SVC/AA Doppler method might be clinically useful for differential diagnosis of each extrasystole in fetus.

P1652-3 DIFFERENT ICD INDICATIONS IN CHILDHOOD

Ali Baykan, Suleyman Sunkak, Ozge Pamukcu, Onur Tasci, Kazim Uzum, Nazmi Narin
Erciyes University, Pediatric Cardiology, Kayseri-Turkey

The ICD is the first-line treatment and prophylactic therapy for patients at risk for sudden cardiac death due to ventricular fibrillation and ventricular tachycardia. Recommendations for secondary prevention in children are similar to ICD implantation guidelines developed for adults, despite a paucity of pediatric randomized controlled trials. In this poster we reported 3 different ICD indications in childhood, which were implanted in our institute. CASE 1A9-year-old male patient who had HCMP diagnosis was admitted to the pediatric intensive care unit after resuscitation because of cardiac arrest. The emergency team stated that while the patient found there was cardiac arrest and the monitorization showed asystole. In intensive care unit no rhythm abnormality was detected except septal hypertrophy in ECG (image 1). Because of presented asystole and suspected VT an ICD implanted and discharged after 5 days of follow-up. CASE 2 A 14-years old male patient admitted hospital because of seizures. In pediatric intensive care unit, ventricular tachycardia was detected at the time of seizures. While receiving IV inotropes frequent VT episodes were detected in 24 hour holter rhythm monitorization. And this condition is diagnosed as Catecholaminergic polymorphic ventricular tachycardia (image 2). IV inotropes were

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

stopped, propranolol initialized. After rehabilitation and decreasing the VT episodes ICD implanted, and discharged with oral propranolol. CASE 3 A 10-years old female patient admitted hospital because of recurrent syncope attacks. ECG revealed sinus rhythm, but QTc interval was calculated 0.50 msn (image 3). Within 24 hours ECG holter monitorization, sustained VT attacks were detected. So that we gave propranolol therapy and implanted ICD.

Discussion: Patients who have survived after sudden cardiac arrest due to malignant arrhythmias would benefit from ICD implantation. The indications for ICD implantation in pediatric patients and those with congenital heart disease have developed in recent years with adult randomized clinical trials. Similar to adults, ICD indications have evolved from secondary prevention of cardiac death.

P1686 - PERMANENT PACEMAKER IMPLANTATION VIA ILIAC VEIN IN SINGLE VENTRICLE PATIENT AFTER BIDIRECTIONAL GLENN PROCEDURE

Andrea Harris[1], *Gurur Biliciler-Denktas*[1], *Mousumi Moulik*[1], *William Douglas*[2], *Chandra Srinivasan*[1]
University of Texas Health Science Center at Houston/Children's Memorial Hermann Hospital, Pediatric Cardiology, Houston-United States[1];
University of Texas Health Science Center at Houston/Children's Memorial Hermann Hospital, Pediatric CV Surgery, Houston-United States[2]

Background: We report transvenous permanent pacemaker placement (PPM) via Iliac vein after failure of epicardial pacemaker system in a patient (pt) with single ventricle (SV) post bidirectional Glenn (BDG) procedure.

Methods: N/A

Results: A 23-year-old morbidly obese female with DS, tricuspid atresia, post BDG procedure as destination palliation presented with one-week history of marked bradycardia with ventricular escape rate between 20-40 bpm. Prior attempt at epicardial PPM placement for history of advanced atrioventricular block was complicated by high pacing thresholds and pocket infection. Attempt to replace pulse generator (PG) which had reached end-of-life and revise non-functioning epicardial ventricular pace-sense lead was unsuccessful and aborted following significant bleeding-related complications. Alternative approaches to transvenous PPM were discussed. An incision was made superior to inguinal ligament and right external iliac vein was cannulated with two long introducer sheaths. Two custom size pace-sense leads (CapSureFix Novus MRI, 85 cm, Medtronic Inc.) were advanced through each of these sheaths and actively fixated into lateral wall of right atrium and left ventricular apical septum achieving optimal pacing thresholds, impedance and sensing margins. Figure demonstrates lead positioning. An abdominal para-umbilical subcutaneous pocket was created for PG and leads were tunneled from the inguinal incision into this pocket. There were no procedural complications. Combination of Aspirin and Clopidogrel was started for thrombotic prophylaxis. Pt developed non-oliguric renal dysfunction related to prophylactic antibiotics following procedure, which did not require any intervention. She had been doing well at her two-months follow-up with normal pacemaker function.

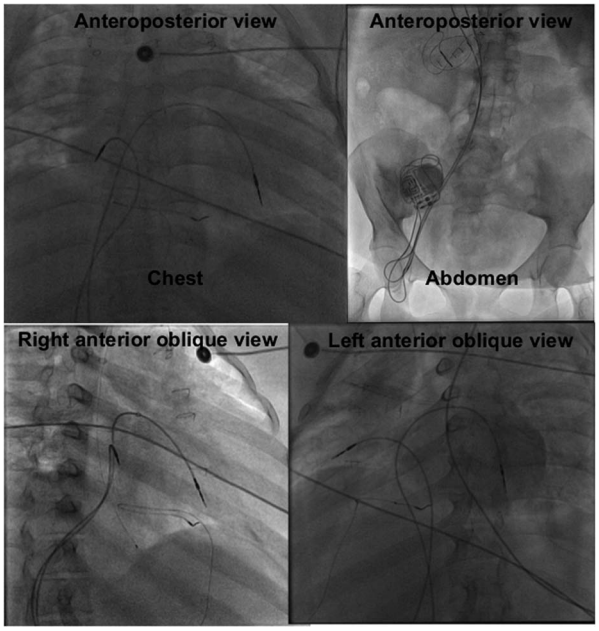

Figure 1.
Fluoroscopic images.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: PPM with trans-iliac vein leads tunneled to abdominal PG offers a less invasive and feasible alternative to epicardial pacemaker system in palliated SV pts, when direct access via upper venous tree is not available post BDG procedure. This approach offers the benefit of unrestricted pt ambulation, optimal pacing thresholds with lowered risk of thromboembolism on anti-platelet agents.

P1691 - EARLY POSTOPERATIVE SUPRAVENTRICULAR TACHYCARDIA AFTER CONGENITAL HEART DISEASE SURGERY

Pei-Yuan Wu[1], Shu-Chien Huang[2], Shuenn-Nan Chiu[3], Jou-Kou Wang[3], Mei-Hwan Wu[3], Ming-Tai Lin[3], Chun-Wei Lu[3], Chun-An Chen[3]
Taipei City Hospital Zhongxiao Branch, Department of Pediatrics, Taipei-Taiwan[1]; National Taiwan University Hospital, Department of Surgery, Taipei-Taiwan[2]; National Taiwan University Hospital, Department of Pediatrics, Taipei-Taiwan[3]

Background: Postoperative supraventricular tachycardia (SVT) after congenital heart disease (CHD) surgery was occasionally seen in early postoperative period but its clinical significance was not clear.
Methods: From 2010 to 2015, all consecutive patients, aged less than 18 years-old, who had early postoperative SVT after cardiopulmonary bypass surgery for CHD in our institution were reviewed. The definition of SVT includes atrial arrhythmia and paroxysmal supraventricular tachycardia.
Results: Totally 29 patients (M/F 19/10) were enrolled. Median age of operation was 4 months (range 1 day – 17.55 years), with 62% of the patients less than 1 year-old. The common underlying cardiac anomalies include complex CHD in 12, transposition of great arteries in 5, and tetralogy of Fallot in 3. Among them, 8 (27%) patients had history of previous cardiac surgery, and 5 (17%) patients had SVT history. Most of the patients with SVT history had multiple cardiac surgery before (Odds ratio 2.76, $p = 0.027$). The pre-operative condition was hemodynamically unstable in 13 patients (45%) with 2 required extracorporeal membranous oxygenator support after surgery. The mean atrial and ventricular rates were 278 ± 89.8 bpm and 196 ± 41.2 bpm, respectively. The SVT was controlled by single dose IV adenosine in 5, IV amiodarone in 17. Only 2 patients need DC cardioversion due to critical hemodynamics. Compared to those requiring IV anti-arrhythmia agents more than 24hr, those who use less than 24hr had shorter ICU stay (14.3 vs. 80.8 days, $p = 0.0073$). Maintenance oral antiarrhythmic agents were needed in 27 patients: 11 required multiple antiarrhythmic agents. The median duration of oral antiarrhythmic agents was 167 days (7-2072 days), and the medication could be discontinued in 18 patients with only one recurrence.
Conclusions: Early postoperative SVT is not uncommon after CHD surgery especially for those with complex CHD and cyanotic CHD. It may cause hemodynamically compromise but can be controlled by medication.

P1700 - ELECTRICAL ABNORMALITIES IN CHILDREN WITH LAMINOPATHIES

María Victoria Lafuente[1], Sebastian Maldonado[2], Soledad Monges[3], Erica Stelmaszewski[1], Mónica Benjamín[2], Diego Longarini[2], Alejandra Villa[1], Alberto Sciegata[2], Horacio Capelli[1]
Children's Hospital,Juan P Garrahan, Cardiology Department, Buenos Aires-Argentina[1]; Children's Hospital,Juan P Garrahan, Cardiac Catheter Laboratory, Buenos Aires-Argentina[2]; Children's Hospital,Juan P Garrahan, Neurology Department, Buenos Aires-Argentina[3]

Background: Lamin proteins are type V intermediate filaments, a mayor component of the nuclear lamina that supports the inner nuclear membrane. Laminopathies (LMNA) mutations have been reported associated to distinct phenotypes, collectively termed laminopathies. These, usually affect skeletal and/or cardiac muscle, white fat distribution, bone and peripheral nervous tissue, and also may cause premature aging with or without myopathy.
*Objectives:*To describe the electrical abnormalities,treatment and mortality in patients with early onset of LMNA-related muscular dystrophies.
Methods: Between 2008-2015, sixteen patients(p)underwent a cardiac check-up with electrocardiogram (EKG), 24 hour Holter monitoring,and transthoracic colour Doppler echocardiography. Median follow- up was 4,3 years(IQR 1,25-6,45).
Results: The mean age onset of symptoms was 2.13 + /-1.7 5 years, and the initial electrical disturbance appeared at10.22 + /-2.39 years. EKG findings: P wave amplitude less than 0.1 mV in 8(53,3%), AV block: in 4(26,6%), bundle branch block in 4, premature ventricular contractions in one and abnormal repolarization in 2 patients. Holter monitoring reported: premature atrial contractions 20%(3p), atrial tachycardia 26,6%(4p). Ventricular arrhythmias included simple premature ventricular contractions 20%(3p), with a pattern of bigeminy,couples and non- sustained ventricular tachycardia. Sick sinus syndrome 6,6% (1p); and second degree AV block Mobitz type I 13,2%(2p)were also documented. Antiarrhythmic treatment: Two patients received amiodarone, betablockers 2 and a combined treatment 2p. A pacemaker was implanted in three patients at 16 and 17years. The indications were sick sinus syndrome and progressive AV block. Three patients died during follow-up. In the univariate analysis, mortality was related to history of sustained atrial arrhythmias (p 0.0001), progression of AV block (p0.0001) and ventricular tachycardia (p 0.01).
Conclusions: The most common electrical disturbances in patients with laminopathies were: progressive decrease in P-wave amplitude, first degree AV block and second degree AV block Mobitz I type and atrial and ventricular arrhythmias. The electrical disturbances developed later than the neuromuscular symptoms. Mortality was related to second degree AV block, sustained atrial tachycardia with decreased left ventricular function and ventricular tachycardia.

P1737 - SINUS ARREST AS UNREPORTED PRESENTATION OF KCNE1 MUTATION

Jenks Albinus Lam[1], Sit Yee Kwok[2], Brian Hy Chung[3], Tak Cheung Yung[2]
Queen Elizabeth Hospital, Paediatrics, Hong Kong-Hong Kong[1]; Queen Mary Hospital, Paediatric Cardiology, Hong Kong-Hong Kong[2]; Queen Mary Hospital, Paediatric and Adolescent Medicine, Hong Kong-Hong Kong[3]

We report a 6-year-old boy who presented with recurrent episodes of unprovoked syncope. His 12-lead electrocardiogram (ECG) demonstrated borderline prolonged QT intervals, with maternal ECG also showed similar findings. Instead of ventricular arrhythmia, sinus arrest with pauses up to 7 seconds was identified as the cause of recurrent syncope, with the use of implantable loop recorder (ILR). Genetic testing revealed a pathogenic mutation in KCNE1, which is known to cause long QT syndrome type 5. Implantable cardioverter-defibrillator was implanted. The early use of ILR allows early detection of underlying arrhythmia and allows timely intervention. This unreported link between sinus arrest and KCNE1 mutation is also discussed.

P1772 - USEFULNESS OF STRESS TESTING IN THE DIAGNOSIS OF CATECHOLAMINERGIC POLYMORPHIC VENTRICULAR TACHYCARDIA

Juan Villafane
University of Kentucky, Pediatrics (Cardiology), Louisville-United States

Background: Catecholaminergic polymorphic ventricular tachycardia (CPVT) is a cardiac channelopathy, which may manifest with sudden death early in childhood. Symptoms are associated with emotional stress or exertion.
Case report: A 4.5-year-old female with history of two abrupt syncopal spells during moderate exertion – one of them resulting in head trauma and unresponsiveness for 30 seconds. No detectable seizure activity. EMS was called and CR monitoring did not show any arrhythmias. The patient was referred to a neurologist who insisted on getting a cardiovascular evaluation. Resting ECG was normal. Echocardiogram showed a small interatrial communication. Holter showed normal heart rates (HR). Ventricular bigeminy and multiform couplets were detected exclusively when HR was over 130 bpm. Stress testing was performed based on the history of exertional syncope and ventricular ectopy. Bidirectional premature ventricular contractions (PVCs) appeared at HRs above 122 bpm. Ventricular ectopy became progressively worse, including ventricular bigeminy followed by non-sustained CPVT. There was no ventricular ectopy when HR dropped <120 bpm. At the end of the test, there was sinus rhythm with normal AV conduction, QT intervals, and T wave morphology. The patient was started on nadolol. Follow-up Holter was unremarkable except for 11 isolated PVCs at HR >120 bpm. There was a brief episode of ventricular bigeminy at HR > 137.
Conclusions: CPVT is a malignant channelopathy that can present in the very young. A child with exertional syncope, a normal QT interval and exercise-induced ventricular ectopy is more likely to have CPVT (than long QT syndrome). Stress testing should be attempted at any age in this scenario.

P1790 - SUPRAVENTRICULAR MICRO REENTRY IN A NEWBORN DUE TO A GIANT ATRIAL SEPTUM ANEURYSM

Franziska Wagner, Roman Gebauer, Robert Wagner, Christian Paech
University of Leipzig - Heart Center, Department for Pediatric Cardiology, Leipzig-Germany

Background/Hypothesis: The focal micro reentry tachycardia (FMRT) is a rare form of atrial tachycardia in children and belongs to the group of supraventricular tachycardias (SVT´s). The reentry circuit is mediated via areas of functional conduction block, occurring in adjacent tissues with differing refractory periods, and the symptoms range from an asymptomatic patient to severe heart failure. The treatment depends on the mechanism of the arrhythmia and the clinical state of the patient. This case is the first one of a newborn presenting with a FMRT possibly associated to a giant atrial septum aneurysm (ASA).
Case Presentation: A 13-days-old male patient was referred to our center due to recurrent tachycardia (240 bpm) in a stable clinical condition. In our center supraventricular reentrant tachycardia was diagnosed after application of adenosine (0,2 mg/kg). Echocardiographically an atrial septal defect with a giant ASA and a very small muscular ventricular septum defect were diagnosed; cardiac function was normal. The SVT could successfully be terminated by the use of electric cardioversion with 5 Joule (2 Joule/kg). A relapse after 3 hours could again be terminated with an electric cardioversion (6 Joule). Therefore we started the substitution of digoxin and sotalol (112 mg/m^2). With this therapy the patient could be discharged in good clinical condition after 4 days. After six months without the history of relapses, the medication has been discontinued. Due to the elucidated pathomechanism described above, we assume a correlation between the ASA and the FMRT.
Conclusion: This is the first report of a newborn with a focal atrial micro reentrant tachycardia, assumingly related to a giant atrial septum aneurysm. The tachycardia was effectively treated by cardioversion and medicinal prophylaxis with digoxin and sotalol.

P1801 - PROJECT ADAM PREVENTION OF SUDDEN CARDIAC DEATH IN CHILDREN AND ADOLESCENTS THE SUCCESSES OF A NATIONAL PROJECT OF SECONDARY PREVENTION INCLUDING CPR AED EDUCATION BROAD NATIONAL COVERAGE AND COLLABORATION TO SAVE LIVES

Stuart Berger[1], Allison Thompson[2], Robert Campbell[3], Anoop Singh[2], Victoria Vetter[4], C. Chris Anderson[5], Naomi Kertesz[6], Moinca Goble[7], Gwen Fosse[7], Ryan Schaefer[5], Richard Lamphier[3]

Lurie Children, Pediatric Cardiology, Chicago-United States[1]; CHW, Pediatric Cardiology, Milwaukee-United States[2]; Children, Pediatric Cardiology, Atlanta-United States[3]; CHOP, Pediatric Cardiology, Philadelphia-United States[4]; Providence Center for CHD, Pediatric Cardiology, Spokane-United States[5]; Nationwide Children, Pediatric Cardiology, Columbus-United States[6]; University of Michigan, Pediatric Cardiology, Lansing-United States[7]

Background: Sudden cardiac death (SCD) in children and adolescents is devastating. Many SCD events occur in schools, which represent community gathering places. A comprehensive program of CPR-AED education of students and staff, emergency preparedness, and AED placement in schools could improve the low bystander CPR rate (20-30%) and out-of-hospital cardiac arrest (OHCA) survival rate (10%).
Materials and Methods: A statewide three-tiered approach to secondary prevention was instituted in Wisconsin in November 1999 with the goals of: (1) Providing education regarding SCD presentation and layperson response, (2) Advocating for mandatory CPR-AED education for students prior to graduation, and (3) Placing AEDs in all schools and playing fields/arenas.
Results: Since the original Project ADAM program in Wisconsin began, 12 other states have joined Project ADAM as affiliate programs. Key elements for a successful program have included administration ownership by children's hospital or academic medical center with a pediatric cardiac program, a physician medical director, and a program director/coordinator. In addition, Project ADAM provides a template that accommodates the variability in affiliate programs with regards to resources, infrastructure, funding, and state laws. Affiliate programs recruit local champions to advocate for the development of emergency action plans, school CPR-AED programs, education about effective CPR and AED use, and funding and maintenance of AEDs. Project ADAM has resulted in greater than 120 lives saved, both children and adults. Additionally, Project ADAM has provided advocacy resulting in the passage of state legislation mandating CPR and AED instruction as a high school graduation requirement.
Conclusions: Project ADAM is a school-based secondary prevention program for SCD that has saved lives of children and adults. Adopted nationwide, such an approach has the potential to significantly improve the relatively poor outcomes associated with OHCA and will likely result in a greater incidence of high quality bystander CPR.

P1892 - NEONATAL ARRHYTHMIAS AND INDEXES OF HEART RATE VARIABILITY IN NEWBORNS

Margaryta Gonchar, Eugenia Ivanova, Alona Boichenko, Irina Kondratova, Natalia Matsiyevska, Tatiana Teslenko
Kharkiv National Medical University, Department of Pediatrics No. 1 and Neonatology, Kharkiv-Ukraine

Aim: to compare the frequency of occurrence and variants of cardiac arrhythmia in full-term and preterm newborns.
Methods: analysis the data of anamnesis, Holter monitoring ECG (Holter ECG), Doppler echocardiography, statistical analysis.
Results: In 79 infants had irregular heart rhythm. The 1st group was included prematurely born children 55 (69.6%), the 2nd group - full-term newborns (24 - of 30.4%). Hypoxic-ischemic CNS damage moderate, and severe degrees of gravity was found in 29 (52.7%) of the 1st group and in four children (29.2%) the 2nd group ($t = 3.13$, $p < 0.05$). Central hemodynamics according to Doppler echocardiography showed the presence of hyperkinetic and hypokinetic types of hemodynamics in almost equal shares (45.8% and 41.7%, respectively) in a group of full-term infants. Significant differences between the groups was observed in patients with normokinetic type of hemodynamics ($t = 5.5$, $p < 0.05$). According to the results of Holter ECG among cardiac arrhythmias have been identified in both groups: atrial extrasystoles – 40.5%, ventricular extrasystoles – 13.9%, episodes of transient AV-block of 1st degree – 10.1%, long QT – 10.1%. No significant differences were between groups in the frequency of occurrence of AV-block of 2nd degree type Mobitz 1 in 4 preterm babies ($7.3 \pm 2.2\%$, $t = 3.13$, $p < 0.05$). Processing of the obtained statistical indices of heart rate variability non-parametric methods have revealed a reliable decrease in SDNN in the group of premature born children ($p < 0.05$). SDNN displays the decrease of the total effect of autonomous regulation of circulation that is associated with the strengthening the regulation of cute, depressing the activity of the autonomous circuit.
Conclusions: A rhythm disorder of the heart in preterm babies was connected to the influence of hypoxic lesions of the CNS in the regulation of cardiac activity largely and to the complexity of the flow adaptation processes.

P1912 - LONG TERM RESULTS OF RADIOFREQUENCY CATHETER ABLATION IN CHILDREN WITH ATRIOVENTRICULAR NODAL REENTRANT TACHYCARDIA

Kazushi Ueshima[1], Yoshihide Nakamura[2], Noboru Inamura[2], Satoru Takeno[2], Tsukasa Takemura[2]
Kindai University, Periatrics, Osaka-Japan[1]; Kindai University, Pediatrics, Osaka-Japan[2]

Background: There are no reports regarding atrioventricular nodal reentrant tachycardia (AVNRT) after RFCA in children. Therefore, we evaluated long-term results of AVNRT after RFCA in children.
Material and Methods: From 1993 to 2001, 71 children underwent RFCA of AVNRT at our institution. We conducted a questionnaire survey for 52 patients and obtained replies from 23. The contents of the questionnaire were follows; Have you ever experienced palpitation after catheter ablation? Did you visit a hospital after treatment because of the recurrence of palpitation or arrhythmia? Are you satisfied with the efficancy of this treatment? Based on the replies, we analyzed the patients' age, sex, body mass index, history of medications, congenital heart disease, one echo after RFCA, and types of AVNRT. Twenty-three patients were divided in two groups; Group A comprised 12 patients with the present of palpitations and Group B comprised 11 patients with absence of palpitations after RFCA.
Results: All patients had experienced palpitations before RFCA; 12 (52%) currently experienced palpitations after RFCA; seven (30%) visited a hospital after RFCA; and 22 (96%) were satisfied with the efficancy of the treatment. The number of patients visiting a hospital after RFCA was significantly higher in Group A (58%) than in Group B(0%), and the frequency of satisfaction by this treatment showed no apparent differences (Group A, 92%; Group B, 100%). In Group A, two patients experienced recurrences. there were significant differences in the recurrence of RFCA between the two groups (A: 58%, B: 17%) with regard to history of medications, whereas others had no differences.
Conclusions: More than half of patients with AVNRT experienced palpitations without recurrences after RFCA. Most of the patients were satisfied with the treatment. In this study, the exact cause of palpitations was unknown; however, palpitations after RFCA might be involved in history of medications.

P1980 - AMBULATORY ARRHYTHMIA DETECTION WITH ZIO® XT PATCH IN PEDIATRIC PATIENTS

Jeffrey Robinson, Christopher Snyder
Congenital Heart Collaborative, Pediatrics, Cleveland-United States

Introduction: A novel device, ZIO® XT Patch (ZIO), can be utilized for ECG monitoring for 14 days. The purpose of this study is to describe the duration of ZIO use by age, as well as time to arrhythmia detection in the pediatric population.
Methods: A single-center, eview of patients ≤17 yrs prescribed a ZIO from 10/14 to 2/16. All data were analyzed, along with duration of ZIO use and time to first arrhythmia. Arrhythmia was defined as supraventricular tachycardia (SVT), advanced atrioventricular block (AV block), or ventricular tachycardia (VT). All ZIO reports were reviewed by a blinded pediatric electrophysiologist. Comparisons were made to 24-hour Holter monitors from the same time period.
Results: A total of 406 ZIO monitors were prescribed for 363 patients; median age 12.7 yrs (0.01-17 yrs), 50% male. The median duration of monitoring significantly increased with age: 1 day (1-14) for 41 ZIO in age <3 yrs, 2 days (1-13) for 57 ZIO in age 3-6 yrs, 3 days (1-14) for 109 ZIO in age 7-12 yrs, and 4 days (1-14) for 199 ZIO in age 13-17 yrs ($p < 0.001$). A total of 499 Holter monitors were performed; median age 4.9 yrs (0.03-17 yrs), 51% male. Median age differed between the ZIO and Holter groups ($p < 0.0001$), but rates of detection were similar: 11% by ZIO vs 10% by Holter ($p = 0.51$). Arrhythmia was identified on: 45 ZIO (35 SVT, 3 AV block, 7 VT) and 48 Holter (34 SVT, 3 AV block, 11 VT). The first arrhythmia on ZIO occurred in <24 hrs of monitoring in 42% patients, 24-71 hrs in 24%, and >72 hrs in 33%, while arrhythmias detected by Holter.

P1981 - CORRELATION BETWEEN ECG ABNORMALITIES AND MARIJUANA USE IN THE PEDIATRIC POPULATION

Jeffrey Robinson, Christopher Snyder
Congenital Heart Collaborative, Pediatrics, Cleveland-United States

Purpose: The effects of marijuana on the cardiac conduction system are ill defined. The purpose of this study is to describe the association between electrocardiogram (ECG) findings and positive drug screening (+ UDS) for marijuana in the pediatric population.
Methods: A retrospective review was conducted from charts dated 10/13-11/14 of patients ≤18 years of age that tested positive for marijuana exposure by urine screen in the Emergency Department (ED). All ECGs performed were reviewed by two blinded pediatric cardiologists.
Results: There were 174 patients identified in the ED with a + UDS with a median age of 15 yrs (0-18 yrs); 42% were male. ECG at time of + UDS was performed on 37 (21%) patients. Abnormal ECG finding was identified in 16/37, of which 15 had another ECG performed on a different date. Comparisons were made between these ECGs; significant differences were noted in those patients with + UDS, including ST segment changes (4 patients), left ventricular hypertrophy (3), and one each: atrial fibrillation, QT prolongation, Mobitz type I block, and right bundle branch block.
Conclusion: Abnormal ECG findings, including serious rhythm disturbances and conduction abnormalities can be identified in pediatric patients under the influence of marijuana. An ECG should be considered on all patients with a positive urine drug screen for marijuana.

P1995 - NOVEL TECHNIQUE OF ATRIAL MAPPING THROUGH PULMONARY ARTERY IN PATIENTS PALLIATED FOR SINGLE VENTRICLE CIRCULATION

Srinidhi Jv Rao, Krishna Vl Kumar, Sarah E Boynton, Vinay Bhole
Birmingham Children, Heart Unit, Birmingham-United Kingdom

We present three cases where a catheter placed in the pulmonary artery (PA) provided clear atrial signals to assist in performing electrophysiological interventions on children palliated for single ventricle circulation.
Case 1: 7 year old girl with double outlet right ventricle, malposed great arteries and hypoplastic left ventricle had undergone cavopulmonary shunt, reduction atrioplasty of right atrium, ablation of incessant focal atrial tachycardia, tricuspid valve replacement and maze procedure. She underwent further electrophysiological studies(EPS) for recurrent flutter. A deflectable quadripolar catheter placed in left PA through internal jugular vein access gave clear atrial signals.
Case 2: 4 year boy with hypoplastic left heart syndrome(HLHS) underwent total cavopulmonary connection with extracardiac fenestrated conduit. He developed incessant atrial tachycardia in the post-operative period unresponsive to medical therapy. A quadripolar catheter placed in right PA gave excellent atrial signals.
Case 3: 3 year old boy with HLHS underwent Norwood procedure and superior cavopulmonary anastomosis had significant right ventricular dysfunction and was noticed to have 2:1 conduction block with 9 second pause for which he underwent epicardial dual chamber pacemaker. He developed atrial tachycardia for which he underwent EPS. A catheter placed in right PA gave excellent atrial signals and could also be used for atrial pacing. Atrial signals from the pulmonary artery were used as reference and for activation mapping using CARTO mapping system in all three patients and for pacing in two patients. There was acute success in two patients whilst the third patient had recurrence despite successful ablations.
Conclusion: Placement of the diagnostic electrophysiology catheter in the PAs is a useful technique for EPS involving children who have undergone cavopulmonary shunt or Fontan completion. This technique can be used to get atrial signals without entering the atrial mass and alternative venous access can be used if there is femoral vein occlusion.

P2031 - TRANS CATHETER BASED ELECTROPHYSIOLOGICAL MANAGEMENT OF ARRHYTHMIAS IN ACHD SINGLE CENTRE EXPERIENCE

Aly Zaki[1], Jaspal S Dua[1], Petra Jenkins[1], Vaikom S Mahadevan[2], Andreas Hoschtitzky[3], Ashish Shah[1], Heiko Schneider[1], James Weatherby[1], Graeme Kirkwood[1], Sahrkaw Muhyaldeen[1]
Manchester Royal Infirmary, Cardiology, Manchester-United Kingdom[1]; UCSF Medical Centre, Cardiology, San Francisco-United States[2]; Manchester Royal Infirmary, Cardiothoracic Surgery, Manchester-United Kingdom[3]

Introduction: Catheter ablation is increasingly used main modality for management of arrhythmias in adult congenital heart diseased (ACHD) population. Literature evidence supporting use of such treatment is based on case-reports and centre experiences. We report three-year data for consecutive ACHD patients undergoing ablation procedures in our centre.
Methods: Retrospective analysis of consecutive arrhythmia ablation procedures in ACHD patients between January 2014 and December 2016. Acute outcome was defined as: (1) Successful: termination of sustained clinical tachycardia by ablation and non-

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

inducibility afterwards; or achieving pulmonary vein isolation (PVI)or cavotricuspid isthmus (CTI) ablation in sinus/paced rhythm; (2) Equivocal: intra-procedure degeneration of clinical arrhythmia into atrial fibrillation (AF) requiring cardioversion followed by substrate modification in sinus/paced rhythm (3) Failed: inability to terminate clinical tachycardia by ablation (excluding PVI); ending the procedure with cardioversion (excluding PVI); or if clinical arrhythmia remained inducible.
Results: 52 ablation procedures were performed in 43 patients (mean age: 41.3y). Underlying ACHD/repair was ASD/VSD: 12 patients (23%), Ebstein: 5(10%), Tetralogy of Fallot/pulmonary stenosis repair: 9(17%), Fontan repair: 9(17%), arterial switch: 3 (6%), Senning: 3(6%), Rastelli: 1(2%), Eisenmenger: 1(2%) and combinations: 9(17%). Average number of arrhythmias/patient was 1.2 (range: 0-4). Ablation was performed for CTI flutter in 20 patients (38%), AVNRT in 3(6%), AVRT in 3(6%), AF in 7(13%), intra-atrial re-entrant tachycardia (IART) in 8(15%), focal atrial tachycardia in 1(2%) and RVOT ectopics in 2(4%). Substrate modification was performed in sinus/paced rhythm in 13 patients (25%). Ablation outcome was successful in 45 cases (86.6%), equivocal in 2(3.8%) and failed in 5(9.6%). There was 1(2%) complication - asystolic arrest following termination of IART by ablation- successfully resuscitated. Average procedure time was 205 min (median 195). Mean hospital stay was 3.6 nights (median: 1).
Conclusion: Our data support that catheter ablation in ACHD patients is safe and has high acute success rate.

P2032 - DYNAMIC QT INTERVAL CHANGES FROM SUPINE TO STANDING IN HEALTHY CHILDREN

Audrey Dionne[1], Anne Fournier[1], Nagib Dahdah[1], Dominic Abrams[2], Paul Khairy[3], Sylvia Abadir[1]
Chu Sainte Justine, Pediatric Cardiology, Montreal-Canada[1]; Boston Children's Hospital, Electrophysiology, Boston-United States[2]; Montreal Heart Institute, Electrophysiology, Montreal-Canada[3]

Background: QT interval variations in response to exercise-induced increases in heart rate (HR) have been reported in children and adults in the diagnosis of long QT syndrome. A quick standing challenge has been proposed as an alternative provocative test in adults, with no pediatric data yet available.
Objective: Characterize physiological QT interval variations during a quick standing test in a cohort of healthy children.
Methods: A standing test was performed in 47 healthy children (mean age 9.3 ± 2.9 years) following 10 minutes in a supine position with continuous ECG recording. QT intervals were measured at baseline, maximal HR, maximal QT, and at each minute of a 5-minute recovery. Measurements were taken in leads II/V5 and corrected for HR (QTc).
Results: Upon standing, HR increased by 26 ± 9 bpm. QT interval was similar at baseline and upon standing (388 ± 32 versus 383 ± 34 msec, $p = 1.0$). However, QTc increased from 429 ± 21 to 493 ± 36 msec ($p < 0.001$). The 95th percentile for QTc at baseline and maximal HR was 457 msec and 550 msec, respectively. At 1 minute of recovery, QT interval was shorter (370 ± 29 msec) compared to baseline (388 ± 32 msec, $p < 0.001$) and standing (383 ± 34 msec, $p = 0.002$). QTc reached baseline values after 1 minute of recovery and remained stable thereafter (428 ± 19 msec at 1 minute, 434 ± 21 msec at 5 minutes, $p = 1.0$).
Conclusion: Significant QTc changes occur in healthy children in response to a standing test, yet with a greater magnitude than reported in adult series. This test needs to be validated in larger pediatric cohorts before its' clinical use.

P2037 - USEFULNESS OF ELECTROCARDIOGRAM IN THE DETECTION OF VENTRICULAR HYPERTROPHY IN ASYMPTOMATIC NEWBORNS

Nurin Jivani[1], Arpit Agarwal[1], Prashant Minocha[2], Sethuraman Swaminathan[1]
University of Miami/jackson Memorial Hospital, Pediatric Cardiology, Miami-United States[1]; University of Miami/Jackson Memorial Hospital, Pediatrics, Miami-United States[2]

Background: Historically, electrocardiogram (ECG) has been a key diagnostic tool in the work-up of congenital heart disease (CHD). Studies published in the past have helped establish the normal range for QRS amplitude and interval duration for newborns. At our hospital, we use ECG to screen infants of diabetic mother and newborns with a heart murmur. All newborns with ECG demonstrating ventricular hypertrophy receive an echocardiogram. Our objective is to determine the yield of echocardiogram performed in newborns with ECG demonstrating ventricular hypertrophy.
Methods: A retrospective chart review of infants born at our hospital, a tertiary care center, between 2013 to 2016 was performed. Of these, 777 full term, asymptomatic newborns had cardiac evaluation including echocardiogram. The ECG findings were reviewed and categorized into 2 groups: Group 1, with ventricular hypertrophy and Group 2, with no hypertrophy (Table 1). Echocardiogram findings were reviewed and divided into 4 categories (Table 2). Fisher's Exact test was used to compare the two groups.
Results: 676 infants had ECG performed as part of their work-up (Figure 1). Of these, 43 (6.4%) newborns had ventricular hypertrophy by echocardiogram. In Group 1, 25/234 (10.7%) newborns had hypertrophy by echocardiogram. Critical CHD was identified in 3 of these 25 newborns. Of note, 2 patients with Critical CHD only had an innocent murmur and echocardiogram was performed solely for ventricular hypertrophy detected on ECG. In Group 2, 18/442 (4.1%) newborns had ventricular hypertrophy by echocardiogram. There was a statistically significant difference in the incidence of ventricular hypertrophy identified between the 2 groups ($p < 0.02$).
Conclusion: ECG is an inexpensive and non-invasive tool to identify ventricular hypertrophy in newborns, although the yield is low. Further research is needed to redefine the voltage criteria and improve the specificity. ECG remains a critical tool in the identification of Critical CHD.

Table 1. Categorization of Bectrocardiogram Findings

Group 1: Ventricular Hypertrophy on ECG (n = 234)	Right ventricular hypertrophy
	Left ventricular hypertrophy
	Septal hypertrophy
	Biventricular hypertrophy
Group 2: No hypertrophy on ECG (n = 442)	Normal sinus rhythm
	Sinus bradycardia or tachycardia
	Non-specific ST-T wave changes, Prolonged QTc
	Axis deviation: right or left
	Premature atrial contraction.
	Premature ventricular contraction
	Atrial flutter. Supraventricular tachycardia

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Table 2. Categorization of Congenital Heart Disease (CHD)

Critical	any CHO requiring immedete htervention Example: critical aortic or pulmonary stenosis, hypoplastic left heart syndrome, transposition of the great arteries
Major	any CHD requiring interventbn within 6 months of life Example: large VSD, atrioventricular septal defect, tetralogy of faItot
Minor	any CHO expected to resolve spontaneously or unlikely to require intervention Example: small PDA, ASD or small muscular VSD.
Normal	No CHD Example: PFO, very small PDA and normal variants

P2052 - HEMODYNAMIC FACTORS INFLUENCING UPON EFFICIENCY OF ANTIARRHYTHMIC THERAPY IN INFANTS, TODDLERS AND PRESCHOOL CHILDREN

Liliya Svintsova[1], Olga Dzhaffarova[1], Irina Plotnikova[1], Igor Kovalev[2], Sergey Popov[1]
Cardiology Research Institute Pediatric cardiology department Tomsk-Russia[1]; Research and Clinical Institute for Pediatrics Pediatric cardiology department Moscow-Russia[2]

Aim: To analyze the results of antiarrhythmic therapy (AAT) in preschool children with arrhythmias.
Methods and materials: 100 patients with arrhythmias got prolonged AAT. Arrhythmias were WPW syndrome, atrial tachycardias, ventricular tachycardias, extrasystole. Children's age was till one year old – 41 pts, from 1 till 3 - 23, from 3 till 7 - 36. Reasons for drug therapy were heart attacks prevention, sinus rhythm recovery or heart rate control at the level of normosystole with permanent and incessant tachycardias; depression and decrease of ectopic activity of arrhythmia focus. The therapy duration varied from 10 days till 12 months. The most children were prescribed monotherapy. When it was ineffective, in 19 patients, they got combined treatment. With the aim of assessment of Holter and EchoCG during prolonged AAT their comparison analysis was carried out initially, at 5-8 day after efficiency criteria appearance, and also in 6 months after therapy withdrawal.
Results: Criteria of effective therapy were reached in 38% of pts. Prolonged AAT was ineffective in 62% of children. The most effectiveness was marked with prolonged amiodarone intake in our patients. The drug was effective in 40,6% of patients, where the children with WPW syndrome at the age of under one year old predominated. The assessment of results of antiarrhythmic therapy using discriminative analysis allows defining factors influencing on its effectiveness. The factors were age and echocardiographic signs of tachyinduced cardiomyopathy (TCMP). Children under one year old with WPW syndrome, paroxysmal tachycardia and without TICM signs have greater chance of effective AAT.
Conclusion: Patients of early age with tachyarrhythmias which aren't accompanied by heart structural changes should expect effective result of drug therapy. Patients after one year old with echocardiographic signs of tachyinduced cardiomyopathy should expect ineffective AAT result and perform RFA.

P2054 - AMIODARONE-INDUCED THYREOPATHIES IN SMALL CHILDREN WITH ARRHYTHMIAS

Liliya Svintsova[1], Olga Dzhaffarova[1], Irina Plotnikova[1], Igor Kovalev[2], Sergey Popov[1]
Cardiology Research Institute Pediatric cardiology department Tomsk-Russia[1]; Research and Clinical Institute for Pediatrics Pediatric cardiology department Moscow-Russia[2]

Aim: The aim of the study was to assess the thyroid hormone levels during prolonged amiodarone therapy in 0–7-year-old children with arrhythmias.
Materials and Methods: A total of 42 patients with WPW syndrome (n = 19), atrial tachycardias (n = 16), and ventricular tachycardias (n = 7) received amiodarone therapy. The duration of amiodarone administration varied from 0.7 to 24 months (Me 6.00; IQR 1.83-9.00). The thyroid hormone levels were estimated at the following time points: before treatment, during the amiodarone treatment at least 3 weeks after the beginning of therapy, and 6 months after amiodarone discontinuation.
Results: The levels of thyroid-stimulating hormone (TSH), total thyroxine, free thyroxine, thyroglobulin increased during amiodarone therapy.
The increases in the total and free thyroxine levels were statistically significant whereas TSH and thyroglobulin increased insignificantly during amiodarone therapy. All these indices significantly decreased 6 months after discontinuation of amiodarone therapy. Comparison of the initial values with the tests results 6 months after amiodarone discontinuation did not show any statistically significant differences. No clinical sings of hypertyrosinemia were observed in our patients during amiodarone treatment. The most significant changes in the levels of thyroid hormones were found in infants. During the entire course of amiodarone treatment, the median values of thyroid hormones did not exceed the upper reference ranges even when statistically significant changes in hormonal status occurred.
Conclusions: Amiodarone-induced changes in thyroid status were reversible and thyroid hormone values normalized 6 months after discontinuation of therapy.

P2139 - FASCICULAR VENTRICULAR TACHYCARDIA CASE REPORT

Marilia Alcoforado Domingues, Salem Fraga, Raizza Costa, Alexandre Abla, Gabriela Mesquita, Iara Malan, Clayne Valadao, Luciana Almenara, Grazielli Gigiane
Instituto Nacional De Cardiologia, Servico De Cardiologia Da Crianca E Do Adolescente, Rio De Janeiro-Brazil

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: The complaint of palpitation in children is a symptom that should be carefully evaluated, especially if it is associated with symptoms of low cardiac output, since it allows adequate diagnosis and treatment, as well as orientation on the prognosis of the patient, depending on the arrhythmia identified.
Case Description: The purpose of this paper is to describe a case of a 11-year-old black male patient with no structural heart disease, with a history of palpitation associated with dizziness and pre-syncope since pre-school age. He was submitted to a Holter and was diagnosed with idiopathic fascicular ventricular tachycardia at the age of 5 years old. Since then, he has made regular use of verapamil. Due to partial symptom control, metoprolol was associated to the treatment. However, there was worsening of dizziness and fatigue, which improved with reduction of the beta-blocker dosage. Ergometric stress test showed no exercise tolerance. Transthoracic echocardiography revealed normal cavity dimensions, without global and segmental contractility alterations and ejection fraction of 54% by the Simpson method.
Discussion: Idiopathic fascicular ventricular tachycardia of the left ventricle is a rare manifestation of arrhythmia. Although it is a ventricular tachycardia, its origin usually occurs in the fascicles of the left branch, presenting a narrower QRS. It usually affects young patients without structural heart disease. It is characterized by its reversibility with the use of intravenous verapamil. Radiofrequency ablation is indicated for the treatment of symptomatic patients, since there is a high rate of success of the procedure, resulting in a life free of adverse events, with a prognosis equal to that of the general population.

P2154 - EVALUATION OF SUSTAINED TACHARRYHTMIAS IN PATIENTS YOUNGER THAN 1 YEAR OF AGE 6 YEARS OF EXPERIENCE IN SINGLE CENTER

Gulhan Tunca Sahin, Taner Kasar, Erkut Ozturk, Alper Guzeltas, Yakup Ergul
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey

Background: Tachyarrhytmias are common cardiac arryhtmias in newborns and infants. In this study, we aim to evaluate the results of non-operational sustained tachyarrhytmias in patients younger than 1 year of age in our center.
Materials and Methods: The study was retrospectively performed in our center between November 2010 and November 2016 Post-operative tacharrhytmias were excluded. Demographical characteristics, type and localization of the tachyarryhtmia, echocardiographic findings and applied medical and/or ablation therapies were evaluated.
Results: In total we had 92 patients (60 male, 32 female). 86 had supraventricular tachcardia (SVT), 6 had Ventricular tachcardia (VT). Median age was 60 days (1-360 days), Median weight was 5 kg (2-10 kg). Common symptoms were palpitation and discomfort (n = 46, 50%) Others were detected during routine inspection (n = 29, 31%) and fetal echocardiography (n = 9,9.7%). 16 of them (18%) had left ventricular dysfunction in first echocardiographies, 9 had congenital heart diseases.The subtypes of SVT were determined in 55 (59%) of the SVTs by both invasive and non-invasive methods. 27 of them had WPW, 11 had FAT, 7 had concealed accessory pathway, 6 had PJRT, 4 had atrial flutter and the remaining 31 had SVT with narrow QRS. 83 of the SVT patients were treated using medical therapy. 9 cases were treated with ablation due to either resistance to medical therapy or left ventricular dysfunction. Commonly used medications were adenosine (all the patients), propranolol (n:70), amiodarone (n:31), flecainide (n:16), propafenone (n:15), esmolol (n:12), digoxin (n:14), sotalol (n:8). 11 cases had medical therapy combined with cardioversion.
Conclusion: Sustained tacharryhtmias in children under 1 year of age are mostly caused of accessory pathways and need multidrug therapy. It should be kept in mind that ablation is an effective alternative therapy in those cases with resistance to medical therapy and/or left ventricular dysfunction.

P2155 - SINGLE CENTER POPULATION BASED RESULTS FOR RADIOFREQUENCY CATHETER ABLATION OF TACHYARRHYTHMIAS IN CHILDREN

Valeria Acevedo[1], Miguel Oryan[1], Patricia Aroca[1], Patricia Alvarez[1], Rodrigo Nehgme[2]
Hospital Roberto Del Rio, Pediatric Cardiology, Santiago-Chile[1]; Arnold Palmer Hospital For Children, Pediatric Cardiology, Orlando-United States[2]

Background: Tachyarrhythmia's are common in pediatric population and catheter ablation has become the definite treatment. The purpose of our study is to examine all catheter ablations performed in pediatric patients in our electrophysiology lab.
Methods: From January 2004 to November 2016, 274 children with tachyarrhythmia were submitted to electrophysiology study. Retrospective analysis of clinical features, electrophysiology study and follow up were performed. The median age (IQR) was 13 years (11-14), 49% female, median weight (IQR) 52 kg (43-64). 94% (257/274) of the patients received antiarrhythmic therapy, 96% (246/257) β-blockers, 18% (46/257) flecainide and 6% (15/257) others. Patients were followed for at least 1 year.
Results: 288 electrophysiology studies were performed in 274 patients, 28 (10%) were normal. Ablation was performed in 82% (215/260) of the studies. We found 176 accessory pathway in 163 patients, 56% (98/176) were left. Atrioventricular nodal reentrant tachycardia (AVRT) was present in 60 (20%) studies, ventricular tachycardia (VT) in 12 (4%) and atrial reentrant tachycardia (ART) in 7 (2%). Global RF ablation success was 94% (203/215). Accessory pathway were successful overall in 94% (142/151) of ablations, 99% (94/95) in left and 86% (48/56) in right ($p = 0.003$ Mantel-Haenszel with Yates correction). AVRT ablation was successful in 96% (46/48), VT in 55% (6/11) and ART in 80% (4/5). We had 8 (3%) minor complications: transitory atrioventricular block, arteriovenous fistula and femoral hematoma. No major complication was reported. The overall recurrence rate was 21/203 (10%), 11% in accessory pathway and 4% in AVRT.
Conclusions: The RF ablation is a safe and effective treatment for pediatric patients with tachyarrhythmia. In our cohort we had similar overall ablation success and recurrence rate as reported in literature.

P2157 - CATHETER ABLATION OF MANIFEST POSTEROSEPTAL ACCESSORY PATHWAY ASSOCIATED WITH CORONARY SINUS DIVERTICULA IN A CHILD WITH CONGENITALLY CORRECTED TRANSPOSITION OF THE GREAT ARTERIES

Yakup Ergul[1], Osman Esen[2], Alper Guzeltas[1]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic And Cardiovasculer Surgery Training and Research Center Hospital, Anesthesia, Istanbul-Turkey[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: To date, a pediatric patient with congenitally corrected transposition of the great arteries (CCTGA) accompanied by WPW syndrome treated by an ablation inside the coronary sinus (CS) diverticula has not been reported. This study presents a successful radiofrequency (RF) catheter ablation of the CS diverticula–sourced manifest accessory pathway in patient who was diagnosed with CCTGA.
Case Report: A 4.5year-old male patient, weighing 18 kg, visited our clinic with a repetitive multiple antiarrhythmic-resistant (including beta-blocker + propafenone + amiodarone) supraventricular tachycardia (SVT). The patient had a pulmonary banding operation when he was 2 months old because of CCTGA, broad perimembranous VSD, right ventricle hypoplasia, and pulmonary hypertension. Also he had a two successful RF catheter ablation operation because of the left posteroseptal region–related AP (WPW), but SVT was recurred. After discussing possible risks with his family, he underwent catheter ablation again. An electrophysiological study was performed after an informed consent was obtained. Considering the patient's age and complex cardiac pathology, EnSite Velocity System (St. Jude Medical Inc.,MN, USA) and fluoroscopy were used during ablation operations. During the electrophysiological study as the earliest area was found as CS ostium, a mapping was done into the CS, and CS diverticula were detected with the help of CS angiogram. Here, the place that was 40 ms ahead of the surface delta was labeled with an RF catheter mapping. To be able to detect the proximity between coronary artery and ablation area, a coronary angiography was performed. Since the ablation area was far from the coronary arteries, RF ablation was performed successfully. The patient was asymptomatic without any drug during the 9-month follow-up, and no preexisting transition was observed on ECG.
Conclusion: Manifest AP ablation can be difficult in congenital heart diseases such as CCTGA. In addition, CS diverticula should be taken into account in recurrent posteroseptal APs.

P2158 - ATRIAL FLUTTER AND NONCONDUCTED BIGEMINY PREMATURE ATRIAL CONTRACTION IN A NEONATE WITH CARDIAC RHABDOMYOMA

Yakup Ergul, Erkut Ozturk Ozturk, Alper Guzeltas
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey

Background: In the present case study, an 8-day-old neonate whose bigeminy nonconducted premature atrial early pulse–related bradycardia and cardiac rhabdomyoma–related resistant atrial flutter were detected and successfully treated was presented.
Case Report: This study presents the case of a baby with birth weight 3100 g born after an unfollowed antenatal pregnancy and visited another medical center with a decrease in the suckling reflex and cyanosis complaints. In the physical examination, tachycardia with an irregular (with a narrow QRS phase) RR interval (up to 200/min) was detected in the baby. In the 2D and color Doppler echocardiographic evaluation, a slight hyperechogenic rhabdomyoma (13 × 15 mm2) near the superior vena cava at atrium fornix was observed in the subcostal apical five-chamber section (left side). It was observed that the tumors did not cause any obstruction in the flow, and the functions of the left ventricle was conserved. Despite these medical treatments, the patient's atrial flutter continued; therefore, the atrial flutter was stopped with cardioversion, which was synchronized with 2 J/kg energy. A frequent-aberrant transitive and bigeminy nonconducted premature atrial contraction (PAC) related bradycardia was detected in the after-cardioversion follow-ups of the patient, and the treatment was carried out after giving oral 3 mg/(kg · day) amiodarone. The atrial flutter and bradycardia attacks of the patient did not repeat during the 3-month follow-up. This patient was still followed up for tuberous sclerosis and was under low-dose amiodarone + propafenone treatment.
Conclusion: In neonates, rhabdomyomas with atrial location can cause problems both by making atrial flutter with fast ventricle transportation and by leading to bigeminy nonconducted PAC-related functional bradycardia. Medical treatment and synchronized cardioversion are usually seen enough to treat that kind of arrhythmia.

P2169 - RADIOFREQUENCY ABLATION OF FAST VENTRICULAR TACHYCARDIA THAT CAUSED AN ICD STORM IN AN INFANT WITH HYPERTROPHIC CARDIOMYOPATHY

Yakup Ergul[1], Erkut Ozturk[1], Sertac Haydin[2], Alper Guzeltas[1]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiovascular Surgery, Diyarbakir-Turkey[2]

Background: An implantable cardioverter defibrillator (ICD) storm involves very frequent arrhythmia episodes and ICD shocks and is associated with poor prognosis in both the short and long term. The radiofrequency catheter ablation (RFCA) process can be used as a valuable salvage treatment for patients with an ICD storm.
Case Report: A two-year-old male patient weighing 12 kg was transferred to our hospital after cardiac arrest (CA) caused by fast VT. Defibrillation was repeatedly applied. The patient's echocardiography revealed non-obstructive hypertrophic cardiomyopathy (HCM). We carried out a propranolol, amiodarone, and flecainide treatment, and for secondary prevention the patient received an epicardial ICD. During the followup, "incessant" fast VT episodes of distorting hemodynamics, ICD shocks, impairment of systolic functions, and development of hypotension occurred; the patient was intubated and moved to the intensive care unit. Despite the intensive medical therapy and antitachycardia pacing, the treatment was ineffective, the VT attacks and ICDshs could not be stopped—more than 50 occurred in one day. The patient was then taken to the catheterization room for electrophysiology study (EPS) and ablation, and then in intubated condition from the ICU with intravenous support treatments and extracorporeal life support (ECMO) to the EPS laboratory. A successfully RFCA was performed salvage treatment for the fast VT that left posterior fascicular's Purkinje fibers and RF "line" lesions were created in the Purkinje area up to the left posterior fascicle(LPF)-HIS connection. After the ablation, the patient was transferred in a stable condition to the ICU with no need for an ECMO. During the six months follow-up after the antiarrhythmic treatment, the patient experienced no more ICDshs.
Conclusion: To our knowledge, this is the first infant case among HCM-diagnosed children with an ICD storm on whom an radiofrequency catheter ablation salvage treatment for the fast VT.

P2183 - IS THERE A CORRELATION BETWEEN ELECTROCARDIOGRAPHIC P WAVE FEATURES AND GOSE INDEX IN EBSTEIN'S ANOMALY

Taner Kasar, Ibrahim Cansaran Tanidir, Pelin Ayyildiz, Alper Guzeltas, Yakup Ergul
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: The aim of the study is to investigate the correlation between GOSE index of the patients with Ebstein's Anomaly and their electrocardiographic p wave amplitude and dispersion.
Patients and Methods: Unoperated patients with Ebstein's Anomaly were included prospectively in the study. The echocardiographic GOSE indexes and the simultaneous ECGs of the patients were recorded. The echocardiographic calculations and ECG evaluations were performed by the same pediatric cardiologist.
Results: 24 patients were evaluated in this study. Twelve of the patients were female (50%). The median body weight was 15 kg (2,5-60 kg), median O2 saturation was 95% (75-100%), median GOSE index was 0,62 (0,2-1,3), median p wave dispersion was 18msec (8-38msec), P max was 86 msec (58-104), P min was 62 msec (18-88) ve P amplitude was 2.7 mm (1.2-5). GOSE index was $<0,5$ in 8 cases, between 0,5-1 in 12 cases and >1 in 4 of the cases. A positive relation was observed between the GOSE index, P max ($r=0.5$, $p=0.02$) ve P amplitude ($r=0.780$, $p=0.001$).
Conclusion: There appears to be a significant correlation between GOSE index which is important in determining the severity and prognosis of the Ebstein's patients and p wave amplitude. Gose index might be predicted by the amplitude of p wave. For the confirmation of the importance of ECG data in prognosis, larger series of patients are needed to be evaluated.

P2191 - A CASE REPORT IS MEXILETINE USAGE EFFECTIVE IN SHORTENING THE QTC DURATION AND IMPROVING T WAVE ALTERNANS IN TIMOTHY SYNDROME

Gulhan Tunca Sahin[1], Alper Guzeltas[2], Yakup Ergul[2]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiologypediatric Cardiology, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[2]

Background: This article aimed to present a case with Timothy syndrome (TS) with cardiac arrest history, prolonged QT, and T wave alternans. TS is a rare multisystemic disease characterized by facial deformation, malign ventricular arrhythmia, syndactyly, immune deficiency, intermittent hypoglycemia, autism, neurocognitive development retardation, and prolonged QT duration (1). After mexiletine administration, the QTc duration of the patient got shortened and her T wave alternans disappeared.
Case Report: A 4.5-year-old female patient, who had a cardiac arrest history, presented with several Torsades de Pointes and ventricular fibrillation attacks during her intensive care follow-ups in another hospital. This patient was directed to our center after seeing a prolonged QTc in her electrocardiograms (ECGs). She had syndactyly on each foot. All other systemic examinations were normal except hypertonicity and contracture that occurred secondary to previous hypoxia. The ECG at arrival was at a normal sinus rhythm, with a heart rate of 90/min and QTc value of 606 ms. In her Holter ECG records, her QTc interval was extremely long (>600 ms), and she had a T-wave alternans. A positive Pg406R mutation in CACNA1C gene was found which is specific in TS. An epicardial implantable cardioverter defibrillator was implanted to the patient, and propranolol treatment was started. However, propranolol alone was not adequate to reduce the heart rate or to improve the T wave alternans. An additional mexiletine treatment was started. In her consecutive electrocardiograms, her heart rate decreased to 78/min, QTc value decreased to 501 ms, and T-wave alternans disappeared.
Conclusion: This case presents particular importance to the authors as it bandies about the idea of mexiletine usage in addition to an initial beta-blocker treatment for preventing T-wave alternans and decreasing the QTc interval in the cases with TS.

P2260 - VENTRICULAR TACHYCARDIA DUE TO NKX2.5 MUTATION A FIRST CASE REPORT

Mani Ram Krishna Singaravelu[1], Christian Turner[1], Janine Smith[2]
Children's Hospital at Westmead, Paediatric Cardiology, Westmead-Australia[1]; Children's Hospital at Westmead, Clinical Genetics, Westmead-Australia[2]

Background: The phenotype of familial arrhythmia syndromes is expanding with the increased use of genetic testing, robust cascade testing as well as the improved ability of implanted devices to recognize different arrhythmias. NKX 2.5 mutations have traditionally been associated with septal defects and cardiac conduction disorders. Recently, the possibility of association of NKX2.5 mutation with ventricular arrhythmias was raised based on animal studies and clinical hypothesis based on one report. We report a child with history of sudden death and AV conduction disorder with a mutation in NKX2.5 who was detected to have a ventricular arrhythmia on pacemaker and was uneventfully upgraded to an implantable cardioverter defibrillator.
Methods: This was a retrospective case record review of a family with history of septal defects, cardiac conduction disorders and sudden cardiac death.
Results: A 15-year-old boy was evaluated because of family history of sudden cardiac death. His father had underwent surgical closure of atrial septal defect in childhood and had been implanted with a permanent pacemaker after atrial fibrillation as diagnosed at 20 years of age. He died suddenly at 35 years of age and rapid ventricular beats prior to death was detected on the pacemaker. His brother had also undergone surgical closure of ASD at 3 years and had died suddenly at 18 years of age. The boy had also undergone ASD closure in early childhood. High degree AV block was detected on Holter and he underwent a pacemaker implantation. Routine pacemaker interrogation revealed 2 episodes of non-sustained ventricular tachycardia. He was upgraded to an implantable cardioverter defibrillator. Genetic testing revealed a causative mutation in NKX 2.5 gene. Family screening revealed evidence of cardiac conduction disorder in his half-sister.
Conclusion: NKX 2.5 mutations can cause ventricular arrhythmias in addition to A-V conduction disorders and a pacemaker may not be life saving in all.

P2302 - EFFECT OF HAART (HIGHLY ACTIVE ANTIRETROVIRAL TREATMENT) ON QTC INTERVAL IN ANTIRETROVIRAL NAÏVE HIV INFECTED CHILDREN A PROSPECTIVE LONGITUDINAL STUDY

Yupada Pongprot, Rekwan Sittiwangkul, Peninnah Oberdorfer
Chiang Mai University, Pediatrics, Chiang Mai-Thailand

Background: Prolongation of QTc interval, a complication which can lead to serious arrhythmia or sudden death, has been well documented in HIV-infected adult. However, there were limited studies in children with conflicting results regarding cause and associated factors.
Objective: To determine the prevalence of prolonged QTc interval and factors associated with longitudinal change after HAART regimen in antiretroviral naïve HIV-infected children.
Method: Prospective longitudinal study of 12-lead EKG in 40 antiretroviral naïve HIV infected children who were enrolled to received HAART at pediatric infectious clinic, Chiang Mai University Hospital, Thailand. The QTc interval (Bazett's formula) were measured at baseline, 1 year and 2 years after HAART regimen. Linear mixed model analysis was used to analysis factors associated with QTc changes over 2 years of treatment.
Result: Of 40 asymptomatic HIV-infected children enrolled, 32 patients (80%) were assigned to efavirenz based regimen and 8 patients (20%) were assigned to navirapine based regimen. There were 35% male and the mean age was 7.8 ± 2.6 years. Median CD4 percentage at baseline was 3% (interquartile range 1-8%) and mean viral load was 5.37 ± 0.38 log10copies/ml. Before initiation of HAART, the mean QTc interval was 409 ± 22 msec and no patient had QTc prolongation. After HAART, mean QTc interval was significant longer to 420 ± 24 msec at 1 year ($p = 0.006$) and 421 ± 27 msec at 2 year ($p = 0.006$). Factors associated with longitudinal increased in QTc interval were increasing age (estimate 1.86, 95% CI 0.52-3.18, $p = 007$) and increasing LDL-cholesterol (estimate 0.16, 95% CI 0.03-0.28, $p = 0.014$).
Conclusion: Asymptomatic antiretroviral naïve HIV-infected children had no QTc prolongation. After HAART regimen, increasing age and LDL-cholesterol level were associated with QTc prolongation.

P2322 - SUCCESFULL RADIOFREQUENCE ABLATION OF ECTOPIC FOCI IN A TODDLER WITH ECTOPIC ATRIAL TACHYCARDIA AND AMIODARONE ANAPHYLAXIS

Hasan Candas Kafali[1], Serkan Unal[2], Alper Guzeltas[1], Yakup Ergul[1]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Anesthesia, Istanbul-Turkey[2]

Background: Ectopic atrial tachycardia (EAT) is a common chronic supraventricular tachycardia (SVT) in children that often resists medical therapy. Untreated, it may progress to tachycardia-induced cardiomyopathy. It is often resistant to medical therapy and radiofrequency ablation is a succesfull and safe therapy option. Amiodarone is a class III antiarrhythmic drug, frequently used and very effective in ventricular and supraventricular arrhythmias; however, it has numerous side-effects, involving many organ systems. However anaphylactic reaction to amiodarone is a very rare caomplication.
Case Report: A two years old girl was referred to our center due to SVT resistant to adenosine. The electrocardiogram revealed a long R-P narrow QRS tachycardia, with blocked p waves under adenosine effect consistent with EAT. Echocardiography revealed only patent formanen ovale with normal left ventricular systolic function. During amiodarone infusion in PICU diffuse maculopapular rash and respiratory distress evolved, so amiodaron infusion was stopped and steroid and antihistaminics were given. The signs dissolved rapidly and class II (propranolo) and classI (flecainid) agents were started. On ambulatory follow-ups recurrent and incessent tachcardia attacks repeated and a class III agent (sotalol) was added to the therapy. Due to incessent tachcardias after multidrug therapy with 3 agents, an electrophysiologic study with successfull radiofrequency (RF) ablation of the ectopic foci was conducted. Conventional and ESV system mapping during tachycardia revealed two different foci in the right atrial appendage. The foci were marked with ESV system and ablated with a 5 F RF catheter successfully. The procedure was accomplished without any complication. At the follow-ups, the patient reports no further episodes of tachycardia.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: In conclusion we want to evoke that antiarrhytmic drug therapy is often ineffective and complicated in EAT in children and radiofrequency catheter ablation of such cases is a safe and succesfull therapy modality, even in younger children.

P2368 - THE PARADOX OF BRADYCARDIA AND WIDE QRS

Andrea Harris, Gurur Biliciler-denktas, Chandra Srinivasan
University of Texas Health Science Center at Houston/Children's Memorial Hermann Hospital, Pediatric Cardiology, Houston-United States

Background: We report the clinical presentation and management of two infants presenting with acute Flecainide toxicity without history forthcoming of medication administration error.
Methods: N/A
Results: Patient (1): 4-month-old male with d-transposition of the great arteries post arterial switch operation and history of atrial tachycardia managed with Flecainide 6 mg/kg/day and Propranolol 3 mg/kg/day. Patient (Pt) presented with 2-day history of decreased activity, lethargy, and electrocardiogram (ECG) showing sinus bradycardia (rate 66 bpm), first degree atrioventricular (AV) delay (PR 92 ms), severe intra-ventricular conduction delay (IVCD, QRS 160 ms – 242 ms), and premature atrial contractions conducted with variable rate-related bundle branch aberrancy (RRBBA). Figure shows representative ECG. Patient (2): 4-week-old female infant with reentrant supraventricular tachycardia managed on Propranolol 5 mg/kg/day and Flecainide 7 mg/kg/day. Pt presented with 2-day history of lethargy, poor oral intake, and ECG showing sinus rhythm with first degree AV delay (PR 206 ms), severe IVCD (QRS 180 ms), and premature atrial complexes conducted with variable RRBBA. In each case, diagnosis of Flecainide toxicity was suspected based on the ECG findings involving first degree AV delay and severe IVCD. High dose intravenous sodium bicarbonate was initiated along with supportive management with resolution of electrocardiographic findings in approximately two days in each case. Admission serum Flecainide confirmed toxic levels (Pt 1: 1.73 mcg/mL; Pt 2: 2.6 mcg/mL; therapeutic range 0.2-1.2). Pt 2 was discharged on optimized dose of Propranolol and Pt 1 was restarted on an appropriate dose 3 weeks post-discharge due to recurrence of SVT, with no further recurrences documented during their follow-up.
Conclusion: Flecainide toxicity remains an important complication seen during management of tachyarrhythmias. Prompt recognition of ECG manifestations and discontinuation of the drug along with institution of high dose intravenous sodium bicarbonate aids in the reversal of ECG manifestations and recovery.

P2410 - THE MEASUREMENT OF QTC IN CHILDREN A SURVEY OF CLINICAL PRACTICE

Norah Yee Sing Yap, Andrew Ho, James P Gnanapragasam
University Hospital Southampton, Paediatric Cardiology, Southampton-United Kingdom

Background: The QT interval is key to the diagnosis of Long QT Syndrome. Accurate and reproducible measurement of the QT interval can be challenging in clinical practice.
Methods: We conducted a questionnaire based survey to evaluate the methodology used in practice in the UK.
Results: The survey of 109 clinicians consisted of Paediatric electrophysiologists (7), Paediatric cardiologists (32), and trainees (27) as well as pediatricians with expertise in cardiology (24) and trainees (19). All participants used Bazett's formula for rate correction. Only 10.1% used additional formulae (7 Fredericia's, 2 Framingham and 2 QT nomogram). 83.3% measured the RR interval preceding the QT interval, 13.9% the concurrent RR interval and 0.9% RR unrelated intervals. 15.7% used manual calipers and 7.4% used electronic calipers for measurement. When intervals were estimated visually (without electronic calipers), the nearest approximation aimed for during measurement varied- 40msec 19.8%, 20msec 35.4%, 10msec 42.7% and 4msec 2.1%. 82.6% preferred lead II or V5 for measurement while the rest used a range of other chest and limb leads as their preferred choice. Of those using multiple cardiac cycles for measurement 50.6% quoted the average, 48.1% quoted the longest QTc and one quoted the range. 50.5% used the 'tangent method' to determine the end of T wave whilst 49.5% used visual assessment. If U-waves were present, 46.8% would always ignore it. 27.5% included U waves that merged with T-waves and 13.8% included U-waves that were at least half the T-waves height. The findings were broadly similar between the clinician categories.
Conclusion: There is no uniformity in the methodology of QTc measurement among clinicians in the UK. This study highlights the need for a nationwide consensus on methodology to ensure accurate and reproducible measurements.

P2412 - IMPROVED SIGNAL RESOLUTION AND FEWER LESION ATTEMPTS USING A MICROFIDELITY ABLATION CATHETER IN PEDIATRIC WPW

Bhavya Trivedi
Florida Hospital for Children, Pediatric Cardiology, Orlando-United States

Introduction: The Intellatip MiFi ablation catheter is an 8mm RF ablation catheter (Boston Scientific) with three circumferentially located microelectrodes at the catheter tip used to provide high fidelity local electrograms (EGMs) for mapping and identification of optimal ablation sites. We hypothesized that the MiFi catheter has utility in pediatric WPW ablation with improved signal resolution to identify accessory pathway (AP) potentials and lead to shorter procedures, reduced fluoroscopy, and fewer lesions.
Methods: Retrospective review of pediatric manifest WPW ablations at our center from Dec, 2012 to Jan, 2017. For safety with 8mm RF ablation, the MiFi catheter was only used in patients >35 Kg and with shorter RF application times. There were 38 cases with standard ablation catheters (Blazer, Boston Scientific, 4/8 mm) and 25 cases with MiFi. In 4 excluded cases, the MiFi catheter was successfully used for mapping only to identify ideal cryoablation site for parahisian AP.
Results: Long term success with at least 1 month follow up was achieved in 36/38 standard (std) cases and 25/25 MiFi cases. First lesion success was achieved in 8/38 (21%) std cases and 14/25 (56%) MiFi ($p < 0.05$). MiFi cases had fewer total lesions (avg 4.3 vs. 11.4;$p < 0.05$). In most MiFi cases (16/25), the microfidelity

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

EGMs demonstrated a clear, sharp, and higher amplitude AP potential (Kent potential) compared to standard ablation distal bipole. Avg total procedure time was not significant, while avg fluoro time (0.04 min MiFi vs. 1.1 min; p = 0.06), and radiation dose (0.45 mGy MiFi vs. 8.12 mGy;p = 0.07) trended toward significance. The intent was to remain fluoroless in all cases. No complications in either group.
Conclusion: These data suggest that the MiFi catheter has benefits over standard ablation mapping for identification of AP potentials in pediatric patients with WPW and allows for fewer total RF lesions with reduced fluoroscopy time.

P2606 - TRANSSEPTAL CATHETER APPROACH FOR LEFT SIDED ACCESSORY PATHWAYS – THE "GENTLE WAY" OF ABLATION FOR CHILDREN AND ADOLESCENTS

Viera Illikova[1], Peter Hlivak[2], Marko Bjelosevic[1], Michal Chalupka[1], Robert Hatala[2]
Childrens Cardiac Center, National Institute of Cardiovascular Diseases, Dept of Arrhythmias and Icu, Bratislava-Slovakia[1]; National Institute of Cardiovascular Diseases, Dept of Arrhythmias and Pacing, Bratislava-Slovakia[2]

Background: Radiofrequency catheter ablation (RFCA) of accessory pathways (APs) is the treatment of choice for AP-mediated supraventricular tachycardias. Since its introduction in children using the transaortic approach via retrograde femoral arterial cannulation for left-sided APs there were concerns regarding mechanical vascular and valvular damage. Thanks to extensive experience with transseptal (TS) punctures in adults this approach is now frequently used. However, the "conventional" retrograde transaortic approach continues to be the preferred choice in children.
Aim: This retrospective single-center analysis is focused on assessment of safety and efficacy of transseptal approach for RFCA of left-sided APs in children.
Material and Methods: In the period of 9 years (1/1/2008–31/12/2016) 67 ablations of left-sided APs via TS approach were performed in 65 children and TS approach was used in additional 11 pts for mapping (AP was ablated at the right side eventually). TS puncture was necessary in 59 pts (75,6%), the remaining 19 had a patent foramen ovale. For TS puncture long fixed-curve or variable curve sheaths were used (SL1 or Agilis, St. Jude Medical, USA) together with the corresponding TS Brockenbrough needles (BRK, SJM). I.V. heparin was administered after the puncture and repeated after 45 minutes.
Results: 59 TS punctures were performed in 57 children (6–18 years old, median 15). All procedures were successful without complications. RFCA was acutely successful in 55/57 pts with successful reablation in 2 patients and clinical long-term elimination of the arrhythmia in all but 1 pt (98%).
Conclusion: RFCA of left-sided APs in children via TS approach represents in our experience a very safe and effective ablation technique. We believe that TS approach for RFCA of left-sided APs eliminates any concerns of damage to subtle vascular and valvular structures in children and should be the approach of choice for experienced operators.

P2617 - UNREPAIRED TETRALOGY OF FALLOT WITH MYOCARDIAL INFARCTION IN AN ADULT PATIENT

Norihisa Toh[1], Atsushi Ueki[1], Nobuhiro Nishii[1], Atsuyuki Watanabe[1], Yosuke Kuroko[2], Yasuhiro Kotani[2], Shingo Kasahara[2], Teiji Akagi[1], Hiroshi Ito[1]
Okayama University, Department of Cardiovascular Medicine, Okayama-Japan[1]; Okayama University, Department of Cardiovascular Surgery, Okayama-Japan[2]

A 66-year-old man with a history of unrepaired tetralogy of Fallot and diabetes mellitus presented to a community hospital for worsening dyspnea and orthopnea. On admission, the patient was in New York Heart Association functional capacity III and continuous infusion of diuretics was administrated. After the admission, his heart rhythm changed from sinus rhythm to junctional rhythm and immediately after the change asystole and subsequent ventricular fibrillation were documented. Ventricular fibrillation terminated spontaneously and then the patient was transferred to our institution for further management. Physical examination was notable for a III/VI systolic ejection murmur and clubbing of the fingers was noted. Blood pressure was 148/84 mmHg and peripheral oxygen saturation 80% in air. Electrocardiography showed first-degree atrioventricular block with a cardiac rate of 70 bpm, rightward axis with right bundle branch block, and prolonged QRS duration (200 msec). Echocardiography revealed wide ventricular septal defect, with over-riding of the aorta, pulmonary valve stenosis with a peak gradient across the valve of 91 mmHg and right ventricular (RV) hypertrophy. The RV contractile function was severely impaired and left ventricular (LV) ejection fraction was decreased as well (30%). Moreover, left ventricular anterior and anteroseptum segments were hypokinesis. Coronary angiography showed 99% stenosis in the proximal left anterior descending artery and coronary stent implantation was underwent subsequently. After further management of heart failure, a cardiac magnetic resonance imaging demonstrated reduced RV and LV ejection fraction (24% and 21%, respectively). Due to the severe biventricular dysfunction, the option of total surgical repair was declined and cardiac resynchronization therapy with defibrillator (CRT-D) was considered. To predict the response of CRT, acute hemodynamic response was evaluated by invasive measurement of LV-dp/dt at baseline and biventricular pacing. LV-dp/dt increased from 720 mmHg/s to 940 mmHg/s after biventricular pacing and thus the patient underwent CRT-D implantation.

P2886 - CARDIAC TUMOUR MASQUERADING AS VENTRICULAR TACHYCARDIA

Saurabhi Das[1], Aritra Mukherji[2], Amitabha Chattopadhyay[2]
Rabindranath Tagore International Institute of Cardiac Sciences, Pediatric Cardiology, Kolkata-India[1]; Narayana Superspeciality Hospital, Pediatric Cardiology, Howrah-India[2]

Background: Cardiac tumours have been identified in 0.02% to 0.04% of the pediatric population. Most common of these tumours are benign. Large tumors may result in compression of cardiac chambers,conduction tissue or coronary vasculature, as well as obstruction of cardiac valves and outflow tracts. Some tumours display the potential for malignant arrhythmias, with an increased risk of sudden cardiac death. In the absence of hemodynamic impairment, observation is the standard care in most cases because many tumours spontaneously regress with time. Case reports have described the use of ICDs for persistent arrhythmias due to nonresectable tumours. We describe the case of a girl with a solitary large cardiac tumor, in the LV free wall, presenting with arrhythmias.
Materials and Methods: 12 year old Ms MD, presented with shortness of breath, NYHA II since early childhood. She had documented ventricular arrhythmia since the last two years, including prolonged episodes of monomorphic Ventricular Tachycardia

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(VT) at a ventricular rate of 150 beats/min to 175 beats/min as well as a slower wide complex rhythm, all of which were asymptomatic.Beta blockade with metoprolol was initiated with some improvement in the frequency. However, persistent arrhythmias prompted a conversion to sotalol. She continued to have asymptomatic episodes of VT, albeit less frequently. Echocardiogram revealed a 16 cm × 7 cm intramyocardial mass on the LV free wall.The mass seemed to be invading the LV cavity ,and was inhomogenous. Serial echocardiograms demonstrated rate related cardiac dysfunction. Cardiac CT scan demonstrated the nature of the tumor and its extent. Excision biopsy was contemplated,but only surgical biopsy was done due to the size and localisation of the tumor,with intraluminal extension, Histopathological specimen confirmed the tumor as a fibroma.
Results: The patient was followed with antiarrhythmic treatment. She has had a mild symptomatic improvement. *Conclusions:* Cardiac tumors, though rare in the general population,can present in a myriad masquerading ways. A good clinical judgement, along with proper imaging can be a saviour.

P2887 - CONCURRENT ANK2 AND RYR2 MUTATION IN A PATIENT WITH REFRACTORY CATECHOLAMINERGIC POLYMORPHIC VENTRICULAR TACHYCARDIA

Jakyoung Yoon[1], *Eunjung Bae*[1], *Kyungjin Ahn*[2]
Seoul National University Hospital, Pediatrics, Seoul-Korea, South[1]; *Eoul National University Hospital, Pediatrics, Seoul-Korea, South*[2]

Backgourd: Inherited cardiac arrhythmia including long QT syndrome (LQTS)and catecholaminergic polymorphic ventricular tachycardia(CPVT)is an important cause of sudden cardiac death in young people.
Case Report: We report a rare case of young patient who developed refractory catecholaminergic polymorphic ventricular tachycardia (CPVT) with borderline QT interval and sinus bradycardia on resting state. He had seizure-like episodes from 15 months old, and put on beta blocker from 7 years old with diagnosis of CPVT. Because of frequent syncope, he received an implantable cardioverter-defibrillator. Nevertheless he experienced ICD storm and frequent ICD shocks , which was partly relieved by thoracoscopic left sympathectomy and flecainide. In molecular genetic testing, concurrent mutations of ANK2 for Long QT syndrome type 4 and RYR2 for CPVT were confirmed.
Conclusion: we demonstrate the simultaneous occurrence of both a putative pathogenic RyR2(Ryanodine receptor 2)mutation and ANK2(Ankyrin 2)mutation in patient with clinically overlapping refractory CPVT and LQTS4 phenotype for the first time in Korea. Further comprehensive functional analysis in vivo and vitro is positively necessary.

P3038 - IMPLANTABLE CARDIOVERTER DEFIBRILATORS IN CHILDREN AND PATIENTS WITH CONGENITAL HEART DISEASES WHAT HAVE WE LEARNT IN TWO DECADES OF FOLLOW UP

Inmaculada Sánchez Pérez[1], *Natalia Rivero Jiménez*[1], *Ana Coca Pérez*[2], *Rocío Tamariz-Martel Moreno*[1], *María Jesús Lamas Hernández*[3], *Tomasa Centella Hernández*[3], *Roberto Matía Francés*[4], *Eduardo Franco Díez*[4], *Javier Moreno Planas*[4], *María Jesús Del Cerro Marín*[1]
Ramón Y Cajal Hospital, Pediatric Cardiology, Madrid-Spain[1]; *Ramón Y Cajal Hospital, Pediatric Intensive Care, Madrid-Spain*[2]; *Ramón Y Cajal Hospital, Pediatric Cardiovascular Surgery, Madrid-Spain*[3]; *Ramón Y Cajal Hospital, Cardiology, Madrid-Spain*[4]

Backgound: Implantable cardioverter defibrillators (ICDs) are a recognized therapy for the prevention of sudden death in adults. However, its use in children or patients with congenital heart disease (CHD) involves multiple drawbacks, and there is little information on the use and implant methodology. The aim of our study was to communicate the characteristics of the patients with ICDs from our center and to study the association between the presence of appropriate therapies and unfavorable events (electrode problems or inappropriate therapies) in both groups.
Materials and Methods: A retrospective, descriptive study.
Results: 46 patients (23% female). Average age of ICDs implant: 19 years (median 16 years). 20 patients with CHD and 26 with hereditary diseases (HD) (canalopathies or cardiomyopathies). 76% ICDs were implanted in secondary prevention. All but 5 were endocavitary systems; 1 epicardial, 2 mixed resynchronizing defibrillators and 2 with accessory subcutaneous coils. About chamber location: 10 single-chambered, 30 bicameral and 6 tricameral. Outcomes with mean follow up of 20 years were: 52% of patients had appropriate therapies, 28% inappropriate theraphies (23% due to supraventricular tachycardia and 5% due to electrode dysfunction). 10 patients presented electrode problems: 4 dislocations and 6 dysfunctions, more frecuent in younger patients. Five patients died, only one secundary to an arrhythmic storm. There was more incidence of appropriate therapies in patients with HD and, curiously, in those with ICDs as primary prevention. There was no difference by age. Inappropriate therapies were more frequent at lower ages, single-chamber devices, HD and ICDs implanted as secondary prevention.
Conclusions: The use of ICDs in children and CHD patients is of unquestionable utility. In our 20-year serie, ICDs have acted adequately in more than half of patients, but there are problems such as electrode dysfunction or inappropriate therapies, more frequent in lower ages.

P3046 - JUNCTIONAL ECTOPIC TACHYCARDIA IN CHILDREN EVALUATING TIME TO RATE CONTROL AND IMPACT ON OUTCOMES

Joel Lim[1], *Yee Hui Mok*[2], *Yee Jim Loh*[3], *Teng Hong Tan*[4], *Jan Hau Lee*[5]
KKH, Paediatric Medicine, Singapore-Singapore[1]; *Kkh, Children's ICU, Singapore-Singapore*[2]; *KKH, Cardiothoracic Surgery, Singapore-Singapore*[3]; *KKH, Cardiology, Singapore-Singapore*[4]; *KKH, Chidlren's ICU, Singapore-Singapore*[5]

Background: Junctional ectopic tachycardia (JET) is the most common tachyarrhythmia in children after surgery for congenital cardiac disease (CHD). It is often self-limiting, but is associated with increased risk of morbidity and mortality. The contributing factors and impact of time taken to achieve rate control of JET is poorly described.
Methods: A retrospective, single-center cohort study of children who developed JET after CHD surgery from January 2010 to June 2015 was performed. We classified the cohort into 2 groups: patients who achieved rate control of JET in $\leq$24 hours and in >24 hours. We examined factors associated with time to rate control and compared clinical outcomes [mortality, duration of mechanical ventilation (MV), length of intensive care unit (ICU) and hospital stay] between the two groups.
Results: Our cohort included 27 children, with a median age of 3 months [interquartile range (IQR): 0.7-38]. The most common CHD lesions were ventricular septal defect (n = 10, 37%), tetralogy of Fallot (n = 7, 25.9%) and transposition of the great arteries (n = 4, 14.8%). 15 (56%) and 12 (44%) patients achieved rate control of JET in $\leq$24 hours and >24 hours respectively. There

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

was a difference in median MV time [97 (21-145) vs 311 (100-676) hours, p = 0.013] and ICU stay [5.0 (2-8) vs 15.5 (5.5-32.8) days, p = 0.023] between the patients who achieved faster rate control than those who didn't. Differences in length of hospital stay and mortality between the 2 groups were not significant.
Conclusion: Our small cohort study demonstrated that time taken to achieve rate control of JET was associated with increased duration of MV and ICU stay, but did not impact mortality or length of hospital stay. Further larger studies are required to validate our preliminary findings.

HUMANITARIAN

P1014 - RESULTS OF INTERNATIONAL ASSISSTANCE FOR PEDIATRIC HEART SURGERY PROGRAM IN A SINGLE UKRAINIAN CENTER

Igor Polivenok[1], Frank Molloy[2], Olga Buchneva[1], Christian Gilbert[3], Mark Danton[4], Ali Dodge-khatami[5], Sri Rao[6], John Breinholt[7], Marcelo Cardarelli[8], William Novick[9]
Zaitcev Institute for General and Urgent Surgery, Cardiac Surgery and Emergency Cardiology, Kharkiv-Ukraine[1]; The William Novick Global Cardiac Alliance, Clinical Nurse Specialist, Educator & Co-founder, Memphis-United States[2]; Penn State Health, St Joseph, Cardiac Surgery, Reading-United States[3]; Royal Hospital For Sick Children, Pediatric Cardiac Surgery, Glasgow-United Kingdom[4]; University of Mississippi Medical Center, Pediatric and Congenital Heart Surgery, Jackson-United States[5]; The William Novick Global Cardiac Alliance, Interventional Cardiology Development Coordinator, Memphis-United States[6]; UT Health Science Center at Houston, Division of Pediatric Cardiology, Houston-United States[7]; Inova Children Hospital, Pediatric And Congenital Heart Surgery, Fairfax-United States[8]; The William Novick Global Cardiac Alliance, Medical Director, Ceo and Founder, Memphis-United States[9]

Background: Surgery for congenital heart disease has been slow to develop in parts of the former Soviet Union. We describe the impact of an 8-year surgical collaborative assistance program between our center and invited teams from countries with developed cardiac programs.
Material and Methods: The refered international pediatric assistance program included four main components: (1) on-site surgical and interventional activity with hands-on training of the local team, (2) medical education, (3) biomedical engineering support, 4) a team-based practice development. Data was analyzed from visiting teams and Kharkiv databases prior to and since commencement of assistance (Period A: 2000–2007 (8 y); Period B: 2008-2015 (8 y)). Out of a total of 1347 surgical and interventional pediatric cases performed during both periods, 979 surgical cases with RACHS-classifiable lesions were analyzed. We compared the following variables between periods: annual case volume, 30 day-hospital mortality, case complexity (RACHS-1), and RACHS-adjusted standardized mortality ratio (SMR: observed/expected mortality). We evaluated the improvement in local surgical skills during Period B.
Results: 154 RACHS-classifiable surgeries were performed during Period A, with a mean annual case volume of 19.3 surgeries (95% CI 14.3–24.2) an overall mortality of 4,6% and a SMR of 3.4. During Period B volume increased to 825 mean annual surgeries ($p < 0.0001$), with an increment to 103.1 mean annual cases (95% CI 69.1–137.2). The increase in case complexity led to a small raise of the overall mortality (5.7%) with a lower SMR (1.4). The proportion of local surgeon led surgeries during trips increased from 0% in 2008 to 98% in the final year of analysis.
Conclusions: This model of assistance to developing programs has improved adjusted mortality, increased case volume, increased complexity and developed independent operating skills in an economically disadvantaged center.

P1028 - PEDIATRIC CARDIAC SURGERY FOOTPRINT ITS GLOBAL IMPACT ON HUMAN DEVELOPMENT

Marcelo Cardarelli
Inova Children Hospital, Surgery, Fairfax-United States

Objective: By using the concept of "Footprint of Global Surgery" we are trying to unveil the positive consequences of changing the natural history of congenital heart disease in low and middle income countries (LMIC). We attempt to measure the footprint of pediatric cardiac surgery in relationship to gains in a number of indicators (Life Expectancy, Education and Income per Capita) conforming the Human Development Index (HDI).
Material & Methods: We collected all clinical data available on patients operated by our organization in 10 LMIC during 2015. We also estimated from our financial data the operative costs incurred in the accomplishment of our missions during that year. Data on HDI indicators were obtained for each country while independent reviewers calculated the incremental difference in life expectancy, education and years of income per capita added by modifying the natural history of the disease by our intervention (surgical repair). The total financial cost of operations was divided by the number of patient reached with the global effort. A cost per surgery was achieved and ascribed to the incremental difference in those indicators.
Results: During 2015 a total of 470 operations were carried out in 444 patients. Overall mortality was 7.8% (n = 35). Thirteen adults with CHD were removed from the final analysis (their surgeries included in our operational costs), leaving the total at 396 studied patients. Organizational expenses for 2015 ($3,460,101) were divided by 444, bringing the cost per patient operated to $ 7,362.00.
Conclusions: The footprint of pediatric cardiac surgery in LMIC is significant. While dimed costly, resources dedicated to global surgery efforts Aggressive healthcare interventions, may result in significant human developmental improvement for LMIC. Global Surgery should be encouraged by international organisms dedicated to global health.

P1070 - DEVELOPMENT OF A SUSTAINABLE NEWBORN CARDIAC SURGICAL PROGRAM IN SIBERIA

Alexander Nikolishin[1], Evgeny Krivoshchekov[1], Frank Cetta[2], Josie Everett[3], Natasha Lusin[3], Nathaniel Taggart[2], Nilas Young[4], Janet Simsic[5]
Institute of Cardiology, Cardiothoracic Surgery, Tomsk-Russia[1]; Mayo Clinic, Pediatric Cardiology, Rochester-United States[2]; Heart To Heart International Children, Heart To Heart International Children, Oakland-United States[3]; University of California, Davis Medical Center, Cardiothoracic Surgery, Sacremento-United States[4]; The Ohio State University, The Heart Center at Nationwide Children's Hospital, Columbus-United States[5]

Background: Worldwide, less than 15% of children born with congenital heart disease have access to appropriate medical care. The purpose for this study was to evaluate the effectiveness of Heart to Heart International Children's Medical Alliance's (H2H) multidisciplinary training program to improve the care of

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

newborns with congenital heart disease in Tomsk Russia by creating a sustainable center of excellence.
Methods: Retrospective review of cardiopulmonary bypass procedures (CPB) and outcomes in newborns (<30 days of age) from 2005 through 2015. H2H's educational program was between 2006 and 2012. H2H's multidisciplinary educational model incorporates 6 key elements: (1) site assessment including demographics, regional need, medical and societal infrastructure, support for program; (2) development of strategic relationships with key stakeholders; (3) annual medical educational missions with emphasis on education; (4) strategic guidance and programmatic leadership development; (5) bi-directional scholarly exchange and continuing education between annual educational mission trips; (6) facilitation of networking and interaction between H2H sites in Russia.
Results: Table1. Volume of newborns undergoing cardiac surgery increased from 4 (3%) in 2005 to 62 (16%) in 2012 (last year of H2H educational program) and was 37 (9%) in 2015. Newborn mortality decreased from 50% in 2005 to 13% in 2012 and was 11% in 2015. Overall mortality decreased from 9% in 2005 to 4% in 2012 and was 2% in 2015.
Conclusions: The goal of creating a comprehensive, sustainable cardiac surgical program to care for newborns with congenital heart disease can be accomplished. The individualized, multidisciplinary training and educational strategy developed by Heart to Heart International Children's Medical Alliance has proven successful in increasing patient complexity over time with excellent surgical results.

Table 1. Outcomes

	Total Cases	Newborn <30 days	1-12 month	>1 year	STAT 4 (mortality)	STAT 5 (mortality)	Newborn Mortality	Overall Mortality
2005	137	4 (3%)	35 (26%)	98 (71%)	0 (0%)	0 (0%)	2 (50%)	12 (9%)
2006	145	16 (11%)	51 (35%)	78 (54%)	20 (25%)	2 (100%)	5 (31%)	13 (9%)
2007	185	16 (9%)	62 (33%)	107 (58%)	23 (13%)	2 (50%)	5 (31%)	14 (8%)
2008	224	16 (7%)	88 (39%)	120 (54%)	28 (14%)	0 (0%)	2 (12%)	5 (2%)
2009	315	26 (8%)	136 (43%)	153 (49%)	47 (17%)	2 (0%)	4 (15%)	18 (6%)
2010	374	25 (7%)	139 (37%)	210 (56%)	43 (12%)	5 (20%)	4 (16%)	11 (3%)
2011	321	20 (6%)	123 (38%)	178 (56%)	25 (8%)	3 (0%)	2 (10%)	7 (2%)
2012	387	62 (16%)	157 (41%)	168 (43%)	47 (4%)	14 (28%)	8 (13%)	16 (4%)
2013	366	33 (9%)	180 (49%)	153 (42%)	19 (10%)	7 (14%)	4 (12%)	5 (1%)
2014	350	36 (10%)	139 (40%)	175 (50%)	21 (19%)	1 (100%)	3 (8%)	8 (2%)
2015	418	37 (9%)	183 (44%)	198 (47%)	26 (15%)	1 (0%)	4 (11%)	8 (2%)

P1091 - GROWING UP WITH PEDIATRIC CARDIOLOGY

Agustin Ramos
Florida Hospital for Children, Pediatrics, Orlando-United States

When I was growing up in Barcelona in the 1950's, pediatric Cardiology did not exist. My father was professor of Pediatrics here in Barcelona and my mother was also a pediatrician. I remember comments such as "Mrs. Rodriguez had a baby, but he died of heart disease". It was accepted because nothing could be done about it. It is remarkable that in only one generation, we have learned, successfully in most cases, to palliate or repair every type of congenital heart disease. In 1961, the 1st Board Examination by the Sub-Board of Pediatric Cardiology was instituted. Surgical repair of most common types of congenital heart disease became commonplace. Mustard and Senning created palliative techniques for transposition of the great vessels. Coronary bypass was invented. Barnard did the first cardiac transplant. Rashkind performed the 1st balloon atrial septostomy. During the 70 s, Jatene introduced the arterial switch procedure for transposition of the great vessels. Prostaglandins were introduced to prevent postnatal ductal closure. Echocardiography revolutionized the diagnosis of infants and children with heart disease. The 1980s saw the development of interventional procedures that transformed the cardiac catheterization laboratory from a diagnostic to a therapeutic tool. The Norwood procedure became an alternative to heart transplantation for hypoplastic left heart syndrome followed by a Glenn and Fontan procedures. Cardiac electrophysiology improved understanding of cardiac arrhythmias resulting in therapeutic ablation techniques for Wolff-Parkinson-White syndrome. In the 1990s balloons were introduced to open structures and devices were developed to close others. MRI and CT scan were used extensively. Fetal echocardiography allowed for the detection of congenital heart disease as early as 16 weeks gestation. Millions of survivors are now living long and productive lives. In 2015, the 1st Board Examination for Adults with Congenital Heart Disease was established.

P1096 - IMPACT AND FUNCTIONING OF SPANISH FAMILIES LIVING WITH A CONGENITAL HEART DISEASE DEVELOPMENT OF A VALIDATED AND CULTURALLY ADAPTED QUESTIONNAIRE

Blanca Egea-Zerolo[1], Cristina Garcia-vivar[2], Julio Cesar De La Torre-Montero[1], Juan Manuel Arribas-Marín[1], Paula Visedo[1], Carlos Pitillas Salvá
Comillas Pontifical University, San Juan De Dios School of Nursing And Physical Therapy, Madrid-Spain[1]; University of Navarra, School of Nursing, Pamplona-Spain[2]; Comillas Pontifical University, Faculty of Humanities and Social Sciences, Madrid-Spain[3]

Congenital Heart Diseases are the most frequent congenital anomalies. They have a significant impact in paediatric morbidity and mortality. CHD represent the congenital disorder with the highest incidence in Spain, with 4,000 new cases every year. Besides, the family's approach may improve or worsen the course of the patient's chronic disease.
Objectives: Know the impact and family functioning of families (including parents, brothers/sisters and the paediatric patient) of a child with complex CHD, who have been subject to more than one surgical/haemodynamic invasive procedure and who will require more interventions in future.
Design: Observational descriptive cross-sectional study project. In this abstract, only the first stage of the study, which aims to develop a validated and culturally adapted questionnaire, is presented.
Subjects and Scope: The sample will include children with heart disease, and their fathers/mothers and brothers/sisters. Data collection will be carried out within families associated to the Foundation Menudos Corazones (1600 associates, with of all ages with CHD).
Method: A questionnaire has been designed using the following validated scales: Family Management Style Framework; "Paediatric Cardiac Quality of Life Inventory; and the Parental Response Style Questionnaire. Two more questionnaires-The Impact of Childhood Chronic Illness on the Family: Psychosocial Adjustment of Siblings, and the Family Social Support Questionnaire have been used after their validation and culturally adaptation to Spanish. The designed questionnaire has been tested with a group of mothers, fathers, children with CHD and brothers/sisters fulfilling the inclusion criteria. The technique used for this pilot stage was the "cognitive interview". The questionnaire will be sent to families associated to the Foundation fulfilling the inclusion criteria for on-line completion.
Conclusions: Obtaining a deep knowledge of families that live with CHD will provide the healthcare team with relevant information for the development of interventions aimed to improve care delivered to these families.

P1242 - BURDEN OF HEART DISEASES IN CHILDREN ATTENDING CARDIOLOGY CLINIC IN A REGIONAL REFERRAL HOSPITAL IN UGANDA

Dorah Nampijja[1], Francis Bajunirwe[2], Elias Kumbakumba[3], Charles Mondo[4]
Mbarara University of Science and Tehnology, Pediatrics, Mbarara-Uganda[1]; Mbarara University of Science and Technology, Community Health, Mbarara-Uganda[2]; Mbarara University of Science and Technology, Paediatrics, Mbarara-Uganda[3]; Mulago National Referral Hospital, Internal Medicine, Kampala-Uganda[4]

Introduction: Patterns and prevalence of heart diseases are different between the high income countries and low income countries. Acquired heart diseases like RHD, cardiomyopathies, pericarditis are still a public health burden while congenital heart diseases still carry a poor outcome among children. The aim of this study was to report the burden and pattern of heart diseases in a semi urban referral hospital in Uganda.
Methods: This was a prospective study in the paediatrics department at a regional referral hospital in Uganda over a period of 20 months. All children from birth up to 12 years who were referred or presented at paediatric department from different areas in the region for an index cardiac evaluation and had their Transthoraxic echo done were included in the study. These children were enrolled and followed up in the cardiology clinic for chronic care. Those who did not turn up for their expected reviews were followed up with phone calls to find out their outcome.
Results: Two hundred and forty children were screened during period and 65.8% had abnormal echocardiological findings. More females than males were had abnormal Echos at 51.9%. VSD were the commonest acyanotic heart disease followed by PDA at 37% and 17% respectively. TOF was highest at 11% followed by Truncus arteriosus at 5.9%. Mean age at diagnosis of congenital heart disease was 28 months (SD 33). RHD was the commonest at 72.5% of the acquired heart diseases. Sixty three percent of children needed and were referred to the national cardiac centre. Only 52% managed to go to the cardiac centre, only 4.4% got surgical intervention. 25% of the children died while 12.7% were lost to follow up.
Conclusion: There is a high burden of heart diseases in our setting with limited access to interventional services.

P1573 - EFFECT AND PROBLEM OF PEER SUPPORT TO THE PARENTS OF FETUS WITH SERIOUS HEART DISEASE

Makoto Nishibatake[1], Hiroe Maekawa[2], Eriko Nagasato[2], Mizuyo Tachioka[2]
Kagoshima Seikyo Hospital, Pediatrics, Kagoshima-Japan[1]; Taniyama Seikyo Clinic, Opd of Pediatrics, Kagoshima-Japan[2]

Introduction: To provide appropriate support to the expectant parents after fetal diagnosis of serious heart disease is essential. However, effective support by medical stuffs to satisfy the client's needs is often difficult because of limited time and manpower. As peer support recently draws attention in the medical or educational fields, we tried to induce it in fetal cardiology.
Methods: Peer support opportunities were arranged to the expectant parents at their second or third visit to fetal cardiac examination. The supporters were selected from the parents of our patients with diseases similar to the client's fetus. At the start of each meeting, the physician briefly introduced the supporter and the clients each other, then they talked for one hour. To prevent the discussion wondering from the subject and to keep time, a nurse attended as a facilitator.
Results: 28 clients were supported by 14 supporters. Two thirds of the fetal heart disease were univentricular heart spectrum for which Fontan-type surgery are expected after birth. The others included biventricular repair candidates and a case of complete AV block. Most important effect of peer support was that the clients could be relieved from anxiety by hearing the supporter's similar experience and coping skills. Also in addition to obtaining useful information such as hospital life, perinatal management and social supports, they could imagine their baby's real future by observing the supporter's children. On the other hand, the outcome of the fetuses is not always good that six fetuses of our series died after birth both pre and post-surgery and that unexpected extracardiac abnormalities including chromosomal abnormality existed.
Conclusions: Peer support is effective for the expectant parents of fetal heart disease. However, we should remember that the supporter's children as well as the client's fetuses are still unstable with their own illness.

P1589 - EFFECTIVE TEACHING METHODS FOR STUDENTS TO LEARN BASIC LIFE SUPPORT AND USE OF AUTOMATED EXTERNAL DEFIBRILLATORS

Keiichi Koizumi, Nobuyuki Katsumata, Yuto Sunaga, Masashi Yoshizawa, Yousuke Kouno, Yohei Hasebe, Hiroaki Kise, Takako Toda, Kanji Sugita, Minako Hoshiai
Faculty of Medicine, University of Yamanashi, Pediatrics, Yamanashi-Japan

Background: In recent years, installations of automated external defibrillators (AEDs) in schools have been increasing in Japan. Despite these efforts, around 40 students die suddenly in schools nationwide each year. To reduce, and even eliminate, occurrence of sudden deaths within schools, students themselves can contribute by acquiring proficiency in cardiopulmonary resuscitation (CPR) methods.
Purpose: We conducted a training session on CPR for students and their families, and examined effective methods of teaching CPR to students.
Method: CPR training sessions consisted of a 40-minute lecture and 60 minutes of hands-on practice. Doctors and nurses who are basic life support instructors authorized by the American Heart Association led the practice portion. Acceptance criteria of practical practice for students were based on those used in an American Heart Association basic life support healthcare provider course. For students and their families, we then conducted a questionnaire on which teaching methods were effective for students.
Results: The number of participating families was 47 (27 students) in the first round and 98 (53 students) in the second round. The questionnaire results showed that in lectures, it was effective to describe CPR in as plain and non-clinical language as possible, and to use animated movies about CPR. In practical skills in these sessions, use of practice manikins and AED trainers used by medical staff were effective means of learning. The instructors judged that students in lower grades of elementary school were capable of using an AED. Students in upper grades of elementary school were capable of performing effective chest compressions and understanding CPR concepts and procedures.
Conclusion: Teaching CPR methods starting at an elementary school age is an effective method for reducing sudden death among students in school.

P1707 - MEDICAL ART THERAPY FOR SYMPTOM RELIEF AND COPING WITH PROCEDURES FOR CHILDREN WITH CONGENITAL HEART DEFECTS UNDERGOING CARDIAC SURGERY

Ekaterina Anikeeva[1], Georgy Plotnikov[2], Tatiana Avdushkina[3], Ivan Halivopulo[4], Natalia Gaponova[5]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Federal State Budgetary Institution "research Institute For Complex Issues Of Cardiovascular Diseases", Department of Research and Education, Kemerovo-Russia[1]; Federal State Budgetary Institution "research Institute For Complex Issues of Cardiovascular Diseases", Laboratory of Critical Care, Kemerovo-Russia[2]; Kemerovo Regional Clinical Psychiatric Hospital, Pediatric Departement, Kemerovo-Russia[3]; Federal State Budgetary Institution "research Institute For Complex Issues of Cardiovascular Diseases", Department of Cardiovascular Surgery, Kemerovo-Russia[4]; Federal State Budgetary Institution "research Institute For Complex Issues Of Cardiovascular Diseases", Intensive Care Unit, Kemerovo-Russia[5]

Background: Creative work can help patients gain insights into life events that may exacerbate their pain and find coping techniques. Nurses spend 90% of their working time with children and may use medical art therapy strategies to offer expressive outlets and pathways to self-organizing for patients.
Purpose: To assess the efficiency of medical art therapy in reducing the anxiety of hospitalized children with CHD undergoing on-pump cardiac surgeries.
Methods: A subgroup of pediatric patients was selected; a single subject research design was initiated with a group of 5 to 8 year-old pediatric patients (n = 40, males – 22, females -18) hospitalized for treatment of CHD. All children with nurses and one pediatric psychologist were proposed to paint, make sculptures and use non-dangerous supplies (disposable gown, gloves, masks, etc.) to express their emotions and fears. The baseline phase began on the first day of each subject's hospital admittance. The intervention phase included art therapy interventions designed to familiarize subjects' with the hospital environment, provide opportunities for control and expression, and respond to subjects' established cognitive structures regarding their medical condition and treatment (at least 5 sessions for each subject). The following assessment instruments were used: the Anxiety Behavior Schedule (ABS), the Children's Health Locus of Control Scale, and the Children's Hope Scale (CHS).
Results: The overall anxiety level according to the ABS was 76.7%. All of the subjects demonstrated reduced externality of locus of control following art therapy intervention. All of the subjects demonstrated high hope on the CHS. The observable anxiety data confirmed reduction in anxiety due to art therapy intervention ($p < 0.05$).
Conclusion: Medical art therapy proved to be effective method in reducing the anxiety among pediatric patients. Opportunities for creative expression can help young patients cope with the psychological challenges of hospitalization and prevent the developmental disorders.

P1865 - ACHIEVING PEDIATRIC CARDIOVASCULAR CENTER EXCELLENCE THROUGH NGO PARTNERSHIP CHILDREN'S HEARTLINK'S SIX YEAR OUTCOMES 2010 TO 2015

Sarah Lovern
Children, Programs, Minneapolis-United States

Background: Children's HeartLink, an NGO with almost 50 years of experience, improves access to quality pediatric care. Children's HeartLink's model supports pediatric cardiac programs in low-resource settings to become sustainable regional centers of excellence by working in concert with dedicated medical volunteers to provide training, mentoring and capacity building.
Materials and Methods: In 2008, Children's HeartLink helped found the International Quality Improvement Collaborative for Congenital Heart Surgery in Developing Countries (IQIC) with the mission to reduce mortality and major complications for children undergoing congenital heart surgery. Today, the IQIC has 47 sites in 22 countries with a registry of 61,247 cases. In 2015, open heart surgical data for five Children's HeartLink partner institutions (2,139 cases) were compared to the aggregate of 28 other centers (10,728 cases).
Results: Between 2010 and 2015, Children's HeartLink Partner sites demonstrated overall reduction in postoperative rates of mortality and infection while also increasing surgical case complexity. Unadjusted in-hospital mortality rate decreased from 4.5% to 3.8%, an overall low in 2014 at 3.6%. Unadjusted 30-day mortality rate decreased from 5.2% to 3.8%. Compared to the overall IQIC aggregate, Children's HeartLink partner sites were consistently lower in-hospital and 30-day post-operative mortality; 3.8% vs. 4.9% and 4.0% vs. 5.3%, respectively. Similarly, overall post-operative morbidity reduced within the same time period. Surgical site infections decreased from 7.6% to 1.5%, bacterial sepsis decreased from 20.4% to 3.9%, and other major infections decreased from 25.5% to 5.2%. Meanwhile, case mix demonstrated increased acuity shifting from 74.1% to 64.3% in RACHS-1 Risk Categories 1 & 2 while increasing in higher Categories 3-6 from 25.8% to 33.3%.
Conclusions: NGO support of pediatric cardiovascular centers accelerates surgical outcomes improvement, demonstrated by reduction of post-operative morbidity and mortality following open heart surgery within Children's HeartLink partner institutions, therefore promoting quality in care and center excellence.

P1910 - MOTHER AND INFANT WELLBEING FOLLOWING CARDIAC SURGERY – A FOLLOW UP

Jennifer Re[1], Samuel Menahem[2], Antoine Guedeney[3], Suzanne Dean[1]
Monash University, Psychiatry, Melbourne-Australia[1]; Monash University, Monashhealth, Melbourne-Australia[2]; Denis Diderot University, Child & Adolescent Psychiatry, Paris-France[3]

Background/Hypothesis: A secure relationship between mother and infant is vital for optimal child outcomes. Parents' experience of a major medical illness in their infants, including CHD, is extremely stressful and may place mothers' and infants' wellbeing at risk. An earlier study showed a correlation between infant social withdrawal at 2 months and maternal distress following infant cardiac surgery. The infants' CHD ranged from VSD closure to a Norwood procedure. The infants were reviewed at 9 months using the same scales and methods for the follow-up.
Materials and Methods: Infant social withdrawal was identified using the Alarm Distress Baby Scale (ADBB), with >5 as the clinical cut-off score. Maternal distress was assessed using self-report measures for maternal depression (Edinburgh Postnatal Depression Scale (EPDS)), anxiety (Spielberger State-Trait Anxiety Scale (STAI)), and parenting stress (Parenting Stress Index-Short Form (PSI-SF)). Infant social withdrawal in relation to maternal distress was then evaluated.
Results: Twenty-two mother-infant pairs were reviewed. Preliminary data showed maternal distress remained high or even increased for some mothers and resolved for others. A high proportion of infants remained socially withdrawn. Infant withdrawal was not as closely associated with maternal distress at 9 months as it was at 2 months.
Conclusions: Whilst 2-month old infants with CHD subjected to previous cardiac surgery had a substantially increased risk of social withdrawal when their mothers reported experiences of maternal distress, at 9 months preliminary data suggests improvements for some but not all mothers and infants, while others remained at risk. A timely input of services to address mothers' distress following the

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

infants' diagnosis of CHD may have seen a more consistent improvement for both mothers and infants at follow-up and may also contribute to better child developmental outcomes.

P1911 - INFANT CARDIAC SURGERY MOTHERS' NARRATIVES

Jennifer Re[1], Suzanne Dean[1], Samuel Menahem[2]
Monash University, Psychiatry, Melbourne-Australia[1]; Monash University, Monashhealth, Melbourne-Australia[2]

Background: Congenital heart disease (CHD) requiring cardiac surgery in infancy causes considerable distress for parents.
Materials and Methods: As part of a larger study, 26 mothers of two-month-old infants who had undergone cardiac surgery were interviewed in depth. The mothers were each invited to tell in their own words their experience of the infant's diagnosis, surgery and hospitalisation. They described what had happened to their infant, their experience as mother and what they perceived were their infant's experiences. They were also asked to comment on the interview process. Using qualitative research methodology, a systematic content analysis of the interviews was performed.
Results: Nearly every participant described acute stress symptoms relating to the diagnosis, the infant's surgery and ICU hospitalisation. Yet most reported that the interview with a psychologist with psychotherapy training helped them to think about and integrate what had happened to them and their infant, suggesting that this experience was probably therapeutic.
Conclusions: An appropriately trained mental health professional, providing a safe space for the mother to communicate her story about the diagnosis, her infant's cardiac surgery and hospitalisation, may provide a brief, and very cost-effective therapeutic intervention for these mothers and babies, with only a minimal increase to a surgical programme's costs. The potential to mitigate the trauma and ease maternal distress, may bring about gains for the mother–infant relationship, reducing infant morbidity, and enhancing quality of life for the mothers and infants.

P1939 - NATIONAL PROGRAM OF CONGENITAL HEART DISEASE DESIGN IMPLEMENTATION AND MIDTERM RESULTS

Carlos Fernando Rosental[1], Paula Campana[2], Mariana Fernandez[3], Angela Sardella[4], Silvina Rosselot[2], Willy Conejeros Parodi[5], Maria Eugenia Olivetti[1], Alejadra Villa[1]
Hospital JP Garrahan, Cardiology, Caba-Argentina[1]; Hospital SM Ludovica, Cardiology, Buenos Aires-Argentina[2]; Hospital Posadas, Cardiology, Buenos Aires-Argentina[3]; Hospital Gutierrez, Cardiology, Caba-Argentina[4]; Hospital Gutierrez, Cardiovascular Surgery, Caba-Argentina[5]

Background: In order to decrease preventable causes of child mortality, a National Program of Congenital Heart Diseases (NPCHD) was created in 2008. Preliminary studies have shown that in Argentina, yearly approximately 6000 infants are born with congenital heart diseases (CHD), of whom 4300 require surgery. There were nearly 1000 unresolved cases generating waiting lists. This was confirmed with mortality reports between 2002 and 2006. Therefore, a national program was designed. The aim of this study was to describe midterm results based on epidemiologic indicators.
Materials and Methods: A network program was designed, prioritizing timely diagnosis and intervention and consisting of public referral centers, treating centers, and a coordination center. Permanent surveillance was used to improve the program and a unified reporting system was developed.
Results: Different indicators were evaluated comparing the latest results with data from 2012. The waiting list decreased while the number of diagnoses increased. Currently, there are 17500 cases in the Registry; a 47% increase between 2010 and 2015. Diagnosis in infants increased from 40% to 70% and in neonates from 18% to 30% (2010-2015). Age at surgery decreased from 297 days to 160 days (53.8%). In 2015, incidence rate was 5/1000 (range 4-9/1000 according to the different provinces). The number of surgeries increased in every age group, with an increase of 100% in neonates. In 2015, 82% underwent surgery in their area of residence.
Conclusions: The NPCHD has provided a framework to improve access to care and decrease inequalities between provinces. This network was the key to reducing waiting lists and mean age at surgery avoiding morbidity and mortality. Surveillance is essential for the development of strategies. This program is a model of care for other vulnerable populations.

P2066 - THE IMPACT OF TRANSPORTATION ON THE ARRIVAL STATUS AND OUTCOMES IN NEWBORNS WITH HEART DISEASE PERSPECTIVE FROM A LOW AND MIDDLE INCOME COUNTRY

Balaganesh Karmegaraj, Mahesh Kappanayil, Abish Sudhakar, Raman Krishna Kumar
Amrita Institute of Medical Sciences and Research Centre, Pediatric Cardiology, Cochin-India

Background: With increasing availability of newborn heart surgeries in low and middle-income countries (LMICs), health systems challenges, specifically relating to transport may need to be addressed.
Objectives: To identify determinants of clinical status at arrival of neonates with congenital heart disease (CHD) transported to a pediatric heart centre, and to study the impact of the arrival status on clinical outcomes.
Methods and Results: 100 consecutive neonates with CHD (January 2016- December 2016) transported to a pediatric cardiac program in Southern India were studied prospectively using a structured database that captured relevant demographic, clinical and laboratory information and specific transport variables. Physicians were available in 34, nurses in 53 and neither in 13 transports; 35 babies were ventilated; 14 required ventilation <2 hours after arrival. Of 43 babies with duct dependent circulation, 27 (63%) were transported without prostaglandin infusion. Problems identified on arrival included hypothermia (23), hypoglycemia (9), cardiac arrest (4), endotracheal tube block (1), high FiO2 in shunt lesions (10), end organ (liver/kidney/cerebral) injury (26) and blood stream sepsis (20). Following stabilisation, 65 were offered cardiac surgery (59 underwent surgery) and 16 underwent catheter intervention, 9 parents opted for comfort care (3 with severe end organ damage), 10 required medical management. Three of 5 deaths before surgery resulted from poor arrival status. End organ injury at arrival was seen in 4/5 patients who died (all 3 surgical deaths and 1 of 2 deaths after catheter intervention). End-organ injury was strongly associated with all cause mortality (27% vs. 4%, $p < 0.003$)
Conclusion: In the absence of organised transport systems, a quarter of neonates with CHD arrived with end organ injury and this significantly impacted their mortality and morbidity. Robust transport systems need to be integrated in plans to develop newborn and infant heart surgery in LMICs.

P2166 - TRANSCATHETER CLOSURE OF PATENT DUCTUS ARTERIOSUS WITH THE AMPLATZER DUCT OCCLUDER IN SUB SAHARAN AFRICA

Jean Claude Ambassa[1], Alfred Kongnyuy[1], Cabral Tantchou Tchoumi[1], Charles Mvondo[1], Alessandro Giamberti[2], Alessandro Frigiola[2], Silvia Cirri[3], Gianfranco Butera [4]
Shisong Hospital, Cardiology, Kumbo-Cameroon[1]; Policlinico San Donato Irccs, Cardiac Surgery, San Donato Milanese-Italy[2]; Ospedal Sant, Anesthesiology, Milano-Italy[3]; Policlinico San Donato Irccs, Congenital Cardiology, San Donato Milanese-Italy[4]

Objectives: To analyze the safety and efficacy of PDA trans-catheter closure in Shisong Hospital Cameroon.
Background: During an 8 year period, a Cardiac Centre was designed and developed in Sub-Saharan Africa. Three partners worked towards the realization of this project (Associazione Cuore Fratello, Associazione Bambini Cardiopatici nel Mondo, Tertiary Systers of St Francis).
Methods: From 2010 to 2015, 45 patients with clinically significant PDA (30 and 15 adults) were treated. Median age was 11yrs (range 2-33years) while median weight was 33 kg (range 14-58 kg). Indications for closure were: cardiac failure (n = 4), failure to thrive (n = 2), left ventricular overload (n = 43), arrhythmias (n = 2). The duct was defined as large (pulmonary pressure > 3/4 systemic pressure), moderate (pulmonary pressure between (1/4-3/4) of the systemic pressure and (QP/QS > 1.5), restrictive (normal pulmonary pressure and QP/QS = 1). Procedures were performed under general anesthesia. The Amplatzer Duct Occluder (ADO I) and MVSD devices were used.
Results: The duct was restrictive in 4 pts, moderate in 2 pts and large in 1 pys. The mean PDA diameter was 6 mm (range 2.5-16mm). Successful device implantation was performed in 37 out of 45 (82%). Three subjects were not closed because of Eisenmenger syndrome. Complications occurred in 2 subjects (8%) who had embolization: in one subject surgery was needed while in one the device was retrieved and the PDA successfully closed using a MVSD device. MVSD was used in three patients while ADO I was used in the other subjects.
Conclusion: Successful and safe percutaneous treatment of PDA can be performed in Sub-Saharan Africa.

P2264 - DEVELOPMENT OF AN AUSTRALIAN NATIONAL POLICY FRAMEWORK FOR PAEDIATRIC CARDIAC AID WORK

Ari Horton[1], David Isaacs[2], Helen Irving[1]
Children's Health Queensland, Centre for Children, Brisbane-Australia[1]; University of Sydney, Sydney-Australia[2]

Background: Healthcare systems and services are receiving increasing numbers of aid-related referrals for cardiac surgical intervention. Paediatric cardiac interventions and surgery are high-cost, resource-intensive services, in demand for both non-funded and privately funded overseas patients. Current practice leads to competition and an individualistic approach to the provision of medical care and raises many ethical and practical issues.
Methods: Paediatric clinical ethics services in Australia collaborated in discussions to develop a potential policy framework for on-shore paediatric cardiac medical aid work. We used a narrative-medicine based approach to explore the stories of this patient group and the medical teams that work with them. We collected qualitative data from families regarding their experiences and their advice for improvements, and from their healthcare teams including social workers. Quantitative data were collected regarding the resourcing costs for different surgeries and the methods of funding from the administration departments of hospital networks and aid organisations involved in the processes.
Results: The completed draft policy framework will be presented to the combined cardiac and cardiac surgical departments in public paediatric health care services in Australia for further discussion and ratification. The policy aims to reduce practice variability, improve outcomes and experiences for patients and families who receive care within the Australian Health-care system and improve distributive justice and rationalisation of limited public resources.
Conclusion: We will present a discussion based on the ethics and practicalities of medical aid work and medical tourism for paediatric cardiac services in an Australian context. The draft framework will be used as the basis for the wider discussion of the provision of services and the ethical practicalities in different nations and health-care systems in the Asia-Pacific region.

P2287 - THE NAMIBIAN CHILDREN'S HEART PROJECT A SIX YEAR REVIEW OF MISSION PATIENTS AND OUTCOMES

Fenny Shidhika F[1], Susan Vosloo[2], Andre Brooks[3], Harold Pribut[4], Liesl Zuhlke[1], Christopher Hugo-hamman[5]
University of Cape Town, Paediatric Cardiology, Cape Town-South Africa[1]; Chris Barnard Memorial Hospital, Cardiac Surgery, Cape Town-South Africa[2]; University of Cape Town, Cardiac Surgery, Cape Town-South Africa[3]; Chris Barnard Memorial Hospital, Paediatric Cardiology, Cape Town-South Africa[4]; Ministry Of Health, Paediatric and Congenital Cardiology, Windhoek-Namibia[5]

Background: Before 2007 there were no cardiac services in Namibia. A service was initiated in 2009 and heart surgery from 2010. However, surgery cannot be offered to infants or patients with complex disease. Through a public-private partnership patients are referred to the Christian Barnard Memorial Hospital in South Africa.
Materials and Methods: This is a retrospective review of the 200 patients referred between 2009 and 2015. Demographics, diagnosis, interventions, morbidity, mortality and follow-up were reviewed. Data was entered using RedCap. Continuous variables expressed as means or medians and categorical variables as percentages. Linear regression models compare variables. Cox regression and Kaplan- Meier curves assess survival.
Results: 188 (94%) had congenital and 12 (6%) acquired disease. Age at presentation ranges from 1 week to 33 years. Lesions include right and left ventricular outflow obstruction, atrio-ventricular and ventriculo-arterial discordance, anomalies of systemic and pulmonary venous drainage, single ventricle, left to right shunts, Rheumatic Heart Disease and Takayasu arteritis. Twenty five (13%) had percutaneous interventions. The majority had definitive repair whilst 30 (15%) had palliative procedures. Palliation was either staged or definitive. RACHS categories were 2 to 5. Early (<30) and late (>30 days) postoperative mortality was 6 (3%) and 2 (1%), respectively. A quarter defaulted follow-up.
Conclusion: Patients present late with consequent added complexity. The relative paucity of newborns with critical CHD is revealing. The number of patients defaulting follow-up represents health system challenges in a developing country. A comprehensive, sustainable local surgical service remains our goal, however in the medium term this humanitarian programme with a unique funding model has achieved good outcomes for indigent patients.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

P2311 - EFFICACY OF A CLINICAL TOOL TO DETECT CONGENITAL HEART DEFECTS IN A RESOURCE LIMITED COUNTRY

Shaad Abqari, Fazil Mohammed Izhar, Tabassum Shahab, Syed Manazir Ali
Amu, Pediatrics, Aligarh-India

Background: Neonatal screening programmes have incorporated pulse oximetry for early diagnosis of CHDs and have been cleared by the FDA for use in newborns. Detection rates for CHD by prenatal ultrasound is ~25-50% and by postnatal newborn physical exams is ~25-50%. The immunization clinic provides a unique opportunity to screen missed and undiagnosed cases especially from non institutional deliveries. This can serve as a second checkpoint beside neonatal screening for the detection of CHD. The present study is undertaken to develop a cost effective screening tool (score) for early detection of CHD and further investigate that how effective is the clinical screening score in detecting undiagnosed or missed cases of congenital heart disease?
Materials and Methods: Children presenting in the OPD at 6weeks of age for immunization or any child presenting for first time (outborn delivery) till 6 months of age in the immunization clinic were subjected to detailed history and examination and findings were recorded on a predesigned proforma and CHD score was recorded. These children were taken for echocardiography for confirmation of the diagnosis of CHD. The sensitivity and specificity of the test was calculated at different cut-off scores.
Results: It is continuing project with a target of screening at least 500 newborns in next 6 months, as a pilot programme initial 30 infants were screened, out of which 4 had CHD. The remaining newborns were normal and had a score of less than 3. All 4 cases of CHD had a score of more than 3 with severity increasing with score.
Conclusions: History and examination based tool can be utilised as an effective method of second screening of newborn in the immunisation clinic for early identification of CHDs.

P2440 - TELL ME ONCE TELL ME SOON PARENTS' PREFERENCES FOR GENETIC CONSULTATIONS FOR CONGENITAL HEART DISEASE

Nadine Kasparian[1], Richard De Abreu Lourenco[2], David Winlaw[3], Gary Sholler[3], Stephanie Knox[2], Rosalie Viney[2], Edwin Kirk[4]
Heart Centre for Children, The Sydney Childrens Hospitals Network and, UNSW Medicine, The University of New South Wales, Sydney-Australia[1]; Centre For Health Economics Research and Evaluation (CHERE), The University of Technology, Sydney-Australia[2]; Heart Centre For Children, The Sydney Childrens Hospitals Network And, Sydney Medical School, The University of Sydney, Sydney-Australia[3]; Department of Medical Genetics, Sydney Children's Hospital and, Unsw Medicine, The University of New South Wales, Sydney-Australia[4]

Background and Hypotheses: An important aspect of designing healthcare services is to understand how individuals choose between services. Discrete choice experiments (DCE) are increasingly used in health services research to understand such choices. In response to the changing landscape of cardiac genetics, we developed a DCE to identify parents' preferences for genetics services for families affected by congenital heart disease (CHD).
Materials and Methods: One-hundred fourteen parents of a child diagnosed with CHD requiring surgery were recruited via the Sydney Children's Hospital Cardiac Service (participation rate: 54%), of whom 22% had previously accessed genetics services for CHD. DCE attributes (n = 4) and levels (n = 3) were developed in consultation with experienced clinicians, and combined in an orthogonal design of nine choice sets. Each participant received all nine choice sets and indicated their preferred consultation type, and whether they would accept a referral to that consultation if offered. Mean choice coefficients were analysed using both conditional logit and mixed logit analyses to incorporate the extent to which there was heterogeneity across participants in what influenced their choices.
Results: Participants overwhelmingly preferred genetics services for CHD that involve only one consultation with both a clinical geneticist and genetic counsellor, that occur with a minimum waiting period of two weeks, and where information is provided verbally and via a website. Such a service, if offered, would result in participation by 93% of parents in our study.
Conclusions: Incorporating a genetic counsellor in all CHD-related genetics consultations and reducing waiting time would result in high uptake by parents. Independent of parent preference, there are clear advantages to such an approach. As we have shown elsewhere, CHD in a child can have profound psychological consequences for families and access to genetic counselling can provide a valuable component of the genetics consultation.

P2443 - THE NEED FOR UNIVERSAL SCREENING OF HEALTH RELATED QUALITY OF LIFE IN YOUNG CHILDREN WITH COMPLEX CONGENITAL HEART DISEASE AND THEIR FAMILIES

Dominique Denniss[1], Gary Sholler[2], David Winlaw[2], Daniel Costa[3], Nadine Kasparian[1]
Heart Centre for Children, The Sydney Childrens Hospitals Network and, Unsw Medicine, The University of New South Wales, Sydney-Australia[1]; Heart Centre For Children, The Sydney Childrens Hospitals Network and, Sydney Medical School, The University of Sydney, Sydney-Australia[2]; Pain Management Research Institute, Royal North Shore Hospital and, Sydney Medical School, The University of Sydney, Sydney-Australia[3]

Background and Hypotheses: Studies examining health-related quality of life (HRQOL) in young children with congenital heart disease (CHD) and their families are sparse. This study aimed to assess maternal perceptions of HRQOL in two groups of young children with CHD; those following a single ventricle (SV) surgical pathway and those requiring biventricular repair. It also aimed to identify the demographic, clinical, psychological and social determinants of HRQOL in these children and their mothers. It was hypothesised that children with SV anomalies and their mothers would have poorer HRQOL than the biventricular group.
Materials and Methods: Participants were recruited via the Sydney Children's Hospitals Network Cardiac Service. Mothers of a child aged 1-5 years with either SVCHD (pre-Fontan) or CHD requiring neonatal biventricular repair and cardiopulmonary bypass were invited to participate. Consenting mothers completed a validated survey instrument assessing HRQOL and a range of demographic, clinical, psychological and social factors.
Results: Eighty-six mothers participated (response rate: 48%). Overall, children with CHD had lower parent-reported HRQOL than normative data and 58% of children scored below the cut-off indicative of a need for clinical investigation. Poorer child HRQOL was strongly associated with SV anomalies (Beta = -0.43, $p < 0.0001$), physical comorbidity (Beta = -0.26, $p = 0.004$), feeding problems (Beta = -0.27, $p = 0.003$), and greater maternal psychological stress (Beta = -0.18, $p = 0.04$). Together these variables accounted for 52% of the variance in child HRQOL. Poorer maternal HRQOL was strongly associated with poorer family functioning (Beta = 0.62, $p < 0.0001$), greater maternal psychological stress (Beta = -0.23, $p = 0.005$), and 'difficult' child temperament (Beta = -0.19, $p = 0.006$); accounting for 73% of the variance in maternal HRQOL.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: Biopsychosocial factors accounted for over half the variance in child HRQOL, and over 70% of the variance in maternal HRQOL. Universal screening of HRQOL in children with CHD and their parents, coupled with early psychological intervention for those at risk, could improve HRQOL in this population.

P2445 - QUALITY OF LIFE EMOTIONAL WELLBEING AND BEHAVIOURAL ADJUSTMENT AS EXPERIENCED BY YOUNG CHILDREN WITH CONGENITAL HEART DISEASE A SYSTEMATIC REVIEW

Dominique Denniss[1], Gary Sholler[2], David Winlaw[2], Nadine Kasparian[1]
Heart Centre for Children, The Sydney Childrens Hospitals Network and, Unsw Medicine, The University of New South Wales, Sydney-Australia[1]; Heart Centre For Children, The Sydney Childrens Hospitals Network and, Sydney Medical School, The University of Sydney, Sydney-Australia[2]

Background and Hypotheses: Current understanding of quality of life (QOL) in young children with congenital heart disease (CHD) is limited. Better understanding of QOL during these formative years could enable earlier identification of difficulties and more timely intervention. This systematic review aimed to synthesise and critically appraise the literature examining QOL, emotional wellbeing and behavioural adjustment in children aged ≤5 years with CHD. It also aimed to identify demographic, clinical, psychological and social determinants of these outcomes.
Materials and Methods: A systematic literature search was performed using five electronic databases; Medline, Embase, PsycINFO, CINAHL, Scopus. Articles were included if they reported on parent-proxy or self-reported outcomes associated with QOL or emotional, social or behavioural functioning for children with CHD with a mean age ≤5 years. Risk of bias was appraised for each article using the QualSyst framework.
Results: Thirty-eight articles were identified for review (31 cross-sectional studies, 3 prospective case-cohort studies, 2 prospective cohort studies, 2 randomised controlled trials), with data from 3,841 children with CHD. Most studies assessing QOL (6/8 studies) found poorer QOL in children with CHD compared to normative data or healthy controls. Behavioural and emotional functioning was poorer in children with CHD than comparator groups in 13/20 studies. All studies assessing adaptive behaviour and functional living skills (11/11 studies) reported impairments, with scores for 8-79% of children indicating a need for clinical intervention. Parental stress was the most common predictor of QOL-related outcomes.
Conclusions: Young children with CHD demonstrate greater impairment than comparator groups in QOL, emotional well-being and behavioural functioning, highlighting the need to identify and respond to these difficulties in clinical settings. The prevalence and determinants of these impairments vary markedly and research effort should be directed towards developing a consistent approach to assessment and more accurately characterising these outcomes in this population.

P2461 - A PEDIATRIC CARDIOLOGY TELEMEDICINE NETWORK IN NORTHEAST BRAZIL MAIN RESULTS FROM FIVE YEARS OF EXISTENCE

Sandra Mattos[1], Sheila Hazin[2], Claudio Regis[3], Fernanda Albuquerque[3], Lucia Moser[3], Thamine Hatem[4], Carolina Freitas[5], Felipe Mourato[6], Thiago Tavares[7], Renata Gomes[8], Rossana Severi[9], Cícera Santos[5], José Lima Filho[10]
Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[1]; Círculo Do Coração De Pernambuco, Cirurgia, Recife-Brazil[2]; Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[3]; Círculo Do Coração, Assitencial, Recife-Brazil[4]; Círculo Do Coração, Enfermagem, Recife-Brazil[5]; Círculo Do Coração, Científico, Recife-Brazil[6]; Círculo Do Coração, Informática, Recife-Brazil[7]; Círculo Do Coração, Estatística, Recife-Brazil[8]; Círculo Do Coração, Imagem, Recife-Brazil[9]; Lika, Diretor, Recife-Brazil[10]

Background: Providing appropriate health care for children with congenital heart disease in middle and low-income countries is a constant challenge. This situation becomes more critical when the country has a continental size, like Brazil, because the few pediatric cardiologists concentrate in large urban centers leaving vast areas completely unconvered. Until 2011, this was the reality in Paraíba, a state from northeast Brazil.
Material and Methods: A partnership between the Government of Paraíba and the NGO - Heart Circle was established in October/2011. The work method was the establishment of a Network of services, with the aid of telemedicine, to provide an integral line of care from screening to surgery and post-operative care.
Results: From 2012 to 2016, 146.422 babies were screened for heart defects and 1.951 abnormalities were identified. The screening program covered 65.5% of the target population (neonates with 34 or more weeks of gestational age in the participant centres) and 49.1% of all births in the public health system in the State in 2012; and in 2016 this coverage reached 95.7% of the target population and 95.1% of all births. Detection of congenital heart disease increased from 4.09 to 13.2 per 1000 live births ($P < 0.001$). Over 20.000 consultations and echoes were supervised via telemedicine and a total of 532 cardiac operations were performed. Over 5.000 professionals received live and/or online training.
Conclusion: In five years, the pediatric cardiology network established a universal screening program for CHD in Paraíba and structured the care for children at different levels according to specific needs. We believe that this work-model can be adapted to other countries and realities around the world.

P2471 - CHD IN THE TIME OF HASHTAGS AND TWEETS E HEALTH LITERACY AND PREFERENCES FOR E HEALTH RESOURCES IN PARENTS OF CHILDREN WITH COMPLEX CONGENITAL HEART DISEASE

Nadine Kasparian[1], Nathan Lieu[1], David Winlaw[2], Andrew Cole[2], Edwin Kirk[3], Gary Sholler[2]
Heart Centre for Children, The Sydney Childrens Hospitals Network and, UNSW Medicine, The University of New South Wales, Sydney-Australia[1]; Heart Centre for Children, The Sydney Childrens Hospitals Network and, Sydney Medical School, The University of Sydney, Sydney-Australia[2]; Department of Medical Genetics, Sydney Childrens Hospital And, UNSW Medicine, The University of New South Wales, Sydney-Australia[3]

Background and Hypotheses: The rapid increase in Internet-based healthcare information, or eHealth, has not been matched with an increase in research examining how patients and families use and experience this information, and any associated clinical implications. This is particularly the case in paediatric cardiology, where there is little existing research. This study aimed to: (a) examine eHealth literacy, beliefs and behaviours in parents of children with complex congenital heart disease (CHD), and (b) identify parents'

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

preferences for the content, format, features and functions of CHD-related eHealth resources.
Materials and Methods: Families of a child born between 2008-2011 and diagnosed with CHD requiring surgery at the Heart Centre for Children in Sydney, were mailed a survey assessing eHealth literacy, beliefs and behaviours, and preferences for CHD-related eHealth resources.
Results: One-hundred thirty-two parents (83 mothers, 49 fathers) completed the survey (response rate: 50%). Mothers (96%) were more likely to access eHealth resources than fathers (83%, $p = 0.009$). Despite high eHealth use, eHealth literacy was relatively low, with widespread gaps in parents' awareness of, access to and communication about eHealth resources. Over 50% of parents reported that decisions regarding their child's healthcare were influenced, to some extent, by eHealth. Barriers to doctor-patient communication about eHealth included limited consultation time and concern about doctor's disapproval. Participants demonstrated a strong desire for 'eHealth prescriptions' (or recommendations) from their healthcare team, and perceived a range of eHealth topics as highly important, including treatment-related complications, and physical, cognitive and emotional development in children with CHD.
Conclusions: This is the first time eHealth literacy has been assessed in parents of children with CHD. Results demonstrate a need for greater education and support as families navigate the complex landscape of CHD-related eHealth. 'eHealth prescriptions' from the cardiac team are highly desired by families and may be a good starting point.

P2474 - BIOPSYCHOSOCIAL CONTRIBUTIONS TO RISK AND RESILIENCE IN INFANTS WITH COMPLEX CONGENITAL HEART DISEASE AND THEIR PARENTS

Nadine Kasparian[1], Claudia Nielson-Jones[1], Dianne Swinsburg[1], Karen Walker[2], Vivette Glover[3], Nadia Badawi[2], Marie-Paule Austin[4], Bryanne Barnett[5], David Winlaw[6], Gary Sholler[6]
Heart Centre For Children, The Sydney Childrens Hospitals Network and, UNSW Medicine, The University of New South Wales, Sydney-Australia[1]; Grace Centre For Newborn Care, The Childrens Hospital at Westmead and, Sydney Medical School, The University of Sydney, Sydney-Australia[2]; Faculty of Medicine, Imperial College London, London-United Kingdom[3]; UNSW Medicine, The University of New South Wales, Sydney-Australia[4]; Raphael Services, St John of God Health Care, Sydney-Australia[5]; Heart Centre For Children, The Sydney Childrens Hospitals Network and, Sydney Medical School, The University of Sydney, Sydney-Australia[6]

Background and Hypotheses: Early life experiences shape brain development, the immune system and responses to stress. For infants with complex congenital heart disease (CHD), experiences associated with diagnosis and treatment can have enduring developmental consequences. This prospective case-control study examines the prevalence and predictors of psychological morbidity in parents following CHD diagnosis. It also examines how biopsychosocial factors may influence developmental outcomes in infants with complex CHD.
Materials and Methods: Parents of babies with a fetal or postnatal CHD diagnosis requiring surgery in the first six months of life ($n = 193$) or healthy fetal morphology scan at 18-20 weeks gestation ($n = 120$) complete neuropsychiatric interviews (at 3-months post-diagnosis and 12-months postpartum) and psychological measures (3-months post-diagnosis and 3-, 6-, 12-months postpartum). Salivary cortisol is collected as a biological indicator of stress reactivity in mothers at 32-weeks gestation, and in mothers and infants at 12-months postpartum. Mother-infant interaction is assessed at 6-months (CARE-Index), infant developmental outcomes are assessed at 12-months (Bayley Scales of Infant Development, Strange Situation), and clinical data are collected via medical records.
Results: Three months post-diagnosis, 45% and 43% of mothers (57% and 47% of fathers) in the fetal and postnatal CHD groups respectively, reported anxiety warranting clinical intervention compared to 19% of mothers (12% of fathers) of typically-developing babies. After controlling for education and income, maternal antenatal anxiety after fetal diagnosis was strongly associated with self-blame ($Beta = 0.28$, $p = 0.02$) and disengagement ($Beta = 0.26$, $p = 0.03$). At 6-months, >60% of mothers in the postnatal CHD group perceived their infant as 'difficult' compared to 8% and 0% in the fetal CHD and control groups, respectively. Biopsychosocial contributions to infant developmental outcomes are being investigated.
Conclusions: Infants with complex CHD experience early adversity and their parents report marked psychological stress. We have developed and are currently evaluating an integrated health system response to these needs.

P2496 - ACTIVE SEARCH FOR CONGENITAL HEART DISEASE MAIN RESULTS FROM FOUR YEARS OF MEDICAL MISSIONS IN NORTHEAST BRAZIL

Sandra Mattos[1], Felipe Mourato[2], Lucia Moser[3], Thamine Hatem[3], Renata Gomes[4], Thiago Tavares[5], Carolina Freitas[6], Juliana Araújo[3], Amanda Ferrão[7]
Círculo Do Coração De Pernambuco, Geral, Recife-Brazil[1]; Círculo Do Coração De Pernambuco, Científico, Recife-Brazil[2]; Círculo Do Coração De Pernambuco, Assistencial, Recife-Brazil[3]; Círculo Do Coração De Pernambuco, Estatística, Recife-Brazil[4]; Círculo Do Coração De Pernambuco, Informática, Recife-Brazil[5]; Círculo Do Coração De Pernambuco, Enfermagem, Recife-Brazil[6]; Círculo Do Coração De Pernambuco, Nutrição, Recife-Brazil[7]

Background: Congenital Heart Disease (CHD) is a major public health problem and the main cause of mortality in neonates when infectious diseases are excluded. In developing regions, the lack of CHD diagnosis can lead to clinical worsening or even death. In such scenario, an annually medical mission performs an active search for CHD in northeast Brazil.
Material and Methods: This is a retrospective study based on the data from an active search (called "The Heart Caravan") performed between 2013 to 2016. The active search covers 13 cities (only 8 in the first year) and takes place in two stages. In the first, local health centres perform a screening of children with symptoms or history of cardiovascular diseases. In the second phase, a multidisciplinary team (paediatric cardiologists, nutritionists, psychologists, nurses, social service and volunteers) performed health consultations and echocardiograms in children and pregnant women to diagnosis CHD or monitored previously diagnosed patients. A frequency analysis was performed.
Results: A total of 4.464 patients were seen in the Caravans. In 2016, however, there were 616 patients seen in relation to the microcephaly outbreak. From the 3.848 patients seen by the cardiology teams, there were 3.532 children and 316 foetuses. In 2016, there were approximately 60% of new patients. The main reason to participate in the caravan was a known CHD (21.11%) or the presence of a heart murmur in children (19.8%). Most patients had a poor background (more than 50% using government social benefits). A total of 1.092 CHD (126 complex CHD) were diagnosed or monitored during the Caravans. In relation to

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

pregnant women, only 30 (9.6%) showed an abnormal foetal echocardiogram.
Conclusion: The Heart Caravans identified and monitored an expressive number of CHD in childhood. These patients were inserted in the health services for appropriate management.

P2503 - LIMITED RESOURCES LONG TERM CLINICAL OUTCOMES IN A PEDIATRIC CARDIAC SURGICAL PROGRAM IN NIGERIA

Olawale Olabiyi[1], Segun Ajayi[2], Myna Shegog[2], Annesha White[3], Queenette Daniels[4], Chris Yilgwan[5], Kemi Ige[3], Bunmi Ode[6], Yahaya Adamu[7], Ikenna Omeje[8]
Pediatrix Medical Group, Methodist Children, Pediatric Cardiology, San Antonio-United States[1]; Hospital for Humanity, Atlanta-United States[2]; Unt Health Science Center, Pharmacy, Fort Worth-United States[3]; , Pediatrics, Abuja-Nigeria[4]; Jos University Teaching Hospital, Pediatrics, Jos-Nigeria[5]; National Hospital, Pediatric, Abuja-Nigeria[6]; National Hospital, Surgery, Abuja-Nigeria[7]; Great Ormond Street Hospital, Surgery, London-United Kingdom[8]

Background/Hypothesis: Congenital heart disease (CHD) is a leading cause of birth defect-associated infant illness and death. The incidence of CHD is 0.8% and virtually all developed countries have sustainable surgical programs. The ability to establish programs in resource limited environments is critical as nearly half (48%) of the deaths due to CHDs occur during infancy. The aim of this study was to assess a newly established sustainable pediatric cardiac surgical program in Nigeria with regard to number of surgeries and cardiac catheterization procedures performed annually. Secondary aims were to identify common comorbidities, average length of stay, and mortality.
Methods: A prospective study design was utilized to follow a cohort of 48 pediatric patients who received cardiac surgery from January 2015 – January 2017. 349 patients were screened from a list of 1566 referred patients. Each patient admitted to the hospital was reviewed by a physician and data was recorded and retrieved from medical records. This study included all patients that had surgical intervention for CHD. Variables collected for data analysis were number of surgeries and cardiac catheterization procedures, number and type of comorbidity, average length of stay, and mortality. Descriptive statistics was used to analyze the data.
Result: Upon establishment of the pediatric cardiac surgical program 48 cardiac surgeries and one cardiac catheterization procedure was successfully performed in 2 years (25 surgeries in year one and 23 surgeries in year two). Major comorbidities were infection, reintubation and bleeding. Findings revealed that average length of stay was 10 days, while mortality was 5 patients.
Conclusion: The establishment of a cardiac surgical program in a resource limited environment is possible. Limitations in completing more surgeries include cultural differences, limited space, nurse and support staff education. Establishing sustainable educational programs in underserved environments can lead to the provision of care for thousands with CHD.

P2512 - ESTABLISHING A PEDIATRIC CARDIAC SURGICAL PROGRAM IN A RESOURCE LIMITED ENVIRONMENT THE NIGERIAN EXPERIENCE

Olawale Olabiyi[1], Segun Ajayi[2], Myna Shegog[2], Annesha White[3], Queenette Daniels[4], Chris Yilgwan[5], Kemi Ige[3], Bunmi Ode[6], Yahaya Adamu[7], Ikenna Omeje[8]
Pediatrix Medical Group, Methodist Childrens Hospital, Pediatric Cardiology, San Antonio-United States[1]; Hospital For Humanity, Atlanta-United States[2]; Unt Health Science Center, Pharmacy, Fort Worth-United States[3]; Pediatrics, Abuja-Nigeria[4]; Jos University Teaching Hospital, Pediatrics, Jos-Nigeria[5]; National Hospital, Pediatrics, Abuja-Nigeria[6]; National Hospital, Surgery, Abuja-Nigeria[7]; Great Ormond Street Hospital, Surgery, London-United Kingdom[8]

Background/Hypothesis: Congenital heart disease (CHD) is a leading cause of birth defect-associated infant illness and death. Incidence is 0.8% and virtually all developed countries have sustainable programs for care. The ability to establish programs in resource limited environments is critical as nearly half (48%) of the deaths due to CHD occur during infancy. The aim of this study was to describe the establishment of a sustainable pediatric cardiac program with multidisciplinary support in a resource limited country and to discuss limitations.
Methods: This descriptive study examined the process of establishing a surgical program over a two year period. A work group was convened with members from Hospitals for Humanity (HFH) a NGO, Garki and National Hospital, Abuja, Nigeria. Current available resources were identified including surgical centers. Agreements were then established with governmental programs. Lastly, HFH connected with medical sub-specialists across the world interested in building a program vs. planning for a single medical mission trip.
Results: Based on published and unpublished data, the work group made recommendations for a standardized approach to educational program development. The organization HFH served as a fundraising instrument to pay for care for patients and acquire equipment for the PICU and operating room. The staff included: surgeons, cardiologists, PICU physicians, PICU nurses and support personnel. The program allowed for an operating room, catheterization lab, 4 PICU and 10 in-patients beds. A total of 48 cardiac surgeries were performed. Although plans are underway to continue the program, limitations included corruption, resources and exposure.
Conclusion: Key factors for success were local physician and government involvement, committed medical staff, and publicity. An unforeseen factor was having ex-patriots return to their country of origin to provide communication and education. A consistent and long term approach is suggested, lengthening the time of each medical mission until a sustainable program is established.

P2548 - PEDIATRIC CARDIOLOGY EXCHANGE PROGRAM BETWEEN GONDAR UNIVERSITY MEDICAL CENTER GONDAR ETHIOPIA AND SHAARE ZEDEK MEDICAL CENTER JERUSALEM ISRAEL

Zemene Tigabu[1], Daniel Lyon Fink[2], Sam Amiel[3]
Gondar University, Department of Pediatrics and Child Health, Gondar-Ethiopia[1]; Shaare Zedek Medical Center, Division of Pediatric Cardiology, Jerusalem-Israel[2]; The American Jewish Joint Distribution, Europe and Africa, Jerusalem-Israel[3]

We describe an ongoing collaboration between the Medical Center at Gondar University, Ethiopia, the Shaare Zedek Medical Center in Jerusalem, Israel and the American Jewish Joint Distribution Committee (JDC). As part of a more general collaboration between our three organizations, starting in March 2012, the division of pediatric cardiology in Jerusalem has partnered with the department of pediatrics in Gondar with reciprocal doctor exchanges facilitated by the JDC. The JDC supplied robust cardiology stethoscopes, electrocardiogram and portable echocardiogram equipment for the Gondar pediatrics department. One author (DLF) has traveled to Gondar for several two week periods to teach the pediatricians cardiac physical examination including auscultation with up to 28 digital demonstration headphone stations, electrocardiography and echocardiography and one author (ZT) has traveled for several three month periods to

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Jerusalem to work integrally with the pediatric cardiology division. We performed a small pilot study screening school children in the Gondar region for asymptomatic clinically evident but undiagnosed rheumatic heart disease finding a rate of 2%. We have also developed a program where ECG and echocardiogram loops are sent by electronic mail for long distance consultation. We are excited with this grass roots model advancing the process of integrating advanced pediatric cardiac care into the local infrastructure in an underdeveloped country.

P2566 - SHINE A SAVE HEART INITIATIVE PROVIDING FREE CURATIVE TRANSCATHETER TREATMENT FOR CHILDREN WITH CARDIAC SHUNT LESIONS IN SOUTH INDIA

Karthik Surya Ramanujam, Premsekar Rajasekaran
Kauvery Hospital, Paediatric Cardiology, Chennai-India

Background: Cardiac shunt lesions form a significant proportion of the disease burden amongst children born with congenital heart disease. While Atrial septal defects (ASD), Ventricular septal defects (VSD) and Patent Ductus Arteriosus (PDA) constitute the major bulk of this group, other shunt lesions such as Coronary fistula, Ruptured sinus of valsalva (RSOV), Aortopulmonary window present from time to time. Majority of these shunt lesions are amenable for transcatheter closure and when undertaken appropriately, offers complete cure at a significantly lower cost than surgery.
Materials & Methods: We report our institutional experience of 410 patients with 395 shunt lesions addressed by the transcatheter route, between April 2014 and January 2017. 21 procedures were self-funded by the patients and 374 procedures were done free of cost for economically challenged children. Of the 374 procedures, 172 (45.8%) were ASD device closure, 115 (30.6%) VSD device closure, 87 (23.2%) PDA device closure, 1 (0.2%) Coronary fistula embolisation and 1 (0.2%) RSOV occlusion. Funding was by an amalgamation of state sponsored welfare schemes, donations from Non Governmental Organisations (NGO), subsidies by the Medical device supplier and by our institution under the project SHINE (Save Heart Initiative). State sponsorship was 50% of the total expenditure and the rest was from donors chiefly the US based NGO SAMAHOPE and the India based NGO Have a Heart Foundation (HAHF).
Results: Four patients of the 172 (2.3%) who underwent ASD device closure had immediate device migration necessitating surgical retrieval along with ASD patch closure. There were no other morbidities or mortalities.
Conclusion: In developing countries where cardiac care is not entirely state sponsored, it is feasible to provide free care safely through a bouquet of charitable measures. Transcatheter management offers a significant reduction in cost burden facilitating the spread of funds amongst more deserving children.

P2612 - LOW AND MIDDLE INCOME COUNTRY PERSPECTIVE OF CONGENITAL HEART DISEASE ASSOCIATED WITH DOWN SYNDROME – PREVALENCE SPECTRUM TREATMENT OUTCOMES AND BIASES

Shwetha Kuthiroly[1], Mahesh Kappanayil[2], Dhanyalakshmi N[1], Brijesh P.kottayil[3], Sunil Gs[3], Krishna Kumar[2], Sheela Nampoothiri[1]
Amrita Institute of Medical Sciences, Pediatric Genetics, Kochi-India[1]; Amrita Institute of Medical Sciences, Pediatric Cardiology, Kochi-India[2]; Amrita Institute of Medical Sciences, Cardiovascular Thoracic Surgery, Kochi-India[3]

Background: There is little published data from Low and Middle-Income countries (LMICs) on Down Syndrome (DS)-associated-CHD or their treatment outcomes. Social stigma, and ignorance often result in delayed diagnosis of CHD and denial of definitive treatment in resource-limited environments.
Objectives: To determine prevalence and spectrum of CHD, and in-hospital outcomes of cardiac surgery/intervention among patients with DS presenting to Pediatric sub-specialty clinics of a tertiary-care center in South-India.
Methods and Results: Clinical records of 764 consecutive patients with karyotype-proven DS who presented (November 2005–January 2017) at a tertiary hospital with well-developed pediatric genetics and cardiology services were analyzed. Of these, 57% primarily presented to pediatric genetics; 31% to pediatric cardiology services and12% presented to other pediatric specialties. Echocardiography was done irrespective of cardiac symptoms/signs in 96%. CHD was present in 44% among those evaluated in genetics, 92% of those who primarily presented to cardiology and 62% of those who presented to other subspecialties. Overall prevalence of CHD was 62%. Most common lesions were complete -atrioventricular-canal-defect (24%), simple-VSD (22%), ASD (19%), PDA (15%), TOF (4%). Surgery/intervention was offered to 256 patients and carried out in 158 (62%). In 38% (n = 98), caregivers refused surgery/intervention. Heart surgery included VSD closure (57), AV Canal repair (44), transcatheter treatment (PDA occlusion-22, ASD closure-3). Outcomes: In-hospital mortality was 2.5%. Morbidity included prolonged (>4 days) ICU stay (24.6%), prolonged (>48 hours) ventilation (12.6%), respiratory complications (10.8%), bloodstream-infection (3.8%).
Conclusions: Echocardiographic screening of all patients with DS is recommended for early diagnosis of CHD. Majority of DS-associated CHD can be treated with low mortality. Prolonged ICU-stay, ventilation and respiratory complications contribute to morbidity must be anticipated and managed appropriately. Biases still lead to denial of treatment to large number of DS patients with CHD in LMICs even in high-expertise centers.

P2703 - IMPLEMENTATION OF NEWBORN SCREENING FOR CHD IN RURAL CHINA

Annamarie Saarinen[1], Jing Yu[2], Jia Chen[3], Guoying Huang[4]
Newborn Foundation, University of Minnesota Children, Research Division, Minneapolis/st. Paul-United States[1]; Mianyang Central Hospital, Pediatrics, Mianyang-China[2]; Mianyang Central Hospital, Pediatrics, Neonatology, Mianyang-China[3]; Children, Peds Cardiology, Genetics, Shanghai-China[4]

The concept of newborn screening for congenital heart disease (CHD) developed slowly from small studies between 2002 and 2009 to larger population based studies in Europe and the U.S. These studies and associated advocacy provided key data driving the US Department of Health and Human Services to formally add CCHD screening to the Recommended Uniform Screening Panel (RUSP) in the United States in 2011. Today, more than 30 international countries have either implemented or are in the process of evaluating newborn screening using pulse oximetry. Challenges remain however, particularly in low-resource health settings. The presentation will focus on implementation methods and results from screening more than 20,000 well-appearing newborns across 18 birth facilities in rural Sichuan Province China, utilizing a low-cost, mobile-phone pulse oximeter to measure blood-oxygen saturations at two points – 12 and 48 hours after birth. Overall incidence of congenital heart disease (CHD) in the region is higher than the national average at 11.74% (vs 6.75%), with 20%~30% of CHD patients dying within the first year.60 babies failed the screening based on a predetermined algorithm. Of those, 18 had a resulting diagnosis of Critical Congenital Heart Disease and additional 25 babies had a secondary

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

diagnosis. Notably, more than 50% of failed screens resulted in a diagnosis of previously unrecognized neonatal pneumonia. Neonatal infection (sepsis and pneumonia) rank among the most common causes of newborn mortality, accounting for more than a quarter of newborn deaths each year. The sensitivity and specificity of screening in identifying non-target conditions combined with reducing missed or delayed diagnosis of congenital heart diseases make this an increasingly high impact screen. The project deployed a train-the-trainer implementation model supported by public health and clinical leadership and robust data collection to identify and improve gaps in follow-up diagnostics, referral pathways and treatment infrastructure.

P2717 - OPTIMIZING OUTCOMES THROUGH GLOBAL COLLABORATION

Annette Imprescia[1], *Dorothy Beke*[1], *Debra Morrow*[1], *Thornton Jason*[1], *Beverly Small*[1], *Jenkins Kathy*[2], *Hickey Patricia*[3]
Boston Children, Nursing, Boston-United States[1]; *Boston Children, Patient Safety and Quality/cardiology, Boston-United States*[2]; *Boston Children, Nursing/patient Services, Boston-United States*[3]

Background: Access to care for children with congenital heart disease in developing countries is often inadequate, and limited resources pose additional challenges to centers that provide pediatric cardiac surgery. Congenital heart surgery carries considerable risk for death, especially in resource-limited settings. Following the 2008 Global Forum on Humanitarian Medicine in Cardiology and Cardiac Surgery meeting in Geneva, the International Quality Improvement Collaborative (IQIC) was established as a solution. Utilizing quality improvement strategies, three key drivers were identified to provide targeted education via monthly webinars in an effort to reduce mortality associated with congenital heart surgery. The key drivers are safe perioperative practice, infection reduction and team based practice through nurse empowerment.
Materials/Methods: Webinars related to each key driver were created by subject matter experts. Slides were disseminated prior to live presentations for individual sites to make accommodations for translation. Following each live presentation, time was allotted for interactive questions, answers and discussion. Each presentation was recorded and uploaded to the IQIC site for participants to copy, and use at their discretion. Follow up questions were emailed through the IQIC and responses were provided by presenters. Based on participant feedback and needs assessment survey data, advanced nursing modules were created and presented to meet ongoing and evolving educational needs.
Results: Since the programs' inception in 2010, 92 webinars have been created and presented. Multiple sites from around the globe were present for each live webinar. Discussion following each presentation included a rich exchange of clarifying ideas and sharing unique insights to programmatic challenges.
Conclusions: The IQIC has proven to be successful by providing interactive and interdisciplinary education, and collegial support in the subspecialty of pediatric cardiac critical care. Longstanding relationships have been forged in all disciplines.

P2723 - EXPERIENCE WITH LATE CORRECTION OF TETRALOGY OF FALLOT IN THE SETTING OF A HUMANITARIAN COLLABORATION PROGRAM

Guarino Laetitia[1], *Rhissassi Jafaar*[2], *El Koraichi Alae*[3], *Royo Carlos*[4], *Eberle Balthasar*[5], *Carrel Thierry*[1], *Hutter Damian*[6], *Kadner Alexander*[1]
University Hospital Bern, Center for Congenital Heart Disease, Dept of Cardiovascular Surgery, Bern-Switzerland[1]; *Hôpital D, Dept of Cardiovascular Surgery, Rabat-Morocco*[2]; *Hôpital D, Dept of Anaesthesia, Rabat-Morocco*[3]; *NGO Terre Des Hommes, Dept De Soins Spécialisés, Lausanne-Switzerland*[4]; *University Hospital Bern, Dept of Anaesthesia, Bern-Switzerland*[5]; *University Hospital Bern, Center for Congenital Heart Disease, Dept of Cardiology, Bern-Switzerland*[6]

Objective: To report our experience and results of late surgical correction of patients with tetralogy of Fallot (TOF) in the setting of a humanitarian collaboration program.
Patients & Methods: Retrospective analysis of the perioperative course of all patients undergoing correction of TOF older than 2 years of age at the University Hospital Bern or the University Children's Hospital Rabat between November 2011 to November 2016.
Results: 25 children (mean age: 68.9 months, range:24-156 months; 40% female) underwent total correction of TOF.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Two patients were initially palliated with a shunt with subsequent correction after 108 and 24 months. Preoperative oxygen saturation was 85 + /- 11%; mean hemoglobin was 146 + /-23 g/l. Preoperative Mean RV/PA gradient was 84 + /-21 mmHg with a Nakata-Index of 162.6 + /-55.6mm2/m2. A valve-sparing correction was performed in all patients. Ventilation time 28.7 + /- 14.6 hours. Length of stay was 11.7 + /-3.3 days. Mortality was 0%. No stroke occurred. No permanent pacemaker had to be implanted. All patients were examined by echocardiography at 1months postoperatively. Due to the character of the program, follow-up is 60% complete with a mean of 17 months (range: 3-43mo). Last echocardiography demonstrated less to mild pulmonary stenosis in 16patients, moderate in 9patients, no severe pulmonary stenosis. 2 patient underwent reoperation (1 patch dehiscence, 1 recurrent pulmonary stenosis).
Conclusions: Late correction of TOF can be safely performed in older children with good postoperative results and low morbidity comparable to reported results for "timely" correction in infants. A valve-sparing correction might be possible in the majority of those patients. Follow-up study for the evaluation of the development of right ventricular and pulmonary valve dysfunction is needed and in progress.

P2729 - PEDIATRIC CARDIAC DEVELOPMENT ASSISTANCE IN IRAQ; 2010 2016

William Novick[1], Frank Molloy[2], Marcelo Carderelli[3], Christian Gilbert[4], Stacey Marr[2], Karen Bowtell[2], Aqeel Mindel[5], Ala Mansour[6], Dhiya Kareem[7]
University of Tennessee Health Science Center, Surgery, Memphis-United States[1]; William Novick Global Cardiac Alliance, Intensive Care, Memphis-United States[2]; William Novick Global Cardiac Alliance, Surgery, Fairfax-United States[3]; , Surgery, -United States[4]; Nasiriyah Heart Center, Surgery, Nasiriyah-Iraq[5]; Najaf Cardiac Center, Surgery, Najaf-Iraq[6]; Basra Cardiac Center, Surgery, Basra-United States[7]

Background: Pediatric cardiac surgery in Iraq prior to 2010 was available in only 2 cities, Erbil and Baghdad. We were asked to assist in the development of pediatric cardiac services in 2009 and began in 2010. Four sites were identified, in 2010 Sulimaniyah and Nasiriyah; Najaf and Basra were added in 2012. We present the results of this unique country-wide program.
Methods: We queried our database for; number of trips, patient operations, RACHS classifications, 30-day/in hospital mortality and surgeon. Two distinct models were used. Model 1; two-week visit by teams (10-16) and Model 2 where a team (6-8) stayed 42-50 weeks consecutively. Standardized Mortality Ratios (SMR) were calculated against contemporary multinational data.
Results: Primary operations (trips)/site: Model 1; Sulimaniyah-39 (2), Basra-68 (4), Najaf-72(5), Nasiriyah-115 (7); Model 2; Nasiriyah-577 (78 operating weeks - over 2y 2 m). Total primary operations 871; RACHS-1 distribution and mortality; 1- 102/2 (1.96%), 2- 397/10 (2.53%), 3-241/46 (19.09%), 4-38/16 (42.11%), 5-1/1, 6-1/1, Non-RACHS and ADULT 91/6. Model 1 visits; 36 operating weeks, 294 surgeries, mean cases/week 8.17 ± 1.84. Model 2 visits - 78 operating weeks (over 2y 2 m), 577 surgeries, mean cases/week 7.4 ± 3.73. No significant difference, p = 0.24. Median age of all the patients 4 years 5 months. Age distribution; 0-30 days-39, 31 days-1 year 146 , 1-18 y 605, adults- 75, no Age 6. Median Age RACHS-1 cases (n = 790), 4.0 years. Unadjusted Mortality, Model 1; 36/294 = 12.2%: Model 2; 46/577 = 7.9% (p = .04). The SMR (95% C.I) Model 1;1.75 (1.23-2.42) and Model 2; 1.43 (1.04-1.91). Risk factors for mortality (OR) neonates (7.46), infant (3.64), *(vs 1-18 y). RACHS 3 (9.54), RACHS 4 (36.36) (vs RACHS 1).
Inferences: Model 2 provided more operations and lower SMR secondary to a continuous presence and 3 sustained programs resulted.

P2785 - PROGRAMMATIC CHANGES TO REDUCE MORTALITY AND MORBIDITY IN HUMANITARIAN CONGENITAL HEART SURGERY

Tyler Wallen[1], Randa Blenden[2], Intikhab Zafurallah[3], Travis Vesel[4], Rodrigo Soto[5]
Mercy Catholic Medical Center, Surgery, Ardmore-United States[1] International Children's Heart Foundation, Nursing, Memphis-United States[2] Birmingham Children's Hospital, Cardiac Intensive Care, Birmingham-United Kingdom[3] International Children's Heart Foundation, Administration, Memphis-United States[4] International Children's Heart Foundation, Cardiac Surgery, Memphis-United States[5]

Background: The International Children's Heart Foundation (ICHF) is a non-governmental organization providing congenital cardiac surgery services to the developing world. A review of the organization's outcomes prompted several programmatic changes aimed at improving mortality and morbidity. The purpose of this study is to analyze the impact of those changes on clinical outcomes.
Materials and Methods: In 2015 the organization implemented several quality improvement policies. These included the following: new sites would not accept patients less than 10 kgs, operative complexity would rise only as local capacity increased, preoperative evaluation was to mirror that of the first world (i.e. withholding operative treatment until all medical illness are stabilized, i.e. viral infection), all sites must have a blood bank, medical subspecialty must be available, 24 hour intensivist coverage must be available and a single ICHF surgeon will provide services for each trip. A retrospective review of a prospectively maintained database was conducted, dividing patients into an Early group (2008-2014) and a Late group (2015-2016).
Results: There were 3,521 patients identified in the Early group and 262 in the Late group. Patients in the late group were older and less likely to admitted to the ICU preoperatively, but more likely to be malnourished (Table 1). Bypass and cross clamp times were similar (Table 2). Patients in the Late group had a significantly lower mortality rate (Early 8.5%, Late 2.29%, $p < 0.0001$). The Late group was less likely to undergo reoperation (Early 11.79%, Late 2.29%, $p = 0.0001$) and re-intubation (Early 10%, Late 5.73%, $p = 0.022$) (Table 3). Mortality for the most commonly performed operations also decreased, although not significantly (Table 4).
Conclusions: Programmatic changes undertaken by ICHF has resulted in a significant decrease in mortality and morbidity in the humanitarian setting.

P2809 - PEDIATRIC CARDIAC ASSISTANCE AND DEVELOPMENT IN EASTERN LIBYA 2012 2016

William Novick[1], Wejdan Amer[2], Marcelo Carderelli[3], Humberto Rodriguez[3], Stacey Marr[4], Karen Bowtell[4], Pavel Shaucheka[4], Eugene Suslin[4], Sergey Liauchonek[5], Frank Molloy[4], Reida El Oakley[6]
University of Tennessee Health Science Center, Surgery, Memphis-United States[1]; Tobruk Medical Center, Surgery, Tobruk-Libya[2]; William Novick Global Cardiac Alliance, Surgery, Fairfax-United States[3]; William Novick Global Cardiac Alliance, Intensive Care, London-United Kingdom[4]; William Novick Global Cardiac Alliance, Anesthesia, Fairfax-United States[5]; Government of Libya, Ministry of Health, Al Bayda-Libya[6]

Background: Prior to the revolution Libya had 1 center performing pediatric cardiac surgery in Tripoli. Following the revolution we were asked to provide pediatric cardiac services and development to Eastern Libya. We began our program in Benghazi in 2012 and were forced secondary to conflict to move to Tobruk in 2015. The results of this program in a region of conflict are presented.
Methods: We queried our database for all trips. Data analyzed were patient demographics, number of trips, primary operations, RACHS Classification, outcomes and surgeon. Models were two-week (Model 1, 14-16 team members) and month-long visits (Model 2, 7-8 team members).
Results: There were 257 males. Median age Benghazi 1.88 yrs, Tobruk 1.27 yrs. Total trips/operations (19/498); weeks/operations, Benghazi (36/260) and Tobruk (27/237). Model 1 mean operations/trip, 20.2 ± 4.4. Model 2 Benghazi, mean operations/trip, 22.71 ± 10.03, Model 2 Tobruk, 34.0 ± 8.3, $p < 0.0001$. Mean operations/week, Model 1, 7.6 ± 1.1; Model 2, 9.8 ± 0.8, $p = 0.009$. RACHS distribution: Benghazi 1-51 (21%), 2- 136 (55.8%), 3- 48 (19.7%), 4- 8 (3.3%), Non-RACHS/ADULT 17, Total 260,. Tobruk 1- 45 (20%), 2- 97 (43.1%), 3- 70 (31.1%), 4- 13 (5.8%), Non-RACHS/ADULT 13, Total 238. Unadjusted mortality: 30/498 (6.02%); RACHS classifiable, Benghazi 10/243 (4.1%), Tobruk 20/225 (8.8%) ($P = 0.03$). RACHS category mortality: Benghazi 1- 0/51 (0%), 2- 2/136 (1.47%), 3- 5/48 (10.42%), 4- 3/8 (37.5%); Tobruk 1- 0/45 (0%), 2- 3/97 (3.09%), 3- 14/70 (20%), 4- 3/13 (23.1%). The SMR Benghazi was 0.804 (0.4-1.4) and Tobruk 1.420 (0.88-2.1). The SMR (95% CI) Model 1 was .64 (.16-1.7) and Model 2 1.24 (.82-1.8). Risk factors for mortality; neonatal age (OR 20.79 = 95% C.I. 6.1-71) and RACHS-1 Category 3 (OR 31.75), and Category 4 (OR 99.9). Local Surgeon primary; Benghazi 91/260, Tobruk 69/238, ($p = .04$).
Inferences: Pediatric cardiac development can be carried out in conflict areas.

P2877 - DEVELOPMENT OF A CARDIAC PEDIATRIC SURGERY PROGRAM AT A PUBLIC HOSPITAL IN LA PAZ BOLIVIA AT 3600 M

Alexandra Heath[1], Erika Perez [2], Natalia Medina[1], Josef Henao[3]
Hospital Del Niño, Pediatric Cardioloy, La Paz-Bolivia[1]; Hospital Del Niño, Cardiac Surgery, La Paz-Bolivia[2]; Hospital Del Niño, Pediatrics, La Paz-Bolivia[3]

Introduction: Only 20% of bolivians have a health insurance. At high altitude congenital heart diseases are twice as frequent as at sea level. Children with CHD depended til the begin of the program on compasive missions and caritative foundations to get a correction of their diseases. Only 12% were operated in this way and 88% died during the natural evolution.
Aim: To organize a cardiac surgery program in the public children hospital "Hospital del Niño".
Method: a) Infrastrutcture and equipment: We considered key services at the hospital, including children surgery, pediatric ICU, la and blood bank. Modernization of infrastructure and adquisition of equipment were organizaed in consence with the help of several organizationd including the german and japanese cooperation b) Personal qualification: 30 nurses and doctors got a qualification in the postoperative managment of children cardiac surgery. We edited togheter a protocol for every single stage of diagnosis and therapy. Satelite hospitals doctors and nurses were capacitated in the early diagnosis of CHD for opportune reference. c) Political support. Several meetings with authorities of the Ministry of Health conduced to the inclusion of medicaments in the national list of drugs. Steps to include financing of cardiac surgeries are underwent in the office of public insurance.
Conclusion: Allready thirty patients were operated in RACHS categories 1-3, including VSD, ASD, Fallot and palliative surgery for more complex CHD. The mortality up to 30 days is 0%. Children with a CHD and without economical resourses have now an oppotunity to be healed.

P2986 - A STRUCTURED INTERVENTION PROGRAMME CAN IMPROVE THE BIOPHYSICAL WELLBEING IN CHILDREN WITH CONGENITAL HEART DISEASE

Sinead Callaghan[1], Margaret Louise Morrison[2], Christopher Mccusker[3], Pascal Mckeown[4], Frank Casey[1]
Royal Belfast Hospital for Sick Children, Queen, Paediatric Cardiology, Belfast-United Kingdom[1]; Royal Belfast Hospital for Sick Children, Paediatric Cardiology, Belfast-United Kingdom[2]; Royal Belfast Hospital for Sick Children, Queen, Paediatric Psychology, Belfast-United Kingdom[3]; Royal Belfast Hospital for Sick Children, Queen, Cardiology, Belfast-United Kingdom[4]

Introduction: Improved survival among children with congenital heart disease (CHD) has shifted focus to long-term physical and psychological outcomes. The benefits of an active lifestyle within the general population have been well described. This study aims to determine if a structured intervention programme can improve

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

both physical and psychological functioning in children with CHD.
Methods: This is a prospective randomised control trial. Patients aged 5-10 years with CHD were identified and invited to participate. Each patient underwent baseline assessment as detailed:
Biophysical assessments: • Weight, height, waist measurements • Heart rate, blood pressure, oxygen saturation
• Exercise stress test–Graded cycle ergometer protocol • Actigraph accelerometer worn for 1 week
Psychosocial assessments: • Kidscreen27 • Strengths and Difficulties Questionnaire • Butler Self-image Profile
Following baseline assessment patients were randomised into intervention and control groups. The intervention group attended a one day education session during which motivational interviewing techniques were used to deliver exercise and positive lifestyle advice. They received an individual written exercise plan to take home and implement. The control group continued with their usual level of care. After 4 months all participants were reassessed.
Baseline Results: • 163 patients were recruited, 100 males (61.3%), mean age of 8.4 years (range 5.3–11.5)
• Patient subgroups: 18.4% acyanotic no intervention, 37.4% acyanotic repaired, 27.6% cyanotic corrected, 16.6% cyanotic palliated • EST duration mean 5.89 mins (SD 2.02), • Actigraph: Average time spent in MVPA 45 mins (SD -27.2) • The 'cyanotic palliated' subgroup had significantly shorter EST duration and lower levels of daily MVPA. This subgroup also scored significantly lower on HrQOL physical wellbeing
Review Results: • There was a significant improvement in performance at peak exercise in the intervention group following the exercise programme
Conclusions: Overall physical and psychological wellbeing is well preserved in the majority of children aged 5-11 years with CHD. A structured intervention programme significantly improved peak exercise capacity.

P3002 - CREATING PROFESSIONAL DEVELOPMENT OPPORTUNITIES FOR PEDIATRIC CARDIAC CRITICAL CARE NURSES IN SOUTH VIETNAM

Adriana Dobrzycka Bechara[1], Mary Tan[2], Tranchau Nguyen[3], Anh Le Doan[4], Bistra Zheleva[1]
Children's Heartlink, International Programs, Minneapolis-United States[1]; National University Hospital, Nursing, Singapore-Singapore[2]; Nhi Dong 1, Pediatric Cardiac Icu, Ho Chi Minh City-Vietnam[3]; University of Medicine and Pharmacy, Nursing, Ho Chi Minh City-Vietnam[4]

Nursing education in low and middle income countries (LMICs) still doesn't meet the needs of patients with congenital heart disease. Little formal continuing medical education (CME) is available for pediatric cardiac critical care nurses to advance their skills and knowledge. To address this need, we partnered with the University of Medicine and Pharmacy and the Nursing Teachers Branch in Ho Chi Minh City to develop a CME course for pediatric cardiac critical care nurses. The course was taught by pediatric cardiac care providers from local teaching hospitals and was delivered in two cycles: 2014-2015 and 2015-2016. Each cycle consisted of three, 3-day long sessions taught over a 12 month period. Topics included congenital heart disease anatomy, post-operative management, family-centered care, Basic Life Support and Pediatric Advance Life Support. Teaching approaches included lectures, case studies, scenarios, and group discussions. Pre and post-test scores were collected for each session and the 3 month BLS/PALS follow up. In Year 1, 37 pediatric cardiac critical care nurses from 12 hospitals in the Mekong Delta participated. In Year 2, 21 nurses from 7 hospitals participated. Participant feedback was positive and changes in BLS/PALS preparedness illustrated a significant gain in knowledge and understanding of practices. In Year 1, 19 nurses scored below 60% in the pre-test compared to 10 in the post-test. In Year 2, 14 scored between 60% and 80%, and five scored below 60% in the pre-test. In the post-test, all participants scored at or above 60%. Throughout the course, Children's HeartLink contributed to curriculum development, funding, speaker and participant recruitment. Challenges included participant recruitment (especially outside of Ho Chi Minh City), communication, and long-term follow up to ensure sustained change in practices. An effective subspecialty nursing CME course in LMICs can be developed and implemented when clinical, educational, and

IMAGING

P1034 - HIGH RISK ANGIOGENIC GENES ARE ASSOCIATED WITH ABNORMAL CARDIAC MECHANICS IN CHILDREN WITH HYPERTROPHIC CARDIOMYOPATHY

Jaime Alkon[1], Mark Friedberg[2]
Joe Dimaggio Children, Pediatric Cardiology, Hollywood, Fl-United States[1]; The Hospital for Sick Children, Pediatric Cardiology, Toronto, On,-Canada[2]

Introduction: We have previously reported diastolic dysfunction in children with hypertrophic cardiomyopathy (HCM) associated with high risk (HR) alleles in angiogenic genes (VEGF, HIF1α, and TP53). This study aimed to investigate myocardial deformation and relaxation in high risk (HR) and low risk (LR) genotypes.
Methods: Subjects with HCM (<21yrs) were prospectively enrolled (2007-2010) and genotyped for VEGF (2578 A/C); (1154 A/G), (634 C/G), HIF1α (145 C/T); (1326 C/T), TP53 (97-29 C/A); (Arg72ProC/G) polymorphisms. Presence of an allele associated with down regulation of angiogenic genes was defined as HR genotype. Systolic and diastolic longitudinal, circumferential, and radial strain and strain rate at each myocardial segment were measured by 2D speckle tracking (EchoPac, GE). HR and LR genotypes were compared by Student's t-test.
Results: Fourteen HCM subjects (mean age 6yrs (range 1-15), 79% male, 79% Caucasian) were enrolled. Frequency of HR alleles A, A, T in VEGF were 64%, 50%, 36%, HIF1α (T, C; 71%, 79%) and TP53 (G, C; 64%, 64%) respectively. Septal and posterior wall thickness was similar between LR and HR except for thicker septum in HR VEGF (1154 A/G) ($p = 0.03$) and posterior wall in HR HIF1α (1326 C/T) ($p = 0.08$). In HR genotypes, both systolic circumferential strain and systolic and diastolic circumferential strain rate were significantly decreased in multiple segments, predominantly at the basal and apical levels (i.e. anteroseptal and anterior segments). HR genotypes had significantly decreased systolic longitudinal strain and strain rate at the basal septum, midseptum and basolateral segments, and decreased basal global radial peak systolic strain.
Conclusions: HR alleles that downregulate angiogenic genes are associated with adverse cardiac mechanics in children with HCM.

P1049 - VEIN OF GALEN MALFORMATION WITH DEXTROCARDIA SINGLE LEFT SIDED SVC ABERRANT RIGHT SUBCLAVIAN ARTERY AND INTRACTABLE CARDIAC FAILURE; CHALLENGES IN MANAGEMENT

Yong Junina Fadzil[1], Rohana Jaafar[2], Faizah Mohd Zaki[3], Suhaila Ahmad[4]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Klinik Pakar Kanak-Kanak Junina, Paediatrics, Petaling Jaya-Malaysia[1]; Ppukm, Paediatrics, Kuala Lumpur-Malaysia[2]; Ppukm, Radiology, Kuala Lumpur-Malaysia[3]; Ppukm, O & G, Kuala Lumpur-Malaysia[4]

Background: Vein of Galen malformation (VOGM) is associated with cardiac anomalies, intractable cardiac failure and signs similar to that of pulmonary hypertension, making management of such cases challenging. We present the challenges we faced in managing a term newborn with VOGM with dextrocardia and single left SVC.
Materials: Madam S was referred to our centre at 33 weeks' gestation for polyhydramnios, abnormal fluid collection in the fetal corpus callosum, and cardiomegaly. Fetal MRI confirmed the presence of VOGM. Fetal echo confirmed dextrocardia, cardiomegaly and dilated left sided SVC. Post delivery echo confirmed the dextrocardia, dilated SVC and cardiomegaly, revealed a large PDA with bidirectional shunting at the PFO and PDA, and tricuspid regurgitation with a pressure gradient of 79 mmHg. She was intubated, ventilated, and started on frusemide. Coil embolisation of 4 feeder vessels to the VOGM resulted in a decrease in SVC diameter and a reduction of ventilator support. Shunting at both PDA and PFO became left to right, and she subsequently developed intractable cardiac failure which remained poorly controlled despite maximising anti failure therapy. Cardiac CT following a failed attempt at ligating the ductus revealed a single left SVC draining into the coronary sinus, a right innominate vein, left sided aortic arch, and an aberrant tight subclavian artery arising from the descending aorta. The child was planned for coil embolisation of a feeder vessel which had increased in diameter. However, baby S became bradycardic and died despite resuscitative efforts during the procedure.
Conclusion: This case highlights the challenges faced in imaging, diagnosing and managing congenital heart disease and cardiac failure in a patient with VOGM. To our knowledge, this is also the first reported case of dextrocardia, single left SVC and aberrant right subclavian artery in a patient with VOGM.

P1084 - HOW DOSE ECHOCARDIOGRAPHY HELPS US BEFORE DURING AND AFTER TRANSCATHETER VENTRICULAR SEPTAL DEFECT CLOSURE PROCEDURE

María Fernanda Biancolini, Julio César Biancolini, Ana María Susana De Dios, Jesús Damsky Barbosa
Elizalde Children's Hospital, Pediatric Cardiology, Buenos Aires-Argentina

Background: Gold standard treatment for ventricular septal defects (VSD) is surgical closure, with minimum mortality but associated risks such as complete AV block (AVB), residual shunt, pericardiotomy syndrome, infection, etc. Transcatheter closure of VSD emerges as an alternative with acceptable morbi-mortality and encouraging results. The purpose of this study is to analyze how echocardiography helps us before, during and after transcatheter VSD closure procedure.
Materials and Methods: A descriptive analysis was performed based on the review of clinical, echocardiographic and catheterization records of patients (p) with transcatheter VSD closure during the period between May 2010 and March 2016 at Pedro de Elizalde Children's Hospital. 51 procedures were performed in 47p. Median age was 7 years old (range 0,33 to 15y). Median weight was 26 Kg (range 4,3-83Kg); 5 procedures were done in p less than 10Kg.
Results: 43 procedures were successful (84,3%), 41 in the first attempt and 2 needed a second procedure. 3p evidenced major complications (6,9%): 1p tricuspid stenosis; 1p hematuria with decrease in blood count ; 1p, <10 kg with muscular infundibular VSD and no aortic prolapse or insufficiency pre procedure, had severe aortic insufficiency immediately post procedure and died. 8 procedures failed in the first attempt, in 2 cases changing the device achieved closure successfully in a second procedure. 6p required surgery (11,7%).
Conclusions: Echocardiography was part of the learning curve and allowed to define fundamental aspects for the correct device selection as VSD anatomic characteristics and its relation with adjacent structures. It's a complementary tool to guide the procedure and provides direct view in key situations as arteriovenous loop, progress, deployment and release of the device, among others. It's essential to assess the correct implantation and stability of the device. It identifies complication during and post procedure and allows decision-making.

P1087 - ISOLATED LEFT COMMON CAROTID ARTERY FROM THE MAIN PULMONARY ARTERY ASSOCIATED WITH TETRALOGY OF FALLOT

Kumiyo Matsuo, Hisaaki Aoki, Futoshi Kayatani
Osaka Medical Center and Research Institute For Maternal and Child Health, Pediatric Cardiology, Osaka-Japan

Background: An isolated left common carotid artery (LCCA) is very rare. It would be caused by partial regressions of the aortic sac and the left fourth arch in early fetal life.
Case Report: The fetus was diagnosed as Tetralogy of Fallot (TOF) at 31 weeks' of gestation. She was born at 40 weeks, weighted 3379 g, and 97% in oxygen saturation. The echocardiography and the computed tomography revealed TOF and right aortic arch, from where a right common carotid artery, right subclavian artery, and left subclavian artery branched in order. LCCA was arising from pulmonary artery (PA) via ductus arteriosus (DA). The both sides of brain vessels were communicated with the circle of Willis. With the concern of steal phenomenon due to the connection between LCCA and PA via DA as the pulmonary resistance decreased, the DA was closed at day 1. The SPECT and the cerebral angiography revealed well left brain perfusion. The neurological and developmental status was well at the age of three months. A total correction of TOF was planned in infancy.
Conclusion: LCCA from PA is very rare, and only eight cases have been reported so far. Fong and Venables postulated according to Edwards hypothesis that the distal migration of the left subclavian artery beyond the left ductus arteriosus with subsequent disappearance of two different segments between ascending aorta and LCCA and between left subclavian artery and left DA, which would produce an isolated left common carotid artery and an aberrant left subclavian artery. Our case would support this concept as we could follow the closure of the vessel between LLCA and PA after birth, which was suggestive of ductal tissue.

P1090 - TISSUE DOPPLER VENTRICULAR FUNCTION PARAMETERS CORRELATION WITH CARDIAC BIOMARKERS IN NEWBORNS WITH CONGENITAL HEART DEFECTS

Ana Luisa Neves[1], Maria Cabral[2], Adelino Leite-moreira[3], José Monterroso[1], Carla Ramalho[4], Hercília Guimarães[5], Henrique Barros[2], João Tiago Guimarães[6], Tiago Henriques-Coelho[7], José Carlos Areias[1]
Hospital S. João, Pediatric Cardiology, Porto-Portugal[1]; University of Porto, Institute of Public Health, Porto-Portugal[2]; Hospital S. João,

Cardiothoracic Surgery, Porto-Portugal[3]; Hospital S. João, Obstetrics, Porto-Portugal[4]; Hospital S. João, Neonatology, Porto-Portugal[5]; University of Porto, Clinical Pathology, Porto-Portugal[6]; University of Porto, Pediatric Surgery, Porto-Portugal[7]

Background/Hypothesis: Our hypothesis is that tissue Doppler parameters of bi-ventricular function correlate with cardiac biomarkers in newborns with congenital heart defects.
Materials and Methods: Between August 2012 and March 2015, newborns with prenatal diagnosis of congenital heart defects were admitted consecutively to a Neonatal Intensive Care Unit. Healthy newborns delivered in the same hospital were recruited as controls. Plasma levels of cardiac biomarkers (brain natriuretic peptide, creatine kinase-MB, troponin I, myoglobin) were measured in the cord blood, and echocardiograms were performed in both groups.
Results: No significant differences in cardiac biomarkers were observed between the congenital heart defect and control groups. The creatine kinase-MB levels differed by type of congenital heart defect and were significantly higher in cyanotic than in acyanotic congenital heart defects, with median levels of 3.1 (2.6–3.8) and 4.6 (3.2–6.1 ng/mL), respectively, $p = 0.007$; the higher levels were found in the transposition of great arteries group. The creatine kinase-MB cord blood levels positively correlated with the tricuspid valve E/E' ($p = 0.002$; $rho = 0.772$). The troponin I levels negatively correlated with the mitral valve lateral annulus slope ($p = 0.04$; $rho = -0.412$).
Conclusions: The creatine kinase-MB cord blood levels correlated with diastolic ventricular function parameter, while troponin I correlated with systolic function parameter, as evaluated by tissue Doppler.

P1099 - PAPILLARY MUSCLE NONCOMPACTION A UNIQUE MECHANISM FOR MITRAL REGURGITATION

Sulafa Ali
Univ of Khartoum, Ped Cardiology, Khartoum-Sudan

Introduction: Noncompaction cardiomyopathy (NCCM) is increasingly being reported with variable clinical presentations. We described the first series of patients with noncompaction cardiomyopathy (NCCM) associated mitral regurgitation (MR)in 2004. Subsequently, many other patients were reported by us and others.
Methods: Prospective follow up of cases of NCCM associated with papillary muscle NCCM and MR.
Results: We identified 25 patients with NCCM associated with MR secondary to papillary muscle affection and followed them for 1-10 years (2004-2015). Clinical presentation includes heart failure in 20 patients and a heart murmur without symptoms in 5. Echocardiographic features in all patients showed NCVM involving papillary muscle base with variable degree of chordal elongation /rupture. The mitral leaflets appear retracted and malcoapting. MR degree varied from mild to severe. Ejection fraction was normal >55% in 15 patients, mildly impaired (45-55%) in 5 and severely impaired in 5 patients. Tow patient had mitral valve replacement with good long term outcome.
Conclusion: In NCCM, papillary muscle affection can lead to MR with characteristic echocardiographic features including chordal abnormalities and malcoaptation.

P1113 - DILATION OF THE AORTA OR NEOARTIC ROOT IN THOSE HAVING UNDERGONE FONTAN PALLIATION

Rohit Loomba, Joe Cava, Michael Earing, Caitlin Quinn, Salil Ginde
Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-United States

Background: Dilation of the aorta or neoaorta occurs after the Fontan palliation. Cardiac magnetic resonance imaging (CMRI) allows for adequate visualization and measurement of the aorta or neoaorta in this setting. This study was conducted to identify risk factors for such dilation.
Materials and Methods: Patients having had undergone Fontan palliation and a subsequent CMRI study at our institution were identified. CMRI studies were then reviewed with the aorta or neoaorta being measured using a coronal cine image in systole. Measurements were z-scored using values for normal aortas. The median z-score for each anatomic site was then calculated with those having a value above the median being classified as dilated. Univariate analysis was then conducted to identify features associated with dilated aortas.
Results: A total of 84 patients were included. Median z-score was 2.93 (-1.80 to 6.37) for the annulus, 2.13 (-3.56 to 6.66) for the sinus, 2.79 (-2.12 to 8.39) for the ST junction, and 2.53 (-1.59 to 20.00) for the ascending aorta. Aortic insufficiency of at least mild severity was present in 21%, while moderate or severe aortic insufficiency was present in 5%. No risk factors were identified for dilated aortic annulus. Moderate or severe aortic insufficiency was associated with a dilated sinus ($p = 0.03$). History of HLHS, DKS procedure, or a BT shunt were associated with dilation of the ascending aorta.
Conclusions: Factors associated with dilated aortic annulus, sinus, ST junction, and ascending aorta were identified in this study. For the entire cohort, moderate or severe aortic insufficiency was associated with a dilated sinus and history of having undergone a DKS was associated with dilation of the ST junction while having HLHS was associated with dilation of the ascending aorta.

P1114 - IS LV DYSSYNCHRONY AN EARLY MARKER OF VENTRICULAR DYSFUNCTION WITH WORSENING AORTIC REGURGITATION IN YOUNGER PATIENTS WITH CONGENITAL AORTIC VALVE DISEASE CLINICAL APPLICATION OF REAL TIME ECHO DERIVED DEFORMATION INDICES

Rodrigo Rios, Salil Ginde, David Saudek, Rohit Loomba, Peter Frommelt
Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-United States

Background: Standard echo protocols primarily rely on left ventricular (LV) ejection fraction and shortening fraction to assess ventricular function. Commonly, these parameters are preserved even with severe aortic valve disease. We measured LV deformation during routine clinically-indicated echocardiograms using 2D speckle tracking in patients with congenital aortic stenosis (AS) and/or aortic regurgitation (AR).
Material and Methods: An advanced echo protocol performed at the ultrasound machine and immediately available to caregivers included 2D LV regional and global circumferential (circ) strain (S) and strain rate (SR) from a short axis view and longitudinal (long) S and SR from an apical view, standard deviation of time to peak systolic circ and long S, and max systolic wall delay to peak S was instituted for all patients with AS and/or AR.
Results: 70 consecutive patients (mean age = 16y, range 1 m to 55y; 50 male, 20 female) completed the echo protocol between 12/2014-4/2015. Sixty-two (89%) patients had a bicuspid aortic valve. Ejection fraction was preserved in all patients regardless of aortic valve disease severity (table), and there were no significant differences in circ S, long S, or long SR between patients based on AS or AR severity. In fact, circ S was significantly higher for patients with severe AS. Dyssynchrony was not seen with

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

dominant AS disease, but circ standard deviation of time to peak strain and circ max wall delay were significantly higher in patients with severe AR compared to mild-moderate regurgitation.
Conclusion: Both traditional echo assessment and 2D deformation indices suggest preserved LV function in younger patients with congenital aortic valve disease, regardless of severity. Real-time deformation analysis does identify progressive dyssynchrony with worsening AR, however, which may be marker of early LV dysfunction. This technique should be added to routine clinical surveillance.

P1115 - SEGREGATING BODILY ISOMERISM POTENTIAL ECHOCARDIOGRAPHIC CORRELATIONS OF MORPHOLOGIC FINDINGS

Cornelia Trembay[1], Rohit Loomba [2], Peter Frommelt[3], Donald Perrin[2], Diane Spicer[4], Carl Backer[5], Robert Anderson[6]
Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-Canada[1]; Hospital for Sick Children, Pediatric Cardiology, Milwaukee-United States[2]; Children's Hospital of Milwaukee, Pediatric Cardiology, Milwaukee-United States[3]; All Children's Heart Institute, Pediatric Cardiology, St Petersburg-United States[4]; Lurie Children's Hospital, Pediatric Cardiology, Chicago-United States[5]; Institue of Genetic Medicine, Pediatric Cardiology, Newcastle Upon Tyne-United States[6]

Background: Bodily isomerism, also referred to as heterotaxy, involves predominantly the thoracic organs, although other organs are usually abnormally positioned. Previously assessed on the basis of splenic anatomy, it is now understood that isomerism is better segregated on the basis of atrial appendage morphology. This allows for anticipation of associated findings. We aimed to assess the accuracy of segregation based on the morphology of the atrial appendages and other structures more easily identified by echocardiography.
Materials and Methods: We reviewed postmortem specimens of hearts from the archives at four institutions categorized as obtained from patients with "heterotaxy". The cardiac structures were analyzed using sequential segmental analysis. Non-cardiac structures were also examined if available. Statistical analysis was performed to compare differences in the settings of right as opposed to left isomerism.
Results: Specimens were available from 188 patients. Of these, 57 had left isomerism, and 131 had right isomerism. Atrial appendages were isomeric in all patients. A coronary sinus was found only in left isomerism, while a terminal crest, or a Eustachian valve, was only in right isomerism. Interruption of the inferior caval vein was associated with left isomerism, while totally anomalous pulmonary venous connection was associated with right isomerism.
Conclusion: Isomerism is uniformly segregated on the basis of the morphology of the atrial appendages, itself defined by the extent of the pectinate muscles. These features themselves, if knowingly sought, should be identifiable in the clinical setting, but other cardiac findings can be used for segregation by the echocardiographer.

P1117 - VESTIBULAR ATRIAL SEPTAL DEFECTS A NECROSCOPY STUDY

Rohit Loomba[1], Robert Anderson[2], Diane Spicer[3]
Children's Hospital of Wisconsin, Pediatric Cardiology, Milwaukee-United States[1]; Newcastle University, Pediatric Cardiology, Newcastle Upon Tyne-United Kingdom[2]; All Children's Hospital, Pediatric Cardiology, St. Petersburg-United States[3]

Background: The vestibular atrial septal defect is a newly described type of interatrial communication that is a defect in the antero-inferior portion of the atrial septum. A result of inadequate muscuiarization of the vestibular spine and mesenchymal cap, the vestibular atrial septal defect represents a true deficiency of the atrial septum. A review of necroscopy specimens from three separate archives was conducted to further characterize vestibular atrial septal defects and associated cardiac findings.
Materials and Methods: Sequential segmental analysis was utilized to analyze hearts in the Farouk S. Idriss Cardiac Registry at Ann & Robert H. Lurie Children's Hospital in Chicago, IL, the Van Mierop Archive at University of Florida in Gainesville, Florida, and the archive at Johns Hopkins All Children's Heart Institute in St. Petersburg, Florida. Hearts with a vestibular atrial septal defect were identified and further characterized to find findings associated with such atrial septal defects.
Results: A total of 2,100 specimens were analyzed. Of these, 68 (3%) were found to have a vestibular atrial septal defect. Such defects were associated with bilateral atrial dilation, fossa ovalis type atrial septal defects, abnormalities of the right sided atrioventricular valve, pulmonary atresia, right ventricular outflow tract obstruction, and the presence of an interventricular communication. Concordant atrioventricular and ventriculo-arterial junctions were present in nearly all cases.
Conclusion: The vestibular defect, therefore, is a recently recognised true atrial septal defect located in the muscular antero-inferior rim of the oval fossa. Our retrospective review of autopsied hearts suggests that the defect may be commoner than previously thought. Diagnosis represents an echocardiographic challenge, as the location of the defect can mimic a multi-fenestrated floor of the oval fossa. Increased awareness of the defect should optimize its future clinical identification.

P1131 - DOUBLE AORTIC VALVE A PREVIOUSLY UNREPORTED ANOMALY

Ashish Katewa[1], Yogesh Sathe[2], Balaswaroop Sahu[3], Shreeharsha Sathpaty[4]
Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiothoracic Surgery, Naya Raipur-India[1]; Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiology, Naya Raipur-India[2]; Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiac Anaesthesiologiology, Naya Raipur-India[3]; Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiac Anaesthesiology, Naya Raipur-India[4]

Background: We present a previously unreported congenital heart anomaly with duplications of aortic valve, aortic sinus and proximal ascending aorta.
Materials & Methods: A six years old girl presented with complains of cyanosis and effort intolerance. On trans-thoracic echocardiography (TTE), she was diagnosed with Double-outlet right ventricle (DORV), ventricular septal defect (VSD) and infundibular stenosis. Surgical correction was scheduled with a plan of routing the VSD to the aorta and resection of infundibular stenosis.
Results: During surgery, the aortic root appeared significantly enlarged which tapered to a normal looking ascending aorta giving a "flask like" appearance. The right atrium was opened after instituting the cardiopulmonary bypass and cardioplegic arrest. In addition to a large sub aortic VSD and infundibular stenosis, the aortic root appeared to be guarded by two seperate aortic valves, oriented antero-posteriorly and separated by a muscle bar. The anterior aortic valve was tricuspid and posterior aortic valve was bicuspid. The VSD was routed to the aorta committing both aortic valves to the left ventricle and infundibular obstruction was resected. The postoperative course was uneventful and hospital discharge occurred on fifth postoperative day. Computed tomography revealed duplications of aortic valve, aortic sinus and

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

proximal ascending aorta. The coronaries arose from the posterior sinus. *Conclusions:* The distal part of the embryological bulbous cordis forms the roots and proximal portions of aortic and pulmonary artery. Duplication occurring at this stage could lead to such an anomaly, although it has never been reported before. We present the first-ever case of duplicated aortic valve, aortic sinus and proximal ascending aorta.

P1132 - LEFT VENTRICULAR OUTFLOW TRACT ANEURYSM FOLLOWING TRAUMA

Ashish Katewa[1], Yogesh Sathe[2], Balaswaroop Sahu[3]
Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiothoracic Surgery, Naya Raipur-India[1]; Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiology, Naya Raipur-India[2]; Sri Sathya Sai Sanjeevani Hospital, Paediatric Cardiac Anaesthesiology, Naya Raipur-India[3]

Background: Congenital or acquired cardiac aneurysms are exceedingly rare in children. Acquired aneurysms may occur due to trauma, ischaemia, infection or iatrogenic injury. We present the rare case of traumatic aneurysm involving left ventricular outflow tract (LVOT).
Materials & Methods: A 6 year-old girl sustained fractures of her left humerus and left hip, and blunt trauma to her left chest after a fall. Her fractures were treated surgically. Six weeks later, transthoracic echocardiography (TTE) performed for diagnostic evaluation of fevers, revealed a pericardial effusion and a cystic mass in the transverse sinus. Subsequent Computerised tomography (CT) showed an aneurysm arising from the LVOT which occupied most of the transverse sinus, compressing the proximal right pulmonary artery, left sided pulmonary veins and the left atrium. The mouth of the aneurysm measured 10*10mm and was located 2mm below the aortic annulus.
Results: Surgical repair was performed through median sternotomy on cardiopulmonary bypass. The Aorta was opened transversely after aortic cross-clamp and cardioplegic arrest. Aortic valve leaflets were retracted to expose the LVOT and locate the aneurysm mouth. The defect was closed with a Darcon patch without disturbing the actual aneurysm. The postoperative TTE revealed a significantly shrunk aneurysm with spontaneous echo contrast. There was no residual communication between the left ventricle (LV) and the aneurysm. The postoperative course was uneventful, requiring mechanical ventilation for 3 hours and hospital stay of 5 days.
Conclusions: Traumatic aneurysms of LV following blunt chest trauma are exceedingly rare at any age and especially so in children. The probable cause is injury to coronary artery branch or contusion of myocardium leading to scarring, thinning of scar tissue and aneurysm formation.

P1135 - ANOMALOUS LEFT CORONARY ARTERY FROM THE PULMONARY ARTERY THE ROLE OF ECHOCARDIOGRAPHY

Xiao-Jing Ma, Yan Gao, Jing Zhang, Xue-Cun Liang, Fang Liu, Bing Jia, Guo-Ying Huang
Children's Hospital of Fudan University, Pediatric Heart Center, Shanghai-China

Objective: Anomalous left coronary artery from the pulmonary artery (ALCAPA) is a rare but potentially life-threatening congenital heart defect, whose detection still remains a challenge. A retrospective analysis was made to elucidate the role of echocardiography in ALCAPA.
Methods: Fifteen consecutive patients, aged from 1 month to 7 years, received the surgery of ALCAPA between August 2012 and October 2016, were included. Echocardiography was carried out in all before surgery, and selective coronary angiography was performed in 7 cases.
Results: (1) In our series, 14 cases were diagnosed as ALCAPA accurately by echocardiography before surgery. Among which, 3 cases was misdiagnosed as dilated cardiomyopathy and 1 case as severe mitral regurgitation by initial echocardiography, all of the 4 cases were corrected as ALCAPA by echocardiography during the follow-up. Another one case was misdiagnosed as coronary artery dilation, which was corrected as ALCAPA by selective coronary angiography. (2) The infant type was found in 13 cases with few collateral vessels manifested as cardiomegaly, left ventricular dysfunction and mitral regurgitation, and the adult type was in 2 cases with abundant collateral vessels remained normal heart size and better cardiac function. (3) After left coronary artery transplantation, 2 cases died within 1 month due to heart failure, and another 13 cases were followed-up for (22.8 ± 15.3) months. The left ventricular ejection fraction increased from (49.4 ± 12.1) % to (64.9 ± 9.1) % ($t = 3.467$, $p = 0.007$). Left ventricular end diastolic diameter decreased to normal range in 9 cases, and the other 4 cases were still enlarged slightly. Functional mitral regurgitation also reduced in degree.
Conclusion: Echocardiography plays an important role during the perioperative period of ALCAPA. The combination of cardiomegaly, left ventricular dysfunction and mitral regurgitation is the diagnostic clue, however, a normal heart size and cardiac function cannot rule out the diagnosis.

P1138 - QUANTITATIVE ASSESSMENT OF LEFT VENTRICULAR ROTATION AND TWIST USING MAGNETIC RESONANCE IMAGING IN PATIENTS WITH REPAIRED TETRALOGY OF FALLOT

Ken-Pen Weng[1], Ming-ting Wu[2], Hsu-Hsia Peng[3]
Kaohsiung Veterans General Hospital, Department of Pediatrics, Kaohsiung-Taiwan[1]; Kaohsiung Veterans General Hospital, Department of Radiology, Kaohsiung-Taiwan[2]; National Tsing Hua University, Department of Biomedical Engineering and Environmental Sciences, Hsinchu-Taiwan[3]

Purpose: Early detection of left ventricle (LV) dysfunction is very important for evaluating clinical outcome in patients with repaired tetralogy of Fallot (TOF). The index of LV ejection fraction (LVEF) may underestimate the degree of deteriorated cardiac function. In patients with repaired TOF, abnormal LV twist by echocardiography has been demonstrated, but there is still no report about LV rotation and twist by magnetic resonance imaging (MRI). We aimed to evaluate LV rotation and twist using MRI in patients with repaired TOF.
Methods: This study consisted of 42 patients with repaired TOF (mean age 22.1 ± 4.8 yrs) and 38 normal subjects (mean age 22.1 ± 1.8 yrs). They all underwent MRI. The volumetric indices, mass, and ejection fraction of both RV and LV were determined. The VØ peak-to-peak (PTP) and the rotation angle, characterizing the twist function of each slice in the LV, were computed. MRI derived parameters were compared between two groups.
Results: Compared to normal controls, patients with repaired TOF had significantly higher RVESVI (62.6 ± 23.0 vs 40.4 ± 9.7 cm3/m2, $p < 0.01$), RVEDVI (120.7 ± 33.2 vs 77.7 ± 11.2 cm3/m2, $p < 0.01$), and RVSVI (56.3 ± 14.3 vs 37.3 ± 7.1 cm3/m2, $p < 0.01$). There was no significant difference between two groups in terms of LVEF (73.2 ± 5.6 vs 70.9 ± 4.5, $p > 0.05$) and RVEF (49.1 ± 6.9 vs 48.1 ± 7.5, $p > 0.05$). Patients with repaired TOF

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

showed a significantly lower VØ PTP (2.7 ± 1.3 vs 5.4 ± 1.6 cm/s, $p < 0.01$) and LV rotation angle (4.9° ± 2.8° vs 8.7° ± 2.4°, $p < 0.01$) than normal controls.
Conclusions: Our results demonstrate that lower LV rotation and twist can provide early information about regional abnormalities of LV before a global ventricular dysfunction in patients with repaired TOF. Assessment of LV rotation and twist using.

P1154 - SEMIAUTOMATIC THREE DIMENSIONAL CT VENTRICULAR VOLUMETRY IN PATIENTS WITH CONGENITAL HEART DISEASE AGREEMENT BETWEEN TWO METHODS WITH DIFFERENT USER INTERACTION

Sang Hyub Park[1], Hyun Woo Goo[2]
Asan Medical Center, Radiology, Seoul-Korea, South[1]; Asan Medical Center, University of Ulsan College of Medicine, Radiology, Seoul-Korea, South[2]

Background: To assess agreement between two semi-automatic, three-dimensional (3D) computed tomography (CT) ventricular volumetry methods with different user interactions in patients with congenital heart disease.
Materials and Methods: In 30 patients with congenital heart disease (median age 8 years, range 5 days–33 years; 20 men), dual-source, multi-section, electrocardiography-synchronized cardiac CT was obtained at the end-systolic (n = 22) and/or end-diastolic (n = 28) phase. Nineteen left ventricle end-systolic (LV ESV), 28 left ventricle end-diastolic (LV EDV), 22 right ventricle end-systolic (RV ESV), and 28 right ventricle end-diastolic volumes (RV EDV) were successfully calculated using two semi-automatic, 3D segmentation methods with different user interactions (high in method 1, low in method 2). The calculated ventricular volumes of the two methods were compared and correlated. A P value <0.05 was considered statistically significant.
Results: LV ESV (35.95 ± 23.49 ml), LV EDV (88.76 ± 61.83 ml), and RV ESV (46.87 ± 47.39 ml) measured by method 2 were slightly but significantly smaller than those measured by method 1 (41.25 ± 26.94 ml, 92.20 ± 62.69 ml, 53.61 ± 50.08 ml for LV ESV, LV EDV, and RV ESV, respectively; $P < 0.02$). In contrast, no statistically significant difference in RV EDV (122.57 ± 88.57 ml in method 1, 123.83 ± 89.89 ml in method 2; $P = 0.36$) was found between the two methods. All ventricular volumes showed very high correlation ($R = 0.978$, 0.993, 0.985, 0.997 for LV ESV, LV EDV, RV ESV, and RV EDV, respectively; $P < 0.001$) between the two methods.
Conclusion: In patients with congenital heart disease, 3D CT ventricular volumetry shows good agreement and high correlation between the two methods, but method 2 tends to slightly underestimate LV ESV, LV EDV, and RV ESV.

P1155 - ATRESIA OF THE BILATERAL PULMONARY VEINS A RARE AND DISMAL ANOMALY IDENTIFIED ON CARDIAC CT

Sang Hyub Park[1], Hyun Woo Goo[2]
Asan Medical Center, Radiology, Seoul-Korea, South[1]; Asan Medical Center, University of Ulsan College of Medicine, Radiology, Seoul-Korea, South[2]

Background: Imaging findings of bilateral pulmonary vein atresia have not been described. To describe cardiac CT findings and clinical outcomes of bilateral pulmonary vein atresia.
Materials and Methods: Three newborns with bilateral pulmonary vein atresia were encountered at our institution during a period of 8 years. We evaluated prenatal echocardiographic findings, clinical presentations, postnatal echocardiographic findings, chest radiographic findings, cardiac CT findings and clinical outcomes.
Results: All newborns presented immediately after birth with severe cyanosis, respiratory distress and acidosis that were unresponsive to medical management. Prenatal and postnatal echocardiographic studies and chest radiography were misleading, inconclusive or nonspecific in making the diagnosis in these children; however cardiac CT clearly demonstrated atresia of the bilateral pulmonary veins with multiple small mediastinal collateral veins and pulmonary edema. Surgical treatments were not feasible for this anomaly. Their clinical outcomes were universally dismal and all infants died within 3 days.
Conclusion: Cardiac CT provides an accurate diagnosis of bilateral pulmonary vein atresia and leads to prompt treatment decision in these children.

P1201-3D PRINTED MODELS FOR SURGICAL PLANNING IN COMPLEX CONGENITAL HEART DEFECTS AN INTERNATIONAL MULTICENTER STUDY

Monasterio,cnr-regione Toscana, Department of Paediatrics,division of Paediatric Cardiology, Pisa-Italy[12]; Bristol Children Hospital, Cardiovascular Surgery, Bristol-United Kingdom[13]; Hospital Reina Sofia, Cardiovascular Surgery, Cordoba-Spain[14]; Hospital Sant Joan De Deu, Department of Paediatrics, Division of Paediatric Cardiology, Barcelona-Spain[15]

Introduction: Three-dimensional printed models (3D-models) provide an unrivalled spatial appreciation of patient-specific cardiovascular structures. However, the impact of this technology on surgical planning in complex congenital heart disease (CHD) is yet to be demonstrated.
Methods: A prospective, observational, case-crossover study involving 10 international centres and 40 patients with complex CHD (median age 3 years, range 1 month- 34 years) was conducted. Magnetic resonance imaging and computed tomography were used to acquire and segment the 3D cardiovascular anatomy. Models were fabricated by fused deposition modelling of polyurethane filament. We sought to evaluate (1) 3D-model dimension accuracy by comparison with medical images, (2) utility of the 3D models by evaluation of subjective satisfaction questionnaire and (3) incremental diagnostic value of 3D-models to plan surgery, comparing decisions made in two scenarios: During routine clinical practice and after inspection of a 3D-model.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: 3D models accurately replicate anatomy with a mean bias of -0.27 ± 0.73 mm. 13 surgeons and 30 paediatric cardiologists completed a satisfaction survey. 96% agree or strongly agree that 3D models provided better understanding of CHD morphology and reduced the chance of complications. 3D models changed the surgical decision in 45% of the cases. Consideration of a 3D-model refined the planned biventricular repair, achieving an improved surgical correction in 20% of cases. In 15% of cases initially considered for conservative management or univentricular palliation, inspection of the 3D-model enabled successful biventricular repair.
Conclusions: 3D models are accurate replicas of the cardiovascular anatomy and improve the understanding of complex CHD. This results in a change in the surgical decision making in 45% of the cases, allowing a better refinement of surgical strategy and surgical correction in cases that would conventionally be considered technically infeasible.

P1214 - IMPROVED ANTENATAL DETECTION AND 30 DAY MORTALITY IN CRITICAL CONGENITAL HEART DISEASE WITH A TWO VENTRICLE OUTCOME A POPULATION BASED STUDY

Kenneth Khor[1], Emma Parry[2], Kirsten Finucane[3], John Beca[4], John Wright[3], Elza Cloete[5], Luke Eckersley[1], Lynn Sadler[2], Tom Gentles[3]
Starship Hospital, Paediatric Cardiac and Congenital Service, Auckland-New Zealand[1]; Auckland City Hospital, National Women, Auckland-New Zealand[2]; Starship Hospital, Green Lane Pediatric and Congenital Cardiac Service, Auckland-New Zealand[3]; Starship Hospital, Paediatric Intensive Care, Auckland-New Zealand[4]; University of Auckland, Liggins Institute, Auckland-New Zealand[5]

Introduction: Isolated reports from selected populations suggest early diagnosis of critical congenital heart disease (cCHD) may result in improved outcome, especially in conditions where the surgical outcome is excellent. However, population-based data are sparse, and their interpretation frequently complicated by the inclusion of complex heart disease and noncardiac comorbidity that may independently influence outcome.
Methods: We undertook a population-based review of cCHD (CHD resulting in operation or death by 30 days) born in New Zealand between 2006 and 2014. Cases were acquired from the National Fetal Cardiology and Cardiac Surgical databases and from the statutory reporting body for perinatal deaths. All diagnoses from 20 weeks gestation and diagnoses made at post-mortem were included. The timing of diagnosis, survival to cardiac surgery and 30-day mortality were reviewed in all livebirths where there was potential for a two-ventricle circulation. Those with a syndrome or additional major noncardiac anomaly were excluded from the analysis as were those born prematurely (<35 weeks gestation).
Results: Of the 436 infants born with cCHD and a potential 2 ventricle circulation, 371 did not have a syndrome or a major non-cardiac abnormality. The rate of antenatal diagnosis increased during the study period ($p = 0.006$) while 30 day mortality declined from 7.0% to 0.9% ($p = 0.049$). Mortality was largely confined to those who died prior to cardiac surgery (Figure). Termination of pregnancy was uncommon and did not vary over the study period.
Conclusions: There has been a significant increase in the rate of antenatal diagnosis, concomitant with a decrease in 30 day mortality in infants with readily treatable cCHD. Earlier recognition of cCHD resulting in appropriate delivery location and a reduced risk of circulatory collapse has very likely contributed to the improved survival.

P1216 - A RARE CASE OF RIGHT VENTRICULAR NON COMPACTION OR AN EARLY PRESENTATION OF ARRHYTHMOGENIC RIGHT VENTRICULAR DYSPLASIA

Giulia Cafiero[1], Ugo Giordano[1], Chiara Mizzon[2], Attilio Turchetta[1], Fiore Salvatore Iorio[2]
Bambino Gesù Children, Department of Pediatric Cardiology and Cardiac Surgery, Sport Medicine Unit, Rome-Italy[1]; Bambino Gesù Children, Department of Pediatric Cardiology and Cardiac Surgery, Rome-Italy[2]

Ventricular non-compaction is a rare type of cardiomyopathy that results from arrest of myocardial development and cases in which the right ventricle is involved are extremely rare. We present the case of a 13-year-old boy observed for the presence of premature ventricular complexes (PVC) detected during the Master step test used for the clearance for competitive sport activity. The boy was a young football player. No symptoms were referred and family history was negative for sudden cardiac death or relevant arrhythmias. The ECG at rest was normal and didn't show major abnormalities in ventricular repolarization. During a maximal exercise test on the treadmill (Bruce protocol) we detected rare presence of PVC (with a morphology of left bundle branch block) only in the recovery period. We performed a 24 hours Holter monitoring that showed sporadic PVC. The echocardiogram showed a non-compaction of the right ventricular which it appeared also slightly hypertrophic predominantly in the apical areas. There was no evidence of other cardiac abnormalities associated. In our case the criteria for diagnosis of ventricular non compaction (end-systolic ratio of the non-compacted to compacted myocardial layer >2) were not reached. The presence of the mild structural alterations of the right ventricle and arrhythmias never described before, could suggest an initial form of arrhythmogenic right ventricular dysplasia (ARVD). The age of the patient is compatible with the appearance of structural abnormalities of the myocardium in the ARVD. A cardiac MRI is scheduled for a better structural definition of the myocardium abnormalities and a close follow-up is mandatory. In any case, the screening for physical activity has been shown extremely useful for an early detection of a possible life-threatening cardiomyopathy.

P1219 - THREE DIMENSIONAL ECHOCARDIOGRAPHY RIGHT VENTRICULAR INDICES ASSESS DISEASE SEVERITY IN PEDIATRIC PULMONARY HYPERTENSION

Pei-Ni Jone, Michal Schäfer, Carlie Bremen, D. Dunbar Ivy
Children, Pediatric Cardiology, Aurora-United States

Background: World Health Organization (WHO) functional class is used to assess pulmonary hypertension (PH) disease severity and identified as a treatment goal that correlates with long term outcomes in PH. Maintaining right ventricular (RV) function is important in the survival of PH patients. Three-dimensional echocardiography (3DE), without geometric assumptions, is more accurate than two-dimensional echocardiography in evaluating RV size and function. We used 3DE RV indices to evaluate pediatric PH patients in different clinical status and assessed disease severity.
Methods: 172 children with PH (mean age 9.4 ±5.6yrs; 51% male; WHO: 1-4) underwent 3DE evaluation of the RV from 2014-2016. Offline analysis on the TomTec 4D RV-Function 2 generated RV indices: 3D end-diastolic volume (EDV), 3D end-systolic volume (ESV), 3D ejection fraction (EF), RV septal and free wall longitudinal strain (LS), tricuspid annular plane systolic excursion (TAPSE), and fractional area change (FAC). Kruskal-Wallis and ANOVA were used to evaluate WHO intergroup variabilities in RV indices. Receiver Operating Characteristics (ROC) analyses were performed to identify the best cut-offs in predicting disease severity between WHO I + II and WHO III + IV.
Results: Patients were classified based on their WHO functional class (I = 78, II = 64, III = 20, IV = 10). Significant differences were found in RV EDV, ESV, EF, and free wall LS between WHO 1-4 classes (all $p < 0.0001$). 3D RV EF is the most sensitive parameter to detect worse WHO functional class. Table 1 demonstrates the ROC analyses.
Conclusions: 3D RV volumes, EF, free wall strain, and FAC correlate with disease severity as assessed by WHO functional class. Future studies should evaluate RV functional indices as echocardiographic targets to achieve treatment goals in pediatric PH patients.

Table 1. Right Heart Indices from ROC Analyses

	AUC	Sensitivity	Specificity	Cut-off
EDV (ml)	0.76	61.3	82.9	137
ESV (ml)	0.78	77.4	66.5	52
EF (%)	0.79	90	65.5	43.7
Septal LS (%)	0.65	35.4	93.5	-8.0
Free wall LS (%)	0.72	54.8	91.7	-12.4
TAPSE (mm)	0.52	24.3	91.3	17.9
FAC (%)	0.78	87.1	68.8	34.1

P1239 - THREE DIMENSIONAL ECHOCARDIOGRAPHIC GUIDANCE OF RIGHT HEART CATHETERIZATION DECREASES RADIATION EXPOSURE IN ATRIAL SEPTAL DEFECT CLOSURES

Pei-ni Jone, Neil Wilson, Gareth Morgan, D. Dunbar Ivy, Michael Ross
Children, Pediatric Cardiology, Aurora-United States

Background: Radiation dose reduction is desirable in children undergoing cardiac catheterizations. Three-dimensional echocardiography (3DE) provides wide field of view and depth of cardiac structures that cannot be seen in two-dimensional echocardiography. 3DE is used in atrial septal defect (ASD) closure and other interventions. The utility of 3DE in guiding right heart catheterization (RHC) without fluoroscopy for ASD closures has not been demonstrated. We used 3DE guidance of RHC for closure of ASDs and evaluated the radiation reduction compared to historical controls.
Methods: 3DE guidance of RHC and ASD closure was performed in children who were of adequate size to fit the 3D transesophageal probe. Live 3D, in the mid-esophageal view at 90°, was used to guide the catheter from inferior vena cava to the superior vena cava. Using 3D Zoom, the ASD was seen from the right atrial (RA) view and the catheter crossed into the left atrium. Using live 3D at the mid-esophageal view at the 0° and rotation of the 3D probe to a left pulmonary vein, the catheter was guided into the left pulmonary vein. Lastly, using live 3D at the mid-esophageal view at 60° with increased maximal lateral width, the RA, right ventricle (RV), and pulmonary arteries were visualized. The catheter was guided from the RA to the RV, then into the main pulmonary artery. ASD closure was performed with 3DE guidance. Fluoroscopy was used sparingly for device advancement and delivery. Fluoroscopy time and radiation was compared to controls in 2015.

Table 1. Patient demographics, fluoroscopy time, and radiation dose.

Patients	Age (yrs)	Weight (kg)	Height (cm)	BSA	Fluoroscopy (min)	Radiation (mGy)	Device
1	5	21.6	117.3	0.84	3.2	3.22	20 mm GSO
2	7	17.8	115	0.75	3.6	2.5	25 mm GSO
3	11	35.2	136.2	1.15	13.2	8.9	20 mm GSO
4	17	55.8	165.3	1.61	3.5	4	25 mm GSO
5	16	70.9	164	1.77	5	9	25 mm GSO
6	16	67.8	169.2	1.78	1.7	3.5	24 mm GSO
7	6	22	116.4	0.84	4.3	2	25 mm GSO

GSO = Gore Septal Occluder

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: 7 patients underwent 3DE guidance of RHC and ASD closures in 2016 (Table 1). There was 67% reduction in fluoroscopy time and 87% radiation reduction demonstrated in 3DE guidance of ASD patients compared to controls (Table 2).
Conclusions: 3DE guidance of RHC and ASD closures resulted in significant reduction in radiation use in children.

Table 2. Fluoroscopy and radiation reduction between controls and 3DE guidance.

	Mean Fluoroscopy (Min)	Mean Radiation (mGy)
2DE ASD controls in 2015	14.5	35.4
3DE Guidance ASD Closures in 2016	4.9	4.7
% Reduction	67%	87%

P1243 - IMPAIRED ELASTIC PROPERTY OF ASCENDING AORTA IN FUNCTIONAL SINGLE VENTRICLE BEFORE FONTAN OPERATION

Tomotaka Murakami, Yoshiki Mori, Nao Inoue, Sachie Kaneko, Yasumi Nakashima
Seirei Hamamatsu General Hospital, Pediatric Cardiology, Hamamatsu-Japan

Background: Aortic dilatation and impaired elastic properties has been reported as aortopathy in patients after Fontan operation. However, it is little known whether these abnormalities are primary or secondary present. Objectives: We hypothesized that aortic wall abnormalities were primary present in functional single ventricle (SV) before Fontan operation, as well as bicuspid aorta and coarctation of aorta.
Methods: We measured the diameter of aorta at 2 different levels (Ascending aorta [As -AO] and descending aorta [d-AO] by 2D echocardiography. Aortic stiffness index, distensibilty were calculated using these diameters and simultaneously measured right arm blood pressure. Seven neonates with functional SV with pulmonary stenosis or atresia (SV group: media age, 1 day) were compared with 7 normal neonates (Control group: median age, 0 day).
Results: Ascending aortic diameter was greater in patients than that in control (Z sore, SV: 1.3 ± 1.1 vs. Control: -0.1 ± 0.6, $p = 0.04$), but descending aortic diameter was similar between groups. Distensibility of As-AO was reduced (SV: 6.4 ± 2.3 mmHg-110-3 vs. Control: 12.1 ± 4.3 mmHg-110-3, $p = 0.009$) and stiffness index of As-Ao was higher in SV group compared to control group (SV: 5.9 ± 1.1 vs. Control 3.0 ± 1.0, $p = 0.01$). Elastic properties of the d-AO were similar between the groups.
Conclusions: Elastic properties are impaired in neonates who have functional SV with dilated ascending aorta. These abnormalities may be primary present before Fontan operation.

P1260 - BIVENTRICULAR FUNCTIONAL PATTERN IN FETUSES WITH CONGENITAL AORTIC COARCTATION

Iris Soveral[1], Laura Guirado[1], Narcis Masoller[1], Mar Bennasar[1], Edda Marimón[1], Juan Carretero[2], Laia Brunet[2], Fatima Crispi[1], Juan Sanchez De Toledo[2], José Maria Martínez Crespo[1], Olga Gómez[1]
Hospital Clínic and Hospital Sant Joan De Déu, Fetal I + d Fetal Medicine Research Center, Bcnatal - Barcelona Center For Maternal-Fetal and Neonatal Medicine, Barcelona-Spain[1]; Hospital Sant Joan De Déu, Pediatric Cardiology, Barcelona-Spain[2]

Background: Neonates and adults with congenital aortic coarctation (CAC) have been shown to present persistent ventricular dysfunction. In fetal life, CAC induces significant right ventricular dominance, however associated biventricular functional pattern has not been fully described.
Methods: A comprehensive echocardiography was performed at third trimester of pregnancy in 21 fetuses with suspected CAC (2011-2016) in which diagnosis was postnatally confirmed. Two gestational-age-matched controls were selected for each case. Gestational age (GA), estimated fetal weight (EFW) and standard morphometric and Doppler parameters were obtained. Biventricular systolic and diastolic function was assessed by M-mode, pulse-wave and tissue Doppler imaging (TDI) techniques, including: stroke volume (SV), cardiac output (CO), peak ventricular filling velocities and ratio (E/A ratio), mitral and tricuspid annular displacement (MAPSE and TAPSE) and peak annular velocities (S',E',A' and E/E' ratio).
Results: GA and EFW at echocardiography were similar between groups (31.2 vs. 32.2, $p = 0.341$). Fetuses with CAC showed a higher tricuspid to mitral ratio (1.5 vs. 1.03, $p = 0.001$) with significant tricuspid regurgitation and reverse flow at the aortic isthmus in 27% and 25% of cases, respectively. While left function was mainly preserved, the right ventricle showed both diastolic and systolic dysfunction with significantly decreased E/A (0.69 vs. 0.77, $p = 0.028$)) and E/E' ratios (5.1 vs. 5.9, $p = 0.042$), increased E' (9.21 vs. 7.69, $p = 0.006$) and S' (8.02 vs. 7.37, $p = 0.037$) and increased stroke volume (5.37 vs. 3.27, $p = 0.003$) and cardiac output (421 vs. 226, $p < 0.001$) compared to controls. Surgery was performed, on average, at the 7th day of life, with no major complications. Results are summarized in table 1.
Conclusions: In the third trimester of pregnancy, right ventricular dominance in fetuses with CAC is associated with increased right cardiac output, higher longitudinal systolic function and abnormal diastolic function in the right ventricle. Despite a lower stroke volume, left ventricular functional parameters remain relatively preserved.

Table 1.

P1264 - IMPROVEMENT OF HYPERECHOGENIC MYOCARDIUM AFTER PRENATAL TREATMENT WITH DEXAMETHASONE IN FETUS EXPOSED TO MATERNAL ANTI SSA RO AND ANTI SSB LA ANTIBODIES

Krista Young[1], Chris Sullivan[2], Kathryn Reed[3], Joshua Copel[4], Jill Buyon[5], Julie Natonabah[6], Brent Barber[6]
University of Arizona School Of Medicine, Department of Pediatrics, Tucson-United States[1]; Genesis Maternal Fetal Medicine, Tucson-United States[2]; University of Arizona School of Medicine, Department of Obstetrics and Gynecology, Tucson-United States[3]; Yale School of Medicine, Department of Obstetrics and Gynecology, New Haven-United States[4]; New York University School of Medicine, Department of Medicine, Division of Rheumatology, New York-United States[5]; University of Arizona School of Medicine, Department of Pediatrics, Division of Pediatric Cardiology, Tucson-United States[6]

Introduction: Immune-mediated cardiac disease (IMCD) occurs when maternal anti-SSA/Ro and anti-SSB/La antibodies transplacentally damage a developing fetal heart. IMCD is characterized by congenital heart block (CHB), valve disease, cardiomyopathy, and endocardial fibroelastosis (EFE). The mortality of immune-mediated CHB is approximately 20%. Appropriate treatment to prevent IMCD has not been standardized.
Case Presentation: A 26-year-old G1P0 at 24 weeks estimated gestational age (EGA), with no symptoms consistent with systemic lupus erythematosus or Sjogren's Syndrome, had a screening fetal ultrasound notable for markedly hyperechogenic myocardium. Subsequent labs demonstrated elevated titers of anti-SSA/Ro (>8), anti-SSB/La (5.4), and ANA (1:2560). Fetal heart rate was normal (152) with a normal mechanical A-V (PR) interval (106-118 ms). Hyperechogenic foci were noted throughout the heart (bilateral ventricular myocardium, papillary muscles, atrioventricular valves, and atria) raising concern for developing EFE. Cardiac anatomy and systolic function were normal.
Management and Outcome: Given the concern for developing progressive cardiac disease with the presumption that the echogenicity represented injury mediated by autoantibodies, maternal treatment with oral dexamethasone was initiated at 4 mg daily. At 33 weeks EGA, a follow-up fetal echocardiogram revealed decreased myocardial involvement with continued normal ventricular function and A-V intervals. Dexamethasone was weaned to 1 mg daily until successful, term delivery of a baby boy (3.4 kg) with no evidence of rash or distress. Newborn electrocardiogram revealed normal sinus rhythm (rate 101) with normal PR interval (118 ms). Follow-up echocardiograms (last at 11 months of age) showed mild persistent hyperechogenicity of the atrioventricular valves, papillary muscles, and chordae but otherwise, normal valve and ventricular function. Following delivery, both mother and baby underwent successful steroid wean.
Conclusion: Studies of medications to prevent or treat IMCD have included corticosteroids, intravenous immunoglobulin, and hydroxychloroquine. This report describes a case using dexamethasone with favorable outcomes.

P1285 - SPECKLE TRACKING ECHOCARDIOGRAPHY TO PREDICT COARCTATION OF THE AORTA IN NEONATES WITH PATENT DUCTUS ARTERIOSUS

Pierre-Emmanuel Séguéla[1], Julie Thomas[1], Zakaria Jalal[1], Xavier Iriart[1], François Roubertie[2], Jean-Baptiste Mouton[3], Jean-Benoit Thambo[3]
Bordeaux University Hospital, Pediatric Cardiology Unit, Bordeaux-France[1]; Bordeaux University Hospital, Cardiac Surgery Unit, Bordeaux-France[2]; Bordeaux University Hospital, Pediatric Cardiac Unit, Bordeaux-France[3]

Background: Coarctation of the aorta (CoA) is challenging to diagnose either in fetuses or in neonates with patent ductus arteriosus (PDA). Speckle tracking echocardiography (STE) allows reliable analysis of myocardial deformation in newborns and seems to provide important insides into regional changes in patients with left ventricular (LV) outflow tract obstruction. The aim of the study was to assess the interest of STE for predicting CoA in neonates with PDA.
Material and Methods: Prospective single-center study in a pediatric cardiac intensive care unit. 28 newborns with either prenatal (n = 12) or postnatal (n = 16) suspicion of CoA and PDA were included. All newborns were evaluated by conventional echocardiography and LV STE. To assess the reproducibility of STE, 14 healthy full-term newborns with PDA were screened. CoA was diagnosed when PDA closed, according to usual echocardiographic criteria.
Results: 11 neonates developed a CoA after PDA closure. Mean gestational age and birth weight were 39.1 ± 1.8 weeks and 3.3 ± 0.62 kg (versus 39.1 ± 1.1 weeks and 2.9 ± 0.60 kg for newborns without CoA, $p = 0.407$ and $p = 0.063$ respectively). STE measurements were possible in 97% of longitudinal strain and 100% of radial strain and circumferential strain. Intra- and inter-observer variability of longitudinal, radial and circumferential strain was good. Longitudinal strain and radial strain were significantly lower in neonates with CoA (-13.98% versus -17.80%, $p = 0.031$, and 19.50% versus 38.35%, $p < 0.0001$, respectively). Circumferential strain was not modified. To predict CoA, a longitudinal strain value of -16.17% provided a sensitivity of 70% for a specificity of 80%. A radial strain value of 28.1% provided a sensitivity of 80% for a specificity of 80%.
Conclusion: LV STE is feasible in newborns with PDA and seems to be efficient for predicting the risk of CoA. Further studies are needed to confirm these results.

P1292 - IMPROVING THE RESPONSE TIME QUALITY AND SAFETY OF STAT X RAYS IN THE CONGENITAL CARDIAC INTENSIVE CARE UNIT

Gary D Goulin, Kathryn S Larkin, Maureen P Davis, Shreya S Sheth
Cedars-Sinai Medical Center, Pediatrics, Los Angeles-United States

Background: Arrival of the postoperative congenital heart patient to the congenital cardiac intensive care unit (CCICU) is a critical time in the patient's course. Chest x-rays (CXRs) are effective in quickly identifying issues leading to adverse outcomes. -Our primary goal was to reduce the time to completion of a STAT CXR from a standard of 60 minutes to 15 minutes. -Our secondary goal was to improve the safety and quality of CXRs by ensuring that a nurse was assisting patient positioning and ensuring the gonad shield was used.
Method: -Baseline data was collected for time to stat CXR and quality and safety metrics. -A process for a "super STAT" CXR was developed. Completion time of less than 30 minutes was the initial benchmark. -Bedside nurses and imaging technologists were educated. -Initial data was collected over 4 months. Follow-up data was obtained 6 and 12 months later.
Results: During the initial study period, the average response time to "super STAT" CXR was 18 minutes (range 36-67 minutes) -Follow up data showed the improvement in response time to 12 minutes (range 9-35 minutes) Patient safety metrics improved. -No repeat CXRs were required in the study period, reducing patient radiation exposure. -Gonad shielding was used 100% of the time. -Improvement was sustained during the follow-up period Quality metrics also improved. -Improvement was sustained during the follow-up period.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: Development of a "super STAT" CxR process leads to a more rapid CXR completion time with fewer significant delays. Increased teamwork and collaboration between nursing and imaging technicians led to improved safety. -Gonad shielding was consistently used and documented. -Radiation exposure was reduced as no CXRs needed retaking. Increased teamwork and collaboration between nursing and imaging technicians led to improved quality. -Patient positioning was more appropriate. -Lines and tubes were moved away from the chest. These results were sustained at 12 months.

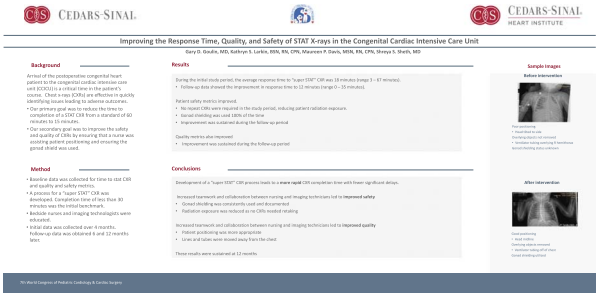

Figure 1.

P1299 - ANALYSIS OF CARDIAC MICROSTRUCTURE AND MYOCYTE AGRREGATES ORGANIZATION IN FETAL HEARTS WITH CONGENITAL HEART DISEASE BY X RAY PHASE CONTRAST SYNCHROTRON IMAGING

Patricia Garcia-Canadilla[1], Chong Zhang[1], Arjan J Geers[1], Catalina Tobon-Gomez[1], Vedrana Balicevic[2], Andrew C Cook[3], Bart Bijnens[1]
Universitat Pompeu Fabra, DTIC, Barcelona-Spain[1]; University of Zagreb, Faculty of Electrical Engineering and Computing,Zagreb-Croatia[2]; University College London, Institute of Cardiovascular Science, London-United Kingdom[3]

Background: Understanding the complexity of heart morphogenesis and the associated functional consequences of congenital heart disease (CHD) is essential for providing appropriate treatment strategies. Since our knowledge on the microstructure of the whole structurally abnormal heart in fetal & paediatric CHD is limited, novel imaging approaches offered by synchrotron facilities can provide structural detail currently not available otherwise. Our aim is to visualize and quantify cardiac ultrastructure in hearts with altered fetal development using X-ray phase-contrast synchrotron radiation-based micro-CT.
Methods: Two fetal hearts, one normal and one with Tetralogy of Fallot (ToF) of 15 weeks of gestation were selected from the UCL Cardiac Archive. While the specimens were kept in formalin, they were settled in water as supporting medium for acquisition. X-ray phase-contrast synchrotron radiation-based micro-CT was performed at 3.6μm resolution in the Diamond Light Source, I13-2 beamline facilities. Several acquisitions were necessary to cover the whole heart along its long axis. The series were reconstructed using state-of-the-art filtered back projection.
Results: Detailed visualization of different cardiac structures such as aortic and pulmonary valves, papillary muscles, tendinous cords of the mitral valve were obtained. The ventricular septal defect as well as the overriding aorta were clearly visible in the ToF fetal heart. In the normal heart, there is a transition in angle of myocyte aggregates from epicardium to endocardium with circumferential layers within both the LV and RV. In the case with ToF, a deep trabecular layer of the LV appears more compacted but also more heterogeneous.
Conclusions: We managed for the first time to acquire μ-resolution microstructural datasets of whole human fetal hearts, illustrating normality as well as congenital malformations, resolving myofibre detail and providing information on cardiac microstructure without the need of slicing and sample processing.

P1320 - CHANGES IN OVERALL VENTRICULAR MYOCARDIAL ARCHITECTURE IN THE SETTING OF A PORCINE ANIMAL MODEL OF RIGHT VENTRICULAR DILATION

Peter Agger[1], Christoffer Laustsen[2], Christine Ilkjær[3], Morten Smerup[4], Jesper R. Frandsen[5], Steffen Ringgaard[2], Michael Pedersen[6], John B. Partidge[7], Robert H. Anderson[8], Vibeke Hjortdal[3]
Aarhus University Hospital, Dept. of Pediatrics, Aarhus-Denmark[1]; Aarhus University Hospital, Mr Research Center, Aarhus-Denmark[2]; Aarhus University Hospital, Dept. of Cardiothoracic And Vascular Surgery, Aarhus-Denmark[3]; Rigshospitalet, Dept. of Cardiothoracic Surgery, Copenhagen-Denmark[4]; Aarhus University Hospital, Center For Functionally Integrative Neuroscience, Aarhus-Denmark[5]; Aarhus University Hospital, Comparative Medicine Lab, Aarhus-Denmark[6]; Rural Clinical School of The Anu College of Medicine, Biology & Environment, Eurobodalla Unit, Batemans Bay, New South Wales-Australia[7]; Newcastle University, Institute Genetic Medicine, Newcastle-Upon-Tyne-United Kingdom[8]

Background: Chronic pulmonary insufficiency often leads to myocardial dysfunction and heart failure. It is not fully known why secondary hypertrophy cannot fully protect against the increase in wall stress brought about by the increased end-diastolic volume in ventricular dilation. It has been assumed that mural architecture is not deranged in this situation, but we hypothesised that there might be a change in the pattern of orientation of the chains of cardiomyocytes, which would contribute to contractile impairment.
Methods: We created pulmonary valvar insufficiency by transvascular suturing of its leaflets in seven piglets, performing sham operations in seven control animals. Using cardiac magnetic resonance imaging after 12 weeks of recovery, we demostrated significantly increased right ventricular volumes in the test group. After sacrifice, diffusion tensor imaging of their hearts permitted measurement of the orientation of the long chains of aggregated cardiomyocytes.
Results: The helical angles in the right ventricle approached a more circumferential orientation in setting of right ventricular dilation ($p = 0.007$), with an increased proportion of surface-parallel chains. In contrast, this proportion decreased in the left ventricle. Also in the left ventricle a higher proportion of E3 angles with a value around zero was found, and conversely a lower proportion of angles was found with a numerical higher value. In the dilated right ventricle the proportion of E3 angles around -90 degrees is increased, while the proportion around 90 degrees is decreased.
Conclusion: Contrary to traditional views, there is a change in the orientation of both the left and the right ventricular cardiomyocytes subsequent to right ventricular dilation. This will change their direction of contraction and hinder the achievement of normalization of cardiomyocytic strain, affecting overall contractility. We suggest that the aetiology of the cardiac failure induced by right ventricular dilation may be partly explained by morphological changes in the myocardium itself.

P1322 - POST MORTEM MICRO CT SCANNING OF FETAL HEART

Claudio M Lombardi[1], Giovanni Botta[2], Zambelli Vanessa[3], Fesslova Vlasta[4]
Studio Diagnostico Eco Vimercate, Dpt. Radiology, Milano-Italy[1]; Oirm Sant, Dpt.asnatomia Patologica, Torino-Italy[2]; University of Milan

Bicocca, School Of Medicine And Surgery, Milano-Italy[3]; Policlinico San Donato IRCCS, Center Fetal Cardiology, Milano-Italy[4]

Congenital heart defects (CHD) represent the most common malformation with approximately 20% of stillbirths and 30% of neonatal deaths due to congenital defects. Fetal cardiac autopsies are crucial in counseling parents after the fetal /child death. Nowadays, the diagnosis of CHD is often anticipated to the first trimester of pregnancy, however the feasibility of routine autopsy in small fetuses is only in about 30% of cases. Conventional MRI or high-field micro-MRI offer only a low resolution in small fetuses and their use in clinical setting is limited by cost, time and space constraints. Therefore, micro CT scan was explored. Micro CT is X-ray imaging in 3D as in hospital CT scans on a smaller scale with massively increased resolution.
Methods: Iodine contrast micro-CT scans were used to examine 22 fetal/neonatal hearts. Images were obtained from routinely fixed 7 whole human fetuses (0.1-90 g, 7-17 w.g.), 14 isolated fetal hearts (0.1-20 g, 11-27 w.g.) and 1 isolated neonatal heart. Samples were scanned using an isotropic resolution of 18 μm and reconstructions were interpreted jointly by four fetal pathologists, fetal cardiologist and radiologist. Cases with gestational ages ≥ 13 w.g. underwent also conventional autopsy with histological sample. Post-mortem assessments were compared to echographic diagnosis.
Results: Micro-CT identified all anatomical structures and abnormalities documented by prenatal echography. In 7 whole fetuses micro-CT excluded structural anomalies. In 14/22 cases it provided all informations obtained with invasive autopsy and in 7 of them it furnished additional diagnostic details. In the neonatal case (object of litigation for a missed diagnosis of CHD) it was useful for discussion among courtroom experts.
Conclusions: Micro-CT study is useful for refining or modifying prenatal echographic diagnosis in small fetuses or neonates. It was also found useful in case of diagnostic controversies.

P1333 - VITAMIN D DEFICIENCY RICKETS AND CARDIOVASCULAR FEATURES IN EARLY CHILDHOOD

Sumitra Venkatesh[1], Shakuntala Prabhu[1], Wasim Kazi[2], Snehal Kulkarni[3]
B.J.Wadia Hospital For Children, Div. of Pediatric Cardiology, Dept. of Pediatrics, Mumbai-India[1]; B.J.Wadia Hospital For Children, Dept. of Pediatrics, Mumbai-India[2]; B.J.Wadia Hospital For Children& Kokila Ben Dhirubhai Ambani Hospital, Div. of Pediatric Cardiology, Mumbai-India[3]

Introduction: -Vitamin D deficiency and hypocalcemia is one of the treatable cardiomyopathy causing cardiac failure in children. This study aimed to correlate vitamin D deficiency with the cardiovascular status in children under 3 years of age.
Methods: -Fifty newly diagnosed cases of vitamin D deficiency rickets under 3 years with atleast 2 clinical signs of rickets and Vitamin D levels (<20 ng/ml) were studied for their cardiovascular status. Children with Congenital heart disease and acquired heart diseases were excluded. Serum calcium/phosphorous/alkaline phosphatase levels, 25 (OH) Vitamin D levels, ECG and 2D Echocardiography were done in all. All the ECG and ECHO parameters were compared with age related norms and body surface area (z score).
Results: - Mean age of children was 11 months with 24/50 (48%) between 3-6 months. The male to female ratio was 1.9:1. 20/50 (40%) were exclusively breastfed, 8(16%) formula fed, 15(30%) were on milk based diet and 7(14%) were on normal diet. 36/50 (72%) had low total serum calcium levels. Prolonged QTc interval (12%) and left axis deviation were the common ECG abnormality noted. 2 D Echocardiogram showed 11(22%) had LVH, 10 (20%) had LV systolic dysfunction, 9 (18%) had LV dilation, 8 (16%) had diastolic dysfunction,7 (14%) had MPI >0.38, and 4 (8%) presented with dilated cardiomyopathy. Abnormal z scores were noted with Vitamin D deficient patients with a statistically significant negative correlation between LVIDd and total calcium levels. Spearman's rank correlation coefficient between vitamin D levels and various LV dimensions was statistically insignificant.
Conclusion: -Left ventricular dysfunction with dilatation and hypertrophy are noted in children with vitamin D deficiency though they are asymptomatic . Hence Cardiac screening should be a standard of care in all children with vitamin D deficiency as the cardiac dysfunction is reversible on supplementation.

P1335 - CARDIOVASCULAR MANIFESTATIONS OF CHILDHOOD ONSET HYPOTHYRIODISM

Introduction: Thyroid hormones exert a direct cellular effect on almost all the tissues of the body including heart. Limited studies are available in the country to assess the various cardiovascular parameters in hypothyroid children and the impact of treatment on these parameters.This study is aimed at studying the cardiac dysfunction in hypothyroidism by electocardiography (ECG) and echocardiography (2DECHO).
Methods: 32 newly diagnosed hypothyroid pediatric patients were studied over a period of 18 months. They were clinically evaluated and underwent relevant investigations, including thyroid profile estimation, cardiac evaluation using E.C.G. and 2D – Echocardiography /colour Doppler.29 patients were reviewed after 3 months of treatment. A p-value of <0.05 was considered statistically significant.
Results: 18/32 (56.3%) were above 10 years with female preponderance (68.8%). Mean value of TSH and Free T4 were 205.58 ± 267.33 μIU/ml and 0.67 ± 0.37 ng/dl respectively. Symptoms and signs were common with TSH (thyroid stimulating hormone) above 50μgm/ml and was statistically significant. Dyslipidemia was found in 22 (68.75%) cases. The most common ECG abnormality observed was prolonged PR interval in 14 (43.8%)cases. The most common echocardiographic finding was septal hypertrophy, seen in 16(50%) cases, followed by left ventricular posterior wall hypertrophy (LVPW) (43.8%), LV dilatation (25%), pericardial effusion (25%) and cardiac dysfunction in 4 cases. On 3 months follow up of 29 subjects, significant improvement of all the deranged parameters were noted with achievement of euthyroidism.
Conclusion: Children with hypothyroidism have significant cardiovascular abnormalities which are proportionally related to TSH level and these changes are completely reversible with treatment. Hence, early diagnosis with optimal treatment reduces the cardiac morbidity in these children.

P1337 - PULMONARY HYPERTENSION IN CHILDREN WITH CONGENITAL HEART DIEASE

Shakuntala Prabhu[1], Sumitra Venkatesh[1], Shashi Yadav[2], Snehal Kulkarni[3]
B.J.Wadia Hospital For Children, Div. of Pediatric Cardiology, Dept. of Pediatrics, Mumbai-India[1]; B.J.Wadia Hospital for Children, Div. of Pediatric Cardiology & Dept. of Pediatrics, Mumbai-India[2]; B.J.Wadia

Hospital For Children & Kokilaben Dhirubhai Ambani Hospital, Div. of Pediatric Cardiology, Mumbai-India[3]

Aim: To note clinical profile of children with congenital heart disease (CHD) with an increased pulmonary blood flow and correlate the grade of Panama functional class (2011) with Echocardiographic data.
Method: 50 children with CHD with an increased pulmonary blood flow based on 2 D Echocardiogram were compared with 50 age and sex matched controls . Demographic data, clinical profile, chest x-ray , echocardiographic data, treatment and severity of Pulmonary hypertension (PAH) as per Panama class was noted .
Results: 40/50 (80%) presented in their first year of life. The most common presenting symptom was dysponea (80%). Tachycardia and tachypnoea were statistically significant in the study group than the controls (p value <0.01). Stunting, wasting and underweight on WHO growth charts was significant (p value for both underweight and wasting <0.01 and for stunting 0.025). 81.5% of children had thrill with PAH and significant association was also noted with palpable P2 and PAH . 25/50 (50%) belonged to class 3 B of Panama functional class and all Class 3B cases had severe degree of malnutrition. The severity of PAH in class 3B, class 3 A and 2 are 52.6%, 42.1% and 5.3% respectively. On comparing degree of PAH on Echocardiogram with Panama class no statistically significant correlation found (p value 0.741). Children with PAH had statistically significant IVS , RV free wall thickness and RV FAC grade as compared to controls.Surgery was advised in all cases of PAH and this was statistically significant (p value 0.01).
Conclusion: Children with CHD and an increased Pulmonary blood flow present with PAH early and are usually of grade 2 severity at presentation. However no linear association was noted between severity on clinical classification and degree of PAH on Echocardiography.

P1355 - FETAL HYPERTROPHIC CARDIOMYOPATHY AS AN EARLY MARKER OF MATERNAL HYPERGLYCEMIA

Carolina Rossi Palmiere[1], *Mona Adalgisa Simões*[2], *Julia Simões Pabis*[3], *Anelise Darabas Dos Santos*[3], *Bruna Ferreira*[3], *Jean Carl Silva*[3], *Mariana Ribeiro E Silva*[3]
Univlle, Medicine, Joinville-Brazil[1]*; Maternidade Darcy Vargas, Neonatal Service, Joinville-Brazil*[2]*; Univille, Medicine, Joinville-Brazil*[3]

Background: Gestational diabetes mellitus (GDM) cause maternal hyperglycemia, which may lead to fetal hypertrophic cardiomyopathy (HCM), and cardiac diastolic function impairment. The aim of the present study was to assess the prevalence of HCM in fetuses of pregnant women with GDM before their treatment using fetal echocardiography.
Material and Methods: This cross-sectional study included 63 fetuses of mothers with GDM and was conducted before initiating treatment. It was conducted in a public maternity clinic at southern Brazil. according to the local regulations for good clinical practices, specifically those of the National Resolution of the National Health Council (CNS, 466/12), after approval from the Research Ethics Committee (CEP011/12) of the institution. It included singleton fetuses of pregnant women diagnosed with GDM, without malformations and other diseases. GDM diagnosis was based on the criteria provided by the American Diabetes Association and an ultrasound was performed between the 24th and 28th gestational weeks. All variables were descriptively analyzed, with quantitative variables expressed as means and standard deviations. Data were statistically analyzed using the Statistical Package for the Social Sciences software, version 21.0.
Results: HCM was confirmed in 54% of the fetuses. Fetal abdominal circumference (FAC) was normal in 73.01% fetuses. HCM was also observed in 50% of fetuses with normal FAC, which reflects the occurrence of interventricular septum alterations prior to FAC alterations.
Conclusions: The result suggests that the HCM reflects the maternal hyperglycemia before FAC alterations. Therefore, the high prevalence and early occurrence of HCM in this population suggest that this is one of the first effects of maternal diabetes on fetuses.

P1356 - CARDIAC FUNCTION OF NEWBORN BABIES OF PREGNANT PATIENTS WITH GESTACIONAL DIABETES MELLITUS

Ana Beatriz Bonchoski[1], *Julia Simões Pabis*[1], *Dercília Cordeiro Dos Santos*[1], *Tainá Juriti Feijó Pinto*[1], *Mona Adalgisa Simões*[2], *Francisco Cesar Pabis*[1]
Univille, Medicine, Joinville-Brazil[1]*; Maternidade Darcy Vargas, Neonatal Service, Joinville-Brazil*[2]

Background: Gestacional diabetes mellitus (GDM) promotes structural and functional abnormalities in the newborn heart. In this context our goal is to evaluate the cardiac function of newborn babies of pregnant patients with GDM by means of Doppler echocardiography data.
Materials and Methods: Were analysed 48 echocardiography exams from newborns's GMD mothers with good clinical control durant pregnancy and who performed routine echocardiographic evaluation during the neonatal period. In these babies the cardiac variables analyzed were: ventricular septum thickness and posterior wall of the left ventricle by M mode, global cardiac funtion by myocardial performance índex (MPI, also known as Tei índex), diastolic function by reason E/A of both mitral and tricuspid valve and sistolic function by the shortening fraction measurement of left ventricle. It was conducted in a private maternity clinic at southern Brazil according to the local regulations for good clinical practices, specifically those of the National Resolution of the National Health Council (CNS, 466/12), after approval from the Research Ethics Committee (CEP 1.572.265) of the institution.
Results: The newborns presented in average 18 ± 12 days old and the incidence of myocardial hypertrophy was 6%. About the echocardiography variables of heart, the shortening fraction was abnormal in 7% and diastolic function of left and right ventricle was irregular with 47% e 30%, respectively. TEI índex was abnormal in 51% of the right ventricle and 57% of the left ventricle.
Conclusions: The newborn's GMD mothers with good clinical control presented low índex of hypertrofic cardiomyopathy at birth and even in the absence of cardiomyopathy the cardiac function has been abnormal in some parameters.

P1374 - REFERRAL PATTERN AND SPECTRUM OF CONGENITAL HEART DISEASES DIAGNOSED AT FETAL ECHOCARDIOGRAPHY IN EASTERN INDIA

Dhritabrata Das[1], *Kanchan Mukherjee*[2]
Fetal Care, Fetal Cardiology, Kolkata-India[1]*; Fetal Care, Fetal Medicine, Kolkata-India*[2]

Background and Aims: Fetal echocardiography is a potential but inadequately utilised tool to detect and prevent major congenital heart diseases (CHD). Our study was designed to find out the referral pattern and spectrum of CHD diagnosed during fetal echocardiography in Eastern part of India.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: A retrospective analysis of all fetal echocardiography performed over two years period (August 2014 to July 2016) in our centres of Kolkata was done. The primary indications for referral for fetal echocardiography were obtained from the obstetric referral prescriptions. Patient details and outcome data were collected from fetal echocardiography report. Fetal echocardiography was performed jointly by same pediatric cardiologist and fetal medicine specialist (author and coauthor).
Results: Total 772 fetal echocardiography reports performed during the study period were reviewed. Gestational age varied from 17 weeks to 37 weeks (Median 22 weeks). 54 women had abnormal fetal cardiac findings (58 studies, 7.5% of total studies). The most common referral for fetal echocardiography was related to maternal indications (283/772). Other indications were abnormal findings in antenatal ultrasonography (186/272), family history of CHD (35/772), prenatal routine screening (236/772), and IVF (32/772). The highest yield of significant abnormal findings was found among patients referred with abnormal prenatal ultrasonography (39%). Whereas detection rate for unselected routine screening was less than 1% (2/236). We analysed the pattern of CHD detected in abnormal scans. Most common finding was conotruncal abnormalities (17/54) followed by single ventricle physiology (15/54). Others included 8 VSD, 4 AVSD, 4 significant arrhythmias, 2 Ebstein's anomaly and 4 had other cardiac abnormalities (tumor/pericardial effusion). Insignificant arrhythmias were excluded.
Conclusions: Majority of referral for fetal echocardiography were for abnormal prenatal ultrasonography, usually during anatomy scan between 18-20 weeks. Routine fetal echocardiography for unselected population has very low detection rate.

P1389 - MEDIUM TERM OUTCOME OF PRENATALLY DIAGNOSED HYPOPLASTIC LEFT HEART SYNDROME AND IMPACT OF A RESTRICTIVE ATRIAL SEPTUM DIAGNOSED IN UTERO

Diana Bernal Quintero[1], Tristan Ramcharan[1], John Stickley[1], Sri J.V. Rao[1], Paul Miller[1], Tarak Desai[1], Tracey Johnston[2], Sam Pretlove[2], David J. Barron[1], Anna N. Seale[1]
Birmingham Children, Paediatric Cardiac Services, Birmingham-United Kingdom[1]; Birmingham Women, Fetal Medicine, Birmingham-United Kingdom[2]

Background/Hypothesis: Surgical outcome data does not reflect outcome of prenatally diagnosed fetuses with hypoplastic left heart syndrome (HLHS); historical data has shown 46.9% overall survival of the intention-to-treat group (ITT). Our aim was to describe outcome of prenatally diagnosed fetuses in the current era.
Methods: Retrospective review of prenatally diagnosed HLHS at Birmingham Women's Hospital over a 10-year period, estimated due dates 01/8/2006 to 31/07/2016. HLHS variants and ventricular disproportion were excluded. Outcome and prenatal variables (Table) were investigated.
Results: We identified 160 fetuses; outcome information was available for 157. There were 44 (28.0%) terminations of pregnancy, 3 (1.9%) intrauterine deaths, 7 (4.5%) babies had compassionate care. There was ITT in the remaining 103/157 (65.6%). Of the ITT group, there were 4 deaths before intervention (3.9%), 99 (96.1%) underwent intervention: a Norwood procedure was performed in 92 (92.9%), an initial hybrid in 6 (6.1%), 1 had coarctation stenting. Survival from birth at 6-months, 1-year and 5-years respectively was 90.3%, 83.5%, 72.5%. Altogether 65 patients are currently alive: 5 with a Norwood circulation, 35 with a cavopulmonary shunt and 24 Fontan circulation (one had cardiac transplantation). Overall survival in the prenatal cohort was 65/157 (41.4%). Multivariable analysis shows a restrictive atrial septum (RAS) is an important factor associated with death, after variable selection HR 1.98 (95% CI 0.93-4.19). There were 6 survivors in this group (n = 15):2 have not completed the Fontan pathway due to unfavorable haemodynamics, 3 are post cavopulmonary anastomosis (all taking sildenafil) and 1 has completed Fontan circulation.
Conclusion: Medium-term outcomes of prenatally diagnosed HLHS have improved however there remains a significant mortality particularly in fetuses with in-utero diagnosis of a RAS where completion of Fontan is particularly unlikely.

Table.

Factor
Restrictive atrial septum
Extra-cardiac anomalies
Tricuspid valve regurgitation
Endocardial fibro-elastosis
Aortic atresia/mitral atresia
Hydrops/pericardial effusion
Estimated fetal weight third trimester

P1397-3D MOTION CORRECTED FETAL CARDIAC MRI EXPERIMENTAL VALIDATION AND CLINICAL APPLICATION

David F A Lloyd[1], Kuberan Pushparajah[1], John Simpson[1], Maria Kuklisova-murgasova[2], Bernhard Kainz[2], Joshua F P Van Amerom[2], Vita Zidere[1], Owen Miller[1], Gurleen Sharland[1], Mary Rutherford[2], Jo Hajnal[2], Reza Razavi[2]
Evelina London Children, Department of Congenital Heart Disease, London-United Kingdom[1]; King, Division of Imaging Sciences and Biomedical Engineering, London-United Kingdom[2]

Background: The accurate diagnosis of congenital heart disease in the fetus is crucial to provide relevant counseling and plan postnatal care. However, visualisation of the extracardiac vasculature is often challenging using echocardiography alone, and MRI, whilst safe, is highly limited by uncontrolled fetal motion.
Materials and Methods: We sought to validate the use of a novel motion-correction algorithm by first applying it to an artificially motion-corrupted 3D balanced steady-state free precession (3D-SSFP) volume, acquired from a one-day old neonate with coarctation of the aorta under general anesthetic with cardiac and respiratory gating. Nine non-contiguous stacks of single images were sythesised (equivalent to standard fetal data), which were then processed by the motion-correction algorithm to produce a three-dimensional volume which could be compared to the original 3D-SSFP sequence. Following this initial experiment, the same technique was applied directly to fetal cases using multiple T2-weighted single-shot fast spin echo sequences, across a range of gestational ages and diagnoses.
Results: The postnatal motion corrected volume generated was qualitatively identical to the "ground-truth" 3D-SFFP volume, demonstrating the same anatomical features (figure 1). To date we have applied this technique to twenty-eight fetuses between 24-36 weeks gestation (mean 32 weeks), predominantly cases with aortic arch abnormalities (coarcation of the aorta, potential vascular rings) and those with undetermined pulmonary arterial or venous anatomy (figure 2). In each case to date, postnatal imaging and/or

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

surgery has confirmed antenatal findings. In some cases, antenatal imaging has provided additional useful insights to inform postnatal management (figure 3).

Conclusions: We have used an artificially motion-corrupted neonatal 3D-SSFP volume, acquired under general anaesthetic with cardiorespiratory gating, to validate a novel motion-correction algorithm for use in fetal cases with promising early results. This technique offers the potential to be a powerful adjunct to fetal echocardiography in cases where the vascular diagnosis would otherwise not be fully resolved before birth.

P1399 - RESTING AND EXERCISE ARTERIAL MECHANICS IN ANTHRACYLINE TREATED LONG TERM SURVIVORS OF CHILDHOOD CANCERS

Vivian Wy Li[1], Anthony Py Liu[1], Karin Kh Ho[2], Jeffrey Pw Yau[3], Daniel Kl Cheuk[4], Yiu-Fai Cheung[4]

The University of Hong Kong, Department of Paediatrics and Adolescent Medicine, Hong Kong-Hong Kong[1]; Princess Margaret Hospital, Department of Paediatrics and Adolescent Medicine, Hong Kong-Hong Kong[2]; Queen Elizabeth Hospital, Department of Paediatrics, Hong Kong-Hong Kong[3]; Department of Paediatrics And Adolescent Medicine, Department of Paediatrics and Adolescent Medicine, Hong Kong-Hong Kong[4]

Background: We aimed to determine arterial mechanics at rest and during exercise in anthracycline-treated long-term survivors of childhood cancers.

Methods: Eighty-seven (50 males) anthracycline-treated long-term survivors of childhood cancers aged 24.1 ± 5.3 years were studied at 15.1 ± 5.6 years after completion of treatment and 60 (30 males) age-matched healthy subjects were recruited as controls. The blood pressures in the right arm were measured by oscillometry, while radial augmentation index (rAI) was determined by applanation tonometry. Carotid arterial stiffness and intima-media thickness (IMT) were assessed using high-resolution ultrasound. Arterial stiffness and blood pressures were determined both at rest and during submaximal supine bicycle exercise testing with achievement of a target heart rate of 70% of age-predicted maximum.

Result: At rest, patients had significantly greater carotid IMT (0.44 ± 0.15 mm vs 0.41 ± 0.01 mm, $p < 0.001$), carotid arterial stiffness (4.04 ± 0.68 vs 3.85 ± 0.61, $p < 0.001$), rAI (64 ± 15% vs 57 ± 13%, $p = 0.008$), and rAI adjusted for a heart rate of 75/min (63 ± 14% vs 58 ± 12%, $p = 0.020$) than controls. During submaximal exercise, patients had significantly greater increase in carotid stiffness than controls ($p < 0.001$), while systolic and diastolic blood pressures remained similar between the two groups (all $p > 0.05$). For the whole cohort, the magnitude of exercise-induced increase in carotid stiffness correlated positively with rAI ($r = 0.18$, $p = 0.027$), adjusted rAI ($r = 0.22$, $p = 0.009$), and carotid IMT ($r = 0.32$, $p < 0.001$) and age ($r = 0.21$, $p = 0.011$). In patients, the cumulative anthracycline dose received was found to correlate positively with rAI ($r = 0.24$, $p = 0.027$) and heart-rate adjusted rAI ($r = 0.25$, $p = 0.019$). Furthermore, the magnitude of exercise-induced increase in carotid arterial stiffness was found to correlate with years after completion of anthracycline ($r = 0.23$, $p = 0.031$), but not cumulative anthracycline dose ($p > 0.05$).

Conclusion: Arterial mechanics are impaired at rest and worsened during exercise in anthracycline-treated long-term survivors of childhood cancers, which may adversely increase left ventricular afterload.

P1406 - LOOKING INTO THE HEARTS OF THALASSEMIC CHILDREN

Shakuntala Prabhu[1], Sumitra Venkatesh[1], Vaibhav Gode[2], Snehal Kulkarni[3], Bharat Agarwal[4]

B.J.Wadia Hospital For Children, Div. of Pediatric Cardiology, Dept. of Pediatrics, Mumbai-India[1]; B.J.Wadia Hospital for Children B.J.Wadia Hospital for Children, Dept. of Pediatrics, Mumbai-India[2]; B.J.Wadia Hospital for Children& Kokilaben Dhirubhai Ambani Hopsital, Div. of Pediatric Cardiology, Mumbai-India[3]; B.J.Wadia Hospital for Children, Pediatric Hemato Oncology Deptartment, Mumbai-India[4]

Objectives: To note spectrum of cardiac abnormalities in transfusion dependent β-thalassemia children by clinical and Echocardiographic evaluation and to correlate its severity with serum ferritin levels.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Design: Observational study at an Urban tertiary referral children's Hospital.
Methods: 100 thalassemic children who received more than 50 blood transfusions and had serum ferritin level >2500 ng/ml were included. Detailed medical history, anthropometry, transfusion details, examination including cardiovascular system were noted. Echocardiogram, Colour Doppler and Tissue Doppler Imaging (TDI) were done to assess cardiac functions. Cardiac dimensions, functions, mass and index were assessed by standard Echocardiographic techniques and were compared to paediatric norms. TDI was performed to assess myocardial involvement.
Results: Cardiac symptoms were largely subclinical. 13 children had tachycardia and 10 were hypertensive for their age. 8/100 had left ventricular dilatation. 85 children had diastolic dysfunction which was seen more in children with Hb <8 g/dL, increasing years of transfusion therapy and increasing ferritin levels (p value: 0.042). 13/100 children had systolic dysfunction. There was a significant correlation between age and systolic dysfunction (p value: 0.017). 32 children had a high cardiac output. There was a significant correlation between increasing serum ferritin levels and TDI abnormalities (p value: 0.006). 45 children had right ventricular dysfunction. There was significant correlation between age and right ventricle dysfunction (p value 0.028).
Conclusion: Cardiovascular manifestations remain predominantly silent in thalassemic children. On Echocardiographic evaluation, LV dilatation, LV diastolic and systolic dysfunctions, impaired myocardial performance, increased cardiac output, moderate TR and RV dysfunction were noted. LV diastolic dysfunction was more common than systolic dysfunction and was noted more in children with longer duration of transfusion therapy and high serum ferritin levels. TDI complimented the conventional Echocardiography in diagnosing diastolic dysfunction.

P1408 - DIFFUSE PULMONARY ARTERIOVENOUS MALFORMATION IN CHILDREN ESSENTIAL VALUE OF CONTRAST ECHOCARDIOGRAPHY

Norazah Zahari[1], Putri Yubbu[2], Amir Hamzah Abdul Rahman[3]
University Malaya Medical Centre, Paediatric (Cardiology), Kuala Lumpur-Malaysia[1]; University Putra Malaysia, Paediatric (Cardiology), Kuala Lumpur-Malaysia[2]; Kuantan Hospital, Paediatric (Cardiology), Kuantan-Malaysia[3]

Background: Pulmonary arteriovenous malformations (PAVMs) although rare, is an important consideration in cyanotic patients of unknown cause. We report 3 diffuse PAVM cases in children detected by contrast echocardiogram.
Case 1: A 1-year-old boy with recurrent respiratory infections since 1-month-old with incidental finding of dextrocardia and situs inversus. He presented at 10-month-old with 2 weeks history of fever and cough with associated respiratory distress requiring ventilator support. He was positive for pulmonary tuberculosis and treatment started. His oxygen saturations remain in low 80 s despite of his clinical improvement. He was cyanosed and clubbed. Echocardiography showed dextrocardia, normal cardiac structure with positive bubble study which raised the suspicion of PAVM. A high resolution computed tomography (HRCT) of the thorax showed no obvious intra-pulmonary shunting or bronchiectatic changes. Pulmonary angiogram confirmed diffuse PAVM.
Case 2: 11-year-old girl with history of right cerebral abscess undergone a burrhole and aspiration. 3 years later she had recurrent abscess at left temporoparietal region, had surgical drainage and 6 weeks of intravenous antibiotics. She had central cyanosis, clubbing, oxygen saturation 85% and upper motor neuron lesion signs. Chest x-ray, CT pulmonary angiogram (CTPA) were normal and echocardiography showed a normal cardiac structure with positive bubble study. Pulmonary angiogram confirmed diffuse PAVM.
Case 3: A 4-year-old boy with history of increasing cyanosis and reduced effort tolerance.Both respiratory and cardiovascular examination were unremarkable. CTPA was normal with positive bubble study on echocardiography. Pulmonary angiogram showed diffuse PAVMs. There were no pulmonary hypertension in all patients.
Conclusion: PAVM is an important diagnosis to consider in persistent hypoxaemia in the absence of respiratory and cardiac disease. Normal HRCT thorax findings does not rule out diffuse PAVM. Hence, contrast echocardiography is essential in diagnosing PAVM. Pulmonary angiogram should be reserved for therapeutic purposes.

P1414 - FETAL ECHOCARDIOGRAPHY FOR RISKY PREGNANCIES IN SULAIMANI GOVERNMENT KURDISTAN IRAQ

Aso Salih[1]
Sulaimani University, Pediatrics, Sulaimanyah-Iraq Diagnosis of congenital heart disease during fetal life not only identifies the cardiac lesion but may also lead to detection of associated abnormalities. This information allows a detailed discussion of the prognosis with parents

Objective: The aim of this study is to evaluate our experience and results of fetal echo for risky pregnancies in sulaimany.
Method: This is prospective descriptive study conducted on 450 pregnant ladies referred for fetal echocardiography from 1st January 2013 still ongoing. Echocardiography done at their first visit at 16-22 weeks in 330 ladies, at 22-28 weeks in 70 cases and 31weeks and above in 50 ladies. Also 2nd visit echo done for 60 patients for follow up at 31-33 weeks gestation.
Result: Among 450 pregnant ladies seen, 98 cases found to have findings, of which 27 diagnosed as hypertrophic cardiomyopathy (just one persist after 6 months post labour), 25 cases as ASD (just 10 left with the defect after labour), 14 diagnosed as a case of tricuspid atersia and single ventricle physiology, 5 AVSD, 5 arrhythmia with hydropis, 5 with MV and TV abnormalities, 4 AS, 3 hypoplastic left heart syndrome, 3 PS, 2 l-TGA and one Coa . For low risk populations of defects no action undertaken, for high risk population decision for termination is one of options Fetal echocardiography examination specifity was 97.8% and sensitivity was 98.3%, positive predictive value was 93.8%, negative predictive value was 99.4%.
Conclusion: The present study showed that fetal echo has great value in detection of congenital heart diseaseprognosis and outcome in high risk pregnancies. It's recommended to familiarize our obstetrician about this important diagnostic test. We should train our ultrasonographer and pediatric cardiologist to increase awareness about this diagnostic.

P1429 - ACCURACY OF COMPUTED TOMOGRAPHY FOR DETECTING GREAT VESSEL STENOSIS OR HYPOPLASIA IN CONGENITAL HEART DISEASE PRIOR TO SUPERIOR BIDIRECTIONAL CAVOPULMONARY CONNECTION COMPARISON WITH CARDIAC CATHETERIZATION AND SURGICAL FINDINGS

Laura Vazquez-Garcia[1], *Monther Obeidat*[1], *Giovanni Di Salvo*[1], *Olivier Ghez*[1], *Guido Michielon*[1], *Michael Rubens*[2], *Zdenek Slavik*[1], *Michael L Rigby*[1], *Alain Fraisse*[1], *Sylvia Krupickova*[1]
Royal Brompton Hospital, Paediatric Cardiology, London-United Kingdom[1]*; Royal Brompton Hospital, Radiology, London-United Kingdom*[2]

Background: This study sought to investigate diagnostic accuracy and safety of computed tomography (CT) in assessing great vessels stenosis/hypoplasia prior to superior bidirectional cavopulmonary connection (BCPC) compared with cardiac catheterisation (CC) and surgical findings.
Methods: Twenty-seven patients (37% after Norwood operation) underwent CT prior to BCPC (16 patients out of them also CC) between January 2010 and June 2016. At the time of BCPC, median age was 229days and median weight 8.3 kg. Proximal and distal pulmonary artery branches, aortic isthmus and abdominal aorta were measured.
Results: Nine right and 11 left pulmonary artery branches were enlarged at the time of surgery. CT did not miss any stenosis/hypoplasia of pulmonary arteries and reported 2 cases of pulmonary arteries hypoplasia that were subsequently considered to be normal at the time of BCPC. The accuracy of CT for detecting stenosis/hypoplasia of either pulmonary artery was 99.7%. No coarctation of aorta was noted at CT and thus not formally assessed at the time of surgery. In terms of absolute vessel measurements and their Z-scores, there was excellent agreement ($r = 0.98$ for both) between CT and CC, very low bias (0.71mm, 0.48; respectively), and clinically acceptable limits of agreement (−0.9 to +2.3mm; -0.7 to +1.7, respectively). Patients received significantly higher radiation dose at CC than CT (median 2.7mSv, IQR 1.7,3.6 versus median 1.2mSv, IQR 1.0,1.9, respectively; $p < 0.040$). Four patients (25%) suffered minor complications from CC and there were no complications from CT scan. All cardiac catheterisations were performed under general anaesthesia whereas no sedation was required for any of the patients for CT.
Conclusions: CT may replace CC for identification of great vessel stenosis or hypoplasia in selected patients before BCPC when there is no suspicion of requiring any intervention prior to surgery. CT requires less radiation, carries less morbidity and can be performed without sedation.

P1464 - PATENT DUCTUS ARTERIOSUS MORPHOLOGY IN DUCTAL DEPENDENT PULMONARY CIRCULATION – HOW DOES COMPUTED TOMOGRAM ANGIOGRAPHY HELPS

Haifa Abdul Latif, Anu Ratha Gopal
National Heart Institute (IJN), PCHC, Kuala Lumpur-Malaysia

Background: Patent Ductus Arteriosus (PDA) in duct dependent pulmonary circulation(DDPC) has a diverse morphology. The objectives of this study are to assess the role of computed tomogram angiography(CTA) to classify type of PDA in DDPC, identify pattern of PDA morphology in different type of ventricular morphology (biventricular, univentricular and Pulmonary atresia with intact septum) and evaluate the impact of PDA morphology in the suitability for PDA stenting.
Methods: This prospective study, performed from January 2013 to December 2015, in all patients with DDPC using a 64 slice dual source CT scanner. The PDA was classified based on its site of origin from the aortic arch either from descending aorta-type I, distal arch-type II, proximal arch-type III or from subclavian artery-type IV.
Results: Total 114 patients, age between 2 days to 6 months and weight from 2 kg to 6.9 kg recruited. Seventy nine patients (69%) were on I.V Prostaglandin infusion. 13(11.0%) patients had type I, 74(65.0%) patients type II, 16(14.0%) patients had type III and 9 (8.0%) patients had type IV PDA. Tortuous PDA was found in 37 (32.4%) majority in those with type II and III PDAs. Site of insertion was onto the left pulmonary artery(LPA) in 62(54.4%), right pulmonary artery(RPA) in 20(17.85%) and main pulmonary artery(MPA) in 30(26.78%). Ipsilateral branch PA stenosis found in 75(66.9%) of patient. The majority of PAIVS (92.7%) has type I PDA while in those with biventricular and univentricular lesions have mainly type II or III PDA. Type IV PDA are more common in biventricular lesion. PDA stenting was successful in 69.2% in type I, 41.9% in type II, 37.5% type III and 67.7% type IV.
Conclusion: CTA provides detail delineation of PDA morphology in DDPC lesions. Tortuous type II and III PDA are less likely to be amenable for PDA stenting.

P1469 - ACCURACY OF ECHOCARDIOGRAPHY IN THE DIAGNOSIS OF TOTAL ANOMALOUS PULMONARY VENOUS CONNECTION

Fatima Ali[1], *Muhammad Khalid*[1], *Naila Nadeem*[2], *Mehnaz Atiq*[1]
Aga Khan University Hospital, Pediatrics, Karachi-Pakistan[1] *Aga Khan University Hospital, Radiology, Karachi-Pakistan*[2]

Hypothesis: Total anomalous pulmonary venous connection (TAPVC) is diagnosed by echocardiography and may be

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

confirmed by other diagnostic modalities. The objective of this study was to determine the accuracy of echocardiography in the diagnosis of different types of isolated TAPVC and TAPVC with other congenital heart defects (CHD) and compare it with CT angiography or observation during surgery.
Patients and Method: Data from the medical records of patients 1 day to 15 years of age, from Jan 2010 to Aug 2016 with echocardiographic diagnosis of TAPVC and had confirmation with either at surgery or with CT angiogram was obtained. Accuracy of echocardiography was defined as complete, partial and missed diagnosis and was compared with CT angiogram or surgery.
Results: Total of 47 patients were enrolled, 33 (70.2%) were males, and 14 (29.8%) were females. 41 (87%) were infants, 18 (38%) were less than 1 month and 6 (13%) were between 1-15 years. CT angiogram was done in 30 patients. 32 (68%) had isolated TAPVC, while 15 (32%) had associated CHD. 18 (38%) were supracardiac, 17 (36%) were cardiac, 8 (17%) infracardiac and 4(9%) were mixed type of TAPVC. Echocardiographic diagnosis of TAPVC was complete in 33(66%), partial in 6(13%), missed in 10(21%) of patients. In Isolated TAPVC 27 (84.4%) patients were diagnosed completely and 5(15.6%) patients were missed, while in TAPVC associated with CHD 4 (27%) patients were diagnosed completely, 6 (40%) were diagnosed partially, and in 5(33%) the diagnosis was missed. The overall accuracy of diagnosis by echocardiography had 66% (sensitivity) with 100% positive predictive value. In isolated TAPVC, sensitivity was found to be 84% as compared to TAPVC associated with CHD (27%).
Conclusion: We conclude that the mixed variety of isolated TAPVC and TAPVC associated with complex CHD should undergo CT angiogram for accurate diagnosis.

P1470 - ASSESSMENT OF CARDIAC FUNCTION IN FETUSES OF GESTATIONAL DIABETIC MOTHERS DURING IN THE SECOND TRIMESTER

Mehnaz Atiq, Anum Ikram, Batool Hussain, Bakhtawer Saleem
Aga Khan University Hospital, Pediatrics, Karachi-Pakistan

Introduction: Fetuses of diabetic mothers may have structural or functional cardiac abnormalities which increase morbidity and mortality. Isolated functional abnormalities have been identified in the third trimester. The aim of the present study was to assess fetal cardiac function (systolic, diastolic and global myocardial performance) in the second trimester in mothers with gestational diabetes, and also to relate it with glycemic control.
Methods: Mothers with gestational diabetes mellitus referred for fetal echocardiography in the second trimester from March 2015 to February 2016 were enrolled as case subjects. Exclusion criteria were pregestational diabetes, presence of structural heart disease, twin pregnancies, intrauterine growth retardation (defined as weight for gestation less than 5th percentile) and polyhydramnios. Non diabetic mothers who had a fetal echocardiogram done between 19-24 weeks for other indications were enrolled as controls. Glycemic control was classified as good if Hb A1c was <6 gm/dl or glucose tolerance test showed serum glucose levels of <160 mg/dl.
Results: 128 mothers were enrolled, 64 were in gestational diabetic group and 64 were in non-diabetic control group. Mean age of mothers was 31 ± 4.9 years (median 29 years) and the mean gestational age at the time of first examination was 23 ± 3.4 weeks (median 22 weeks). Functional variables showed that isovolumetric relaxation and contraction times were significantly prolonged in fetuses of diabetic mothers ($p = 0.001$ and 0.01 respectively). Myocardial performance index and mitral E/A ratios were significantly abnormal in the diabetic group ($p < 0.001$ and $p = 0.03$ respectively)). Mitral annular plane systolic excursion (MAPSE) was less in the diabetic group ($p = 0.01$). The only functional cardiac variable found abnormal in mothers with poor glycemic control was prolonged isovolumetric relaxation time ($p = 0\text{-}03$).
Conclusion: Functional cardiac abnormalities can be detected in the second trimester in fetuses of gestational diabetes and timely intervention can improve postnatal outcomes.

P1471 - PRENATALLY DIAGNOSED LARGE INTRAPERICARDIAL RHABDOMYOMA WITHOUT HEMODYNAMIC COMPROMISE

Mehnaz Atiq, Mehwish Rizvi
Aga Khanuniversity Hospital, Pediatrics, Karachi-Pakistan

Introduction: Rhabdomyoma of the heart is the most common cardiac tumor. It is associated with tuberous sclerosis in 60-80% of cases. In a review of 266 fetuses with cardiac rhabdomyoma, only one had pericardial rhabdomyoma. We present two fetuses with pericardial rhabdomyoma diagnosed prenatally without hemodynamic compromise.
Case 1: 28 year old woman with a gestational age of 32 weeks was referred for fetal echocardiogram which showed a huge intrapericardial tumor measuring 33mm x 18mm with trace pericardial effusion (figure 1). There was no evidence of hydrops fetalis.
Post natal echo showed a large extracardiac tumor intrapericardial with a few hyperechoeic tumors masses in the left ventricular myocardium and in the interventricular septum. None of the tumor masses were producing hemodynamic abnormalities. Conservative management with echocardiographic follow up showed regression in the intrapericardial tumor by one year of age. Magnetic resonance imaging of the brain showed tubers in the brain.
Case 2: 21 year old woman was referred for fetal echocardiography at 26 weeks of gestation with the diagnosis of an extracardiac tumor. There was no hydrops fetalis. Fetal echocardiogram showed a mass measuring 28×20mm in the pericardium adjacent to the left ventricle with no evidence of cardiac compression (figure 2). No intracardiac or intramural myocardial echogenic densities were seen. The diagnosis was intrapericardial rhabdomyoma since the appearance was homogenous as opposed to

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

teratoma which has an inhomogeneous appearance. Postnatal follow up showed a reduction in size of the pericardial rhabdomyoma to 14 × 14mm at seven months after birth. The child was referred to a neurologist for screening of tuberous sclerosis.
Conclusion: Primary cardiac tumors are rare and intrapericardial rhabdomyomas are uncommon. Teratoma is the most common intrapericardial tumors, and is easily diagnosed due to the presence of calcified foci and cystic areas. Rhabdomyomas are homogenous.

P1477 - ASSESSMENT OF SINGLE VENTRICLE'S MYOCARDIAL FUNCTION IN GUCH PATIENTS AFTER THE TOTAL CAVOPULMONARY CONNECTION BY TISSUE DOPPLER IMAGING AND MAGNETIC RESONANCE IMAGING

Yuliia Pozniak[1], Igor Lebid[1], Tetyana Yalynska[2], Yevgeniya Iershova[2], Valentina Khanenova[1], Nadia Rudenko[1], Yuliia Klymyshyn[1]
Ukrainian Children's Cardiac Center, ACHD Department, Kyiv-Ukraine[1]; Ukrainian Children's Cardiac Center, Radiology Department, Kyiv-Ukraine[2]

Objective: Was to estimate the single ventricle's myocardial function in GUCH-patients after the Total Cavopulmonary connection (TCPC) by echocardiography (Echo) and Magnetic Resonance Imaging ().
Material and Methods: From 2003 to 2016 132 patients were performed operation TCPC. Eighteen patients elder 18 y. were included to this work (10 males, 8 female, mean age 21.3 ± 1.9 y, 18-23 years). EDV, ESV, EDI, EF (Simpson's method) recorded by Echo and MRI. Peak S, E, A, ratio E/A, Myocardial Performance Index (MPI) estimated by Echo (TDI).
Results: The peak S (9.2 ± 1.8 mm) by TDI and EF (51 ± 5%) by MRI had direct significant correlation ($r = +0.6$, $p < 0.05$). MPI by TDI (0.51 ± 0.03) and EF (51 ± 5%) by MRI had inverse significant correlation ($r = -0.3$, $p < 0.05$). EDV (58.4 ± 15 ml), ESV (29 ± 8 ml), EF (44 ± 5%) (Simpson method) by Echo did not correlate with the same indexes estimated by MRI (100 ± 18 ml, 46.5 ± 9.1 ml, 51 ± 5% resp.).
Conclusions: Echo indices (peak S, MPI) could use for assessment of single ventricle's myocardial function in GUCH-patients after the TCPC, by their according to the MRI. Volumetric indices and EF assessment by Echo have a poor interdependence with MRI.

P1491 - LEFT VENTRICLE NONCOMPACTATION AND EBSTEIN'S ANOMALY REPORT OF FOUR NEONATAL CASES

Carin Cristina Walter, Sheila Tubio Gómez, Juan Manuel Carretero Bellón, Joan Sanchez De Toledo Sancho
Hospital Sant Joan De Déu, Pediatric Cardiology, Barcelona-Spain

Background: Left ventricular noncompactation (LVNC) is a rare disease characterized by prominent myocardial trabeculations. Clinical features ranges from no symptoms to heart failure. It can be an isolated malformation or associated with other cardiopathies, like Ebstein's anomaly (EA). This association and the clinical behavior in the pediatric literature has rarely been reported. We describe four neonatal cases of LVNC and EA emphasizing on the short and medium term follow-up.
Materials and Methods: This is a retrospective study reviewing patients admitted in the Pediatric Cardiology Unit of the Hospital Sant Joan de Déu diagnosed of EA and LVNC. We collected information on the prenatal and postnatal diagnosis, clinical presentation, management and follow-up.
Results: In the last four years we detected 6 cases of EA with LVNC in 4 cases. The prenatal echocardiography described EA in 2 patients; the other 2 were described as normal although one had increased nuchal translucency. LVNC was detected at birth in 3 patients, and the other one at the first month. Two cases had heart

Table 1.

Patient	Drugs during pregnancy	Prenatal findings	Weight at Birth (grams)	Sex
1	No	EA Septal myocardial hypertrophy	3590	M
2	No	No	2700	F
3	Lithium, Quetiapine, Adalimumab	EA Hypoplastic right ventricle	2810	F
4	No	Increased nuchal translucency	3210	F

Patient	Neonatal echocardiography	Evolution	Interventions	Current age and treatment
1	EA	1 month of age: Acute cardiac failure and Diagnosis of the LVNC	No	4 years. Captopril and carvedilol
2	EA, LVNC, VSD	Neonatal HF and SVT (WPW)	Radiofrequency ablation	3 years. No treatment
3	EA LVNC	SVT	Glenn procedure	2 years. Flecainide
4	EA LVNC	Idiopathic pericardial effusion	No	2 years. ASA

M: male; F: female; EA: Ebstein's Anomaly; LVNC: left ventricle noncompactation; VSD: Ventricular septal defect; HF: Heart failure; SVT: Supraventricular tachycardia; WPW: Wolff-Parkinson-White syndrome; ASA: acetylsalicylic acid

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

failure during the first month with satisfactory evolution; however one is still treated with captopril and carvedilol. Two patients had supraventricular tachycardia (SVT). One was treated with flecainide and the other one required radiofrequency ablation due to a Wolff-Parkinson-White syndrome. This patient had a severe EA and required Glenn procedure. One patient receives prophylactic acetylsalicylic acid.
Conclusions: In the last 20 years, we diagnosed 26 cases of EA, but only in the last 4 years we find this rare association. Further, half of the patients had a fetal diagnosis of EA, none of LVNC. That reflects an under pre and postnatal diagnosis. Although an initial adverse clinical outcome was observed in 50% of patients, a satisfactory recovery was seen. Despite these encouraging data, the long-term evolution remains to be clarified.

P1493 - PREDICTIVE ROLE OF GLOBAL LONGITUDINAL STRAIN IN FUNCTIONAL SINGLE LEFT VENTRICLE

Alessia Del Pasqua, Carolina D, Marcello Chinali, Claudia Esposito, Maria Iacomino, Sergio Filippelli, Adriano Carotti, Paolo Guccione, Fiore S. Iorio, Maurizio Bevilacqua, Fabrizio Drago, Gabriele Rinelli
Bambino Gesù Pediatric Hospital, Pediatric Cardiology, Rome-Italy

Introduction: Limited data are available about global longitudinal strain (GLS) in patients with functional single ventricle, particularly single left ventricle (FSLV), and its clinical usefulness.
Purpose: To evaluate clinical utility of GLS compared to traditional echocardiographic parameters of systolic function in FSLV at pre Fontan stage and to identify potential correlation between GLS and haemodynamic data.
Methods: We retrospectively collected data about 22 consecutive patients from December 2011 to January 2016 (10 tricuspid atresia, 8 pulmonary atresia intact interventricular septum, 4 tricuspid and pulmonary atresia). Mean age at Glenn: 5 ± 50 months, mean age at pre Fontan catheterization: 54 ± 26 months. We identified two groups. Group 1 (13 patients): patients with haemodynamic findings adequate for Fontan completion who subsequently underwent successfully Fontan operation. Group 2 (19 patients): patients not eligible for Fontan completion or presenting early Fontan failure (2/19). Echocardiographic data analyzed were: LV ejection fraction (EF) by Simpson monoplane, four chamber 2D speckle GLS (4CGLS), mitral regurgitation. Catheterization data analysed included LV end-diastolic pressure and mean pulmonary pressure.
Results: There were no differences between groups in terms of LVEF ($59.7 \pm 4.5\%$ vs $57.5 \pm 3.7\%$, $p = 0.23$), LV end-diastolic volume (44 ± 27 ml vs 42 ± 20 ml, $p = 0.85$), mean pulmonary pressure (11.1 ± 1.2 vs 13 ± 2; $p = 0{,}7$), transpulmonary gradient (3.8 ± 1.2 vs 4.4 ± 1.6), mitral regurgitation. Significantly lower 4CGLS ($-25.7 \pm 3.1\%$ vs $-20.8 \pm 5.1\%$; $p = 0.01$) was found in Group 2 associated with higher LV end-diastolic pressure (7.1 ± 1.2 vs 9.1 ± 1.9; $p = 0.01$). Patients with worse 4CGLS showed a mild tendency to have higher LV end diastolic pressure ($R = 0.29$; $p = 0.19$).
Conclusion: Despite comparable values of LVEF and mitral regurgitation, patients not eligible for Fontan or with early Fontan failure had significantly lower 4CGLS compared to subjects who successfully underwent Fontan completion. 4CGLS might play a role in FSLV assessment and provide useful non-invasive information in pre Fontan assessment.

P1494 - CORONARY IMAGING UTILIZING GADOLINIUM CARDIAC MAGNETIC RESONANCE COMBINED WITH AN INVERSION RECOVERY GRADIENT ECHO SEQUENCE UTILITY IN CONGENITAL HEART DISEASE

Mark Fogel[1], Sara Partington[2], David Biko[3], Matthew Harris[1], Kevin Whitehead[1]
CHOP, Pediatrics/Radiology, Philadelphia-United States[1]; CHOP, Medicine/Pediatrics, Philadelphia-United States[2]; CHOP, Radiology, Philadephia-United States[3]

Background/Hypothesis: Coronary imaging in congenital heart disease and particularly in pediatrics can be challenging. We hypothesized that utilizing cardiac magnetic resonance (CMR) with an inversion recovery gradient echo sequence (IR-GRE) combined with gadolinium would be successful in visualizing the coronary arteries in the vast majority of cases.
Materials/Methods: All patients who presented for CMR and underwent IR-GRE between October 2010 and September 2016 were included. Gadolinium was either "dripped" in over the first third of the sequence or, if utilizing gadofosveset, administered as a bolus and IR-GRE performed immediately afterwards. Indications were either for coronary imaging or for imaging other structures (eg aorta) and coronaries were visualized.
Results: 1044 patients were found (54% male, age 14.3 + 12.6 years, range 3 days - 44 years) with 720 < 19 years. A whole range of diagnoses were included such as hypoplastic left heart syndrome, tricuspid atresia, transposition of the great arteries, bicuspid aortic valve, suspicion of anomalous coronary to name a few. Proximal coronary arteries were visualized in 987 (94.6%) – see figure. IR-GRE was successful even in patients with braces artifact where routine coronary imaging would fail. Myocardial scarring was able to visualized as well in the same exam – see figure. Of the remaining 57 patients, 28 (49%) were <1 year old and 13 (23%) were teenage males; success rate in the pediatric age range was 94%. 117 (12%) presented with a suspicion of an anomalous coronary of which anomalous right coronary from the left sinus was the most common finding ($N = 85$, 72.6%).
Conclusions: CMR utilizing IR-GRE combined with gadolinium has a high success rate (94.6%) in visualizing the coronary arteries in congenital heart disease and in the pediatric age range (94%); myocardial scarring was also visualized. Most failures were due to age <1 year or being a teenage male.

P1497 - SINGLE CORONARY ARTERY ARISING FROM PULMONARY ARTERY IN A PATIENT WITH DOUBLE OUTLET RIGHT VENTRICLE

Belen Toral[1], Ana Caro[2], Marta Flores[2], Miguel Angel Granados[2], Leticia Albert[2], Constanza Liebana[3], Miguel Rasero[3], Lorenzo Boni[4], Marta Olmedilla[5], Laura Diaz[5]
Hosptal Universitario 12 Octubre, Pediatric Cardiology, Madrid-Spain[1]; Hospital Universiatrio 12 Octubre, Pediatric Cardiology, Madrid-Spain[2]; Hospital Universiatrio 12 Octubre, Radiology, Madrid-Spain[3]; Hospital Universiatrio 12 Octubre, Cardiac Surgeon, Madrid-Spain[4]; Hospital Universiatrio 12 Octubre, Picu, Madrid-Spain[5]

Background: Anomalous origin of a single coronary artery form the pulmonary artery (ASCAPA) is a rare anomaly, described in literature as isolated clinical cases. We report a patient with postnatal diagnosis of ASCAPA, based on echocardiographic and CT images.
Materials and Methods: A female fetus was referred at 20 weeks' gestation with diagnosis of tetralogy of Fallot. At 40 weeks' gestation caesarean section was planned. Postnatal echocardiography showed double outlet right ventricle (DORV) with mild pulmonary stenosis, and biventricular dysfunction. Great arteries had a side-by-side arrangement. As for coronary arteries anatomy, we could only detect one coronary artery arising from the posterior wall of the main pulmonary artery, with an interarterial course. No right coronary artery was seen emerging from the aortic root. To complete the diagnosis a cardiac CT scan was performed using a 64 slice CT scanner. A retrospective, gated cardiac CT angiography was performed at 125 bpm. Analysis of the coronary arteries showed a single coronary artery (SCA) arising from de left and posterior side of the pulmonary trunk. The SCA bifurcated after a short course into a right coronary artery and a left main coronary artery. With these findings, surgery for translocation of the SCA was planned. The preoperative findings were confirmed intraoperatively and reimplantation of the SCA into the aorta was successfully performed using the double-flap technique. Postoperative course was complicated by right ventricular dysfunction and severe aortic regurgitation, requiring valvular replacement. DORV was surgically addressed 3 months later.
Conclusions: We present a rare case of ASCAPA associated to DORV. Fine diagnosis of coronary system is fundamental for a successful surgical treatment. Echocardiography alone could not rule out a dual coronary artery system, which was finally possible thanks to the actual advances in cardiac CT imaging techniques.

P1523 - ANALYSIS OF THE COMPOSITION OF CORONARY ARTERIAL CALCIFICATION POST KAWASAKI DISEASE WITH SINGLE SOURCE DUAL ENERGY CT

Nobuyoshi Kusano, Satoshi Marutani, Noboru Inamura, Toru Shinohara, Tsukasa Takemura
Kindai University, Faculty of Medicine, Pediatrics, Osakasayama-Japan

In recent years, compositions of materials can become to be analyzed with dual-energy computed tomography (DECT), the effective atomic number (EAN) of coronary arterial calcification (CAC) was close to one of calcium oxalate monohydrate in adults. In this study, we examine the compositions of calcification of coronary arterial lesions of Kawasaki disease (KD-CAL) using EAN.
Object and Method: We had undergone DECT in 11 patients with KD-CAL. Exclusion criteria included patients who did not have a calcification more than 1mm and ones whose raw data had been erased. Age at KD was 0-6 years old (median 3 years old) and one at imaging was 15-45 years old (median 36 years old). DECT was performed with a prospective ECG-gated step and shoot technique. We reconstructed the field of view to 6.0 cm of the images and placed regions of interest (ROI) of 0.7mm diameter within the calcification 3 per 1 CAL at random. We calculated the distributions of the mean, median and maximum EANs, and compared the EANs with clinical records in every ROI.
Result: We obtained 69 EANs from 23 CALs. The median was 13.27 ± 0.83, the mean was 13.24 ± 0.80, the maximum was 13.59 ± 0.72, and these were close to the EAN of CAC. The analysis of every ROI, there were significant differences between age of KD (<1, 13.77 ± 0.52 vs $\geqq 1$, 13.16 ± 0.80, $p < 0.01$), time from onset of KD (<32, 13.69 ± 0.59 vs $\geqq 32$, 13.15 ± 0.80, $p < 0.01$) and BMI (<22, 13.70 ± 0.47 vs $\geqq 22$, 13.06 ± 0.88, $p < 0.01$).
Conclusion: The compositions of calcification of KD-CAL were close to ones of CAC. It was suggested that compositions of calcification of KD-CAL were different in age of KD, time from onset of KD and BMI. It is necessary to be careful about the onset of CV events.

P1531 - THE STUDY OF NEONATES WITH ISOLATED ABERRANT RIGHT SUBCLAVIAN ARTERY

Sheng Ling Jan[1], Sheng Ching Chan[2], Yun Ching Fu[1], Ming Chih Lin[1]
Taichung Veterans General Hospital, Department of Pediatrics, Taichung-Taiwan[1]; Ta-Jen University, Department of Nursing, Pingtung County-Taiwan[2]

Background: The left aortic arch with an aberrant right subclavian artery (aRSCA) is rare but the most common congenital anomaly of the aortic arch. Although most cases of isolated aRSCA are asymptomatic, there are few reports concerning the clinical manifestations of neonates with isolated aRSCA.
Methods: A total of 1737 fullterm neonates, 900 males and 837 females, were received echocardiographic screening between January 2014 to March 2016. Among these patients, neonates with or without isolated aRSCA were studied, including the demographic data, perinatal history and clinical manifestations were recorded and analyzed during infant period.
Results: A total of 15 (0.9%) female predominant neonates, 6 males and 9 females, had isolated aRSCA (group 1) who were compared with 20 normal neonates (group 2). There were no significant difference in maternal age, gestational age, para gravity and gender in both groups but smaller baby's size (birth length and weight, $p = 0.023$ and 0.025, respectively) in Group 1. Although there

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

were no significant difference in clinical manifestations, including developmental history, gastrointestinal and respiratory symptoms, neonates with aRSCA had higher incidences of mild developmental delay and feeding difficult than normal neonates (21% vs 0%, p = 0.061; 36% vs 20%, p = 0.264, respectively). The growth rates of body length and weight for age during the infant period were not significantly different between both groups.
Conclusions: The incidence of neonates with isolated aRSCA was low. They had smaller size at birth and some had mild developemental delay and feeding difficult, but no significant different growth rates.

P1548 - THREE-DIMENSIONAL ECHOCARDIOGRAPHY DATA IN THE AV VALVE SURGICAL ANATOMY CONSIDERATIONS IN PATIENTS WITH FUNCTIONAL SINGLE VENTRICLE

Victoria Plakhova[1], Irina Baryshnikova[1], Dmitry Kovalev [2], Ivan Yurlov[2], Timur Danilov[2]
Bakoulev Scientific Center for Cardiovascular Surgery radiology Moscow-Russia[1]; Bakoulev Scientific Center for Cardiovascular Surgery congenital heart desease Moscow-Russia[2]

Background: The atrioventricular valves regurgitation is one of the most significant risk factors worsening surgery outcomes in patients with univentricular hemodynamics. Three-dimensional echocardiography, applied since 2008 in our series, makes the anatomy of the atrioventricular valve and further intervention more clear. The goal of the study is to determine the possibility and benefits of the presurgery three-dimensional echocardiography in patients with functional single ventricle and atrioventricular valve regurgitation.
Materials and methods: An advanced transthoracic three-dimensional echocardiography systemic atrioventricular valve reconstruction protocol was applied in 43 patients with functional single ventricle of different types before or after surgery. The age of patients ranged from 3.2 to 30 yrs. The anatomy and function of the leaflets, the ring size, the degree and location of atrioventricular valve regurgitation was assessed in three-dimensional mode and compared with intraoperative data. 28 patients underwent atrioventricular valve regurgitation correction: 7 at the stage of the BCPC, 20 - at the Fontan procedure, 1 - after the Fontan procedure.
Results: All patients survived early and late after surgery. Three-dimensional echocardiography reconstruction data matched intraoperative anatomy of the atrioventricular valve in 96.5% of cases and supported preoperatively planned effective surgery. In 1 case the atrioventricular valve replacement was needed instead of the planned reconstructive surgery.
Conclusion: Three-dimensional echocardiography method allows you to get a clearer idea about the anatomy of the atrioventricular valve, his work, to determine the localization of regurgitation zones. The data obtained in most cases allow to plan upcoming volume method and the atrioventricular intervention valve. Three-dimensional reconstruction of the AV valves in patients with functional single ventricle can be recommended for inclusion in the standard echocardiographic examination protocol.

P1579 - THE EVALUATION OF PATENT DUCTUS ARTERIOSUS MORPHOLOGY IN DUCT DEPENDENT PULMONARY CIRCULATION USING THREE DIMENSIONAL COLOR FLOW ECHOCARDIOGRAPHY "ECHOCARDIOGRAM ANGIOGRAM"

Abdul Muhaimin Ahmad[1], Mazlyfarina Mohamad[2], Haifa Abdul Latif[4], Mazeni Alwi[1]
Institut Jantung Negara, PCHC, Kuala Lumpur-Malaysia[1]; Universiti Kebangsaan Malaysia, Diagnostic Imaging & Radiotherapy Programme, Kuala Lumpur-Malaysia[2]

Background: Computed Tomogram angiography (CTA) is usually performed to delineate patent ductus arteriosus (PDA) tortuosity morphology in duct-dependent pulmonary circulation (DDPC) if two-dimensional echocardiography fails to provide PDA morphology information. Recently three-dimensional echocardiography color flow (3DECF) is able to create three dimensional color object "echocardiogram angiogram" to visualize a large degree scale in a single image.
Objective: To evaluate the relationship and accuracy of 3DE color flow in the assessment of PDA size and tortuosity in comparison to CTA. Methodology: A prospective study was performed from November 2014 until November 2015. Random selection involved 26 patients with DDPC who underwent CTA for PDA assessment. All patients underwent 3DECF study within 24 hours of CTA procedure. PDA was assessed for tortuosity and size of ampulla and the pulmonary end. The 3DECF data was compared against CTA which was blinded to the operator.
Results: Offline analysis of measurement PDA size was feasible in all patients, however delineating tortuosity of PDA with suppression tissue could be determined in 25/26 patients (96%). There was no significant difference between 3DECF and CTA in measurement of size pulmonary end (0.51 mm ± 0.14; 0.52mm ± 0.11, P-value = 0.92) and ampulla PDA (0.29mm ± 0.08; 0.27mm ± 0.97, P-value = 0.5) .There was a good correlation between 3DECF and CTA in determining tortuosity of PDA (r = 0.945) with inter-rater agreement K = 0.649. The 3DECF was highly accurate in detecting curved PDA (Sensitivity 100%; Specificity 100%) than detecting tortuosity with more than two curves (Sensitivity 88%; Specificity 100%).
Conclusion: 3 DECF is comparable to CTA in delineating the PDA size and tortuosity. However, the development of microarray transducer 3DE need to be improve for less stitching effect in acquisition full volume.

P1587 - TRENDS IN THE NUMBER OF NEW CASES OF ENDOMYOCARDIAL FIBROSIS SEEN IN THE UGANDA HEART INSTITUTE A TEN YEAR REVIEW

Twalib Aliku[1], Sulaiman Lubega[2], Judith Namuyonga[2], Andrea Beaton[3], John Omagino[4], Peter Lwabi[2]
Gulu University, Paediatrics and Child Health, Gulu-Uganda[1]; Uganda Heart Institute, Paediatric Cardiology, Kampala-Uganda[2]; Children's National Health System, Paediatric Cardiology, Washington DC-United States[3]; Uganda Heart Institute, Cardiothoracic Surgery, Kampala-Uganda[4]

Background/Hypothesis: Endomyocardial fibrosis (EMF), a neglected tropical disease, has historically been an endemic disease in Uganda. Recent reports from Nigeria and India have reported a reduction in new cases, leading to the theory that EMF is a vanishing disease. There is no data on epidemiological trends of EMF in Uganda. We aimed to fill this gap, by describing the trend of new pediatric EMF cases diagnosed at the Uganda Heart Institute (UHI).
Materials and Methods: We conducted a retrospective chart review of echocardiographic reports for all patients (aged <18 years) diagnosed with EMF who were seen in the division of Paediatric Cardiology of the UHI from January 2007 to December 2016. Patients presenting for repeat follow up evaluation were excluded. All transthoracic echocardiograms were reviewed by Paediatric cardiologists.
Results: A total of 102 cases of pediatric EMF were seen at the UHI during the ten years. Males comprised 59.8% (61/102) of cases. The mean age of the study population was 11.7 years (SD 3.3 years), with the youngest patient being 16 months old. Right

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Ventricular EMF was the most common form seen in 67.6% (69/102) of patients, the remaining being cases of biventricular EMF (most of which had predominant right ventricular involvement). No case of pure LV involvement was seen. Intracardiac thrombi were seen in ten cases. Pulmonary hypertension was documented in only 4 cases (3.9%), all of whom had biventricular EMF with significant mitral regurgitation. The total annual number of new cases of EMF declined over the period (n = 17 in 2007; n = 6 in 2016, see table 1).
Conclusions: There was a progressive decline in the number of new cases of EMF diagnosed at the UHI each year during the study period. This trend is similar to that observed in some parts of the world.

Table 1. Number of New Pediatric EMF Cases by Year over the Study Period

Year	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016
EMF Cases	17	20	13	9	10	15	5	3	5	6

P1588 - CARDIAC CATHETERISATION UNDER MRI GUIDANCE USING A PARTIAL SATURATION APPROACH IN PATIENTS WITH CONGENITAL HEART DISEASE

Mari Nieves Velasco Forte[1], Sebastien Roujol[1], Kuberan Pushparajah[2], Nick Byrne[3], Israel Valverde[1], Bram Ruijsink[1], Tobias Schaeffter[4], Kawal Rhode[1], Reza Razavi[1]
King, Division of Imaging Sciences & Biomedical Engineering, London-United Kingdom[1]; Evelina London Children, Paediatric Cardiology, London-United Kingdom[2]; King, Medical Physics, London-United Kingdom[3]; King, Medical Physics and Metrological Information Technology, Berlin-Germany[4]

Background: MRI represents a promising alternative to fluoroscopy to guide cardiac catheterisation. However, simultaneous high contrast visualization of catheter, soft tissue and blood remains challenging. In this study, we evaluated a novel passive tracking sequence based on partial pre-saturation (pSAT) for MR-guided catheterization in patients with congenital heart disease.
Methods: The technique was initially tested using a 3D-printed phantom. Two patients (12 and 39 years-old) in whom an XMR was indicated for pulmonary vascular resistance assessment were recruited. Underlying diagnosis were severe right pulmonary stenosis and atrioventricular septal defect (child and adult, respectively). MR-guided catheterization was performed using a real-time single shot acquisition with bSSFP readout (TR/TE = 2.6 ms/1.3ms,flip angle = 60°, FOV = 370 × 370mm2,voxel size = 2.2 × 2.5mm2,bandwidth = 1190 Hz,SENSE factor = 2.5, partial Fourier = 0.65,acquisition time = 145ms,linear ordering). The balloon of the wedge catheter was filled with 1%Dotarem® for positive contrast visualization. A partial saturation prepulse (modified flip angle to 30°) was applyed before the acquisition of MR-images. The sequence was run in interactive mode, the imaging plane location was modified in real time using pre-programmed pedals.
Results: The balloon of the wedge catheter was clearly depicted during navigation in the phantom with the pSAT sequence(Figure 1). Right heart catheterization was performed in both patients (Figure 2). The pSAT sequence was successful to passively track the catheter and simultaneously visualize soft tissue and blood. However, in the child, the catheter lacked the stiffness required to cross the pulmonary valve, therefore the procedure was completed with X-ray support using a braided non-MRI compatible catheter over a wire. The procedure was completed solely under MRI-guidance in the adult patient. Total procedure time was 172 and 170 minutes, cardiac catheterisation time was 55 and 25 min in child and adult, respectively.
Conclusions: The proposed pSAT sequence provides simultaneous high contrast visualization of the catheter balloon, soft tissues and blood. This technique provides excellent passive tracking capabilities during MR-guided catheterization.

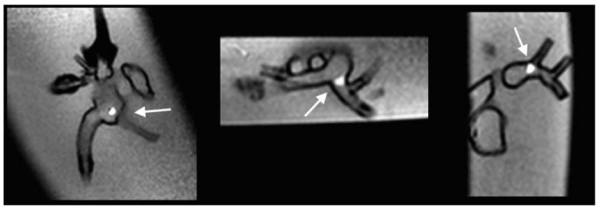

Figure 1.
Example real-time images acquired in the 3D printed heart phantom with balloon wedge catheter using the pSAT sequence. The catheter tip (arrows) could be easily tracked and visualized in different imaging plane orientations.

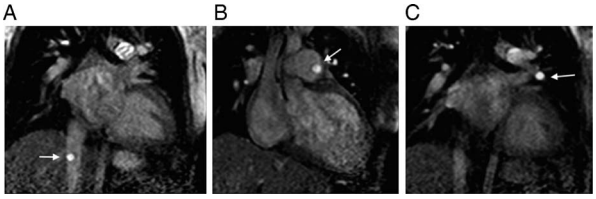

Figure 2.
Real-time images acquired in the adult patient using the pSAT sequence. Note balloon of the wedge catheter (arrows) at the inferior vena cava (A), main pulmonary artery (B) and left pulmonary wedge (C). The pSAT sequence provided excellent and simultaneous visualization of catheter tip, blood and soft tissues.

P1598 - SENSITIVITY AND SPECIFICITY OF FETAL ECHOCARDIOGRAPHY IN HIGH RISK PREGNANCIES A SINGLE CENTER EXPERIENCE FROM EGYPT

Shaimaa Rakha, Hala Elmarsfawy
Mansoura University Children Hospital, Mansoura University, Egypt, Pediatric Cardiology Unit, Mansoura-Egypt

Background: Advances in fetal Echocardiography training among pediatric cardiologists has led to improved antenatal detection of congenital heart diseases. Nevertheless, this subspecialty is still evolving in developing countries. No research has determined fetal echocardiography sensitivity and specificity in developing countries like Egypt.
Subject and Methods: Study was a retrospective analysis of pregnant females referred to cardiology unit in Mansoura university children hospital, Egypt, for fetal echocardiography according to indications of American Heart Association. All cases who fulfilled the indications and had detailed fetal and neonatal echocardiogram were included. Results of fetal and postnatal echocardiography were compared to assess sensitivity, specificity of fetal Echocardiography. Minor lesion was defined when no postnatal

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

intervention is needed and Major when postnatal intervention was scheduled.
Results: Out of 227 referred cases from January 2011 to January 2016, comparisons were possible in 164 fetuses as 63 were either dead (stillborn or terminated) or lost follow up. Mean age of ladies included in the study was 26.64 ± 5.428 years and mean gestational age at referral was 27.59 ±5.41 weeks ranging (16-39 weeks). Sensitivity and specificity calculation for fetal echocardiography were performed by comparing fetal and neonatal diagnoses. Cases had minor differences (n = 3), 2 fetuses were diagnosed as VSD but normal postnatal and one normal prenatal was proved to have mild pulmonary stenosis postnatal. Prenatal diagnosis in our study was accurate in 98.17% of cases but accuracy in diagnosing major lesions 100%. Sensitivity of fetal echocardiography in our study was 98.64% and specificity of 97.78%.
Conclusion: Fetal echocardiography is considered a sensitive and specific tool for prenatal congenital heart diseases detection even in developing country like Egypt. Obstetricians' awareness in developing countries should be raised regarding the high accuracy of fetal echocardiography in high risk pregnancies to guide antenatal and early neonatal management of congenital heart diseases.

P1609 - THE ARCHITECTURE OF THE RIGHT VENTRICULAR MYOCARDIUM CHANGES THROUGH THE CARDIAC CYCLE

Camilla Omann[1], Christoffer Laustsen[2], Vibeke E. Hjortdal[1], Peter Agger[3]
Aarhus University Hospital, Dep. of Cardiothoracic and Vascular Surgery T, Aarhus-Denmark[1]; Aarhus University Hospital, Mr Research Centre, Aarhus-Denmark[2]; Aarhus University Hospital, Dep. of Cardiothoracic and Vascular Surgery T & Dep. of Pediatrics, Aarhus-Denmark[3]

Background: Right ventricular heart failure constitutes a significant clinical challenge in several patients with congenital heart disease. Changes in the myocardial structure has recently been suggested as a contributing factor to heart failure. However, no studies have investigated the normal three-dimensional rearrangement of the cardiomyocytes through the cardiac cycle in the healthy right ventricle. In the present study, we have investigated these dynamic changes by the use of diffusion tensor magnetic resonance imaging.
Methods: 14 healthy female domestic 20 kg pigs were included. The hearts were excised and randomized to fixation in either diastole or systole. The orientation of the cardiomyocytes was quantified using diffusion tensor magnetic resonance imaging and compared between systole and diastole.
Results: From diastole to systole the orientations of the cardiomyocytes changed most pronounced in the endocardium. In both ventricles, the cardiomyocytes changed from a more circumferential orientation in diastole to a more longitudinal orientation in systole. In the right ventricle, the increase in angulation from diastole to systole was 6.45° [4.4; 8.6]° whereas this angulation change in the left ventricle was 8.2° [5.8; 10.6]°. The two ventricles differed with regards to change in transmural orientation of the cardiomyocytes. In the left ventricle, the transmural angulation increased from diastole to systole with 5.0° [4.2; 5.9]°. Cardiomyocytes located in the right ventricle showed no significant change in transmural orientation through the cardiac cycle.
Conclusion: The architecture of the entire myocardium changes through the cardiac cycle. This rearrangement is provided by continuous changes in the orientation of cardiomyocytes. The movement of cardiomyocytes is, however, different in the right and left ventricle indicating that the normal physiological remodelling of the myocardium differs between the ventricles. These results must be taken into account when assessing remodelling in the diseased myocardium, particularly in patients with right ventricular heart failure.

P1613 - ASSESSMENT OF EARLY ATHEROSCLEROSIS IN CHILDREN WITH WHITE COAT AND ESSENTIAL HYPERTENSION

Alexander Jurko[1], Tomas Jurko[2], Alexander Jurko[1], Michal Mestanik[3], Lucia Vargoncikova[1], Andrea Mestanikova[3], Ingrid Tonhajzerova[3]
Ltvsro, Pediatric Cardiology, Martin-Slovakia[1]; Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Neonatology Clinic, Martin-Slovakia[2]; Comenius University in Bratislava, Jessenius Faculty of Medicine in Martin (JFM CU), Department of Physiology JFM CU, Martin-Slovakia[3]

Introduction: Sonographic intima media thickness measurement of the carotic artery (cIMT) is considered a valid surrogate marker for cardiovascular risk allowing assessment of atherosclerotic changes at very early stage. Elevated blood pressure in adults is associated with increased cIMT. However, its effect on arterial health is less understood in a paediatric population. Thus, the aim of this study was to evaluate cIMT in adolescents suffering from essential and white coat hypertension.
Methods: One hundred thirty eight children – 46 (23 boys) children suffering from WCH, 46 (23 boys) patients with essential hypertension and 46 age/gender-matched healthy controls (age-period from 14 to 18 years) - were examined under standard conditions. The mean IMT of the carotid arteries was measured by high-resolution B-mode ultrasound (Prosound F75 Aloka).
Results: Statistical analysis revealed significant differences in the mean cIMT between the both hypertensive groups (WCH, EH) and control group (0,45 ± 0,05 mm for WCH; 0,47 ± 0,06 mm for EH vs 0,40 ± 0,04 mm; $p < 0.001$). No significant differences were found between WCH and essential hypertensive groups.
Conclusions: Our results revealed significantly higher mean cIMT in children suffering from white coat and essential hypertension indicating early atherosclerotic changes associated with increased cardiovascular risk already in adolescent hypertension. Importantly, WCH should not be considered a harmless trait and has common features with essential hypertension.
Support: VEGA 1/0087/14, project "Biomedical Center Martin" ITMS code [26220220187] co-financed from EU sources.

P1635 - MITRAL VALVE PERFORATION AMONG CHILDREN SEEN AT THE UGANDA HEART INSTITUTE A SERIES OF NINE CASES

Twalib Aliku[1], Sulaiman Lubega[2], Emmy Okello[3], John Omagino[4], Peter Lwabi[2]
Gulu University, Paeditrics and Child Health, Gulu-Uganda[1]; Uganda Heart Institute, Paediatric Cardiology, Kampala-Uganda[2]; Uganda Heart Institute, Adult Cardiology, Kampala-Uganda[3]; Uganda Heart Institute, Cardiothoracic Surgery, Kampala-Uganda[4]

Background: Mitral valve perforation is a rare complication of infective endocarditis (IE), especially in those receiving inadequate therapy. In Africa rheumatic valvular heart disease (RHD) is a major underlying cause of IE. The perforation of mitral valve worsens any pre-existing mitral regurgitation (MR) and hence is associated with increased mortality. There are few reports on mitral valve perforation from sub-Saharan Africa.
Objectives: We describe the clinical presentation and outcomes of children with echocardiographically diagnosed mitral valve

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

perforation followed up at the Uganda Heart Institute (UHI) from July 2011 to June 2013.
Methods: We reviewed the clinical and echocardiographic data of patients with mitral valve perforation, defined as MR with multiple jets, an area of echolucency on anterior mitral leaflet (AML) or perforated aneurysm on the AML.
Results: A total of nine patients were diagnosed to have mitral valve perforation, 8 being female. The median age was 12 years (range 15mo-14years). None had prior cardiac surgery, penetrating chest trauma, cardiac catheterization or radiofrequency ablation. All patients were treated for a long standing febrile illness suggestive of IE prior to cardiology referral. Blood cultures were positive in only one patient which grew Streptococcus viridans. Two patients had no predisposing heart lesion on echo, while the rest had underlying RHD. All patients had severe MR through multiple jets while one patient had additional severe aortic regurgitation. Two patients had visible vegetations on the AML. Two patients had a ruptured AML aneurysm. Four patients (44.4%) died within two months of diagnosis. None had heart surgery since this was not routinely available at UHI at the time.
Conclusion: RHD is a major underlying cause of IE and subsequent mitral valve perforation in our settings. Many patients with mitral valve perforation have high immediate mortality.

P1637 - AN ANALYSIS OF VOLUME TIME CURVES (VTC) OF THE LEFT VENTRICLE (LV) BASED ON FAST FOURIER TRANSFORMS (FFT)

Christian Winkler, Katharina Linden, Johannes Breuer, Ulrike Herberg
University Hospital Bonn, Pediatric Cardiology, Bonn-Germany

Objectives: For the measurement of LV volume, 3D real-time Echocardiography (3DRTE) has been established as an accurate and safe method. As a result, the volume can be computed and plotted as a time-dependent signal, which is defined as a VTC. The VTC allows the analysis of the systolic and diastolic function. However, these signals are difficult to analyze and process. Aim of our study is to define mathematical functions of the VTC, which allow a better quantification, assessment and comparison of the systolic and diastolic function.
Methods: In 320 healthy and 20 children with congenital heart disease, 3DRT datasets of LV were acquired using the iE33 ultrasound scanner (Philips; transducer X7-2 and X5-1). 3D datasets were segmented with ImageArena (TomTec), a semi-automatic software tool. We used Python for the following data processing. The resulting VTC was used to reconstruct the volume curve for multiple heart beats, assuming a steady state. The missing data were interpolated. We used the FFT to decompose the signal into a representative sum of trigonometric functions. For an analysis, we use the amplitude spectrum of the VTC, shown in figure 1.
Results: We successfully implemented the FFT and used it to compare the VTC of healthy and pathological hearts. In an experiment, we showed that a healthy VTC superimposed with noise can be detected in the diagram of the amplitude spectrum. The noise represents a malfunction of the heart and is modelled as sinus wave in our experiment. Consequently, the noise can be detected and methods can be adjusted to eliminate malfunctions.
Conclusions: The FFT is a crucial method to analyze VTC and to derive information how a cardiac dysfunction could be treated. The decomposition of VTC into mathematical function can be useful to customize medications, plan interventions or configure pacemakers.

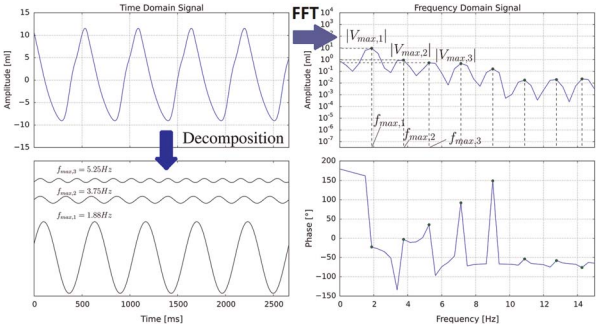

Figure.

P1644 - EVOLUTION OF BACTERIAL ENDOCARDITIS OF MITRAL VALVE IN CHILDREN UNDER ONE YEAR

Alberto Robredo
Children and Women Hospital, Cardiology, Salta-Argentina

Background: The significant insufficiency and prolapse of the mitral valve (MV) is a rare condition in infants. The early diagnosis of bacterial endocarditis (BE) in this condition requires a great clinical suspicion at this age. The objective is to show the unfavorable evolution of three cases of BE on MV with prolapse and insufficiency in children under one year.
Material and Methods: We analyzed BEs on MV in the last 5 years: 1) Male 7 months old with a history of 2 months before surgery of aorta and ductus coarctation with very good evolution. He entered with sepsis and heart failure in respirator. He was diagnosed with BE caused by wart in MV with severe insufficiency and positive blood cultures. He died due to multiorgan failure. 2) Female, 8 months old without history, enters with sepsis. Diagnosed by echocardiogram with Myxomatous MV with prolapse and severe insufficiency and a wart of more than 1 cm. Blood cultures negative. She presents cerebral embolism with severe encephalic compromise. The MV was replaced with unstable evolution and died 6 months later. The diagnosis of BE was through pathological tests of surgical samples. 3) Male, 2 months old, presents BE with positive blood cultures and wart in Myxomatous MV by echocardiogram. He presented poor evolution due to associated factors. None of them had a proved entrance.
Results: All three patients had Myxomatous MV with prolapse and severe insufficiency with unfavorable evolution of the BE despite the efforts made.
Conclusions: It is advisable a thorough exploration in infants to search insufficiency and prolapse of MV, due to the bad evolution of BE, for a further strict prophylaxis compliance.

P1671 - TRANSIENT DIASTOLIC DYSFUNCTION IN ACUTE PHASE OF KAWASAKI DISEASE WITHOUT CORONARY ARTERY LESION

Tadaaki Abe[1], Seiichi Sato[2]
Niigata City General Hospital, Pediatrics, Niigata-Japan[1]; Okinawa Prefectural Nanbu Medical Center & Children's Medical Center, Pediatric Cardiology, Okinawa-Japan[2]

Impaired left ventricular (LV) systolic function during acute phase of Kawasaki disease (KD) without coronary artery lesion has been described in some reports. Our purpose of this study is to investigate LV diastolic function in acute phase of KD. We retrospectively studied 82 KD patients admitted to Niigata City

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

General Hospital from August 2013 to December 2015. Mean age of the patients at admission was 2.8 + /- 2.1 years, and 68% were boys. All the patients underwent transthoracic echocardiography by just one echocardiographer in acute phase (AP) (10.8 + /- 2.0 days of illness) and in recovery phase (RP) (49.1 + /- 9.8 days of illness), and they were administered intravenous immunoglobulin before the first echocardiography. We compared echocardiographic measurements in AP and RP, which contained LV diastolic dimensions (LVDd) transformed to z-scores, LVEF by Pombo's equation, isovolemic relaxation/contraction time (IVRT/IVCT), total ejection isovolemic index (Tei index), the early mitral inflow velocity to interventricular septum annular early diastolic velocity (IVS E/e'), the early mitral inflow velocity to lateral mitral annular early diastolic velocity (LV E/e'), and the early tricuspid inflow velocity to tricuspid annular early diastolic velocity (RV E/e'). Differences were evaluated by t-tests and statistical significance was achieved with p value < 0.05. Ten of 82 patients had transient coronary artery dilatation, but all of the lesions were regressed. IVS E/e', LV E/e', Tei index, and IVRT were significantly increased in AP compared with RP ($p = 0.005$, $p < 0.001$, $p = 0.03$, and $p = 0.004$, respectively). There were no significant differeces in LVDd, LVEF, IVCT, and RV E/e'. In conclusion, echocardiographic parameters which indicate LV diastolic function were worse in about 10 days than 50 days of illness in KD. These paremeters of diastolic function may be more sensitive than those of systolic function in subtle myocardial injury in acute phase of KD.

P1678 - PERSISTENT PERICARDIAL EFFUSION IN A NEWBORN. A CLUE FOR EXRALOBAR PULMONARY SEQUESTRATION

Timur Meşe[1], Murat Muhtar Yilmazer[1], Rahmi Özdemir[2], Bariş Güven[3], Aysun Hacer Sritaş[4]
Izmir Dr.Behçet Uz Children's Hospital, Pediatric Cardiology, Izmir-Turkey[1]; Dumlupinar University Evliya Çelebi Training and Research Hospital, Pediatric Cardiology, Izmir-Turkey[2]; Tepecik Training and Research Hospital, Pediatric Cardiology, Izmir-Turkey[3]; Izmir Dr. Behçet Uz Children's Hospital, Pediatrics, Izmir-Turkey[4]

Introduction: Here we report an unusual case of an pulmonary sequestration diagnosed was made through persistent and localised pericardial effusion.
Case: Twenty five days-old boy reffered from neonatology outpatient clinic for the evaluation of a grade 1/6 systolic murmur. His physical cardiac examination and 12-lead-electrocardiogram was normal. Chest x-ray revealed cardiothoracic ratio with upper limit of normal and highligtened thymus. Echocardiographic examination revealed normal anatomic cardiac structure and function with an unusual local pericardial effusion on the lateral border of left ventricle (4 mm in systole and 3.6 mm in diastole). Although the child had no sign of respiratory or cardiovascular signs sent home to visit again. After a week pericardial effusion was persisting with no oblivious change in the effusion volume. His second chest x-ray was also reported by radiologist as normal. Cardiac MR was taken to visualize the detailed anatomy of cardiac structure. A MRI confirmed the slight pericardial effusion on lateral border of left ventricle. In addition consolidated inferior left lobar pulmonary area was noted and computed tomography (CT) evaluation was also suggested. A CT scan of the chest with intravenous contrast showed triangular shaped mass in the left lower lobe without pleural effusion (Figure 3. CT1). An aortic branch was directed to the extra lobar sequestrated pulmonary area (Figure 3. CT2).
Conclusions: Pulmonary sequestration has the incidence of %0.1. About %15-25 of extrapulmonary form constitude sequestration with main differential structure is having its own pleura and mostly situated on left lung. Most of the extrapulmonary sequetrations presented in neonatal period with infection or cyanosis. Localised persistent pericardial effusion must be evaluated rigoriously for the etiologial aspects especially in newborns and congenital pulmonary pathologies must be keep in mind.

P1683 - CARDIAC LIPOMA

Susana Uriel[1], Gloria Sánchez[2], Noemí Cañete[2], Dimpna Albert[1], Marc Figueras[3], Stella Pie[1], Lluís Mayol[1], Raúl Abella[4], Ferran Rosés[3]
H. Dr J. Trueta, Paediatrics, Girona-Spain[1]; H. Dr J.Trueta, Radiology, Girona-Spain[2]; H. Vall Hebrón, Paediatrics, Barcelona-Spain[3]; H. Vall Hebrón, Cardiac Surgery, Barcelona-Spain[4]

Background: Cardiac lipomas are uncommon benign primary cardiac neoplasms. Typical locations are the endocardium of the right atrium and the left ventricle. They are usually asymptomatic but symptoms, when present, depend on the location within the heart and the tumor's size. Diagnostic modality of choice is cardiac MRI. Treatment guidelines have not yet been established due to the very low prevalence of these tumors and are thus guided by the patient's symptomatology.
Materials and Methods: We present a case of a twelve year old boy with a non invasive and asymptomatic cardiac lipoma which was detected as an electrocardiogram anomaly. An echocardiogram performed which revealed an hyperechoic mass on the left side of interventricular septum (see Figure 1). Then a cardiac MRI was performed for better tissue characterization The MRI revealed a long, fat containing mass next to the interventricular septum, without extension or invasion into other cardiac parts. The mass appeared to represent a lipoma base on its imaging characteristics (see Figure 2).
Results: The case was discussed by a team of cardiologists and cardiacs surgeons, which recommended to the family wait and see due to the lack of in the patient symptoms, and the high biopsy risk based the tumor's location. No increase in tumor size was detected in the following cardiac MRI and no arrhythmias appeared on the follow up (one year). The patient is still asymptomatic.

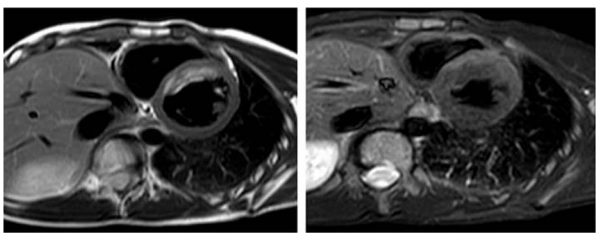

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: Cardiac lipomas are rare benign tumors of the heart which are usually asymptomatic. Diagnostic modality of choice is cardiac MRI. Treatment guidelines have not yet been established, but are guided by the patient's symptomatology. Follow up is recommendable.

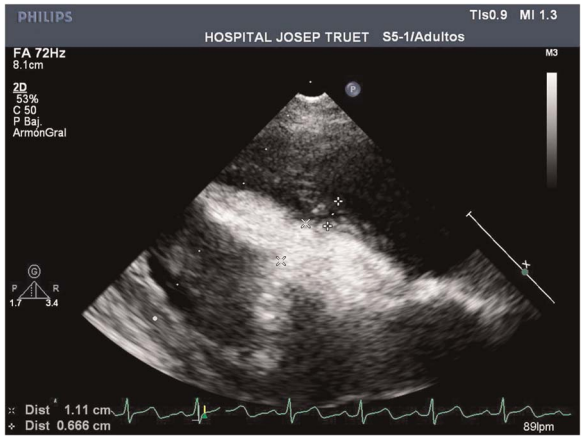

Figure 2.

P1687 - RIGHT CERVICAL AORTIC ARCH PRESENTING WITH A PULSATILE NECK MASS IN A CHILD

Murat Muhtar Yilmazer[1], Timur Meşe[1], Rahmi Özdemir[2], Bariş Güven[3]
Izmir Dr. Behçet Uz Children's Hospital, Pediatric Cardiology, Izmir-Turkey[1]; Dumlupinar University Evliya Çelebi Training and Research Hospital, Pediatric Cardiology, Kütahya-Turkey[2]; Tepecik Training and Research Hospital, Pediatric Cardiology, Izmir-Turkey[3]

Case: A 9-year-old Syrian girl was referred to our pediatric cardiology clinic for evaluation of a pulsatile neck mass. She has been examined for Turner Syndrome due to short stature but chromosomal analysis demonstrated a 46 chromosomes present, and the XX. Physical examination revealed a prominent pulsation above the right sternoclavicular area.A systolic murmur, grade 1/6, in the aortic position was heard. Transthoracic echocardiography (TTE) revealed normal ventricular morphology and functions and tricuspid aortic valve with no regurgitations or stenosis. However images of the aortic arch could not be obtained with the usual suprasternal angulation. We were able to demonstrate the aortic arch by angulation of the probe slightly to the right. However branching of the aortic arch could not be demonstrated clearly. As TTE was insufficient for determination of detailed configuration of the aortic arch, cardiac catheterization and angiography were performed. Aortography in left lateral position demonstrated a high-lying aortic arch extending cranially to the toracic aperture (figure 1A). Normally the aortic arch lies behind the lower part of the manubrium sterni and does not exceed to the sterno-clavicular joint. In this case, a portion of the ascending aorta and the aortic arch exceeded the sterno-clavicular angle and extended to the neck. An angulation which was not create any obstruction in the aortic lumen shown in the descending aorta. Although the branching pattern of the aorta was usual, all 3 branches were thinner than normal (figure 1B). Pressure gradient were recorded in 3 major branches and no stenosis was detected. Computed tomographic angiography revealed a right cervical aortic arch extending to the neck and turned downward on itself to become the descending aorta which was the cause of angulation in descending aorta detected by angiography (figure 1C and 1D).

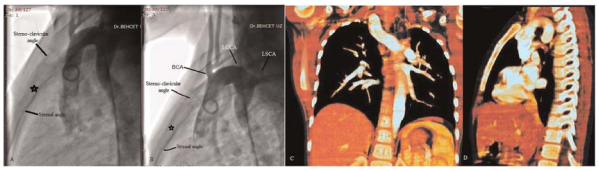

Figure.

P1690 - CHRONOLOGICAL SERIAL CHANGES OF SYSTOLIC AND DIASTOLIC FUNCTION BY USING TISSUE DOPPLER IMAGING (TDI) IN HEALTH NEONATES WITHIN THE FIRST 3 DAYS OF LIFE

Kee Soo Ha, Eun Hee Lee, Jeong Hee Shin, Hyun Joo Cho, Byung Min Choi, Gi Young Jang, Chang Sung Son
College of Medicine, Korea University, Pediatrics, Seoul-Korea, South

Background: Several significant hemodynamic changes by closure of PDA take place during transition from the fetal to neonatal environment. There are many echocardiographic researches assessed by TDI during transitional period but they have not represented serial changes during immediate postnatal period within 48 hours after birth. The goal of the present study was to evaluate delicate echocardiographic serial changes assessed by TDI parameters within 48 hours after birth in full term infants.
Materials and Methods: One-center, prospective, observational longitudinal cohort study in healthy newborns. They underwent standard echocardiography and TDI from 12 to 72 hours after birth and followed at 12 hours intervals during the first 3 days of life. Chronological cardiac morphometry, functional systolic and diastolic parameters including TDI were measured in LV and RV.
Results: 56 infants were measured serially two or three times with 12-hour interval. Changes of aortic VTI, closure of PDA, LV CO, MV and TV diastolic parameters, RV TDI E', A' and S', LV MPI and RV MPI, LV and RV EDV showed significant or insignificant differences between postnatal age before and after 24 h.
Conclusions: It is meaningful that our study departmentalized basic data of immediate changes of cardiac morphometries, functional, diastolic parameters, and TDI within postnatal 72 hours. Two parameters of postnatal age 24 h and PDA closure have an important effect on cardiac changes during immediate transitional period.

P1696 - PREDICTING THE NEED FOR SURGICAL REPAIR OF PRENATALLY DIAGNOSED COARCTATION OF THE AORTA

Conall Morgan[1], Brigitte Mueller[2], Callaghan Jull[1], Luc Mertens[1], Mark Friedberg[1], Vitor Guerra[1], Ra Han[1], Varsha Thakur[1], Mike Seed[1], Edgar Jaeggi[1], Cedric Manlhiot[2], Lynne Nield[1]
The Hospital for Sick Children, Labatt Family Heart Centre, Toronto-Canada[1]; University of Toronto, Cardiovascular Data Management Centre, Toronto-Canada[2]

Background: In prenatally diagnosed coarctation of the aorta, it is difficult to predict which neonates will require early surgical intervention.
Methods: From January 2005 to December 2015 fetal cases referred for suspected coarctation were reviewed. Patients with an apex forming left ventricle with antegrade flow across the mitral and aortic valves were included for analysis.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: A total of 110 patients were identified. 3 patients (3%) suffered in-utero demise. Median gestational age at diagnosis was 31 weeks (IQR 23-35 weeks). Postnatally, 47 patients (44%) underwent a biventricular repair, 56 patients (52%) required no intervention and 4 patients (4%) underwent a staged biventricular repair. Area under the curve was 0.9013. In univariate analysis a hypoplastic transverse arch (OR 4.33 [1.92-10.3], p = 0.001), an increase in LVOT peak Doppler (OR 1.02 [1-10.3], p = 0.03), and an increase in pulmonary valve z-scores (OR 1.61 [1.18-2.32], p = 0.005) increased the odds of requiring postnatal surgical repair significantly. An increased isthmus diameter (OR 0.23 [0.11-0.42]/mm, p = < 0.001), arterial duct diameter (OR 0.64 [0.48-0.84]/mm, p = 0.002) and increased aortic (OR 0.72 [0.54-0.94/z, p = 0.02), mitral (OR 0.58 [0.42-0.78]/z, p = 0.001) and ascending aorta (OR 0.52 [0.38-0.7]/z, p < 0.001) z-scores significantly decrease the odds of requiring surgery postnatally in the univariate analysis. In multivariate analysis, an increase in LVOT peak Doppler (OR 1.05 [1.03-1.09]/cm per sec, p = < 0.001) increases the odds of requiring a surgical repair, while an increase in ascending aorta z-score (OR 0.60 [0.40-0.84]/z, p = 0.005) significantly decreases the odds of requiring a surgical repair postnatally.
Conclusions: Peak LVOT Doppler and ascending aorta z-score can help in predicting which fetuses will require early surgical intervention.

P1704 - MYOCARDIAL FISTULISATION AND CORONARY ARTERIAL ECTASIA IN CHILDREN WITH UNIVENTRICULAR CIRCULATION – AN UNDER RECOGNISED PROBLEM

Daragh Finn[1], Kevin Walsh[1], David Roberson[2], Colin Mcmahon[1]
OLCHC, Crumlin, Cardiology, Dublin-Ireland[1]; Advocate Christ Hospital and Medical Center, Oak Lawn, Il 60453, Cardiology, Naperville-United States[2]

We describe three children, each with a univentricular circulation, who had evidence of diffuse fistulisation of the myocardium at cardiac catheterisation. One of the children had documented normal coronary arteries and myocardium at catheterisation prior to development of the fistulisation process. The same child also developed extensive veno-venous collaterals. All children had evidence of elevated pulmonary arterial pressures and were treated with a combination of sildenafil and bosentan pulmonary vasodilators. The presence of chronic hypoxaemia, elevated filling pressures and the use of pulmonary aterial vasodilators could potentially have contributed to coronary endothelial dysfunction, thereby giving rise to the coronary vasculopathy. This may necessitate early referral for orthotopic cardiac transplantation. Diffuse fistulisation of the myocardium in children and young adults with univentricular circulation may be an under-recognised occurrence and coronary angiography should be considered in these patients.

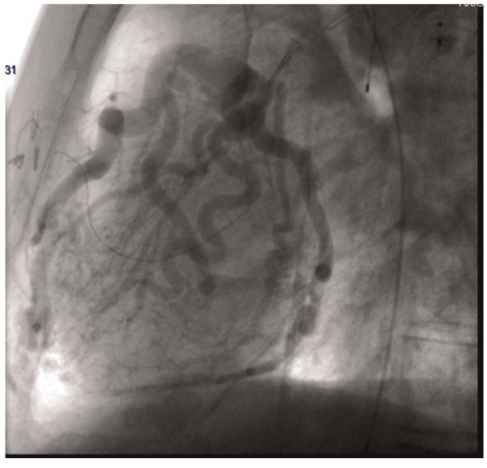

Figure.

P1715 - CARDIAC MAGNETIC RESONANCE AS A FOLLOW UP TOOL IN PATIENTS WITH GIANT CORONARY ARTERY ANEURYSMS SECONDARY TO KAWASAKI DISEASE IN A MEXICAN POPULATIO

Martha Maria Esparza-Jimenez Moran[1], Luis Martín Garrido-García[2], Roberto Cano-Zarate[3], Aloha Meave[3], Patricia Cravioto-Quintana[4]
Instituto Nacional De Pediatría, Pediatrics, Mexico City-Mexico[1]; Instituto Nacional De Pediatría, Cardiology, Mexico City-Mexico[2]; Instituto Nacional De Cardiología, Cardiac Mri, Mexico City-Mexico[3]; Instituto Nacional De Pediatría, Teaching Department, Mexico City-Mexico[4]

Background: Kawasaki's disease (KD) is an infancy systemic vasculitis that without treatment is associated with coronary abnormalities and cardiovascular damage in nearly 25% of the cases. Prognosis is directly related to the presence and severity of the coronary lesions. Cardiac Magnetic Resonance (CMRI) is a non-invasive tool used for an accurate determination of cardiac function in several pathologies.
Objective: To describe the findings in Cardiac MRI as an anatomic and functional evaluation in the long-term follow-up of patients with a history of KD and giant coronary aneurysms.
Material and Methods: Cross-sectional, observational and descriptive study of patients with history of KD and giant aneurysms (z-score >10) treated in the Instituto Nacional de Pediatria in Mexico City, Mexico from August 1995 to June 2015.
Results: We performed a CMRI in 23 patients with a mean age of 104.7 months (range 24 to 192 months). Mean time between diagnosis of KD and the cardiac MRI was 83.16 months. 16 patients were male (70%). We found abnormalities in the CMRI in 18 patients, with presence of coronary artery aneurysms in 12 cases. The ventricular function was abnormal in 12 cases, including 2 patients without coronary artery lesions.
Conclusions: CMRI is a useful tool in the follow-up in patients with KD showing not only the presence of coronary abnormalities, but also provides functional evaluation that could be present in patients without coronary aneurysms.

P1722 - CARDIAC MAGNETIC RESONANCE IN LONG TERM FOLLOW UP FOR TETRALOGY OF FALLOT CHILEAN EXPERIENCE

Francisca Arancibia-galilea[1], Paulo Valderrama[1], Gonzalo Urcelay[1], Pedro Becker[2], Rodrigo González[2], María Elisa Castillo[1], Rodrigo Parra[3]
Pontificial Catholic University of Chile, Cardiology And Respiratory Disease, Santiago-Chile[1]; Pontificial Catholic University of Chile, Cardiovascular Disease, Santiago-Chile[2]; Pontificial Catholic University of Chile, Radiology, Santiago-Chile[3]

Background: Tetralogy of Fallot (ToF) is the most common cyanotic congenital heart disease. Surgically repaired patients may present long-term complications: pulmonary regurgitation (PR) and right ventricle (RV) enlargement and dysfunction, amongst others. Cardiac magnetic resonance (CMR) is the gold standard for RV evaluation, but it is not widely available in our country.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Objective: Describe CMR results in long-term follow-up of our ToF population that has no undergone pulmonary valve replacement (PVR).
Materials and Methods: All CMR performed at our institution between 2007 and 2012 in repaired ToF patients with no PVR were included. Pulmonary valve regurgitant fraction (RF), ventricular end diastolic (EDV) and systolic volumes (ESV), and ejection fraction (EF) were examined.
Results: 122 CMR were performed in 114 patients (59% male). Mean age at CMR was 15.4 ± 7.4 yo. Median age at surgery was 12.2 months-old (2-27 months-old). 78% of patients received transannular patch (TAP) and 22% underwent pulmonary valve-sparing repair. Severe PR (RF > 40%) was present in 53.3%. RVEDV was 157.3 ± 38.6 ml/m2 and RVESV was 85.3 ± 27 ml/m2 (median ± SD). RVEDV was >150 ml/m2 in 48.4% and >170 ml/m2 in 32.8% of patients. Patients with TAP showed larger RV volumes compared with those without TAP: RVEDV 165.6 ± 39.5 vs 133.6 ± 30.7 ml/m2 ($p < 0.01$) and RVESV 90 ± 27.7 vs 73.3 ± 24.8 ml/m2 ($p < 0.02$). Mean RVEF was 46.4 ± 7.1% and left ventricle EF 55.8 ± 7.6%. Systolic dysfunction was seen in 43.7% of patients for RV and 35.2% for LV. There was no difference in RVEF nor LVEF regarding surgical technique. Patients with RVEDV >170 ml/m2 showed worse RVEF that those with smaller RVEDV (47.9 ± 7% vs 43.2 ± 6.4%, $p < 0.01$).
Conclusions: Almost half of patients showed significant RV enlargement, demonstrating that our population is having CMR late in their follow-up. TAP was associated with larger RVEDV and RVESV, but no worse RVEF in this cohort. Larger RVEDV was associated with worse RVEF.

P1750 - ECHOCARDIOGRAPHIC FINDINGS IN CHILDREN WITH CONGENITAL ZIKA VIRUS

Lúcia Maria Vieira De Oliveira Salerno[1], Carolina Vieira De Oliveira Salerno[2], Mônica Becker[3], Luzia Kayne Sousa Carneiro Frota[3], Álvaro Monteiro Perazzo[2], Juliana Vieira De Oliveira Salerno[4], Pedro Rafael Salerno[5], Pedro Rafael Vieira De Oliveira Salerno[6], Liana Ventura[7], Camila Ventura[8]
FAV, Echocardiography, Recife-Brazil[1]; UFPE, Student, Recife-Brazil[2]; UFPE, Echocardiography, Recife-Brazil[3]; FCMPB, Student, João Pessoa-Brazil[4]; Esperança Hospital, Cardiovascular Surgery, Recife-Brazil[5]; , Student, Recife-Brazil[6]; FAV, Pediatric Ophtalmology, Recife-Brazil[7]; FAV, Ophtalmology, Recife-Brazil[8]

Background/Hypothesis: The Zika virus (ZIKV) is an arbovirus, transmitted mainly by mosquitoes of the genus Aedes. An increase in children born with microcephaly was noted in 2015 in regions of Brazil with high transmission of ZIKV, particularly the northeast. Several malformations were reported in babies born with congenital ZIKV in the country since. The need to verify the virulence of Zika as the pivot of cardiac changes in children born with microcephaly was noted.
Methods: In this study, 40 infants clinically diagnosed with ZIKV-related microcephaly (cephalic perimeter <32 cm), were submitted to echocardiography (ECHO). Those with microcephaly of other known cause or presented debilitation culminating in failure to perform the ECHO were excluded.
Results: From the children with presumed or confirmed congenital ZIKV examined, there were 22 females. The mean age was 6.79 month (range 3 to 10 months). The cephalic perimeter at birth range from 25 to 32 cm - mean 28.5 cm. The gestational age of maternal ZIKV infection in 21 patients was the first trimester of pregnancy, 10 in the second and 4 in the third, 4 mothers were unable to report the period of infection. Thirty-six mothers referred symptoms during pregnancy such as fever (18), exanthema (36), arthralgia (20), myalgia (17), headache (19), cough (4) and conjunctival hyperemia (12). Regarding the ECHO exam, 12 patients had patent foramen ovale (PFO), 3 had small ostium secundum interatrial communication (ASD), one small patent ductus, one ventricular muscular septal defect (VSD) that closed spontaneously and 23 had normal ECHO.
Conclusions: Among children evaluated in this data, there was no association between ZIKV and complex congenital heart diseases. The echocardiographic findings were small defects without hemodynamic repercussions.

P1776 - SUBCLINICAL LEFT VENTRICULAR DYSFUNCTION IN JUVENILE DERMATOMYOSITIS PATIENTS A TWO DIMENSIONAL SPECKLE TRACKING ECHOCARDIOGRAPHIC STUDY

Maria De Fátima Diniz[1], Adriana Sallum[2], Gabriela Leal[1], Katia Kozu[2], Nadia Aikawa[2], Alessandro Lianza[3], Clóvis Silva[2]
Instituto Da Criança Do Hospital Das Clínicas Da Universidade De São Paulo, Ecocardiografia, Santo André-Brazil[1]; Instituto Da Criança Do Hospital Das Clínicas Da Universidade De São Paulo, Reumatologia, São Paulo-Brazil[2]; Instituto Da Criança Do Hospital Das Clínicas Da Universidade De São Paulo, Ecocardiograma, São Paulo-Brazil[3]

Background: Little is known about left ventricular (LV) function in pediatric patients with juvenile dermatomyositis (JDM), especially in asymptomatic individuals with preserved ejection fraction (EF). The study aimed to identify subclinical LV systolic and diastolic dysfunction in JDM using two-dimensional speckle-tracking echocardiography (2DST).
Methods: 20 consecutive JDM patients without cardiac symptoms were enrolled between July to December 2016. A control group included 20 healthy volunteers (informed consent was obtained).
Results: Patients and controls had similar sex and age. Median of JDM duration was 7(0-16) years and 5/20 (25%) had active disease, as defined by PRINTO criteria (2012). The median Myositis Damage Index (MDI) severity score was 0 (0-0.142) and the median MDI extent score was 0 (0-0.209). Conventional echo revealed preserved LV EF (≥ 55%) in all individuals, although values were lower in JDM (65 ±5.28%x75 ± 5.43%; $p = 0.005$). LV diastolic function parameters were similar. In the JDM group, 2DST identified significant reduction of LV peak systolic longitudinal strain (-18.2 ± 3.35%x-23.2 ± 3.45%; $p < 0.0001$) and strain rate (-1.1 ± 0.32 s-1x-1.35 ± 0.27 s-1; $p = 0.039$) and lower longitudinal strain rate in early diastole (1.63 ± 0.37s-1 × 1.97 ± 0.62 s-1; $p = 0.047$). LV peak systolic circumferential strain and strain rate and circumferential strain rate in early diastole were not different. There was a negative correlation between creatine-phosphokinase (CPK) levels and LV peak systolic longitudinal strain ($r = -0.5$; $p = 0.023$). Patients with a MDI severity score >0.027 showed lower LV peak systolic longitudinal strain than those with MDI ≤0.027 (-15.34 ± 3.3%x-19.14 ± 2.87%; $p = 0.024$).
Conclusions: LV longitudinal 2DST derived strain was able to detect early systolic and diastolic dysfunction in pediatric JDM patients. LV peak systolic longitudinal strain impairment seems to correlate with muscular damage and CPK levels.

P1780 - INTRACARDIAC ECHOGENIC FOCI REVISITED

Jaheedah Roane[1], Timothy Lee[2], Diane Reformina[1], Zhanna Rotyman[1], Puneet Bhatla[1], Achiau Ludomirsky[1]
New University Langone Medcial Center, Pediatric Cardiology, New York-United States[1]; New University Langone Medcial Center, Cardiothoracic Surgery, New York-United States[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background/Hypothesis: The clinical importance of intracardiac echogenic foci(ICEF)on prenatal ultrasound remains debatable amongst pediatric cardiologists and obstetricians. It has previously been discredited as a marker of triploidy and no clear association with congenital heart disease (CHD) has been established. Yet it continues to be a frequent reason for referral for fetal echocardiogram. The aim of this study was to assess the presence of CHD in patients with ICEF and to determine if it represents echocardiographic artifact. We hypothesized that there is no significant association between ICEF and CHD and that ICEF represents echocardiographic artifact.
Materials and Methods: The institutional fetal echocardiography database was retrospectively searched for reports containing the diagnosis of echogenic focus from November 2014-November 2016. Each study was evaluated by a single reviewer. The presence of ICEF in the 3 standard views analogous to the apical 4 chamber, parasternal short axis, and parasternal long axis views was recorded. In addition, the presence of CHD, pericardial effusion, and/or fetal arrhythmia for each study was documented. Statistical analysis was performed using cross-tabulation with chi-square analysis.
Results: 55 patients, yielding 145 studies were reviewed. 6 patients (10.9%) had CHD, which included VSD(n = 3), PA/VSD(n = 2), and vascular ring(n = 1). ICEF was noted in all 3 views in 33 studies(23%), in 2 views in 45 studies(31%), in 1 view in 22 studies (15%), and resolved in 45 studies (31%)(see table). Of those studies with ICEF noted in all 3 views, 19%(n = 6) were associated with CHD, indicating a significant association in this highly selective population ($p = 0.039$).
Conclusions: There is a higher incidence of CHD in fetuses with ICEF compared to the general population. The presence of ICEF was more likely to be identified in multiple views, suggesting it is unlikely echocardiographic artifact.

P1787 - CHARACTERIZATION OF CARDIAC TUMORS IN CHILDREN BY CARDIAC MAGNETIC RESONANCE

Paulo Valderrama[1], Constanza Galleguillos[1], Rodrigo Parra[2]
Pontificial Catholic University of Chile, Cardiology and Respiratory Disease, Santiago-Chile[1]; Pontificial Catholic University of Chile, Radiology, Santiago-Chile[2]

Introduction: Cardiac tumors are rare in childhood, with a prevalence of 0.0017 to 0.28% in autopsy series. In most cases the diagnosis is established by echocardiography, however, the ability to define the extent and determine the type of tumor is limited. The aim of this study is to analyze the clinical utility of cardiac magnetic resonance (CMR) in patients referred for a probable diagnosis of cardiac tumor.
Methods: Retrospective study. All CMR performed between 2002 and 2016 with a suspected diagnosis of cardiac tumor in the Clinical Hospital of the Pontifical Catholic University of Chile were included. The tests were performed for tissue characterization with sequences T1 and T2-weighted, STIR and T1W with fat suppression before and after administration of gadolinium intravenously; multi-plane cine sequences including ventricular function study; phase contrast flow measurements, angio-resonance, perfusion studies and myocardial viability.
Results: A total of 1,091 CMR studies were performed. In 2.8% (31) the diagnosis was cardiac tumor. The median age at diagnosis was 3 years (range 4 days - 15 years). 55% were women. 32.3% were rhabdomyomas, 25.8% fibromas, 16.1% malignant, 12.9% vascular and 12.8% others (thrombi, papillary fibroelastoma and myxoma). There was 100% concordance between CMR and biopsies performed.
Conclusions: The findings in our series are similar to those described in the literature. CMR is very useful in the evaluation of cardiac tumors, because in the majority of the cases determines its etiology through tissue characterization. In addition, it accurately defines the location, extent, borders of the tumor and the functional impact either secondary to the involvement of cardiac structures or to obstructive phenomena.

P1789 - BIVENTRICULAR IMPACT OF MILD TO MODERATE PULMONARY VALVE STENOSIS IN FETAL LIFE

Laura Guirado[1], Fàtima Crispi[1], Narcís Masoller[1], Mar Bennasar[1], Edda Marimón[1], Iris Soveral[1], Juan Carretero[2], Josep Maria Martinez[1], Mark Kevin Friedberg[3], Olga Gómez[1]
BCNATAL - Barcelona Center For Maternal-Fetal and Neonatal Medicine (Hospital Clínic and Hospital Sant Joan De Déu), Barcelona University, Fetal Medicine Unit, Barcelona-Spain[1]; Hospital Sant Joan De Déu, Barcelona University, Pediatric Cardiology, Barcelona-Spain[2]; Hospital For Sick Children And University of Toronto, The Labatt Family Heart Center. Division of Cardiology, Toronto-Canada[3]

Background: Pulmonary valve stenosis (PS) represents a common cardiac defect. There is limited information on fetal cardiovascular changes associated with PS. Such information may be valuable to improve prenatal counseling and postnatal management.
Methods: A comprehensive echocardiography including morphometric and functional parameters was performed on 16 fetuses with isolated PS and 48 controls matched by gestational age at scan (+ /- 2 weeks). Cases were follow-up until 12 months of life. Fetal PS-cases were grouped according to the need of postnatal pulmonary valvuloplasty (PV).
Results: The study groups were similar in fetal ultrasound and perinatal characteristics. Median gestational age at PS diagnosis was 33.4 weeks (range 20.0-36.5) and most cases corresponded to mild and moderate PS. Six newborns required performing a postnatal PV. Fetuses with PS presented with larger and more globular hearts with increased myocardial wall thickness (Figure 1). Despite preserved RV systolic function, PS-cases showed increased biventricular cardiac output (CO) and signs of diastolic dysfunction, with higher ductus venosus pulsatility index (0.72 ± 0.31 vs. 0.53 ± 0.16, $p < 0.004$) and tricuspid E/E´ratio (7.52 ± 3.07 vs 5.76 ± 1.79, $p < 0.02$). Fetuses with PS displayed a compensatory increase in left ventricular (LV) ejection fraction ($79.3 \pm 8.23\%$ vs. $67.6 \pm 11.3\%$, $p < 0.003$) and mitral annular-plane systolic excursion (5.94 ± 1.38 mm vs. 5.0 ± 1.22 mm, $p < 0.03$). Finally, fetuses requiring a postnatal PV showed a significantly smaller RV and

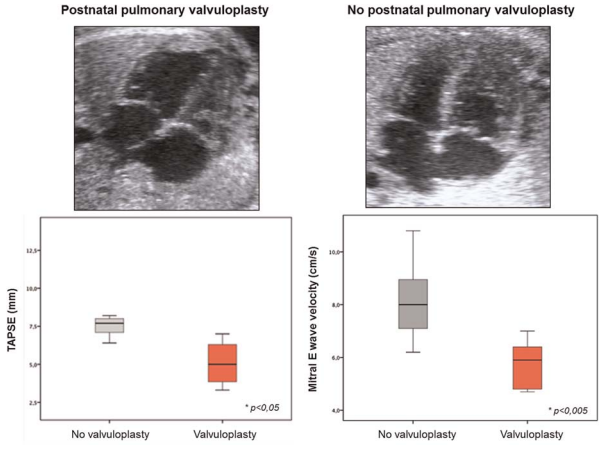

Figure.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

pulmonary valve diameter, reduced tricuspid annular-plane systolic excursion, increased LV CO and more pronounced signs of LV diastolic dysfunction.
Conclusions: fetuses with PS presented with more hypertrophic, larger, and globular hearts at third-trimester of pregnancy associated with a higher biventricular CO, impaired biventricular relaxation and signs of increased LV systolic function. Our data suggest that RV and LV functional parameters could be useful for predicting the need for.

P1795 - IDENTIFYING SICKLE CELL ANEMIA PATIENTS WITH PULMONARY HYPERTENSION USING 2D SPECKLE TRACKING STRAIN MEASUREMENTS

Mark Michael[1], Ashwin Karanam[1], Shalu Narang[2], Ela Roman[1], Rowan Walsh[1]
Children's Hospital of New Jersey, Pediatric Cardiology, Newark-United States[1]; Children's Hospital of New Jersey, Pediatric Hematology, Newark-United States[2]

Background: Sickle cell anemia (SCA) is a common hemoglobinopathy. Pulmonary hypertension (PH) is a known complication of SCA and can contribute to premature death. Continuous wave spectral Doppler interrogation of the tricuspid regurgitation (TR) jet is used to estimate pulmonary artery pressure (PAP). Limited echocardiographic acoustic windows or the absence of TR may preclude estimation of PAP. 2D speckle tracking right ventricle strain offers a unique tool to assess changes in ventricular performance and therefore may allow identification of patients with such changes secondary to pulmonary hypertension. The present study evaluates global longitudinal strain (GLS) imaging in SCA patients with and without pulmonary hypertension.
Methods: Thirty-eight patients with SCA were included in the study. Twenty-one patients with TR velocities greater than 2.5 m/s were compared to seventeen age-matched patients with normal estimated PAP. GLS of the right and left ventricles was assessed. Non-parametric analysis was performed using Mann Whitney U test.
Results: The group without pulmonary hypertension ($N = 17$) had a median RV strain of -16.2 and an interquartile range (IQR, or the 75th percentile – 25th percentile) of 4.70. The group with pulmonary hypertension ($N = 21$) had a median RV strain of -12.7 and IQR of 6.43. These median values were significantly different ($U = 75$, $p = 0.002$). There was no difference in LV strain values between the two groups.
Conclusions: Global RV strain values are significantly lower in SCA with PH compared to SCD patients with normal estimated pulmonary pressure. RV GLS can be performed during echocardiographic evaluation of SCA patients for PH and may have utility in identifying such patients when there is inadequate TR to estimate PAP. Ranges of RV and LV GLS in patients with hemoglobinopathies continue to be established.

P1806 - CARDIAC MAGNETIC RESONANCE IMAGING AND ECHOCARDIOGRAPHIC PREDICTORS OF SINGLE VERSUS BIVENTRICULAR REPAIR IN A LARGE COHORT OF PATIENTS WITH WELL FORMED VENTRICLES AND COMPLEX GREAT ARTERIAL RELATIONS

Hannah Bellsham-Revell[1], Michael Harris[2], Meryl Cohen[2], Mark Fogel[2]
Evelina London Children, Paediatric Cardiology, London-United Kingdom[1]; Children, Paediatric Cardiology, Philadelphia-United States[2]

Background: Decision-making regarding single (SV) or biventricular(BV) repair can be challenging. Areas of concern include valvular function and the potential route for baffling the proposed systemic ventricle to the aorta. We present a cohort of these patients, assessed by cardiac magnetic resonance (CMR) and echocardiography prior to decision-making.
Materials and Methods: Patients with complex ventriculoarterial connections, referred for CMR assessment (August 2005-October 2016) to aid in determining SV versus BV repair were identified. Demographics, procedures and clinical course were recorded, as well as volume and vascular data from CMR and echocardiogram closest to the time of CMR. MRI volumes were measured both with hypothetical baffle closure of the ventricular septal defect (VSD) as well as imaginary closure of the defect as a continuation of the septum.
Results: Forty-seven CMR scans(forty patients) were identified. Ten scans in 8 patients were excluded(1 death pre-definitive surgery, 7 surgery awaited). Twenty-one patients underwent SV palliation and 16 BV. There was no significant difference in the great vessel arrangement between the two groups, but heterotaxy syndrome was significantly associated with SV palliation (SV 47.4%, BV 14.3%, $p = 0.035$) as was non-committed VSD or a partial/complete canal defect (SV 47.5%, BV 7.1%, $p = 0.011$). VSD size was not significantly different. There were no significant differences between the groups in CMR volumes or changes in CMR volumes with virtual baffle, although the change in the right ventricular end-diastolic volume approached significance (SV -15%, BV -9%, $p = 0.085$).
Conclusions: There were no significant differences between patient groups in CMR volumetry, although patients with severely hypoplastic ventricles may have already been selected for a SV pathway. Presence of heterotaxy or a non-committed or canal-type defect were predictors of SV pathway. The size of the VSD was not significantly different, suggesting that position rather than size of the VSD is more important.

P1832 - INTRAVENTRICULAR KINETIC ENERGY IN HEALTHY CHILDREN AND IN THOSE WITH HYPOPLASTIC LEFT HEART SYNDROME

James Wong, Radomir Chabiniok, Adelaide De Vecchi, Bram Ruijsink, Kuberan Pushparajah, Tobias Schaeffter, Reza Razavi
Kings College London, Imaging Sciences, London-United Kingdom

Background: In hypoplastic left heart syndrome (HLHS) the right ventricle (RV) performs as a systemic ventricle, however the adaptation is incomplete. Patients experience early circulatory failure and those with the largest left ventricle (LV) remnants have poorer outcomes. Intra-cardiac kinetic energy (KE) differs between the healthy LV and RV and is sensitive to changes in systolic and diastolic function. We compared intra-cardiac KE in healthy children to those with HLHS to study the energetic limits imposed on the systemic RV and how residual LV size affects the KE profile.
Methods and Methods: 4D flow MRI was acquired in 8 healthy children (1-16 years) and 30 children with HLHS (1-16 years) undergoing clinical MRI (15 HemiFontan, 15 Fontan). Intraventricular KE was measured throughout the cardiac cycle and indexed to ventricular volume. LV remnant was grouped into shape (slit-like or globular) and size (median volume = 2.4mls).
Results: Two intra-cardiac KE peaks were present reflecting systole, and the fused inflow of early diastole. The healthy LV displayed a larger diastolic peak compared to the healthy RV ($p < 0.05$). Compared to the healthy RV those with HLHS had a similar diastolic peak in the presence of preserved function, but

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

despite increased mass ($p < 0.001$) and volume ($p < 0.05$). No differences emerged between stages of surgery. Globular shaped LV remnants had the lowest RV diastolic KE compared to slit-like LV remnants ($p = 0.005$). This was also related to the size of the LV remnant with lower KE seen in those with larger median LV size (LV >2.4mls; $p = 0.016$).
Conclusions: In HLHS, the RV displays incomplete physiological adaptations to its role as a systemic ventricle with diastolic KE limited by the inherent RV morphology. This is further influenced by larger, globular LV remnants acting as stiff piggy-back ventricles with adverse effects on diastolic momentum.

P1864 - INITIAL EXPERIENCE IN THE USE OF CARDIAC MAGNETIC RESONANCE IN THE EVALUATION OF THE BORDERLINE LEFT VENTRICLE

Constanza Galleguillos[1], Claudia Trincado[1], Paulo Valderrama[1], Rodrigo Parra[2]
Pontificial Catholic University of Chile, Cardiology and Respiratory Disease, Santiago-Chile[1]; Pontificial Catholic University of Chile, Radiology, Santiago-Chile[2]

Introduction: The definition of left ventricular (LV) hypoplasia is based on the presence of a left ventricle unable to sustain the systemic circulation. Intermediate forms, called the borderline LV, represent a challenge during the neonatal period because its evaluation will determine the biventricular or univentricular repair, with important implications for the prognosis. As a complementary study, the use of cardiac magnetic resonance (CMR) has been increasing due to its ability to provide valuable information.
Objective: To show the initial experience in the use of CMR as an additional tool in the evaluation of borderline LV.
Methods: All patients evaluated at the Clinical Hospital of the Pontifical Catholic University of Chile between 2013 and 2016, with a LV volume measured by echocardiogram of less than 20 mL/mt2 in which there was controversy about the surgical approach were included. All patients underwent an echocardiogram and CMR during the first month of life, prior to surgery.
Results: 5 patients were recruited, all female. Follow-up was from 5 to 27 months. Echocardiography underestimated LV volume compared to the CMR measurement, with differences between 10.1 and 23.5 mL/mt2. In one case, the LV volume was less than 20 mL/mt2 and the flow through the LV outflow tract was less than 1 L/min/mt2. This patient underwent univentricular repair and the other four cases followed the biventricular route. Four patients underwent interventional catheterization (3 patients who followed the biventricular pathway and the patient who followed the univentricular approach). These interventions were not related to the choice of the surgical pathway. No deaths were recorded during follow-up.
Conclusions: CMR is a valuable complementary tool in the assessment of borderline LV. Studies with a greater number of patients and long-term follow-up are needed.

P1868 - PSEUDOANEURYSM OF THE LEFT VENTRICULAR OUTFLOW TRACT IN AN INFANT

Zoe Vetten[1], Christian Brizard[2], Darshan Kothari[1]
Princess Margaret Hospital for Children, Cardiology, Subiaco-Australia[1]; Royal Children's Hospital, Cardiac Surgery, Melbourne-Australia[2]

Introduction: Pseudoaneurysm of the left ventricular outflow tract (LVOT) is rare but potentially fatal. It may develop following infection, cardiac surgery, trauma or systemic inflammation. We describe a case of LVOT pseudoaneurysm in an infant with complex congenital heart disease and multiple previous surgeries.
Case Report: An 11-month-old boy with repaired double outlet right ventricle (DORV), transposed great arteries (TGA) and large inlet ventricular septal defect (VSD) presented with three months of wheeze. Previous surgery included Arterial Switch with PA band placement in the neonatal period. At 6 months of age, he underwent VSD closure and creation of a LV-aorta tunnel, including resection of a large conus. The onset of wheeze was associated with fever and coryza, however it persisted beyond the infective symptoms. Echocardiogram demonstrated a large aneurysm between the anterior mitral valve leaflet and aortic annulus. Cardiac CT angiogram confirmed the presence of a large, lobulated aneurysm (40x28 × 22mm) arising from the lateral aspect of the LVOT and projecting posterosuperiorly. Mass effect on the left atrial appendage, left common pulmonary vein and distal left main bronchus with gas trapping was apparent. At operation, a large false aneurysm of the LVOT extending posterior to the aorta and cephalad to the left atrium was identified. The walls were thick and muscular with a neck measuring 12mm, originating from the site of previous surgery. It was hypothesised that previous resection of the conus had weakened the mitral-aorta continuity. Full resection was achieved by exposing the false aneurysm from the aortic and mitral valves, and reconstructing the LVOT with CardioCel. Twelve months post-operatively, the child remains asymptomatic with no residual aneurysm and a widely patent LVOT on echocardiogram.
Conclusion: Pseudoaneurysms of the LVOT are rare in children, with potentially devastating outcomes. Expedient surgical excision is required due to the risk of rupture.

P1879 - THE DESCENDING AORTIC DOPPLER IN VASCULAR RINGS PREDICTS PRESENCE OF DIVERTICULUM OF KOMMERELL

Ranjini Srinivasan[1], Anjali Chelliah[2], Amee Shah[3], Jonathan Ginns[4], Wyman Lai[3], Stephanie Levasseur[3]
Columbia University Medical Center, Pediatric Cardiology, New York-United States[1]; Columbia University Medical Center, Ediatric Cardiology, New York-United States[2]; Columbia University, Pediatric Cardiology, New York-United States[3]; Columbia University, Cardiology, New York-United States[4]

Background: Vascular rings (VR) are rare congenital anomalies of the great arteries. We noted some patients with VR had descending aortic Doppler tracings similar to patients with coarctation of the aorta. This has not been described in the literature. We hypothesized that the descending aortic flow pattern in VR is different from normal, even without aortic obstruction, and correlates with anatomical characteristics of the VR.
Methods: We reviewed descending aortic Doppler features of pediatric and adult patients with different types of VR who were evaluated at our center from 2005 to 2016 and compared them with age-matched controls. Patients with a patent ductus arteriosus and left sided obstructive lesions were excluded. The anatomy of the ring and presence of diverticulum of Kommerell (DK) in patients with a right aortic arch and aberrant left subclavian (RAA) were confirmed by magnetic resonance imaging, computed tomography scan or operative data. Mann-Whitney, logistic regression and ROC analyses were performed.
Results: Of 80 patients, 28 (35%) had double aortic arch (DAA), 45 (56%) had RAA, of which 21 (47%) had confirmed DK. VR patients had higher end diastolic velocity and lower systolic/diastolic ratio compared to controls. This remained true when both RAA and DAA were each analyzed against controls (table 1). RAA patients with DK had lower pulsatility indices compared to those without a

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Diverticulum (p = 0.039) (table 2). Pulsatility index ≤4.12 was associated with DK with 62% sensitivity and 92% specificity.
Conclusions: The presence of elevated end diastolic velocity and lower systolic to diastolic ratio in the descending aortic Doppler of patients without arch obstruction suggests the possibility of a vascular ring while a lower pulsatility index in patients with RAA suggests the presence of DK. These findings may permit new insights into the aortic flow disturbances in these patients.

Table 1. Doppler variables in vascular ring patients compared to normal controls; RAA and DAA compared to normal controls.

Doppler Variable	VR Median (IQ range)	Control Median (IQ range)	P-value*	P-value **	All RAA Median (IQ range)
PSV(m/s)	0.83 (0.40)	0.85 (0.45)	0.307		0.86 (0.43)

P1900 - ECOCARDIOGRAPHIC EVALUATION OF PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM AND CRITICAL PULMONARY STENOSIS

Julio Cesar Biancolini, Maria Fernanda Biancolini, Ana Maria De Dios, Jesus Damsky Barbosa
Hospital Pedro De Elizalde, Cardiology, Ciudad De Buenos Aires-Argentina

Background: To identify the echocardiographic criteria that guided the therapeutic behavior in pulmonary atresia with intact ventricular septum (PAIVS) and critical pulmonary stenosis (CPS) in newly born.
Materials: Descriptive and retrospective analysis based on the review of clinical records of 32 patients with PAIVS or CPS in newborn from 2008 to 2016 at Pedro de Elizalde Hospital. Patients were grouped according to the degree of RV development in: Mild hipoplasia (MI): TV Z score between -1 to > -2.5; RV > 30 cm3/m2; TV/MV ratio >0.8; PA Ring >1.25 cm/m2. Moderate (MO): TV Z score: -2.5 to -4.5; RV < 30 cm3/m2 and >10 cm3/m2; TV/MV: 0.5 < 0.8. Severe (SV): Z TV <-4.5; RV < 10 cm3/m2; ratio TV/MV <0.5; RV with two or fewer portions; Presence of coronary fistulas and coronary circulation RV dependent.
Results: Z score of the TV ring defined the initial behavior in 89% of patients (p). The results were: Biventricular: in 18/32p: 16p CPS and 2p PAIVS, RVOT permeabilization: Initial valvuloplasty in all MI (surgical valvotomy 3p MO hipoplasia, 2p shunts). Univentricular 12/32: 2p MO and 10p SV; 2 ended up as 1-1/2 ventricular. 6p has more than one coronary fistula; receive initially shunt. 3p deaths.
Conclusions: In PAIVS and CPS, the uni or biventricular future depends on several factors: type of atresia, RV anatomy, function, size of the tricuspid ring, amount of coronary fistulas in connection with RV and presence of RV-dependent coronary circulation. In our experience, the use of the TV Z score was the most reliable selection criteria, in the absence of significant tricuspid regurgitation or Ebstein anomaly, in which the TV/MV ratio and RV/LV volume was used as a more effective criterion for assessing the degree of development of the RV. If RV-dependent coronary circulation is present, no decompression of the RVOT will be indicated.

P1902 - EXTENSIVE MYOCARDIAL CALCIFICATION IN A NEWBORN INFANT DETECTED BY ECHOCARDIOGRAPHY IN ENTEROVIRUS MYOCARDITIS

Yukari Newman[1], Steve Shipton[1], Levy Avram[2], Berry Bligh[3]
Princess Margaret Hospital, Cardiology, Subiaco-Australia[1]; Sir Charles Gardener Hospital, Microbiology, Nedlands-Australia[2]; Princess Margaret Hospital, Histopathology, Subiaco-Australia[3]

A 7 day old female was admitted to ICU with persistent junctional re-entry tachycardia. She was subsequently diagnosed with an enterovirus (Coxsackie B4) causing myocarditis and poor systolic function requiring VA ECMO. Large echogenic masses in the myocardium were observed on echocardiography one week after presentation. The patient remained in heart failure and developed echocardiographic features of severe restrictive cardiomyopathy. The family declined more intensive treatment and the baby died aged 61 days. This is the first time we have seen this echocardiographic picture. A full review of the chart was performed including all clinical investigations and imaging. The autopsy report and histology were reviewed and discussed with the histopathologist. In addition a literature search was performed to review myocardial calcification and myocarditis in the newborn. The initial echocardiogram showed normal cardiac anatomy, reduced ventricular systolic function and normal myocardial appearance. Echogenic masses were noted in the interventricular septum (IVS) on Day 10. Serial echocardiography demonstrated deteriorating systolic and diastolic ventricular function, worsening AV valve regurgitation and diffuse effusions. The masses became highly echogenic and some were also detected in the left ventricular (LV) free wall. On autopsy, extensive damage due to myocarditis with marked calcification, fibrosis and persistent chronic inflammation was documented. It was noted to be particularly marked in the IVS and LV free wall with damage to 30-40% of the cardiac mass. This resulted in a restrictive cardiomyopathy causing congestive cardiac failure and widespread effusions and oedema. These features were consistent with those demonstrated by echocardiography. We described an unusual presentation of early myocardial calcification of a newborn with severe myocarditis. There is a recognised association of Coxsackie B with dystrophic myocardial calcifications. Myocardial inflammation, fibrosis and necrosis lead to calcium phosphate deposits. This is an indication of severe, usually irreversible myocardial damage and predicts a poor outcome.

P1919 - PEDIATRIC ECHOCARDIOGRAPHIC NOMOGRAMS FOR TWO DIMENSIONAL RIGHT VENTRICULAR SUB COSTAL VIEW DIAMETERS AND AREA A NEW ADDITIONAL APPROACH TO MEASURE THE RIGHT VENTRICLE

Massimiliano Cantinotti[1], Eliana Franchi[2], Giulia Corana[2], Cecilia Viacava[2], Marco Scalese[3], Isabella Spadoni[2], Nadia Assanta[2]
[1]Fondazione CNR-Regione Toscana, G. Monasterio Massa and Pisa, Italy [2] Institute of Clinical Physiology, Pisa, Italy, Pediatric Cardiology and Guch Unit, Massa-Italy[1]; Fondazione CNR-Regione Toscana, G. Monasterio Massa and Pisa, Italy, Pediatric Cardiology and Guch Unit, Massa-Italy[2]; Institute of Clinical Physiology, Pisa, Italy, Epidemiology and Statistic, Pisa-Italy[3]

Background: The sub-costal examination is part of routine examination in pediatric echocardiography, and may allow to visualize right ventricular (RV) dimensions and function offering the advantage to include also the infundibulum. Despite this nomograms for RV dimension in sub-costal view are lacking.
Methods: We prospectively studied healthy Caucasian Italian children (0-18 yrs) by two-dimensional echocardiography. Echocardiographic measurements included: sub-costal end diastolic and end-systolic area (subc-RVED-area, subc-RVES-area) and basal-apical and later-lateral (at the tricuspid valve attachment) diameters (subc-RVED-AP-diameter, subc-RVED-ll-diameter, subc-RVES-AP-diameter, subc-RVES-ll-diameter), 4 chamber end diastolic and end systolic area (4ch-RVED-area, 4ch-RVES-area) and length (4ch-RVEDl, 4ch-RVESL) end diastolic basal and mid-cavity diameters. Heteroscedasticity was accounted for by White or Breusch-Pagan test. Age, weight, height, heart rate and body surface area (BSA) were used as independent variables in different analyses to predict the mean values of each measurement. Structured Z scores were then computed. Agreement analysis of RV diameters and areas in sub-costal and 4-chamber view were made.
Results: In all, 732 subjects (age 0 days-17 years; 48% female; BSA 0.12-2.12 m2) were studied. The Haycock formula was used when presenting data as predicted values (mean ± 2 SDs) for a given BSA and within equations relating echocardiographic measurements to BSA. The predicted values and Z-score boundaries for all measurements have been presented. Good correlations were found among diameters and area calculated in sub-costal view with those evaluated in 4-chamber view. Pearson's coefficients were: Subc-RVED-AP-diameter vs 4-chRVED-length ($r = 0.84, p = 0.000$), subc-RVES-AP-diameter vs 4-chRVES-length ($r = 0.69$, $p = 0.000$), subc-RVED area vs 4ch-RVED-area ($r = 0.872$, $p = 0.000$), subc-RVES area vs 4ch-RVES-area ($r = 0.784$, $p = 0.000$).
Conclusions: We report pediatric echocardiographic nomograms for RV diameters and areas calculated by sub-costal view. Good correlations emerged among RV measurements in sub-costal view and those obtained in 4-chamber view.Our data may implement normative data for 2-dimensional echocardiography evaluation of the RV in children.

P1929 - ISOLATED MIDDLE LOBE SCIMITAR VEIN TO RA WITH VANISHING RIGHT MIDDLE PULMONARY VEIN

Sudeep Verma[1], *Rajendra Kumar Jain*[2], *Gouthami V*[3], *Nagarajan R*[3], *Anil Dharmapuram*[3], *I M Rao*[3]

Kims Hospital, Peditaric Cardiac Sciences, Hyderabad-India[1]; *Kims Hospital, Department of Cardiology, Secunderabad-India*[2]; *Kims Hospital, Pediatric Cardiac Sciences, Secunderabad-India*[3]

Background: Scimitar syndrome comprises of pulmonary sequestration with total or partial drainage of right lung mainly to IVC along with aberrant supply from descending aorta. We are presenting rare case of isolated middle lobe scimitar to RA with normal drainage of right lower lobe vein. Right upper vein has got dual supply to LA via small caliber vein and through scimitar vein via intercommunicating channel.Test Balloon occlusion of scimitar vein demonstrated the presence of native hypoplastic middle pulmonary vein which was not demonstrated during initial catheterization and CT scan.

Description: 12 years old girl referred for dyspnea class II. Examination revealed wide and fixed split S2 with mid systolic ejection murmur at second intercostal space. Echocardiographic evaluation revealed large ostium secundum ASD with adequate rims and normal pulmonary venous drainage. While attempting ASD device closure it was realised that right middle pulmonary vein with scimitar morphology was draining abnormally at SVC to RA junction. Right upper lobe lung having dual supply via scimitar vein to RA through intercommunicating channels as well to LA through hypo plastic right vein. Right lower pulmonary vein was draining normally to LA. Test Balloon occlusion of scimitar vein with 16 × 40 TYSHAK balloon revealed hypoplastic right middle vein to LA which was not seen earlier. In view of hypoplastic right middle and upper pulmonary veins and hypo plastic right middle lobe option of rerouting of pulmonary veins by blocking scimitar vein was not considered. Patient underwent successful surgical ASD closure and rerouting of scimitar vein to left atrium.

Conclusion: Typical profile of the middle pulmonary vein draining into RA with associated absent middle lobe bronchus clinches rare diagnosis of isolated middle lobe scimitar. Redirecting blood flow through upper or middle lobe veins through intercommunicating channels is possible if caliber of

P1936 - ISOLATED CONNECTION OF A LEFT SIDED SUPERIOR VENA CAVA TO THE LEFT ATRIUM A RARE CAUSE FOR CENTRAL CYANOSIS

Michael Kaestner[1], *Ronald Handke*[2], *Olchvary Julia*[3], *Pfeifer Jochen*[3], *Rentzsch Axel*[3], *Abdul-Khaliq Hashim*[3]
University Hospital ULM, Pediatric Cardiology, ULM-Germany[1]; *Outpatient Office, Pediatric Cardiology, Trier-Germany*[2]; *University Hospital Homburg, Pediatric Cardiology, Homburg-Germany*[3]

Background: Congenital heart disease is a well-known cause for cyanosis in children which usually resolves after surgical correction of the respective defect. However, not every abnormality needs surgical correction but may have an impact for the patient when in need for medical treatment. We report a rare case of isolated connection of a left sided superior vena cava (SVC) to the left atrium and the clinical consequences.
Case: A 7y/o boy was incidentally found to have low oxygen saturation measured on an open house presentation of the local ambulance service. This was confirmed by repeated measurements by a pediatric cardiologist, who suspected abnormal drainage of a persisting left superior vena cava on echocardiogram. Magnetic resonance imaging demonstrated this finding with an isolated connection of a left superior vena cava to the left atrium (Figure). There was no connecting vein to the right SVC.
Conclusion: The parents refused surgery and the boy was send home with an emergency health card for documentation of this finding as this has an impact in case of possible therapeutic intervention and medical treatment.

1. Any kind of intravenous line should not be done from the left arm or left neck side or all medication will be applied to the arterial system directly and the patient is at high risk for cerebral and arterial complications.
2. The electrodes of electric devices like pacemakers or automatic implantable cardioverter defibrillator should be implanted from the right veins or need surgical implantation with epicardial electrodes.
3. Open heart surgery on heart-lung-machine will need selective cannulation of the left SVC.
4. In case of cardiac transplantation, the surgeon should do end to side connection of the left SVC to the right SVC or should perform left sided bidirectional cavo-pulmonary anastomosis.

P1943 - MYOCARDIAL DEFORMATION IMAGING FOR ASSESSMENT OF YOUNG PATIENTS WITH KAWASAKI DISEASE

Rumen Marinov[1], Krasimira Hristova[2], Anna Kaneva[1], Dimitar Pechilkov[3], Albena Telcharova[4], Ivan Chakurov[5]
National Heart Hospital, Department of Paediatric Cardiology, Sofia-Bulgaria[1]; National Heart Hospital, Department of Cardiology, Sofia-Bulgaria[2]; National Heart Hospital, Department of Paediatric Cardiac Intensive Care, Sofia-Bulgaria[3]; University Hospital, Clinic of Paediatrics, Sofia-Bulgaria[4]; Tzaritza Ioanna Hospital, Department of Paediatric Oncology and Haematology, Sofia-Bulgaria[5]

Aim: To assess global and regional left ventricular (LV) function and to predict the long-term prognosis of Kawasaki disease patients.
Material and Methods: 82 children were included in the study – 62 with Kawasaki disease(mean age 9,4 ±3,9 years), 8 of whom with a residual coronary aneurism and 20 healthy controls (mean age 9,6 ±4, 8). Apical and basal short axis for 2D images were acquired in addition to apical four, three and two-chamber views. Global and regional peak systolic strain - longitudinal, radial and circumferential on the LV was derived and the strain curves (eLL, eCC, eRR) were extracted using a commercial software. Data are presented as means ± standard deviation. Student's T-test integrated in SPSS 19.0 was used. A value of $p \leq 0.05$ was considered significant.
Results: LV function was normal in both Kawasaki disease with no aneurysms and healthy controls groups, but there was a significat difference in the ejection fraction 65,39 ± 4,1vs. 71,9 ± 3,2 ($p = 0.003$), LV diastolic diameter (LVDD) z-score 0.7 ± 1,0 vs.-0,3 ± 0,8 ($p = 0.001$) and global longitudinal strain(GLS) measurements of the LV -19,23 ± 1,98% vs -21,73 ± 0.92% ($p = 0.03$). Significantly reduced GLS was found in the group of Kawasaki patients with aneurysms compared to controls -17,94 ± 1,69% vs -21,73 ± 0.92%. ($p < 0{,}001$) The regional peak systolic longitudinal strain (LS) was also reduced significantly, especially on the basal and middle LV – segments.
Conclusion: Decreased segmental regional LS values are a sign of regional hypokinesia with a possible local segmental ischemia in the group of Kawasaki with coronary aneurysms and are certain predictor of development of LV dysfunction in the future. Lack of significant differences of GLS in the Kawasaki group without an aneurysm is associated with still normal or lightly impaired global LV function and these group shoud be closely observed for ventricular dysfunction in the future.

P1952 - LIMITATIONS AND POTENTIAL OF CLINICAL APPLICATION USING PATIENT SPECIFIC THREE DIMENSIONAL HEART MODELS THREE YEAR EXPERIENCE OF SIMULATION OF CARDIAC SURGERY AND CATHETER INTERVENTION

Koichi Kataoka[1], Masaaki Kawada[2], Daisuke Matsubara[3], Kensuke Oka[3], Shun Suzuki[3], Takaomi Minami[3], Tomoyuki Satoh[3]
Jichi Children's Medical Center Tochigi, Pediatric Operating Suite and Intensive Care Unit, Shimotsuke-City-Japan[1]; Jichi Children's Medical Center Tochigi, Pediatric and Congenital Cardiovascular Surgery, Shimotsuke-City-Japan[2]; Jichi Children's Medical Center Tochigi, Pediatrics, Shimotsuke-City-Japan[3]

Background and Objective: In 2014, we established simple and inexpensive methods using a personal three-dimensional (3D) printer to create patient-specific 3D heart models for planning of surgery, simulation of catheter intervention, explanation for patients/their families, and education of trainees/medical students. Here we report the limitations and potential of clinical application using 3D models through our 3-year experience.
Methods: Using OsiriX (Pixmeo, Switzerland), DICOM (Digital Imaging and Communications in Medicine) data of contrast-enhanced MDCT (multi-detector computed tomography) scan were converted into 3D image data and stored as STL (Standard Triangulated Language) files for 3D printing. UP Plus 2 personal 3D printer (Tiertime Technology, People's Republic of China) was subsequently utilized to print ABS (acrylonitrile butadiene styrene) resin solid model (solid model) for each lesion. If necessary, transparent silicone hollow model (hollow model) was additionally created using solid model as a mold. All processes were performed at our own institution.
Results: The time/cost needed to create solid and hollow models were 5–24 h/5,000 JPY and 3–7 days/10,000–20,000 JPY, respectively. Solid model was helpful in understanding the spatial relationship among the great vessels and trachea and so on. Hollow model had good reproducibility for understanding intracardiac structures and was useful in the surgical planning of complex/rare anomalies, even if their vascular wall thicknesses were not very accurate. Although its hardness rendered it unsuitable for training in detailed surgical techniques, hollow model was suitable for simulation of occluder deployment for patent ductus arteriosus with calcification in adults. X-ray transparency of hollow model was appropriate for catheter manipulation; because the catheter/device was visible from the outside, it was useful for training in catheter interventions.
Conclusions: From the viewpoint of fidelity for anatomical accuracy, there were some limitations in these models; however, high-quality simulation becomes possible using these features.

P1954 - A NOVEL FIBRILLIN 1 GENE MISSENSE MUTATION ASSOCIATED WITH MARFAN SYNDROME A CASE REPORT

Jae Hyeon Yu[1], Jae Won Yoo[2], Hongryang Kil[3]

School of Medicine, Chungnam National University, Chungnam National University Hospital, Cardiac Surgery, Daejeon-Korea, South[1]; *School of Medicine, Chungnam Naional University, Chungnam National University Hospital, Pediatrics, Daejeon-Korea, South*[2]; *School of Medicine, Chungnam National University, Chungnam National University Hospital, Pediatric Cardiology, Daejeon-Korea, South*[3]

Background: Marfan syndrome (MFS) has highly variable clinical manifestations, resulting from genetic heterogeneity of pathogenic variants of the fibrillin-1 gene (FBN1) and TGFBR2 gene. We report a novel mutation of FBN1 gene in a case with MFS, who presenting rather Ehlers-Danlos syndrome like phenotypic manifestations

Case: A two-year-old girl was referred to the hospital with complaints of cardiac murmur and hypermobile joints. She was observed to have a dolichocephaly with down-slanting palpebral fissures, loose skin, and skeletal abnormalities including long and thin fingers, marked joints laxability, pectus deformity, scoliosis and pes planus. Her height was 50 percentile for age and the arm span to height ratio was 1.0. The grade 2 to 3 precordium regurgitant murmur was noted on apex. The severe farsightness and depigmentation of retinal pigment epithelium in fundus were identified, but no ectopia lentis on ophthalmologic examination. The progressive severe mitral valve insufficiency, aortic root ectasia (z score 2.8-3) and enlarged LVID (z score >2) were revealed on echocardiographic examination (Fig. 2). The chromosome analysis showed normal karyotype (46,XX). The genetic testing of COL5A1, COL5A2 gene for Ehlers-Danlos syndrome was normal. A novel missense mutation of FBN1 gene was identified with diagnostic exome sequencing. A heterozygous base substitution, c.3222 C > G in exon 27, resulting in a cysteine substitution by tryptophan at codon 1074 (p.1074 C > W) (Fig. 3) . No mutation was found in the TGFBR2 gene. The diagnosis was established by aortic root ectasia (z >2) and a bona fide FBN1 mutation. Her systemic scoring by revised Ghent nosology was 12 at five year od. Pedigree revealed her estranged father and a paternal cousin who apparently share marked joints laxability similar to that of proband. She was treated with beta-blocker and Angiotensin receptor blocker.

Conclusion: FBN1-associated fibrillinopathies are a group of diseases with dynamic phenotypic correlations.

Universitair Ziekenhuis Gent, Paediatric Cardiology, Gent-Belgium[1]; *Universiteit Gent, Paediatrics, Gent-Belgium*[2]; *Universitair Ziekenhuis Gent, Cardiology, Gent-Belgium*[3]

Introduction: Patients with repaired coarctation remain at higher risk of hypertension and LV dysfunction despite successful repair at young age and abnormalities may initially be present only when the heart is stressed, i.e. during exercise. Echocardiography is difficult or impossible to do during a bicycle exercise test. This is the first study where submaximal isometric handgrip test is studied in conjunction with echocardiography in children with repaired coarctation.

Methods: Case-control study with 19 children with repaired coarctation (mean age 12,78y ± 2,33) compared to 19 matched controls. Isometric handgrip test with echocardiography followed by bicycle ergometry was performed in both groups.

Results: During exercise the blood pressure increased from 114 ± 11/64 ± 4 mmHg to 132 ± 14/79 ± 7 mmHg. There was no significant difference found between the groups. HR increased from 76 ± 22 bpm to 88 ± 21 bpm. ΔHR was significantly lower in coarctation patients compared to controls (p = 0,01). LVM was

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

106 grams with no difference between the two study groups. All subjects had normal FS (>28%). E decreased with 2,73%, A increased with 20,33% whereas E/A decreased with 25,46% during exercise. E and A wave were significantly prolonged in coarctation patients at rest and during isometric exercise ($p < 0,05$). Tissue Doppler imaging of the ventricles: E' decreased with 3,88%, A' increased with 28,57% and S decreased with 2,96%. S wave was significantly decreased ($p < 0,01$) whereas the E/E' ratio was significantly increased ($p < 0,001$) in the coarctation patients at rest and during exercise compared to controls. PWV, lower in coarctation patients, increased significantly with 13,99% ($p < 0,001$) during isometric exercise.
Conclusion: The results show a normal systolic and impaired diastolic LV dysfunction in children with successful early repair with no further deterioration of the diastolic function during exercise.

P1977 - EARLY DETECTION OF MYOCARDIAL DYSFUNCTION AFTER ANTHRACYCLINE TREATMENT IN ASYMPTOMATIC PEDIATRIC CANCER PATIENTS COMPARISON OF LEFT VENTRICULAR GLOBAL STRAIN MEASURED WITH TRIPLANE AND 2D SPECKLE TRACKING

Erman Cilsal[1], Ayşe Deniz Oguz [2], Fatma Sedef Tunaoglu[2], Serdar Kula[2]
Adana Numune Training and Research Hospital, Pediatric Cardiology, Adana-Turkey[1]; Gazi University Hospital, Pediatric Cardiology, Ankara-Turkey[2]

Objective: Two-dimensional (2D) speckle tracking echocardiography (STE) are more useful to determine subclinical dysfunction. We firstly aimed to determine the left ventricular strain of pediatric cancer patients with normal ejection fraction treated with anthracycline using the 2D STE. We also compared global longitudinal strain values with using conventional 2D-STE and Triplane-STE in patients receiving anthracyclines.We also compared global longitudinal strain values with using conventional 2D-STE and Triplane-STE in patients receiving anthracyclines.
Methods: This study included 23 cross-sectionally enrolled pediatric cancer patients receiving anthracycline chemotherapy (median age: 14 years, range 6-19) and 17 controls matched for age, gender and body surface area. Patients had received a median cumulative dose of 150 mg/m2 (range 60-360 mg/m2).In all children standard 2D, M-mode, Doppler and 2D-STE and triplane-STE imaging data were obtained.
Results: 1. Patient group had a higher heart rate when compared with controls ($p = 0.016$). 2. Measurements were taken from the base of the interventricular septum; ETs (Ejection time) values were significantly decreased and MPIs values were significantly increased in patients; measurements are taken from the base of the left ventricular free wall; mS velocities were showed statistically significant difference (respectively $p = 0.022$, $p = 0.042$ and $p = 0.001$). 3. Cancer patients had a lower longitudinal and circumferential myocardial deformation of the left ventricle (respectively $p = 0.003$, $p = 0.01$). 4. Longitudinal strain values measured with Triplane method was significantly reduced in anthracycline group. Correlation between Longitudinal strain values measured with 2D and 3 P STE were also demonstrated in anthracycline group (Table 1).
Conclusion: Systolic and diastolic functions are considered in asymptomatic patients with normal ejection fraction after chemotherapy. This study confirms the subclinical LV dysfunction in patients after receiving anthracyclines with using Doppler and STE methods. We also exhibit the feasible and reproducible use of the triplane STE analysis for assessment of global LV function in the pediatric population.

P2049 - RIGHT ATRIAL MASS IN A CHILD TUMOR OR THROMBUS A CASE REPORT

Francis Emperador[1], Julia Gonzalez[1], Rahaf Waggass[2], Emilia Amaya[1], Imran Al Saeed[1], Al Alriefy Majid[3], Alfredo Sanchez[1], Abdullah Zahrani[1], Mohammed Basksh[1], Rojan Abraham[1]
King Abdulaziz Medical City National Guard, Cardiac, Jeddha-Saudi Arabia[1]; King Abdulaziz Medical City and King Saud Bin Abdulaziz University For Health Sciences., Cardiac, Jeddha-Saudi Arabia[2]; King Abdulaziz Medical City and King Saud Bin Abdulaziz., Cardiac, Jeddha-Saudi Arabia[3]

Background: One of the most common complication of indwelling central venous catheters in infants and children is right atrial thrombosis; the majority of the available research limited to case studies or retrospective small cases series. Thrombosis is associated with coexisting diseases like malignancy. In this report, it is described the presentation, treatment, technique of complete resection, and outcome of 11 years old with a thrombus vs tumor in right atrium.
Case Report: An 11 years-old boy with a diagnosis of synovial sarcoma of the pelvis treated with radiotherapy, surgical resection and chemotherapy with complete remission on computerized tomography scan. Patient had a porta-cath that had not been used or flushed for several months.Later he presented with a two weeks history with cough, chest pain on the side of the porta-catheter, shortness of breathless with minimal activity, orthopnea, exercising intolerance and limited physical activity. Computerized tomography scan showed large filling defect noted involving the right atrium crossing the tricuspid valve to the right ventricle,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

otherwise pelvic collection was solved. Transthoracic echocardiography showed a large mass (24 × 42mm) in the right atrium obstructing the right ventricle inflow with mildly depressed ventricular function. Diagnosis of right atrial mass (thrombus versus tumor) with a probably thromboembolic event was made. Patient was successfully managed with mass surgical resection. Histopathology confirmed the diagnosis of thrombus without cytology atypical or evidence of malignancy.
Conclusion: There are no pediatrics studies addressing the risk of pulmonary embolism or mortality associated with right atrial thrombus.The incidence of Right atrial thrombus in children with cancer and indwelling catheters is about 8.3% (1). Echocardiography is the primary modality for initial evaluation of symptomatic patients but definitive diagnosis requires histologic confirmation. 1.-Korones DN, Buzzard CJ, Asselin BL, Harris JP. Right atrial thrombi in children with cancer and indwelling catheters. J Pediatr .1996; 128:841-846.

P2050 - PRELIMINARY EVALUATION OF SYSTOLIC RV FUNCTION USING STRAIN IMAGING IN POST TOF CORRECTION PRESERVED VS NON PRESERVED PULMONARY VALVE

Nalinimalar Kumarasamy[1], Yazmin Yusoff Azudin[1], Hasri Samion[2]
National Heart Institute, Noninvasive Cardiolab, Kuala Lumpur-Malaysia[1]; National Heart Institute, Paediatric Cardiology, Kuala Lumpur-Malaysia[2]

Introduction: Right ventricle dysfunction is well known to cause significant late morbidity and mortality in post TOF correction patients and strain imaging has been an emerging tool in assessing RV function.Our aim in this preliminary study is to quantitatively evaluate systolic RV function between preserve and non-preserve pulmonary valve.
Method: 12 asymptomatic patients(9 non preserve,3 preserve pulmonary valve)were selected and underwent strain imaging using VVI. Mean age was 14.75 and median age was 15. Systolic RV strain,strain rate (SR) and longitudinal displacement were measured in 4 RV segments free wall and septum excluding the apex.
Results: Results showed no statistically significant difference between preserve and non-preserve PV in strain (-12.91% + /- 4.12 vs -14.80% + /-3.00) p = 0.48, SR (-1.08 s/1 + /- 0.46 vs -0.89 s/1 + /- 0.16) p = 0.51 and longitudinal displacement (5.30mm + /- 1.31 vs 5.96mm + /- 1.15) p = 0.45.
Conclusion: Due to limited sample size, we were not able to make a concrete conclusion based on the results between these 2 group of patients. Therefore, further investigation with larger sample size is crucial and inter relation strain imaging between right and left ventricle is recommended to further ascertain this.

P2070 - EFFICACY OF TISSUE MITRAL ANNULAR DISPLACEMENT DURING POSTOPERATIVE PERIOD IN PEDIATRIC CARDIAC SURGERY

Kentaro Omoya[1], Atsushi Terazawa[1], Tetsuya Yamamoto[1], Naoki Kuwabara[1], Hiroko Goto[1], Satoshi Okugi[2], Yuki Nakayama[2], Yusuke Iwata[2], Takamasa Takeuchi[2], Takashi Kuwahara[1]

Background: Cardiac function temporarily decreases after heart surgery. Although echocardiography is a useful and repeatable modality, its postoperative use is limited because of the poor echo window. Tissue mitral annular displacement (TMAD) shows significant correlation with the left ventricular (LV) ejection fraction obtained by cardiac magnetic resonance imaging. We evaluated the detection rate of the available echocardiographic techniques just after operation in our pediatric cardiac surgery and compared TMAD and other index.
Methods: In this retrospective study, 111 consecutive patients with biventricular circulation were assessed using either the iE33 S8-1 or S5-1 probe within 1 h after the operation. We evaluated which index among the following was testable: TMAD, modified Simpson (four chamber view) (mS-4CV), modified Simpson (biplane) (mS-BP), and Pombo (LV short axis).
Results: Among all patients evaluated, 53 patients (48%) could be tested with TMAD, 45 (41%) with mS-4CV, nine (8%) with mS-BP, and 40 (36%) with Pombo. In median sternotomy (N = 104), the detection rate of TMAD (46%) was the highest; however, in left side thoracotomy (N = 7), the detection rate of Pombo (86%) was the highest. Finally, for 68 cases (61%), either TMAD or Pombo was possible.
Discussion: TMAD and mS-4CV were assessed by the same image; however, TMAD is useful in postoperative period. While TMAD was calculated using three tissue points, mS-4CV required all LV walls in the four chamber view. The detection rate of Pombo was low; however, combining TMAD and Pombo improved the detection rate to 61%. It resulted in the difference of based image between the four chamber and LV short axis views. Our study shows that TMAD and Pombo were useful for both the pre- and the post-operative period and provided a good evaluation rate.

P2085 - RIGHT VENTRICULAR LONGITUDINAL STRAIN FREE WALL VERSUS 4 CHAMBER STRAIN ANALYSIS. A COMPARISON IN DIFFERENT CONDITIONS

Guillermo Larios[1], Isha Crossley[2], Mieke Driessen[3], Luc Mertens[1], Andreea Dragulescu[1], Mark Friedberg[1]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Netherlands[2]; University Medical Center Utrecht, Utrecht-The Netherlands[3]

Background: Right ventricular(RV) myocardial deformation measured by 2-D speckle tracking is useful to assess RV systolic function. There is however, no consensus on how to measure RV longitudinal strain with respect to inclusion or exclusion of the septal wall(RV-SWS). The objective of this study was to compare RV strain values analyzing only the free wall(RV-FWS) versus the RV-4-chamber (RV-4C = RV-FWS + RV-SWS) in patients with different diseases affecting the RV, in relation to RV ejection fraction(RV-EF).
Methods: We analyzed 163 patients (90 children and 73 adults) between 4-74 years with the following diagnoses: repaired Tetralogy of Fallot (TOF,n = 38), atrial septal defect (ASD,n = 14), pulmonary hypertension (PAH,n = 22), systemic RV (SysRV,n = 15) and 74 healthy controls. Two observers traced the RV 6 segments using a RV-centered 4-chamber view. The peak(PK) and end-systolic(ES) strain were recorded. We calculated the difference between RV-FWS(3-segments) and RV-4C(6-segments) and correlated them with cardiac magnetic resonance derived RV-EF.
Results: RV-FWS, RV-SWS and RV-4C for each group are presented in the Table. The highest RV-FWS and RV-4C was seen in ASD and the lowest in the SysRV group. The largest difference between RV-FW and RV-4C analysis was in the ASD group and the smallest in the ToF group. Small, but significant differences were found between PK and ES strain (paired t-test in RV-4C, $p < 0.05$ in all groups except for SysRV). The best correlation with RV-EF by group using RV-FW/RV-4C were: Controls: RV-4C(ES), r = -0.28, p = 0.06, ToF: RV-4C(ES), r = -0.45, p = 0.01, ASD: no correlation, PAH: RV-FWS(PK), r = -0.73, p = 0.01 and SysRV: RV-FWS(ES), r = -0.8, $p < 0.01$.
Conclusions: The RV-FWS and RV-4C yield different results and correlation with RV-EF depending on the underlying disease. This may reflect the different timing and magnitude of septal function in different conditions. In patients exposed to high RV pressures, RV-EF correlates more closely with RV-FWS than with RV-4C. Uniform approach to RV strain analysis may not yield optimal data across all conditions.

P2090 - ETHICAL CONSIDERATIONS IN FETAL DIAGNOSIS OF CONGENITAL HEART DISEASE A NARRATIVE REVIEW

Angira Patel[1], Tara Swanson[2], Sarah Wilkens[1], Patricia Smith[3], Jessica Fry[4]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Ann & Robert H. Lurie Children, Pediatric Cardiology, Chicago-United States[1]; University of Missouri-kansas City School of Medicine, Pediatric Cardiology, Kansas City-United States[2]; Northwestern University, Feinberg School of Medicine, Chicago-United States[3]; Ann & Robert H. Lurie Children, Neonatology, Chicago-United States[4]

Background/Hypothesis: Prenatal examination with fetal echocardiography has increasingly become the primary mode of diagnosis for most congenital heart disease. This shift in diagnosis from postnatal to prenatal, in turn, has altered conversations regarding management discussions, prognostication, and treatment options to prior to birth. Given that these discussions can be based on incomplete information and evolving disease processes, ethical dilemmas can and often do arise. This narrative review aims to evaluate the existing evidence on ethical dilemmas encountered in the prenatal diagnosis of congenital heart disease.
Methods: We searched MEDLINE via PubMed, Embase, and Google Scholar to identify studies assessing ethical issues in fetal diagnosis of congenital heart disease. We used controlled vocabulary when possible; search terms included: "ethics," "ethical," "fetus," "fetal," "cardiology," "prenatal counseling", "echocardiography," and "congenital heart disease."
Results: We identified 61 articles spanning the years 1983–2016. Fourteen studies were published between 1983–1999, 22 between 2000–2009, and 25 between 2010–2016. We identified 4 categories of articles: 23 opinion/commentary/ethical analysis, 16 review papers, 19 cross-sectional survey studies, and 3 case-series papers. On analysis of the studies, the following ethical themes emerged: what comprises appropriate counseling for families, the factors that influence counseling and decision making including termination of pregnancy, fetal cardiac intervention, and the influence of concomitant genetic diagnosis in decision making.
Conclusion: There is a critical need to explore ethical questions related to the fetal diagnosis of congenital heart disease. There is currently a paucity of data in this area. Existing literature is mainly comprised of opinion, commentary, and review papers. Future studies should focus on evidence-based approaches to understanding the emerging ethical issues identified in this narrative review.

P2091 - CHARACTERISTICS AND OUTCOMES IN A SPANISH REGISTRY FOR CHILDREN WITH BICUSPID AORTIC VALVE (REVAB)

Objectives: Define demographics, valve morphology, associated diseases and complications in a nationwide registry.
Methods: Online registry under the auspices of Spanish Society of Pediatric Cardiology and Congenital Heart Diseases (SECPCC) started on May 2016 for pediatric patients (<18 years of age) with bicuspid aortic valve.
Results: A total of 944 patients from 28 hospitals were introduced by November 2016. Mean age at diagnosis was 3.0 ± 4.0years, 52.3% before 1 year of age. There was a prenatal suspicion of congenital heart disease in 9.9% of patients. Family history of bicuspid aortic valve was known for 6.3% of patients. The majority were male, 68.6%. Valve morphology was horizontal in 52.5% and only 34.1% were pure. A total of 589 (62.4%) had an isolated bicuspid aortic valve, 265 (28.1%) had concomitant left sided obstructive lesions (including coarctation of the aorta, interrupted aortic arch, subaortic stenosis or mitral stenosis), 121 ventricular septal defect (12.8%); and others (55, 5.8%). A total of 281 patients (29.7%) had 380 interventions: 263 on the aortic arch (216 surgical, 47 percutaneous), 94 aortic valvuloplasty (77 percutaneous, 17 surgical), 10 mechanical aortic valves, 8 Ross, 2 Bentall, 1 Yacoub and 2 substitution of the ascending aorta. At a mean age of 7.2 ± 4.9years, 166 patients (17.6%) had $\geq$ moderate aortic stenosis and 62 (6.5%) had $\geq$ moderate aortic regurgitation. The mean aortic root and the ascending aorta were 0.1 ± 1.7 SD and 1.1 ± 2.2 SD respectively, 8% had dilatation of the aortic root and 25.8% of the ascending aorta (z-score >2). Mean progression of the aortic root and the ascending aorta was 0.2 ± 0.6 SD/y and 0.3 ± 0.7 SD/y respectively. A total of 20 endocarditis have been reported (2.1%), 1 aortic dissection and 9 exitus (median 2 months, range birth to 13.8years).
Conclusions: Pediatric patients with bicuspid aortic valve are not exempt from complications during childhood, thus close follow-up is warranted.

P2096 - EARLY CHANGES IN LEFT VENTRICLE MYOCARDIAL FUNCTION AND MASS IN OBESE NON–HYPERTENSIVE MEXICAN CHILDREN

Elisa Lopez Lena-Hernandez[1], Clara A. Vazquez-Antona[1], Eloisa Colin-Ramirez[2], Daniel Hurtado-Sierra[1], Laura Trujeque-Ruiz[1], Catalina Sanchez-Cornelio[1], Maite Vallejo-Allende[2]
Instituto Nacional De Cardiologia Mexico, Pediatric Echocardiography, Ciudad De Mexico-Mexico[1]; Instituto Nacional De Cardiologia Mexico, Socio Medicine Research, Ciudad De Mexico-Mexico[2]

Background: Previous studies have reported structural and functional changes of left ventricle (LV) associated with adult obesity, and abnormalities of LV longitudinal myocardial deformity in severely obese adolescents. The aim of this study is to evaluate early changes in LV myocardial function in children with obesity without hypertension.
Methods: We performed a cross-sectional study in children between 6-15 years old, who underwent anthropometric, biochemical and LV function evaluation by conventional bi and three-dimensional echocardiography, and analysis of longitudinal myocardial deformity using the Speckle Tracking technique. The comparison between groups was performed using the ANOVA test, and multiple comparisons with the Bonferroni method.
Results: 133 children were included, with an average age of 9.5 years. They were divided into three groups according to their body mass index Z score: normal weight (n = 49), overweight

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

(n = 33), and obesity (n = 51). The obesity group showed lower blood levels of HDL cholesterol (45 mg/dl vs. 58 mg/dl, $p < 0.05$) and higher levels of triglycerides (130 mg/dl vs. 76 mg/dl, $p < 0.05$) compared to the normal weight group. The obesity group showed a higher left atrium diameter (28.4mm vs. 25.7mm, $p < 0.05$), LV diastolic diameter (41.9mm vs. 25.7mm, $p < 0.05$), LV 2Dmass (103.4 g vs. 75.6 g, $p < 0.05$), and LV 3Dmass (86.7 g vs. 60.4 g, $p < 0.05$) in comparison with the normal weight group. Conventional indicators of LV function, including ejection fraction, showed no significant differences between groups, while the global myocardial deformation was lower among obese children than normal weight group (-20.0% vs. -23.8%, $p < 0.05$). There were no significant differences between overweight and normal weight group. *Conclusions:* These results support the relevance of echocardiographic methods to assess the function, anatomic structure and myocardial deformation of the left ventriclein pediatric patients with obesity. Although overweight was not associated with significant changes, it is important to avoid its progress towards obesity to prevent early cardiovascular abnormalities.

Table 1. General characteristics of all three groups of study

	Normal Weight (n = 49)	Overweight (n = 33)	Obesity (n = 51)	P value
Age (years)	9.4 ± 2.5	9.4 ± 2.0	9.8 ± 1.8	0.688
BMI Z score (Kg/(m)^2)	0.17 ± 1.1	1.44 ±0.3 $^{\alpha}$	2.81 ±0.6 $^{\beta}$	<0.001
SBP (mmHg)	94 ± 10.8	97 ± 8.1	97 ± 21.5	0.672
DBP (mmHg)	62 ± 8.3	65 ± 5.5	62 ± 16.7	0.480
Glu (mg/dl)	90 ± 6.3	90 ± 4.2	91 ± 5.4	0.556
TC (mg/dl)	159 ± 24.2	163 ± 26.9	164 ± 26.2	0.669
HDL (mg/dl)	58 ± 12.8	50 ± 12.2$^{\alpha}$	45 ± 9.1$^{\beta}$	<0.001
LDL (mg/dl)	95 ± 22.2	103 ±24.7	128 ± 149.4	0.211
TGL (mg/dl)	76 ± 34.4	92 ± 38.8	130 ± 41.8$^{\beta}$	<0.001

BMI: body mass index. SBP: Systolic blood pressure. DBP: Diastolic blood pressure. Glu: glucose. TC: total cholesterol. LDL: Low-density cholesterol. HDL: High-density cholesterol. TGL: triglycerides. The comparison between groups was performed using the ANOVA test and multiple comparisons with the Bonferroni method, were **β** $p < 0.05$ was used for the comparison between normal weight versus obesity group, and **α** $p < 0.05$ for normal weight versus overweight group.

Table 2. Left ventricular structure dimensions and mass of each group.

	Normal Weight (n = 49)	Overweight (n = 33)	Obesity (n = 51)	P value
LA (mm)	25.7 ± 3.1	26.9 ± 4.6	28.4 ± 4.8$^{\beta}$	0.013
LA Z score	0.96 ± 0.86	0.89 ± 1.04	0.83 ± 1.08	0.821
LVDD (mm)	38.8 ± 3.6	41.8 ± 4.5$^{\alpha}$	41.9 ± 4.4$^{\beta}$	0.001
LVDD Z score	-0.5 ± 0.68	-0.19 ± 0.79	-0.56 ± 0.95	0.109
LVSD (mm)	24.6 ± 2.7	25.9 ± 4	26.3 ± 5.2$^{\beta}$	0.141
LVSD Z score	-0.2 ± 0.85	-0.31 ± 0.84	-0.2 ± 0.94	0.841
IVSD (mm)	6.7 ± 1.2	7.1 ± 1.5	7.4 ± 1.6$^{\beta}$	0.061
SIVD Z score	0.29 ± 0.78	0.47 ± 0.74	0.16 ± 1.5	0.523
LVPW (mm)	5.9 ± 1.3	6.6 ± 1.1	6.6 ± 1.9$^{\beta}$	0.046
LVPW Z score	0.38 ± 0.87	0.33 ± 1	0.13 ± 1	0.433
LV Mass (g)	75.6 ± 26.7	81.7 ± 26.1	103.4 ± 29.9$^{\beta}$	< 0.001
LV Mass Z score	-0.79 ± 1.1	-0.56 ± 1.15	0.3 ± 1.1$^{\beta}$	< 0.001
LV Mass (g/m^2)	67 ± 21.3	66 ± 13.8	71.1 ± 13.3	0.357

LA: left atrium. LVDD: left ventricular diastolic diameter. LVSD: left ventricular systolic diameter. IVSD: interventricular septum diastolic diameter. LVPW: left ventricular posterior wall. LV: left ventricle. The comparison between groups was performed using the ANOVA test and multiple comparisons with the Bonferroni method, were **β** $p < 0.05$ was used for the comparison between normal weight versus obesity group, and **α** $p < 0.05$ for normal weight versus overweight group.

Table 3. Left ventricular parameters of systolic and diastolic function of each group.

	Normal weight (n = 41)	Overweight (n = 19)	Obesity (n = 41)	P value
LVEF (%)	64.6 ± 4.7	64.7 ± 5.3	64.1 ± 6	0.855
LVSF (%)	35.8 ± 5.2	38.7 ± 7.5	38.2 ± 9	0.168
Em/Am Ratio	1.7 ± 0.31	2.2 ± 1.9	1.6 ± 0.32$^{\beta}$	0.043
Em/Am Ratio Z score	-0.31 ± 0.63	-0.12 ± 0.65	-0.35 ± 0.75$^{\beta}$	0.401
LVS MPI	0.39 ± 0.08	0.4 ± 0.08	0.45 ± 0.45	0.662
LVS MPI Z score	0.35 ± 0.84	2.68 ± 11.1	0.53 ± 1.19	0.176
LVM MPI	0.37 ± 0.07	0.38 ± 0.09	0.41 ± 0.11	0.235
LVM MPI. Z score	0.26 ± 0.86	0.48 ± 0.93	0.64 ± 1.27	0.262

LVEF: left ventricular ejection fraction. LVSF: left ventricular shortening fraction. Em/Am Ratio: e wave and a wave relation. LVS MPI: left ventricular septum myocardial performance index. LVM MPI: left ventricular mitral myocardial performance index.
The comparison between groups was performed using the ANOVA test and multiple comparisons with the Bonferroni method, were
β $p < 0.05$ was used for the comparison between normal weight versus obesity group, and **α** $p < 0.05$ for normal weight versus overweight group.

Table 4. Left ventricular longitudinal myocardial deformity, represented in segments and global strain, of all study groups.

Segment	Normal Weight (n = 49)	Over-weight (n = 33)	Obesity (n = 51)	P value
1	-21 ± 5.6	-24 ± 7.4	-21 ± 8.2	0.082
2	-19 ± 3	-20 ± 5.1	-19 ± 4.9	0.548
3	-19 ± 4.1	-21 ± 4.4	-18 ± 4.8	0.092
4	-21 ± 4.3	-23 ± 5.1	-18 ± 6$^{\beta}$	0.001
5	-24 ± 4.7	-24 ± 5.5	-22 ± 3.8	0.327
6	-22 ± 3.6	-24 ± 5.1	-21 ± 8.7	0.075
7	-23 ± 6	-23 ± 6.6	-19 ± 5.8$^{\beta}$	0.002
8	-22 ± 4.1	-25 ± 6.8	-22 ± 5.3	0.098
9	-22 ± 3.2	-23 ± 5.6	-21 ± 4.8	0.170
10	-21 ± 4.5	-22 ±4.8	-19 ± 5.2$^{\beta}$	0.015
11	-23 ± 4.2	-22 ± 4.3	-21 ± 5	0.313
12	-24 ± 4.3	-23 ± 6.3	-22 ± 6.1	0.375
13	-24 ± 5.7	-20 ± 5.7$^{\alpha}$	-18 ± 5$^{\beta}$	<0.001
14	-26 ± 4.8	-23 ± 5.3$^{\alpha}$	-23 ± 3.9$^{\beta}$	0.004
15	-26 ± 5.4	-25 ± 5.8	-23 ± 3.9$^{\beta}$	0.015
16	-24 ± 3.3	-21 ± 4.3$^{\alpha}$	-20 ± 5$^{\beta}$	<0.001
17	-25 ± 3.7	-22 ± 4.2$^{\alpha}$	-20 ± 3.4$^{\beta}$	<0.001
LGS (%)	-23.5 ± 2.2	-22.2 ± 2.6	-20 ± 2.3$^{\beta}$	<0.001

LGS: longitudinal global strain. The comparison between groups was performed using the ANOVA test and multiple comparisons with the Bonferroni method, were **β** $p < 0.05$ was used for the comparison between normal weight versus obesity group, and **α** $p < 0.05$ for normal weight versus overweight group.

P2098 - SPECTRUM OF THROMBOEMBOLIC MANIFESTATIONS IN CONGENITAL CYANOTIC HEART DISEASES

Amitabha Chattopadhyay[1], Biswajit Bandyopadhyay[2], Aritra Mukherji[1], Indira Banerjee[1], Prabhat Kumar[1], Suman Paul Chowdhury[1], Lokesh Kukatla[3], Arif Faizan[4]
Narayana Superspeciality Hospital, Howrah, West Bengal, India, Pediatric Cardiology, Kolkata-India[1]; Rabindranath Tagore International Institute of Cardiac Sciences, Mukundapur,Kolkata,India, Pediatric Cardiology, Kolkata-India[2]; Rabindranath Tagore International Institute of Cardiac Sciences, Mukundapur,Kolkata,India, Radiology,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Kolkata-India[3]; Narayana Superspeciality Hospital, Howrah, West Bengal, India, Radiology, Howrah-India[4]

Background: Thromboembolic manifestations are common in congenital cyanotic heart diseases (CCHD) due to high haematocrit,coagulation abnormalities, low platelet counts and an unpredictable response to fluid shifts. We present nine patients with varied manifestations.
Materials and Methods: Children with CCHD presenting with thromboembolic manifestations at Rabindranath Tagore International Institute of Cardiac Sciences and Narayana Superspeciality Hospital, during the period July 2014 – June 2016, formed the study group.
Results: The background CCHD resulting in the manifestations were Tetralogy of Fallot, Pulmonary atresia/VSD and single ventricle - pulmonary stenosis. 5 were males and 4 were females, with age range of 6 months to 16 years. The different presentations were: prolonged fever and brain abscesses (2), occipital infarct resulting in cortical blindness (1), severe pain abdomen due to splenic infarct (1), portal vein thrombosis (1), medullary infarct resulting in cranial nerve palsy and nasal regurgitation (1), post diarrhoeal irritability with complete occlusion of the superior sagittal sinus and raised intracranial tension (1), hyperpyrexia following cardiac catheterisation (1), fever and convulsions with bilateral thalamic infarcts generalising to extensive bilateral cerebral infarcts (1). Children with brain abscesses were treated with abscess drainage and antibiotics for six weeks. Children with occipital infarct, splenic infarct and medullary infarct, were treated conservatively. The children with superior sagittal sinus thrombosis and portal vein thrombosis had warfarin therapy and complete dissolution of the clots were noted in 3 months. The child with hyperpyrexia after cardiac catheterisation passed away shortly after the incident and the child with thalamic infarcts died 7 days after onset of symptoms.
Conclusions: Thromboembolic episodes present with myriad manifestations. Anticipation of atypical signs and symptoms may save the patient with appropriate therapy on time. Imaging of the concerned body part should be prompt, and repeated if necessary, to understand the lesions in details and their evolution, to guide the therapy.

P2101 - RATE AND TRENDS IN PRENATAL DETECTION OF COMPLEX CONGENITAL HEART DISEASE A SINGLE CENTER EXPERIENCE

Sudheer Gorla[1], Abhishek Chakraborty [2], Rubee Gogol[1], Perla Orozco[1], Sethuraman Swaminathan[1]
Jackson Memorial Hospital, Pediatric Cardiology, Miami-United States[1]; Jackson Memorial Hospital, Pediatrics, Miami-United States[2]

Background: Complex congenital heart disease (CCHD) is a major cause of morbidity and mortality in the pediatric population. Incidence of congenital cardiac anomaly is 10 per 1000 live births, 30% of which is CCHD. Fetal echocardiography is the main modality of prenatal identification of CCHD. The objective of this study is to define the rate and trends in prenatal detection of CCHD at our center.
Methods: Retrospective chart review of patients with CCHD, born in Jackson Health System, between January 2000 and November 2016, was done. Presence or absence of prenatal diagnosis, indication for fetal echocardiogram, gestational age at diagnosis, and outcome at 1-month of age were analyzed.
Results: A total of 350 CCHD patients were born during the study period, representing 3.1 per 1000 live births. The overall prenatal diagnosis rate of CCHD was 65.6%. The rate of diagnosis increased over the study period from low 50's early on to mid-high 80's near the end of the study. Lowest detection rate was noted for total anomalous pulmonary venous return (25%), coarctation of the aorta (44%), tetralogy of Fallot (48%) and transposition of great arteries (54%). Highest detection rate was noted for tricuspid atresia (90%) and unbalanced AV septal defect (83%). The most common indication for a fetal echocardiogram was abnormal prenatal ultrasound (78.8%). There was no mortality benefit at 1 month associated with prenatal diagnosis.
Conclusions: There is increasing rate of prenatal diagnosis of CCHD over the study period. This can be attributed to changes in the protocol of obstetric screening ultrasound and indications for fetal echocardiogram. In spite of these improving detection rates, certain CCHD have a lower rate of detection. Though there is no significant advantage in 1-month mortality in the prenatal detection group, there might be significant difference in early and late morbidity.

P2112 - IN UTERO PROGNOSTICATING FETAL ECHOCARDIOGRAPHIC MARKERS IN ABSENT PULMONARY VALVE SYNDROME A CASE SERIES

Tlj Choo[1], Xy Ng [2], S Sundararaghavan[1], Ck Chen[1], Th Tan[1]
KK Women's & Children's Hospital, Paediatric Subspecialties - Cardiology Service, Singapore-Singapore[1]; KK Women's & Children's Hospital, Cardiac Centre, Singapore-Singapore[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Background: Tetralogy of Fallot with Absent Pulmonary Valve is a rare but a well-described complex cardiac lesion that can be reliably diagnosed on prenatal ultrasound. Risk stratification and the identification of infants requiring perinatal resuscitation, however remains to be defined.
Methodology: The fetal echocardiography database of a KK Women's and Children's Hospital, a tertiary center was reviewed retrospectively over a 5 year period from 2011 to 2016 and cases of Tetralogy of Fallot with Absent Pulmonary Valve were identified, the echocardiographic data and clinical histories were analyzed.
Results: During the study period, 5 cases of Tetralogy with Absent Pulmonary Valve were diagnosed prenatally. There was severe pulmonary regurgitation with normal biventricular function in all patients. The pulmonary regurgitation VTI ranged from 16.2 to 45.9 cm. The main pulmonary artery to aortic annulus ratio ranged from 1.12–1.50. 2 patients were noted have arterial ducts. There were 2 pregnancy terminations and 1 neonatal death. None of the fetuses developed hydrops. All 3 patients who had been followed-up in utero required intubation and ventilation at birth. The infant who died in the neonatal period had an associated cystadenomatoid malformation of the left lung. 1 patient had DiGeorge Syndrome.
Conclusion: Tetralogy of Fallot with Absent Pulmonary Valve remains a critical congenital heart disease with all live-born infants requiring resuscitation at birth in our series. The fetuses with associated extra cardiac conditions tended to have a worse prognosis. The ratio of main pulmonary arterial dimension to aortic annulus dimension measured in systole was greater in neonates requiring respiratory support. Indexed measurements and Doppler derived indices during fetal life may help in further risk stratification.

P2114 - PERICARDIAL CYST IN A 3 YEAR OLD BOY A DIAGNOSTIC AND THERAPEUTIC CHALLENGE

Sanja Dorner[1], Tamer Salha[2]
University Hospital Osijek, Department of Pediatrics, Osijek-Croatia[1]; University Hospital Osijek, Department of Radiology, Osijek-Croatia[2]

The authors present a 3 year old boy, who underwent a chest X-ray for the first time due to respiratory infection. The chest X-ray revealed an oval shaped mass along the left contour of the heart. It was thought to be a pneumonia and was treated with antibiotics. The following year, the boy had influenza and the chest X-ray was done again. Again it showed the same formation along the left contour of the heart above the apex. Various diagnostic procedures were done to determine pathology. The microbiological samples did not prove TBC or any other infection, a bronchoscopy excluded bronchial anomalies or a foreign body in the bronchi. An echocardiography has been made and the heart was found to be morphologically and functionally normal, but the cyst was seen along the left ventricle sized 9 × 19 mm and filled with fluid, without compression effects on the surrounding structures. A cardiac MRI confirmed the diagnosis of pericardial cyst in left lung lingui. Since the boy was asymptomatic and the control cardiac MRI and the echocardiography showed milder regression in size - to now we have not decided to treat the patient surgically. The pericardial cyst is rare, occurring with a frequency of 1 in 100 000 people and is usually an incidental finding. It makes 7% of all the masses in the mediastinum and 33% of mediastinal cysts. In early childhood it is even more rare, and may represent a diagnostic challenge in distinguishing the pericardial cyst from other, less benign mediastinal masses. For smaller cysts and asymptomatic patients most authors recommend only follow up by series of echocardiography and cardiac MRI as we did in our patient. Our boy is doing well, still is asymptomatic after 5 years follow up

P2124 - CARDIAC FUNCTION IN PEDIATRIC PATIENTS WITH CONGENITAL ADRENAL HYPERPLASIA

Christiaan F Mooij[1], Milanthy S Pourier[2], Gert Weijers[3], Chris L De Korte[3], Hedi L Claahsen-Van Der Grinten[1], Livia Kapusta[4]
Radboud University Medical Center, Pediatric Endocrinology, Nijmegen-The Netherlands[1]; Radboud University Medical Center, Pediatrics, Nijmegen-The Netherlands[2]; Radboud University Medical Center, Music, Nijmegen-The Netherlands[3]; Radboud University Medical Center, Pediatric Cardiology, Nijmegen-The Netherlands[4]

Background: Congenital adrenal hyperplasia (CAH) is characterized by cortisol deficiency and hyperandrogenism. Both hyperandrogenism and treatment with supraphysiological doses of glucocorticoids may cause unfavorable changes in the cardiovascular risk profile of CAH patients. Data on the cardiac function in CAH patients are scarce.
Methods: The cardiac function of 27 pediatric CAH patients, aged 8-16 years, was evaluated by conventional echocardiography and 2D myocardial strain (rate) imaging. Results were compared to a selected cohort of 27 age and gender matched healthy controls. Data on hydrocortisone dosage in CAH patients were collected. Blood was withdrawn in CAH patients to evaluate 17-OH-progesterone and androstenedione concentrations.
Results: Left ventricular parameters (IVSd, LVIDd, LVIDs, EF and FS) are normal in all CAH patients, and do not differ from controls. In contrast, LVPWd is significantly lower in CAH patients compared to controls (5.55 vs 6.53 mm; P = 0.009). The LVPWd Z-score is significantly lower in CAH patients yet within the normal range (-1.12 vs -0.35; P = 0.002). LV mass and LV mass index are normal and comparable in both patients and controls. Isovolumetric relaxation time is significantly lower in CAH patients (49 vs 62 ms; P = 0.003). No associations were found between left ventricular parameters and BMI SDS, hydrocortisone dose, androstenedione and 17-OH-progesterone, respectively. Global longitudinal, radial and circumferential strain were normal compared to controls. Global radial strain rate was significantly higher compared to healthy controls (2.58 vs 2.06 1/s). Time to peak global longitudinal, radial and cicumferential strain did not differ between CAH patients and controls.
Conclusion: Cardiac evaluation of pediatric CAH patients showed no signs of left ventricular hypertrophy or ventricular dilatation. We found a thinner LVPWd in CAH patients, this finding was not associated with treatment or hyperandrogenism. A shorter isovolumetric relaxation time in CAH patients suggested increased left atrial pressure.

P2159 - DOPPLER ANALYSIS OF FETAL PULMONARY VENOUS FLOW IN HYPOPLASTIC LEFT HEART SYNDROME OUR EXPERIENCE IN THE LAST FIVE YEARS

Elisa Castaño[1], Lucia Deiros[1], Estefanía García[1], Ángela Uceda[1], Roberto Rodriguez[2], Angel Aroca[3], Paloma Sanz[1], Viviana Arreo[1], Carlos Labrandero[1], Federico Gutierrez-larraya[1]
Hospital Universitario La Paz, Pediatric Cardiology, Madrid-Spain[1]; Hospital Universitario La Paz, Gynecology and Obstetrics, Madrid-Spain[2] Hospital Universitario La Paz, Cardiac Surgery, Madrid-Spain[3]

Background: Hypoplastic left heart syndrome (HLHS) is a rare heart defect that results in a significant increase in morbidity and mortality. Advances in fetal diagnosis, as well as changes in the legislation regarding the interruption of pregnancy, have reduced the incidence of this entity in newborns. Several studies suggest that the fetal pulmonary venous flow pattern relates to the severity and outcome of these patients.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: We did a retrospective review of prenatal diagnosis of HLHS in the last 5 years. An analysis of fetal pulmonary venous doppler was carried out. According to the literature, three patterns were defined: Type A, continuous forward flow; Type B, reversal A-wave; and Type C, bidirectional flow.
Results: 21 prenatal diagnosis of HLHS were reviewed. In 14 cases pregnancy was terminated by parental choice (66%). In the 7 cases remaining, fetal pulmonary venous flow pattern was analyzed: 3 A, 3B and 1 C. Delivery at term in all cases. None of the newborns required reanimation at birth. All of them were admitted to neonatal ICU. In one patient (A type) therapeutic effort was limited because of parental decision. The six remaining patients were surgically intervened (Norwood-Sano) between the 5-7th days of life. Only two infants (1B, 1 C) required balloon atrial septostomy before surgery. Both required ECMO after intervention and died a few days later due to refractory hypoxemia. The four other patients reached the surgery without any complications.
Conclusions: - HLHS is an entity with a high rate of pregnancy interruption, this limits the appearance of the most severe clinical presentations. - Abnormal fetal pulmonary venous flow (especially Type C) may be associated with refractory hypoxemia after surgery and a poorer outcome. - The doppler analysis of fetal pulmonary veins should be performed in all cases of HLHS, in order to improve prognostic information to the parents

P2164 - THE ROLE OF INTRAOPERATIVE EPICARDIAL ECHOCARDIOGRAPHY IN PEDIATRIC CARDIAC SURGERY

Erkut Ozturk[1], Hasan Candas Kafali[1], Pelin Ayyildiz[1], Selman Gokalp[1], Yakup Ergul[1], Sertac Haydin[2],Alper Guzeltas[1]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[1]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiovascular Surgery, Istanbul-Turkey[2]

Background: Recently the need for intraoperative echocardiography (transesophageal or epicardial) has been increased especially during congenital cardiac surgeries. In case of improper conditions for transesophageal echocardiography (TEE) like low body weight, inappropriate anatomy of the jaw, large tongue etc. intraoperative epicardial echocardiography (IEE) can be performed. We aimed to evaluate the findings and results of IEE patients.
Materials and Methods: Patients who had IEE between December 2015-December 2016 were analysed retrospectively. The age, gender, body weight, preoperative transthoracic echocardiography findings and IEE reports were evaluated in detail.
Results: 180 patients who had IEE were included in the study. 51% were females and 49% were males. The median age was 10 months (1month-7 years) and median body weight was 7.7 kg (3.3-61 kg). Patients were operated with the diagnosis of TOF (70 patients), VSD (50 patients), ASD (30 patients), complete AVSD (16 patients) and others cardiac diseases like mitral valve disease, subaortic ridge, pulmoner venous return anomaly (14 patients). Minor residual lesions were determined in 19.4% (n = 35) of patients without a need for re-entry to the cardiopulmonary bypass circulation (CPB). There were major residual lesions in 6.1% (n = 11) of patients that required re-entry to CPB. 4 of these major residua were in patients with VSD (large residua from the VSD patch), 4 with TOF (3 were severe right ventricular outflow tract stenosis, 1 was residua from VSD patch), 3 with complete AVSD (all were severe mitral regurgitation). No major complication was determined during IEE, only transient bradycardia was observed in 3 of the patients.
Conclusion: IEE provides a good guidance during congenital cardiac surgery in children. IEE helps to clarify the operative plan and helps to decrease morbidity and mortality due to unnecessary invasive procedures.

P2167 - CAN ABNORMALITIES OF THE MITRAL VALVE APPARATUS IDENTIFY GENOTYPE POSITIVE PHENOTYPE NEGATIVE FORM OF HYPERTROPHIC CARDIOMYOPATHY IN CHILDREN

Renzo Calderon-Anyosa, Matthew J O'Connor, Anirban Banerjee
CHOP, Cardiology, Philadelphia-United States

Background: Although described in adults with overt hypertrophic cardiomyopathy (HCM), abnormalities of mitral valve (MV) apparatus have been studied infrequently in children with HCM. Especially, little is known about MV in children with HCM gene mutations, without overt left ventricular (LV) hypertrophy (genotype positive, phenotype negative, GpPn). This study aims to describe two-dimensional echocardiographic (2DE) abnormalities of MV apparatus in GpPn children. We hypothesize that subtle variations in LV papillary muscles (PM) may be observed in GpPn children.
Methods: In this retrospective study, 2DE images of 27 GpPn and 27 control patients, were analyzed. Measurements included: apical displacement of PM base, angle between anterolateral PM and LV lateral wall, PM length, inter-PM distance at tips and area of PM in end-diastole and end-systole, length of MV leaflets in diastole, LV outflow tract dimension in systole. ANCOVA, multivariate logistic regression and ROC analysis were performed; a $p < 0.05$ was considered significant. Intraclass correlation (ICC) was applied.
Results: Of 27 GpPn children, 13 (48.15%) showed MYBPC3, 5 (18.52%) MYH7, 4 (14.81%) MYL2 mutations and 5 (18.52%) presented with other mutations. Echocardiographic characteristics are described in table 1. There was a significant increase in angle between anterolateral PM and LV lateral wall ($35.70° \pm 1.43$ vs. $28.43° \pm 1.43$, OR: 1.15 IC95%: 1.03–1.29), and decrease in inter-PM distance in end diastole (1.56 cm ± 0.07 vs. 1.84 cm ± 0.07, OR: 0.06 IC95%: 0.01–0.78) in the multivariate analysis. A cut point of > -0.3 was calculated for the multivariate model with 85.19% Sensitivity, 81.48% Specificity and 0.89 AUC (95% CI 0.80–0.98) (graph1), ICC: 0.966.

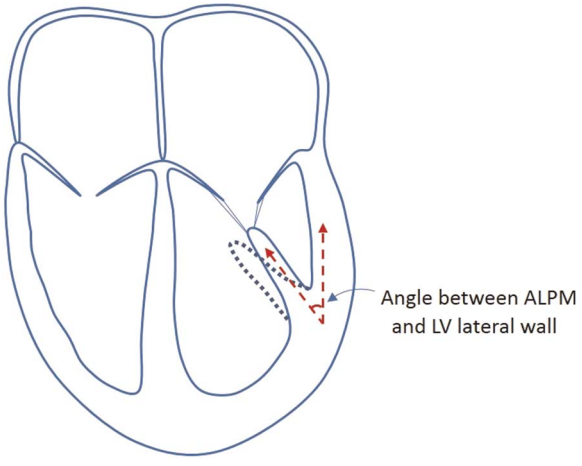

Figure 1.
Angle change in Genotype Positive, Phenotype Negative Patients

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusions: GpPn children may manifest subtle abnormalities of MV apparatus. These echocardiographic parameters may serve as potential tools for identifying children with HCM gene mutations, without overt LV hypertrophy. Future multicenter, longitudinal studies may provide further insight.

P2175 - ABNORMALITIES OF THE MITRAL VALVE APPARATUS IN CHILDREN WITH HYPERTROPHIC CARDIOMYOPATHY

Renzo Calderon-Anyosa, Matthew J O'connor, Natesa G Pandian, Anirban Banerjee
CHOP, Cardiology, Philadelphia-United States

Background: Abnormalities of the mitral valve (MV) apparatus have been described in adults with hypertrophic cardiomyopathy (HCM). However, MV apparatus has been studied infrequently in children with HCM. We aim to outline two-dimensional echocardiographic (2DE) abnormalities of MV apparatus in children with HCM.

Methods: In this retrospective study, 2DE images of 35 HCM and 35 control patients, were analyzed. Measurements included: Apical displacement of base of anterolateral papillary muscle (ALPM), angle between ALPM and Left ventricular (LV) lateral wall, PM length, inter-PM distance at the tips in end diastole and end systole, MV leaflet length in diastole, LV outflow tract (LVOT) dimension in systole and area of PM base in diastole, both in short axis views. Student's T test was performed; a $p < 0.05$ was considered significant. Intraclass correlation (ICC) was assessed.

Results: Our cohort of 35 HCM children constituted a heterogeneous group of 29 (82.85%) non-syndromic HCM and 6 (17.14%) Friedreich's ataxia. Out of these non-syndromic HCM, 25.7% had obstructive HCM. The echocardiographic characteristics are described in table 1 and figure 1. The most important ones are 1) significant apical displacement of the base of PM 2) increase in the angle between ALPM and LV lateral wall, 3) elongation of entire ALPM, 4) elongation of MV leaflets and 5) decrease in inter-PM distance both in systole and diastole. ICC: 0.966.

Conclusions: Children with HCM manifest various MV apparatus abnormalities. In this descriptive study, the correlation between

Measurements of the Mitral valve apparatus

these parameters and clinical characteristics were not evaluated. We speculate that anomalies of MV may play a mechanistic role in LVOT obstruction and mitral regurgitation. Some MV abnormalities noted in this study may serve as adjunct diagnostic tools, in unusual cases of HCM. Further multicenter studies may offer a better understanding of the role of the MV apparatus in children with HCM.

P2177 - FETAL ECHOCARDIOGRAPHIC PREDICTORS FOR PERINATAL MORTALITY OF TRICUSPID VALVE MALFORMATION AND EPSTEIN ANOMALY

Fumiko Torigoe[1], Inamura Noboru[2], Shigetoyo Kogaki[1], Keiihi Ozono[3], Futoshi Kayatani[4]
The Department of Pediatrics,osaka Univercity Graduate School of Medicine, Pediatlic Cardiology, Osaka-Japan[1]; The Department of Pediatrics Kinki University, Pediatlic Cardiology, Osaka-Japan[2]; The Department of Pediatrics,Osaka Univercity Graduate School of Medicine, Pediatlics, Osaka-Japan[3]; Osaka Medical Center And Research Institute For Maternal and Child Health All Rights Reserved, Pediatlic Cardiology, Osaka-Japan[4]

Background: Tricuspid valve malformation and Ebstein anomaly (TVM/EA) diagnosed by fetal echocardiography shows huge clinical variety of severity and prognosis during perinatal period. Although Celermajer index and Simpson Andrews Sharland (SAS) score are well-established predicting scoring system for its prognosis, they do not reflect the hemodynamic impact of left ventricular function which is recently considered as more important in TVM/EA physiology. Therefore in this study, we aimed to clarify the predicting value of left ventricular function in TVM/EA fetuses.
Subjects and Methods: We reviewed the clinical records of 36 TVM/EA fetuses diagnosed between 2000 and 2015. We compared alive and dead cases by uni- and multi-variate analysis of the gestational age at diagnosis, cardiothoracic ratio (CTAR), direction of pulmonary flow and ductal flow, right-left ventricular ratio, tricuspid regurgitation (TR) velocity, Celermajer index, SAS score, and left ventricular (LV)-Tei index.
Results: Among 36 fetuses, two were terminated, one lost to follow-up, and two died in utero before 22 weeks of gestation. Of 31 fetuses, 12 were dead in perinatal period (perinatal mortality was 39%). The multivariate analysis revealed that TR velocity was significantly lower (3.2 ± 0.5 m/s vs 2.2 ± 0.5 m/s, $p < 0.01$) and SAS score was significantly higher (3.0 ± 0.5 points vs 6.0 ± 0.7 points, $p < 0.01$) in the dead cases. Absent pulmonary flow and retrograde ductus flow were also correlated with death. Importantly, LV-Tei index was significantly higher in dead cases (0.5 ± 0.05 vs 0.8 ± 0.08 $p < 0.01$). In contrast, there was no significant difference in gestational age, Celermajer index, CTAR, and right-left ventricular ratio. Finally we found that the combinational scoring system including TR velocity, pulmonary and ductal flow, and LV-Tei index could more efficiently predict the perinatal mortality of TVM/EA.
Conclusion: Our novel combinational scoring method including LV-Tei index is highly predictable for the perinatal mortality of TVM/EA. LV function might be a key regulator of prognosis in TVM/EA fetuses.

P2180 - COMPLICATION OR COINCIDENCE SUPERIOR VENA CAVA ANEURYSM AFTER SINGLE VENTRICLE PALLIATION OPERATION

Ibrahim Cansaran Tanidir[1], Taner Kasar[1], Pelin Ayyildiz[1], Aysel Turkvatan[2], Alper Guzeltas[1]
Istanbul Saglik Bilimleri Universitesi Istanbul Mehmet Akif Ersoy Gogus Kalp Ve Damar Cerrahisi Egitim Ve Arastirma Saglik Biliml, Pediatric Cardiology, Istanbul-Turkey[1]; Istanbul Saglik Bilimleri Universitesi Istanbul Mehmet Akif Ersoy Gogus Kalp Ve Damar Cerrahisi Egitim Ve Arastirma Saglik Biliml, Radiology, Istanbul-Turkey[2];

Background: Aneurysmal dilation of the SVC is a rare anomaly. Also it is ever rarer especially after single ventricle palliations like Glenn anastomosis or Fontan-Kreutzer procedure. Here in we report 5 casesof aneurysmal dilation of the SVC after single ventricle palliation.
Materials and Methods: Between January 20010 and November 2016 2950 cardiac catheterization procedure and more than 2584 congenital cardiac surgery was performed in our hospital. Among them, 75 patients had diagnostic cardiac catheterization before Fontan palliation for routine evaluation and 13 patients had cardiac catheterization after Fontan palliation for other reasons, 152 patients underwent single ventricle palliation (112 Glenn anastomosis and 40 Fontan). We detected 5 patients (2.2%) with SVC aneurysm.

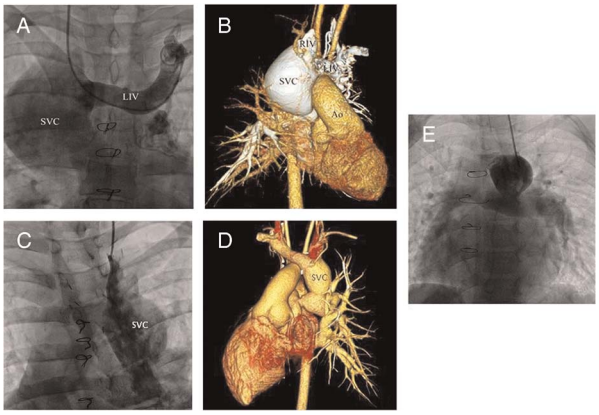

Figure 1.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: (See Table-1)
Conclusion: The majority of the reported SVC aneurysms are either isolated pathology or secondary to connective tissue diseases. SVC aneurysms after single ventricle palliation is extremely rare and surprising. The common feature in all reported patients was the region of the aneurysm, yet we don't know why.

Table 1.

Patient	Sex	Age (years)	Cardiac pathology	Surgery	SVC aneurysm size {mm}	Mean PAP

P2190 - THE USE OF 3D TECHNOLOGIES FOR SURGICAL PLANNING OF COMPLEX CONGENITAL HEART DISEASE FIRST EXPERIENCE IN TURKEY

Okan Yildiz[1], Volkan Tuncay[2], Ibrahim Tanidir Cansaran[3], Behzat Tuzun[1], Alper Guzeltas[3], Kerem Pekkan[2], Sertac Haydin[1]
Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiovascular Surgery, Istanbul-Turkey[1]; Koc University College of Engineering, Mechanical Engineering, Istanbul-Turkey[2]; Saglik Bilimleri University Istanbul Mehmet Akif Ersoy Thoracic and Cardiovasculer Surgery Training and Research Center Hospital, Pediatric Cardiology, Istanbul-Turkey[3]

Background: Double outlet right ventricle (DORV) and transposition of great arteries (TGA) are conotruncal anomalies with considerable heterogeneity of intracardiac anatomy. Echocardiographic imaging does not always provide the information needed to design an intracardiac baffle directing left ventricular out flow through the VSD to the aorta for biventricular repair. A three dimensional (3D) model of the heart based upon data derived from computed tomography (CT) may contribute to a more complete appreciation of the intracardiac anatomy. In this prospective study, we wanted to share our experience with surgical planning based on 3D modeling for complex intracardiac anatomy.
Methods: Based on CT images performed in selected patients with complex DORV and TGA anomalies, the intracardiac anatomy was segmented. Out of each patient's data set we generated a virtual computer model (3D mesh) and an STL-file that was printed as a 3D plaster model if necessary. Cuttings were made on the 3D mesh obtained to display the heart and associated anatomical structures were clarified.
Results: We printed two 3D models and created eight virtual models of patients with complex intracardiac anatomy and 4 of them were operated on (Table1). The models helped the pediatric cardiologists to better understand the spatial relationships between the ventricular septal defect and the great vessels, and the surgeons to identify risk structures, and to plan the surgical strategy in detail. There was a strong correlation between the 3D models of these patients and the anatomic state detected during the operation. However, information regarding valves, chordae and papillary muscles was insufficient in 3D models.
Conclusions: 3D cardiovascular models accurately replicate the patient's anatomy and are extremely helpful for planning surgery in complex intracardiac anatomy. In our experience, it enhances the alignment of pediatric cardiologists and surgeons by strengthening interdisciplinary team work. They may potentially reduce operative time and morbi-mortality.

P2201 - INCREASE OF PROSTAGLANDIN E2 IN REVERSAL OF DUCTAL CONSTRICTION AFTER DIETARY RESTRICTION OF POLYPHENOLS

Izabele Vian, Paulo Zielinsky, Ana Maria Zilio, Melissa Markoski, Maximiliano Shaun, Camila Brum, Jesús Zurita-peralta, Alessandro Olszewski, Antonio Piccoli Jr, Luiz Henrique Nicoloso
Institute of Cardiology, Fetal Cardiology Unit, Porto Alegre-Brazil

Background/Hypothesis: It has already been demonstrated that substances with antiinflammatory effects which inhibit prostaglandin synthesis, such as nonsteroidal antiinflammatory drugs (NSAID) and polyphenol-rich foods, may cause fetal ductal constriction (DC). Reversal of DC after maternal restriction of polyphenols has been reported, but its relation to prostaglandin concentration has not yet been demonstrated. This study was performed to test the hypothesis that dietary intervention to decrease ingestion of polyphenol-rich foods improves DC and is followed by increase in prostaglandin E2 (PGE2) levels.
Material and Methods: Clinical trial with a healthy group as comparator. The interventional group (IG) was made up of third-trimester mothers whose single fetuses had DC, excluding those exposed to NSAID, and the control group (CG) only by third-trimester normal fetuses. The IG was submitted to dietary orientation to restrict polyphenol-rich foods and both groups answered a food frequency questionnaire after fetal Doppler-echocardiographic examination and blood draw for PGE2 levels analysis. After two weeks, the women were again submitted to fetal echocardiogram, dietary assessment and blood draw.
Results: Forty mothers were recruited for the CG and 35 for the IG. Mean maternal age (26.6 years) and mean BMI (30.12 kg/m2) were similar among the groups. In intragroup analysis, after dietary orientation the IG showed decrease in median polyphenol consumption (1234.82 to 21.03 mg/day, $p < 0.001$) and increase in median concentration of PGE2 (1091.80 to 1136.98 pg/ml, $p < 0.05$), in addition to normalization of Doppler signs of DC (decrease of mean systolic [1.92 to 1.34 m/s, $p < 0.001$] and diastolic [0.45 to 0.22 m/s, $p < 0.001$] velocities and increase in mean pulsatility index [1.96 to 2.53, $p < 0.001$]). In the same analysis, the CG did not show significant changes.
Conclusions: Dietary intervention to restrict polyphenol-rich foods in third trimester fetuses with ductal constriction increases prostaglandin E2 levels, with improvement of this condition.

P2239 - LV NON COMPACTION IN SUBJECTS WITH COARCTATION OF THE AORTA – PREVALENCE AND EFFECTS ON CARDIAC FUNCTION

Preeti Choudhary[1], Christian Hamilton-Craig[2], Shelby Kutty[3], Raj Puranik[4], David Celermajer[4]
University of Sydney, Department of Medicine, London-United Kingdom[1] Prince Charles Hospitsl, Department of Cardiology, Brisbane-Australia[2] University Medical Centre, Department of Cardiology, Omaha-United States[3] Royal Prince Alfred Hospital, Department of Cardiology, Sydney-Australia[4]

Background/Hypothesis: Left ventricular non-compaction (LVNC) has been associated with heart failure, arrhythmia, systemic thromboembolism and sudden cardiac death. CoA is one of the most common congenital lesions observed in a patient cohort with LVNC, however the prevalence of LVNC in patients with coarctation of the aorta (CoA) and its clinical significance remains unknown. We sought to evaluate the prevalence of LVNC in patients with repaired CoA as well as its effect on LV size and function.
Methods & Results: 268 patients (Mean age 26 (IQR 21-37) years, 63% male) undergoing cardiac MRI for clinical follow-up were included from three tertiary centres for adult congenital heart disease. Clinical data was obtained from medical records and correlated with ventricular volumes and function. LVNC was defined as a diastolic non-compacted:compacted dimension ratio >2.3 in the worst affected segment on a long-axis view as per current cardiac MRI criteria. The prevalence of LVNC was 8.2% (22 patients), with a mean end-diastolic NC:C ratio of 3.12 + /-0.8. The LV apical segment was affected in all 22 patients (100%), mid-segment in 11 patients (50%) and basal segment in 1 patient (5%). Indexed LV end-diastolic volumes (108 + /-32mL vs. 92 + /-22mL; $p = 0.006$) and stroke volumes (115 + /-28mL vs. 97 + /-24mL, $p = 0.003$) were significantly higher in the LVNC group compared to patients without LVNC. No significant differences in LV ejection fraction (56 + /-8% vs. 58 + /-11%; $p = 0.46$) were observed.
Conclusions: LVNC is relatively common in patients with repaired CoA and is associated with increased LV end-diastolic volumes and stroke volumes.

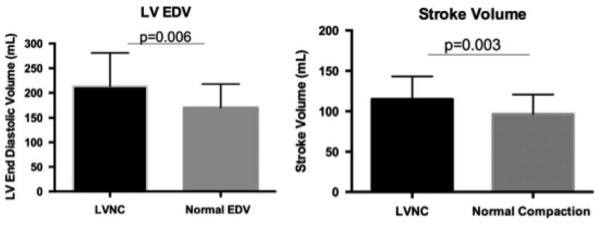

Figure.
LV Volumes in LV Non-compaction (LVNC) versus normally compacted controls, in patients with repaired coarctation.

P2272 - SIGNIFICANT DIAMETER HETEROGENEITY BETWEEN AORTIC ROOT AND AORTIC ANNULUS IN BICUSPID AORTIC VALVE

Anne Fournier[1], Lea-marie Meloche-Dumas[1], Frederic Dallaire[2], Samuel Blais[2], Dahdah Nagib
Chu Mere-Enfant Sainte-Justine, Cardiology, Montreal-Canada[1]; CHUS, Cardiology, Sherbrooke-Canada[2]

Background: Bicuspid aortic valve (BAV) is associated with aortic dilatation and potential dissection. There are 3 major patterns of leaflets fusion in BAV: left and right coronary leaflets fusion (BAV-1), right and non-coronary leaflets fusion (BAV-2), and the rare three-leaflet fusion (BAV-3). We sought to determine the pattern of dilatation according to commonest types of BAV fusion.
Methods and Results: In this retrospective cross-sectional study, echocardiography reports were reviewed to evaluate the homogeneity of normalized diameters of the aortic valve, the aortic root and the ascending aorta according to fusion morphology. From 216 BAV patients followed at CHU Sainte-Justine between 2009 and 2014 (mean age at echocardiography 1 was 7.19 ± 5.56 years; 74.5% males), 155/216 (71.8%) had BAV-1, and 61/216 (28.2%) had BAV-2; $p = NS$ for age. Aortic valve stenosis was present in 66/216 (30.6%) patients, with a lower prevalence 39/155 (25.2%) in BAV-1 compared to 27/61 (44.3%) in BAV-2 ($p = 0.006$). There was no statistically significant difference in the ascending aorta between the study groups (Table 1). However, BAV-1 had increased aortic root Z-score compared to BAV-2 ($p = 0.0007$) despite a trend towards larger aortic annulus in BAV-2 ($p = 0.11$). The difference was not significant between BAV-1 and BAV-2 in cases with valvular stenosis (0.67 ± 1.50 vs. 0.17 ± 1.73; $p = 0.48$), but significant in the absence of stenosis (0.79 ± 1.57 vs. -0.25 ± 0.98; $p = 0.00035$). Altogether, there was no significant differences in the ascending aorta dimension in either case (BAV-1 vs. BAV-2, or valvular stenosis vs. no stenosis).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Although not necessarily dilated (mean Z < 2.0), type-1 BAV fusion aortic roots are larger than in type-2. The observed difference suggests potential modifications in patient approach with this valvular disease according to the type of fusion.

Table 1. Z-scores based on fusion type (mean ± SD)

	BAV-1	BAV-2	p value
Aortic Valve (AV)	0.43 ± 1.71	0.88 ± 1.90	0.11
Aortic Root (AR)	0.70 ± 1.50	-0.08 ± 1.34	0.0007
Ascending Aorta (AA)	1.45 ± 2.13	2.04 ± 2.15	0.07

P2315 - TYPES AND OUTCOMES OF CONGENITAL CARDIAC MALFORMATION IN INDONESIAN PATIENTS WITH ISOMERIC HEART

Olfi Lelya, Oktavia Lilyasari, Poppy S Roebiono, Indriwanto Sakidjan, Radityo Prakoso, Anna U Rahajoe, Ganesja M Harimurti
Faculty of Medicine - Universitas Indonesia, Department of Cardiology and Vascular Medicine, Jakarta-Indonesia

Background: Isomerism or Heterotaxy syndromes are rare congenital anomalies which has high morbidity and mortality. This term includes patients with a wide variety of very complex cardiac lesions. The hallmark of this cardiac anatomy includes isomeric right or left atria, which can be diagnosed by echocardiography.
Objectives: To describe the types of congenital cardiac malformation in patients with isomeric heart based on echocardiography and its outcomes.
Methods: We reviewed all patients with isomeric heart who were assessed and managed at National Cardiovascular Center Harapan Kita, Jakarta, Indonesia from January to December 2016. Isomeric heart was diagnosed by echocardiography and most of them had undergone cardiac surgery.
Results: There were 54 patients with isomeric heart with age ranged from 10 days to 27 years old. Thirty four (63%) were patients with right isomeric heart, 20 (37%) with left isomeric heart. The overall most common cardiac anomalies were atrio-ventricular septal defect in 38 (70%), double outlet right ventricle in 19 (35%), pulmonary atresia in 15 (27%), and total anomalous pulmonary venous drainage in 12 (22%) patients. Surgery was performed in 32 (66%) patients age ranged from 12 days to 13 years old with hospital mortality 9 (16%) patients. The most common cause of death of these patients were severe infection 2 (22%), arrhythmia 1 (11%), and additional airway anomaly 1 (11%). Five (9%) patients died before surgery due to infection, severe hypoxia, gastro-intestinal problems or airway problems. From all 14 deaths, 6 (43%) patients were neonates and 7 (50%) had extra cardiac total anomalous pulmonary venous drainage.
Conclusion: The most common cardiac anomaly found in our isomeric heart patients was atrio-ventricular septal defect. The early outcome of these patients is still not satisfactory despite of better medical facilities and surgical management.

P2323 - FUNCTIONAL PRENATAL ECHOCARDIOGRAPHIC PATTERN AS A PREDICTOR OF SEVERITY OF POSTNATAL AORTIC COARCTATION

Laia Brunet[1], Juan Carretero[1], Joaquim Bartrons[1], Olga Gomez[2], Iris Soveral[2], Josep Maria Martinez[2], Joan Sanchez-De-Toledo[1]
Hospital Sant Joan De Déu, Pediatric Cardiology, Barcelona-Spain[1]; Fetal I + d Fetal Medicine Research Center, BCNATAL - Barcelona Center for Maternal-Fetal and Neonatal Medicine (Hospital Clínic and Hospital Sant Joan, Fetal Cardiology, Barcelona-Spain[2]

Background: Coarctation of the aorta (CA) is a common form of congenital heart defect which may require an intervention during infancy. Our main goal was to identify an echocardiographic prenatal ventricular functional pattern associated with the severity of CA.
Materials and Methods: Retrospective review of patients with suspected CA with prenatal functional echocardiography, which diagnosis was postnatally confirmed between June 2011 and September 2016 in our institution. Comprehensive echocardiography was performed at third trimester of pregnancy. Biventricular systolic and diastolic functions were assessed by M-mode, pulse-wave and tissue Doppler imaging (TDI techniques). Postnatal transthoracic echocardiographic was obtained to measure the aortic valve, ascending aorta and the transvers and isthmic arch. Z-scores were calculated. Clinical courses were also reviewed. Statistical analysis comparing functional prenatal parameters with the size and the z-scores of the aorta was conducted.
Results: Twenty one patients were admitted to the NICU and 20/21 patients received prostaglandin infusion. All interventions were performed between 2 and 12 days of life (3/20 balloon angioplasty, 8/20 end-to-end repair, extended arch repair 7/20 and Norwood approach 1/20) except in one case which underwent balloon angioplasty at 103 days of life. A negative correlation between prenatal Pulmonic Valve size and postnatal Transverse arch diameter ($r = -.55$, $p < 0.01$) and positive correlation between Right End-Systolic Sphericity and Isthmic diameter ($r = .81$, $p < 0.01$) was found. Those patients undergoing extensive arch repair/Norwood operation had higher prenatal Right Cardiac Output (RCO) compare to those undergoing Angioplasty/end-to-end repair (0.6 ± 0.3 vs 0.9 ± 0.3, $p = 0.04$). No other significant correlations between echocardiographic prenatal ventricular functional pattern and the severity of CA were found.
Conclusions: In our study patients requiring extensive arch repair had significantly higher prenatal RCO compared with those requiring simple arch reconstruction. Larger series are needed to assess whether there is a functional parameter that could better predict the postnatal severity of the CA.

P2332 - ALTERATION IN CEREBRAL BLOOD FLOW IN CHILDREN WITH CONGESTIVE HEART FAILURE DUE TO VENTRICULAR SEPTAL DEFECT

Nurdan Ozturk - Tasar[1], Ali Yildirim[2], Pelin Kosger[3], Duran Karabel[3], Nevzat Uzuner[4], Zubeyir Kilic[3], Birsen Ucar[3]
Sinanpasa State Hospital, Clinic of Pediatrics, Afyon-Turkey[1]; Pediatric Cardiologist, Eskisehir-Turkey[2]; Eskisehir Osmangazi Universty, Department of Pediatric Cardiology, Eskisehir-Turkey[3]; Eskisehir Osmangazi Universty, Department of Neurology, Eskisehir-Turkey[4]

Aim: We aimed to investigate the effect of ventricular septal defect (VSD) and heart failure on cerebral blood flow (CBF) and whether there is any improvement in CBF after the treatment of heart failure and any relationship with serum NT-proBNP.
Method: Forty children with VSD (13 of them had heart failure) aged between 1-36 months were included in the study group. Control group consisted of 25 healthy children at age of 1-36 months. Maximum, minimum and mean blood flow velocities and pulsatile indexes of right and left medial cerebral arteries were assessed through the temporal window by transcranial Doppler ultrasonography. CBF measurement and serum NT-proBNP

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

analysis were repeated in patients with heart failure a month after the beginning of anticongestive therapy. All cases were scored and grouped according to the Ross scoring system. The groups were also compared in terms of defect diameters, cardiac structural changes, left ventricular systolic functions and the findings related with pulmonary hypertension determined by echocardiography. The correlations between echocardiographic measurements and CBF parameters were analyzed.
Results: Although no difference was found between the patient and control groups for CBF ($p > 0.05$), right and left maximum CBF velocities significantly increased after anticongestive therapy in patients with heart failure ($p = 0.04$; $p = 0.01$, respectively). NT-proBNP level of patients with heart failure was significantly higher than the patients with VSD without heart failure ($p = 0.04$) and control groups ($p < 0.001$). NT- proBNP levels negatively correlated with right and left maximum CBF velocities ($r = -0.39$, $p = 0.013$; $r = -0.32$, $p = 0.043$, respectively).
Conclusion: Although no difference was found among study groups for CBF velocity, occurrence of an increase in CBF velocity after anticongestive therapy and negative correlations between CBF velocity and both the defect diameter and NT- proBNP levels have shown that hemodynamic status due to VSD and heart failure has an effect on CBF.

P2339 - RISK FACTORS FOR PROGRESSIVE AORTIC DILATATION IN CHILDREN WITH BICUSPID AORTIC VALVE (DATA FROM REVAB)

Anna Sabate-Rotes[1], Carolina Juzga[1], Ariadna Ayerza-Casas[2], Lorenzo Jimenez-Montañes[3], Silvia Escriba-Bori[4], Maria Aranzazu Gonzalez-Marin[5], Moises Sorli[6], Monica Rodriguez[7], Olga Dominguez-Garcia[8], Sara Rellan[9], Manuel Prtillo-Marquez[10], Marta Yagüe[11], Roser Alvarez-Perez[12], Marc Figueras-Coll[13], Silvia Teodoro[14], Rosa Collell[15], Bernardo Lopez-Abel[16], Begoña Manso[17], Ruth Solana[18], Bibiana Riaño[19], Erika Rezola[20], Henar Rojo-Sombrero[21], Teresa Cantero[22], Ronald Isla[23], Marisol Jimenez-Casso[24], Ma Angeles Tejero[25], Ana Maria Perez-Pardo[26], Ana Moriano[27], Beatriz Plata-Izquierdo[28], Carlos Salido-Peracaula[29]
Hospital Vall De Hebron, Pediatric Cardiology, Barcelona-Spain[1]; Hospital Lozano Blesa, Zaragoza-Spain[2]; Hospital Miguel Servet, Zaragoza-Spain[3]; Hospital Son Espases, Mallorca-Spain[4]; Hospital De Ciudad Real, -Spain[5]; Hospital De Cartagena, -Spain[6]; Hospital De Monteprincipe, Madrid-Spain[7]; Hospital Virgen De La Salud, Toledo-Spain[8]; Hospital Clinico, Valladolid-Spain[9]; Hospital De Merida, Badajoz-Spain[10]; Hospital 12 De Octubre, Madrid-Spain[11]; Hospital Sant Pau, Barcelona-Spain[12]; Hospital Josep Trueta, Girona-Spain[13]; Hospital Parc Tauli, Sabadell-Spain[14]; Hospital Sant Joan, Reus-Spain[15]; Hospital Santiago De Compostela, -Spain[16]; Hospital Virgen Del Rocio, Sevilla-Spain[17]; Hospital Infanta Leonor, Madrid-Spain[18]; Hospital San Pedro, Logroño-Spain[19]; Hposital De Donostia, -Spain[20]; Hospital Principe De Asturias, Madrid-Spain[21]; Hospital De Palencia, -Spain[22]; Hospital De Nens, Bracelnoa-Spain[23]; Hospital General, Segovia-Spain[24]; Hospital Reina Sofia, Cordoba-Spain[25]; Hospital General De Catalunya, Sant Cugat Del Valles-Spain[26]; Hospital Lluis Alcanyis, Xativa-Spain[27]; Hospital De Salamanca, -Spain[28]; Hospital De Jerez, -Spain[29]

Objectives: Define risk factors for developing progressive aortic dilatation in children with bicuspid aortic valve.
Methods: A total of 393/944 patients had 2 visits introduced in the Spanish registry for children with bicuspid aortic valve (REVAB), from the Spanish Society of Pediatric Cardiology and Congenital Heart Diseases (SECPCC). Only patients with at least 1 year between visits were included. Progression was defined as standard deviations adjusted by weight and height per year followed.
Results: Mean progression of sinus of Valsalva was 0.21 ± 0.59 SD/y and was related with younger age at both first and second visit -3.12, $p = 0.002$ and -3.87, $p < 0.001$, and concomitant coarctation of the aorta 3.08, $p = 0.002$. However, patients with aortic regurgitation had less progression -1.99, $p = 0.047$. No association was found with aortic stenosis -0.053, $p = 0.596$, morphology of the aortic valve (pure 1.56, $p = 0.12$, horizontal -1.69, $p = 0.09$) or time of follow-up -1.89, $p = 0.06$. In the multivariate analysis, only patients who were younger at second visit and with concomitant coarctation of the aorta remained associated with progression of the aortic root dilatation, -3.52 $p = 0.001$ and 2.77 $p = 0.006$ respectively. Mean progression of ascending aorta was 0.29 ± 0.67 SD/y and was related with younger age at second visit -2.74, $p = 0.007$, left sided obstructive lesions 2.36, $p = 0.019$, and shorter follow-up -2.55, $p = 0.011$. There was no association with age at first visit -1.75, $p = 0.08$, aortic stenosis -0.27, $p = 0.788$, aortic regurgitation -1.17, $p = 0.242$, or morphology of the aortic valve (pure -0.98, $p = 0.327$, horizontal 1.71, $p = 0.088$). In the multivariate analysis, patients younger at second visit, with concomitant left sided obstructive lesions and shorter follow-up remained associated with progression of the ascending aorta dilatation: -2.04 $p = 0.04$, 2.19 $p = 0.03$ and -2.08 $p = 0.039$ respectively.
Conculsion: Younger patients with concomitant coarctation of the aorta or other left sided obstructive lesions are at higher risk of progression of the aortic dimensions.

P2341 - DIFFERENT PATTERNS OF AORTIC DIMENSIONS IN CHILDREN WITH BICUSPID AORTIC VALVE (DATA FROM REVAB)

Anna Sabate-Rotes[1], Carolina Juzga[1], Ariadna Ayerza-Casas[2], Lorenzo Jimenez-Montañes[3], Silvia Escriba-Bori[4], Maria Aranzazu Gonzalez-Marin[5], Moises Sorli[6], Monica Rodriguez[7], Olga Dominguez-Garcia[8], Sara Rellan[9], Manuel Portillo-Marquez[10], Leticia Albert[11], Roser Alvarez-Perez[12], Marc Figueras-Coll[13], Silvia Teodoro[14], Rosa Collell[15], Bernardo Lopez-Abel[16], Begoña Manso[17], Ruth Solana[18], Bibiana Riaño[19], Erika Rezola[20], Henar Rojo-Sombrero[21], Teresa Cantero[22], Ronald Isla[23], Marisol Jimenez-Casso[24], Ma Angeles Tejero[25], Ana Maria Perez-Pardo[26], Ana Moriano[27], Beatriz Plata-Izquierdo[28], Carlos Salido-Peracaula[29]
Hospital Vall De Hebron, Pediatric Cardiology, Barcelona-Spain[1]; Hospital Lozano Blesa, Zaragoza-Spain[2]; Hospital Miguel Servet, Zaragoza-Spain[3]; Hospital Son Espases, Mallorca-Spain[4]; Hospital De Ciudad Real, -Spain[5]; Hospital De Cartagena, -Spain[6]; Hospital Monteprincipe, Madrid-Spain[7]; Hospital Virgen De La Salud, Toledo-Spain[8]; Hospital Clinico, Valladolid-Spain[9]; Hospital De Merida, Badajoz-Spain[10]; Hospital 12 De Octubre, Madrid-Spain[11]; Hospital Sant Pau, Barcelona-Spain[12]; Hospital Josep Treuta, Girona-Spain[13]; Hospital Parc Tauli, Sabadell-Spain[14]; Hospital Sant Joan, Reus-Spain[15]; Hospital De Santiago De Compostela, -Spain[16]; Hospital Virgen Del Rocio, Sevilla-Spain[17]; Hospital Infanta Leonor, Mardid-Spain[18]; Hospital San Pedro, Logroño-Spain[19]; Hospital De Donostia, -Spain[20]; Hospital Principe De Asturias, Madrid-Spain[21]; Hospital De Palencia, -Spain[22]; Hospital De Nens, Barcelona-Spain[23]; Hospital General, Segovia-Spain[24]; Hospital Reina Sofia, Cordoba-Spain[25]; Hospital General De Catalunya, Sant Cugat Del Valles-Spain[26]; Hospital Lluis Alcanyis, Xativa-Spain[27]; Hospital De Salamanca, -Spain[28]; Hospital De Jerez, -Spain[29]

Objectives: Define age-wise patterns of aortic dimensions among children with bicuspid aortic valve.
Methods: From the Spanish registry for children (<18 years) with bicuspid aortic valve (REVAB), under the auspices of Spanish Society of Pediatric Cardiology and Congenital Heart Diseases (SECPCC), patients with isolated bicuspid aortic valve (589) were compared to patients with concomitant congenital anomaly (including coarctation

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

of the aorta, interrupted aortic arch, subaortic stenosis, mitral stenosis, ventricular septal defect and others, 355). Dimensions of the aorta were adjusted by weight and height (standard deviations, SD).
Results: Overall, patients with isolated bicuspid aortic valve had larger dimensions of the aortic root and the ascending aorta: 0.2 ± 1.6 SD vs -0.1 ± 1.9 SD and 1.5 ± 1.9 SD vs 0.4 ± 2.4 SD, $p = 0.005$ and $p < 0.001$ respectively. Age-wise aortic dimensions differed between the groups (see figures attached). Patients with isolated bicuspid aortic valve (green) had larger sizes of the aortic root at birth with a decrease until 6 years of age and then stabilized; the ascending aorta was also larger, with a mean over 2 SD, at birth and started growing even more between 6 and 10 years of age, and then stabilized. Patients with concomitant congenital disease (violet) had smaller sizes of the aortic root at birth with an increase until 5 years of age, then stabilized and after 12 years of age started increasing again. Similarly, patients with concomitant congenital disease had smaller ascending aorta at birth, with an increase until normalization or even slightly dilatation with a peak at 8 years of age and then stabilized.
Conclusions: Patients with isolated bicuspid aortic valve have larger aortic dimensions at birth with little change over somatic growth. On the other hand, patients with concomitant congenital anomaly have smaller aortic sizes at birth with a trend towards progressive dilatation over somatic growth.

P2342 - NATIVE T1 MAPPING OF LEFT VENTRICLE OF CHILDREN WITH POST CORONARY RELATED CARDIAC SURGERY

Johan Aref Jamaluddin[1], Ashish Chikermane[2], Simon Mcguirk[3]
Universiti Putra Malaysia, Paediatric, Serdang-Malaysia[1]; Birmingham Children's Hospital, Paediatric Cardiology, Birmingham-United Kingdom[2]; Birmingham Children's Hospital, Paediatric Radiology, Birmingham-United Kingdom[3]

Background/Hypothesis: Myocardial fibrosis is a major independent predictor of adverse cardiac outcomes in children with congenital heart diseases. T1 mapping of left ventricular (LV) wall using Cardiac Magnetic Resonance Imaging (CMR) has emerged as an alternative technique in detection of fibrosis. Primary objective of this study is to ascertain T1 mapping values of children with congenital heart diseases where the primary corrective surgery involved coronary arteries re-implantation/transfer. This cohort was hypothesized to have early fibrosis evidence with T1 parameters which are higher than controls.
Methods: 25 paediatric patients (mean age 12.7 + /- 3.8 years old) who either had arterial switch Operation/Anomalous Left Coronary Artery from Pulmonary Artery (ALCAPA) repair/Ross procedure/double switch operation were included in the study. All had undergone CMR from March-December 2016 at Birmingham Children's Hospital, Birmingham, United Kingdom. A single breath-hold Modified Look-Locker Inversion-recovery (MOLLI) pulse sequence was used on a mid-ventricular short axis imaging plane. 27 patients were also included as control.
Results: All patients in the cases group had normal LV function (mean LVEF : $65.8 \pm 10.8\%$, LVEDVi 68.3 ± 11.4 ml.m2, SVi 44.4 ± 8.8 ml.m2). In comparison of native T1 values of inter-ventricular septum, no significance difference were found between case cohort and control (982.7 ± 36.8 vs 979.7 ± 29.0, $p = 0.74$). Native T1 values of LV free walls were also not statistically different between the two groups (954.7 ± 41.1 vs 956.6 ± 24.9, $p = 0.84$). However in the cases cohort, T1 of LV free wall are lower than inter-ventricular septum (954.1 ± 41.4 vs 982.7 ± 36.8, $p = 0.015$).
Conclusions: Native T1 values are not significantly higher in children who had cardiac surgery with coronary re-implantation/transfer and normal post-surgical left ventricular function. However, further study needs to be performed in the cohort with impaired left ventricular function.

P2348 - EXTRA CELLULAR VOLUME IMAGING OF LEFT VENTRICULAR WALLS IN CHILDREN WITH CONGENITAL HEART DISEASES AND IMPAIRED VENTRICULAR FUNCTION

Johan Aref Jamaluddin[1], Ashish Chikermane[2], Simon Mcguirk[3]
Universiti Putra Malaysia, Paediatric, Serdang-Malaysia[1]; Birmingham Children's Hospital, Paediatric Cardiology, Birmingham-United Kingdom[2]; Birmingham Children's Hospital, Paediatric Radiology, Birmingham-United Kingdom[3]

Background/Hypothesis: In children with congenital heart diseases, myocardial fibrosis is a possible long term complication with impairment of left ventricular function. Extra-Cellular Volume (ECV) imaging of left ventricular (LV) walls using Cardiac Magnetic Resonance Imaging (CMR) offers early detection of fibrosis before late gadolineum enhancement (LGE) changes are seen. Aim of the study was to determine ECV of a cohort of children with congenital heart diseases and any association with their left ventricular function.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: 19 children with congenital cardiac conditions who had undergone CMR from March to December 2016 at Birmingham Children's Hospital UK were included in the study. All subjects underwent CMR (Siemens Avanto 1.5 T scanner) to assess LV function, measurement of ECV on T1-mapping (MOLLI sequence) and standard late gadolinium enhancement (LGE) imaging. ECV values were determined from 5 different LV wall segments on short axis images (inter-ventricular septum, anterior, antero-lateral, inferio-lateral, inferior segments).
Results: 4 children (age 10.9 ± 3.9 years old) had impaired LV ejection fraction (44.5 ± 6.0%) and increased LV end diastolic volume indexed (82.2 ± 14.5 ml.m2). One of the children had LGE changes seen on the inter-ventricular septum. ECV parameters of the inter-ventricular septum were higher in children with impaired LV function (38.6 ± 7.0% vs 30.0 ± 3.5%, $p = 0.002$). No significant difference were found in the ECV of LV free walls (32.2 ± 5.2% vs 28.7 ± 5.7%, $p = 0.279$).
Conclusions: ECV technique has promising possibility in detection of myocardial fibrosis in children with impaired LV function, similar as adult studies. In those with poor LV function, there is a strong possibility that area of fibrosis is in the inter-ventricular septum. However, normal ECV parameters will need to be determined first in children before comparing with those with cardiac illnesses.

P2349 - THE TREND CHANGE IN CARDIAC IMAGING IN CONGENITAL HEART DISEASE EXPERIENCE OF TERTIARY CENTER IN INDONESIA

Oktavia Lilyasari, Poppy S Roebiono, Karina N Pratiwi, Anna U Rahajoe, Indriwanto Sakidjan, Radityo Prakoso, Yovi Kurniawati, Ganesja M Harimurti
National Cardiovascular Centre Harapan Kita Jakarta, Indonesia, Department of Cardiology and Vascular Medicine, Faculty of Medicine Universitas Indonesia, Jakarta-Indonesia

Background: Cardiac imaging is fundamental for diagnosing and evaluating of congenital heart disease (CHD). Transthoracic echocardiography (TTE) as the first-line imaging modality in CHD, has some limitations. The use of cardiac computed tomography (CT) and cardiac magnetic resonance imaging (CMRI) as further non-invasive diagnostic modalities are now being reconsidered instead of invasive diagnostic cardiac characterization.
Objective: To evaluate the change of cardiac imaging for CHD at National Cardiovascular Center Harapan Kita Jakarta, Indonesia.
Method: Data was obtained through a retrospective manner over 4 years from diagnostic medical records of CHD patients from 2013-2016.
Result: During the study period, an average of 8182 diagnostic tests were performed annually. The number of total studies TTE, diagnostic cardiac catheterization, Cardiac CT and CMRI procedures change significantly over time. The average use of TTE, diagnostic cardiac catheterization, cardiac CT and CMRI annually are 7089 cases, 452 cases, 167 cases and 473 cases per-year respectively. The use of cardiac MRI (0.83%, $p = 0.01$), and cardiac CT (3.77%, $p < 0.072$) increased linearly. Whereas that the use of echocardiography (88.9%, $p = 0.005$) and invasive diagnostic catheterization decreased (6.49%, $p = 0.458$) with relatively stable number of non-surgical CHD intervention (45.71%, $p = 0.844$). Cardiac CT evaluation is mostly performed in younger patients whom require evaluation of anatomy, great artery and anomaly of vein. Cardiac MRI examination was especially performed in older patient whom require anatomy, tissue characterizations, volume, function, and flow measurement. Invasive diagnostic catheterization was mostly performed among patients whom require hemodynamic evaluation.
Conclusion: Diagnostic imaging on CHD underwent changes due to the development of the use of CMRI and Cardiac CT. The choice of further imaging modalities following echocardiography examination depends on the clinical questions that remain to be addressed.

P2352 - EARLY ATHEROSCLEROTIC CHANGES AND MYOCARDIAL FUNCTIONAL ALTERATIONS IN CHILDREN WITH ISOLATED BICUSPIT AORTIC VALVE

Pelin Kosger[1], Ali Yildirim[2], Duran Karabel[3], Tugcem Keskin[3], Birsen Ucar[3], Zubeyir Kilic[3]
Eskisehir Osmangazi Universty, Department of Peditaric Cardiology, Eskisehir-Turkey[1]; Eskisehir Osmangazi Universty, Pediatric Cardiologist, Eskisehir-Turkey[2]; Eskisehir Osmangazi Universty, Department of Pediatric Cardiology, Eskisehir-Turkey[3]

Objectives: Bicuspid aortic valve (BAV) is the commonest congenital cardiac malformation with a prevalence of % 0,5 to 2%. It is frequently associated with dilatation, aneurysm and dissection of the ascending aorta. The purpose of the following study is to evaluate function of the left ventricle and stiffness, elasticity and strain of ascending aorta and epi-aortic vessels wall and thickness of the carotis intima media in pediatric patients with BAV.
Methods: Twenty four pediatric BAV patients (mean age 11.7 ±3.1 years) with no or mild valvuler impairment and 20 healty control subjects (mean age 11.9 ± 3.1) were included in the study. Global myocardial functions were evaluated with tissue Doppler derived myocardial performance index. We assessed the mean and maximal values of carotid intima-media thickness (CIMT) of the carotid artery. Aortic and carotid strains, distensibilities and stiffness indexes were derived.
Results: Diastolic blood pressure values of BAVs were higher than controls ($p < 0.001$). Diastolik and systolic diamaters of assendan aorta and sinotubuler junction and sinüsvalsalva diameters were higher than the control group (respectively <0.001, <0.001, $p < 0.05$, $p < 0.04$). Maximal values of CIMT of bilateral carotid arteries were higher than controls (respectively $p = 0.006$, $p = 0.003$). Isovolumetric contraction time, isovolumetric relaxation time and myocardial performance index obtained with tissue Doppler echocardiography were higher in BAVs (respectively $p = 0.016$, $p < 0.001$, $p < 0.01$). No significant differences were found in elastic properties of aorta and carotid arteries. . There was positive correlation between CIMT and isovolumetric relaxation time, diastolic and systolic blood pressure and diastolic diameter of assendan aorta.
Conclusions: In patients with isolated BAV, the blood pressure profile was elevated and was associated with left ventricular dysfunction and early atherosclerotic changes.

P2355 - EVALUATION OF MYOCARDIAL RESERVE WITH LOW DOSE DOBUTAMINE STRESS ECHOCARDIOGRAPHY IN PATIENTS WITH SEVERE LEFT ATRIOVENTRICULAR VALVE REGURGITATION IN THE LATE POSTOPERATIVE PERIOD OF ATRIOVENTRICULAR SEPTAL DEFECT REPAIR

Daniela Lago Kreuzig[1], Gerusa Souza Vilas-Boas[1], Natalia Freitas De Deus Vale Aragao[1], Renata Burini Chaccur[1], David Costa Le Bihan[1], Rodrigo Bellio De Matos Barretto[2], Jorge Eduardo Assef[2], Simone Rolim Fernandes Fontes Pedra[2]

Instituto Dante Pazzanese De Cardiologia, Echocardiography Laboratory, Sao Paulo-Brazil[1]; Instituto Dante Pazzanese De Cardiologia, Echocardiography, Sao Paulo-Brazil[2]

Background: The management of oligosymptomatic patients with severe left atrioventricular valve (LAVV) regurgitation in the late follow-up of atrioventricular septal defect (AVSD) repair is still challenging. Surgical repair follows the echocardiographic guidelines for mitral valve, where surgery is suggested when there is left ventricular (LV) dysfunction or increased LV systolic diameter. However, ejection fraction (EF) remains preserved for a long period of time, despite of the grade of mitral valve insufficiency. Dobutamine stress echocardiography (DSE) has shown to be a sensitive test for detection of subclinical cardiac dysfunction and can potentially assess functional myocardial reserve (MR). This study aimed to evaluate MR of oligosymptomatic patients with severe LAVV regurgitation in the late follow-up after AVSD repair.
Methods: 27 oligosymptomatic outpatients (18.6 ± 12.8 years-old) were studied. EF (Simpson's rule) and LV Global Longitudinal Strain (GLS) were measured at rest and after 10 minutes of dobutamine infusion (5 mcg/kg/min). Preserved MR was considered when EF increased at least 5% or the resting value.
Results: 18 patients had partial AVSD, 9 had the total form. At rest, mean EF was 64 ± 4.2% (55-72%) and GLS 20.9 ± 2.6% (15.9-26.4%). During stress, EF increased to 74.4 ± 7.1% (59-85%), GLS to 24.2 ± 2.9% (17.1-30.4%). 3 patients (11%) had no MR. In those, increment on GLS at stress was significantly lower than in preserved MR group (17.3 ± 1.07% to 18.2 ± 1.14% vs 21.4 ± 2.37% to 24.9 ± 2.1%; p:0.005). A cut-off point of 1.5% increment in GLS during stress was identified as preserved MR (Kappa index: 1).
Conclusion: This study detected the occurrence of 11% of absent MR in this group, which reflects the inadequate heart responses to stressing life situations and, therefore, it turns earlier the moment of surgery. The increment of LV GLS less than 1.5% after Dobutamine infusion was related to absent myocardial reserve.

P2365 - FREQUENCY OF CARDIAC PATHOLOGY IN FETAL ECHOCARDIOGRAPHY

Nurdan Erol[1], *Yusuf Izzet Ayhan[1], Fikret Gökhan Göynümer[2]*
Istanbul Medeniyet Universitesi Göztepe Education and Research Hospital, Pediatric Clinics, Istanbul-Turkey[1]; Istanbul Medeniyet Universitesi Göztepe Education and Research Hospital, Jinecology and Obstetric Clinicr, Istanbul-Turkey[2]

In this study; a frequency of cardiac pathology was examined in patients who were sent to the Pediatric Cardiology Clinic for fetal echocardiography.
Material and Method: In this study; the results of 839 patients who had fetal echocardiography in the pediatric cardiology clinic between 2009-2016 have been examined retrospectively using Microsoft Excel 2010.
Results: Within the study 818 fetuses of 839 mothers have been examined. 19 cases were multiple pregnancy, whereas in 4 cases examination was done for two separate fetuses. 85% of the cases were patients from our hospital's obstetric clinic, the remaining from other clinics. The average age of the mothers was 30 (17-55). The average gestation week was 25 (18-37). When the reason for fetal echocardiography was examined it was found out that 29.22% didn't have a reason,18.95% had maternal reasons, 32.89% had fetal reasons, 5.38% had familial reasons and the rest had multiple reasons. In 17.18% of the cases cardiac pathology was detected during fetal echocardiography. 2.86% of the cases had serious cardiac anomalies. Hyper echogenic focus was seen in 8.46% of the cases. Only 34.68% had newborn echocardiography in our clinic; and the cardiac pathology percentage was 16.15%. In 5.31% of the cases where cardiac pathology was seen in fetal echocardiography, the anomaly wasn't witnessed later on during newborn echocardiography. In 29.71% cases that weren't diagnosed with cardiac pathology in fetal echocardiography, cardiac pathology was seen in newborn echocardiography.
Conclusion: Fetal echocardiography is mostly a reliable, non-invasive method for diagnosing cardiac pathology. However, in some cases it was seen that cardiac pathology was seen in newborn echocardiography when it wasn't seen in fetal echocardiography; and vice versa. This shows that although fetal echocardiography gives accurate results in many cases, it isn't safe to assume that it is a reliable method in each case.

P2379 - PRENATAL RINGS DIAGNOSED IN PRENATAL TIME. CORRELATION WITH POSTNATAL IMAGE ON MDCT

Estefania Garcia Cerro[1], Lucía Deiros Bronte[1], Elisa Castaño Andreu[1], *Ángela Uceda Galiano[1], Luis García-Guereta Silva[1], Cesar Abelleira Pardeiro[1], Montserrat Bret-Zurita[2], Roberto Rodríguez González[3], Luz Polo López[4], Federico Gutierrez-Larraya[1]*
Hospital Universitario La Paz, Cardiología Pediátrica, Madrid-Spain[1]; Hospital Universitario La Paz, Radiodiagnóstico, Madrid-[2]; Hospital Universitario La Paz, Ginecología, Madrid-[3]; Hospital Universitario La Paz, Cirugía Cardiaca Infantil, Madrid-[4]

Background: Vascular rings (VR) are congenital abnormalities of the aortic arch consisting of vascular structures that encircle and sometimes compress the airway and esophagus. The most frequent complete VR are double aortic arch (DAA) and the right arch with anomalous left subclavian (RAA + ALSA) and left persistent ductus. In recent years, with prenatal diagnosis, it has been an increased frequency of VR with respect to as described in postnatal series, demonstrating greater percentage of asymptomatic patients during follow-up. Multidector computed tomography (MDCT) is the standard gold test for VR study. Our main objective has been to study the concordance of prenatal ultrasound on the MDCT findings.
Materials and Methods: Retrospective study of patients with prenatal diagnosis of VR in La Paz Children's Hospital between 2010-2016 which performed in postnatal life MTCD.
Results: In total, we had 19 patients (12 patients diagnosed AAD and 7 patients RAA + ALSA). 100% of patients who were diagnosed of VR by fetal echocardiography, the existence of a ring was confirmed by MCTD. Regarding the type and morphology of ring, only in one case was defined in prenatal ultrasound the RAA + ALSA, described in MTCD as AAD + suspended left subclavian artery. 36% of patients presented secondary symptoms to ring (57% of these secondary to DAA), being the most frequent respiratory symptoms. 100% of symptomatic patients required surgery (78% first year of life). Surgery of the ring was performed in two asymptomatic patients during a surgical procedure for another heart disease.
Conclusions: After the incorporation of the 3-vessel and tracheal views, the detection of VR in prenatal period has increased the frequency and improved knowledge of natural history. The concordance in our hospital between the diagnosis of VR by fetal echocardiography respect to MDCT is very high (94.7%), allowing a great precision prognostic.

P2382 - EVALUATION OF HOME FETAL HEART RATE DOPPLER MONITORING FOR SURVEILLANCE OF FETAL ARRHYTHMIAS

Grace Freire[1], Neil Goldenberg[2], Jade Hanson[2], Amre Devendra[2], Marilyn Willhm[1]
JHACH, Cardiology, St Petersburg-United States[1]; JHACH, Research, St Petersburg-United States[2]

Background: Standard of care (SOC) for outpatient monitoring of fetal arrhythmias (FA) includes assessments in obstetrical office 2-3 times/wk. plus frequent fetal echocardiograms. At Johns Hopkins All Children's Hospital (JHACH), this SOC was changed to add home monitoring for 1-2 min 3 times/day with a fetal heart rate monitor (FHRM) which was provided to mom carrying babies with FA. The study's primary objective was to determine concordance of the FHR's obtained with both methods, home FHRM and Doppler ultrasound (DU) at the office. Secondary objectives are to compare time to diagnosis, time to treatment, and outcomes of fetuses monitored with the FHRM as compared to the previous SOC.
Methods: A retrospective cohort study was implemented (Table 1). We studied two cohorts: Cohort 1: (Jan 2008-May 2013, previous SOC), and Cohort 2: (May 2013- October 2016, modified SOC). FHR data obtained with FHRM and the FHR obtained by DU after the second visit were compared for agreement/concordance. Secondary objectives and prenatal and postnatal survival will be compared between the cohorts in upcoming analysis.
Results: For cohort 2, data on 13 subjects was available. Bland-Altman analysis (Figure 1) showed that the mean difference in FHR between the FHM and DU was -0.27 (95% CI = -2.87-2.33). The limits of agreement (+2 SD of the mean) ranged from -8.89- + 8.35. Barring 1 measurement, all the other measurements had good agreement between the paired measures. The concordance correlation coefficient was 0.98 (95% CI = 0.96-0.99), indicating strong agreement. Good compliance with outpatient monitoring was noted and there was no evidence of perinatal complications.
Conclusions: There was strong agreement in FHR between the measures obtained with the home monitors and the Doppler ultrasound. Based on these preliminary results, the addition of adjunctive home FHR monitors to the SOC appears to be feasible and likely reliable.

Table 1. Study design/ Timeline

Old SOC	New SOC	Concordance FHR	Log Book Data	Fetal Echo Data	Time to diagnosis/ treatment	Survival/ Postnatal Outcomes
Cohort 1 Retrospective 1/1/2008-5/31/2013				X	X	X
	Cohort 2 Retrospective 6/1/2013-9/21/2016	X	X	X	X	X

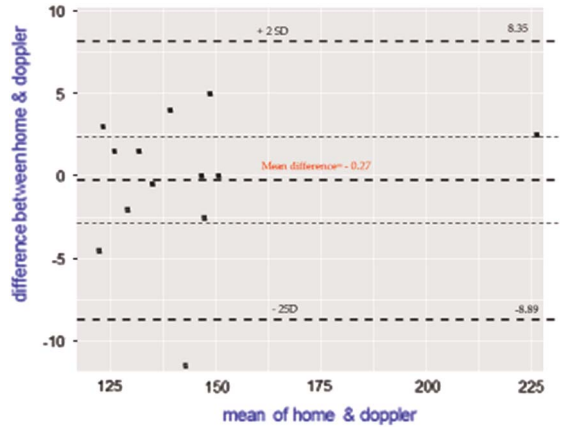

Figure 1.

P2392 - IMPACT OF FIRST TRIMESTER CARDIAC SCREENING ON UN NATURAL HISTORY OF CONGENITAL HEART DEFECTS

Hana Jicinska[1], Pavel Vlasin[2], Michal Jicinsky[3], Ilga Grochova[4], Viktor Tomek[3], Julia Volaufova[5], Jan Skovranek[3], Jan Marek[6]
University Hospital Brno and Faculty of Medicine, Masaryk University, Department of Paediatric Cardiology, Brno-Czech Republic[1]; Fetal Medicine Center, BRNO-Czech Republic[2]; Charles University in Prague and Motol University Hospital, Children's Heart Center, 2nd Faculty of Medicine, Prague-Czech Republic[3]; Fetal Medicine Center and University Hospital Sv. Anny, Brno-Czech Republic[4]; Louisiana State University Health, School of Public Health, New Orleans-United States[5]; Great Ormond Street Hospital for Children and Institute of Cardiovascular Sciences Ucl, London-United Kingdom[6]

Background: The study analyzed the impact of first trimester screening on the spectrum of congenital heart defects (CHD) later in pregnancy, and on the outcome of fetuses and children born alive with CHD.
Materials and Methods: The spectrum of CHD, associated comorbidities (chromosomal and/or structural non-cardiac anomalies) and outcome of fetuses either diagnosed with CHD by echocardiography in the first trimester (Group I, 127 fetuses), or only in the second trimester screening (Group II, 344 fetuses), were analyzed retrospectively between 2007 and 2013. Second trimester fetuses diagnosed with CHD between 2007 and 2013 were also compared with Group III (532 fetuses diagnosed with CHD in the second trimester from 1996 to 2001, the period before first trimester screening was introduced).
Results: The spectrum of CHDs diagnosed in the first and second trimesters in the same time period (from 2007 to 2013) differed significantly, with a greater number of comorbidities (chromosomal and/or structural non-cardiac anomalies) ($p < 0.0001$), CHDs with univentricular outcome ($p < 0.0001$), intrauterine deaths ($p = 0.01$) and terminations of pregnancy ($p < 0.0001$) in Group I in comparison to Group II. In Group III, significantly more cases of CHD with univentricular outcome ($p < 0.0001$), intrauterine demise ($p = 0.036$) and early termination ($p < 0.0001$) were identified in comparison to fetuses diagnosed with CHD in second trimester between 2007 and 2013. The spectrum of CHD seen in the second trimester groups differed after first trimester screening was implemented.
Conclusions: First trimester screening had a significant impact on the spectrum of CHD and on the outcomes of pregnancies with CHD diagnosed in the second trimester. Early detection of severe forms of CHD and significant comorbidities resulted in an increased pregnancy termination rate in the first trimester.

P2408 - USEFULNESS OF THREE DIMENSIONAL ECHOCARDIOGRAPHY FOR THE ASSESSMENT OF RIGHT VENTRICULAR FUNCTION IN CHILDREN WITH ARRHYTHMIA – A PRELIMINARY REPORT

Halszka Kaminska[1], Bozena Werner[2]
Medical University of Warsaw, Dept. of Pediatric Cardiology and General Pediatrics, Warszawa-Poland;[1] Medical University of Warsaw, Medical University of Warsawdept. of Pediatric Cardiology and General Pediatrics, Warszawa-Poland[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

The accurate assessment of right ventricular function in children is still a diagnostic challenge. Cardiovascular magnetic resonance (CMR) is considered the gold standard in assessing RV function. Majority of arrhythmic disorders in children are classified as idiopathic as no link to abnormal cardiac morphology or function can be found. The aim of the study was to assess right ventricular function in children with arrhythmia using three-dimensional echocardiography and compare it to two-dimensional echocardiography and cardiac magnetic resonance.
Methods: The study group consisted of 18 children aged 6-17 years, average 13,5 ± 2,7 years, with arrhythmic disorders: 13 with ventricular arrhythmia (5 with single ectopic beats, 8 with complex arrhythmia) and 5 with supraventricular arrhythmia. In all children 2D and 3D echocardiography and in 7 also CMR were performed. The right ventricular ejection fraction (EF) was assessed and compared using Spearman correlation test.
Results: 15 out 18 patients had normal heart morphology while in 3 arrhythmogenic right ventricular cardiomyopathy was recognized. The values of right ventricular EF measured in 3D were 29,1- 60%, mean 44,7 ±10,5%, in 2D: 28,9-71% mean 51 ± 13% and in CMR 25-53% mean 41,9 ± 11,2%. The reduction of EF in 3D from 22,9% to 42% was observed in patients with complex ventricular arrhythmia, while in children with supraventricular arrhythmia or single ventricular beats EF was from 48,5% to 60%. Very high significant correlation ($R = 0.89$, $p < 0.05$) between values of EF obtained by 3D-echocardiography and CMR was found. High significant correlation between 3D EF and Simpson 2D EF ($R = 0.66$, $p < 0.05$) was observed.
Conclusions: 1. Impaired right ventricular function is observed in patients with severe ventricular arrhythmia. 2. 3 D-echocardiographical analysis of right ventricular function may be valuable tool for clinical assessment of children with arrhythmia.

P2418 - THE ASSESSMENT OF CHILDREN WITH HYPERTROPHIC CARDIOMYOPATHY ASSOCIATIONS OF SPECKLE TRACKING ECHOCARDIOGRAPHY AND LATE GADOLINIUM ENHANCEMENT CARDIAC MAGNETIC IMAGING

Sylvia Krupickova[1], Ying Hui Chee[1], Winston Banya[2], Giovanni Di Salvo[1], Inga Voges[1], Michael Rigby[1], Nitha Naqvi[1], Victoria Jowett[1], Sanjay K. Prasad[3], Piers E.f. Daubeney[1]
Royal Brompton Hospital, Paediatric Cardiology, London-United Kingdom[1]; Royal Brompton Hospital, Research Office, London-United Kingdom[2]; Royal Brompton Hospital, NIHR Cardiovascular Biomedical Research Unit, London-United Kingdom[3]

Background: We sought to identify surrogate markers of left ventricular (LV) fibrosis in children with hypertrophic cardiomyopathy (HCM) using 2D speckle tracking and to clarify the relationship between deformation indices, extent of LV myocardial fibrosis and hypertrophy.
Methods: Twenty-seven patients under the age of 18 years with an established diagnosis of HCM, who underwent both echocardiographic and CMR investigations, were enrolled in this single tertiary centre retrospective study. Twenty-seven age- and sex-matched healthy controls had an echocardiogram only. Myocardial strain was analysed against the extent of fibrosis assessed by late gadolinium enhancement at MRI and myocardial thickness.
Results: Patients had a significantly higher mean (SD) ejection fraction of 70.8% (8.2) vs 61.2% (6.2), $p < 0.001$ and shortening fraction than controls (44.7%, IQR (37.0, 48.5) vs 36.7% (32.0, 41.7%, $p = 0.001$), but significantly worse global longitudinal (median -18.0, IQR(-14.6,-20.6) vs -21.5 (-19.1,-22.5), $p = 0.002$), radial (28.1, SD(9.4) vs 44.6, SD(11.6); $p < 0.001$) and circumferential strain (-23.8, SD(5.3) vs -27.8, SD(5.6); $p = 0.009$). Fibrosis was present in 11 of 25 patients (44%). The interaction of segmental fibrosis and hypertrophy was associated with attenuated radial ($p = 0.037$) and longitudinal strain ($p = 0.001$). When myocardial segments were analysed, the radial strain diminished significantly as the amount of fibrosis increased ($p = 0.04$). No association was found between the extent of segmental fibrosis, myocardial thickness, and circumferential and longitudinal strain.
Conclusions: Myocardial deformation indices are decreased in patients with HCM. Myocardial fibrosis and hypertrophy have an independent impact on global and regional systolic function however it is likely that they are not the only factors to play a role.

P2430 - CARDIAC EVALUATION FOR DETECTION OF CONGENITAL HEART DISEASE IN ASYMPTOMATIC TERM NEWBORNS A NEW LOOK AT THE ALGORITHM

Arpit Agarwal, Nurin Jivani, Prashant Minocha, Sethuraman Swaminathan
University of Miami/Jacksom Memorial Hospital, Pediatric Cardiology, Miami-United States

Background: The incidence of congenital heart disease (CHD) is 1% of live births in the United States. Of these, 25% are major or critical CHD. In 1994, the American Heart Association produced guidelines for the evaluation of CHD in neonates. A lot has changed since then, including widespread use of fetal echocardiogram and screening pulse oximetry for detection of CHD. We evaluate the value of these tests in today's context and propose a revised algorithm for the detection of CHD.
Methods: We reviewed asymptomatic term newborns who had cardiac evaluation including electrocardiogram (ECG) and echocardiogram, from 2013 to 2016. Murmurs were categorized as benign sounding (innocent) or pathologic based on the intensity and quality of the murmur. ECG findings were divided into normal, QRS abnormality and other abnormalities (Table 1). Echocardiograms were classified into 4 groups – Normal study, Minor, Major or Critical anomaly (Table 2).
Results: 777 newborns underwent cardiology evaluation during the study period. All the patients had echocardiogram and 676 had ECG. Among these, 3 critical, 8 major and 517 minor CHD were identified. The distribution of CHD, correlated with type of murmur and ECG is described in Table 3. All major and 1 critical CHD were present in patients with pathological murmur. Two patients with innocent murmur and abnormal ECG had critical CHD. Patients without any murmur with or without abnormal

Table 1. Categorization of Electrocardiogram findings.

QRS voltage Abnormality (n = 283)	Right ventricular hypertrophy
	Left ventricular hypertrophy
	Septal hypertrophy
	Biventricular hypertrophy
Other abnormalities (n = 79)	Sinus bradycardia or tachycardia
	Non-specific ST-T wave changes, Prolonged QTc
	Axis deviation: right or teft
	Premature atrial contraction, Premature ventricular contraction
	Atrial flutter. Supraventricular tachycardia
Normal (n = 314)	Normal ECG and normalvariants

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

ECG, those with innocent murmur and normal ECG did not have any significant CHD.

Conclusion: Pathologic murmurs when present should be evaluated by echocardiogram. ECG may be helpful in detecting critical CHD in newborns with innocent murmur. Newborns with innocent murmur and normal ECG do not have major CHD and can be followed as outpatient. Based on our findings, we propose an algorithm for a systematic approach to cardiac evaluation of asymptomatic term newborns. (Figure 1).

Table 2. Categorization of Congenital Heart Disease

Critical (n = 3)	
Major (n = 8)	any CHD requiring immediate intervention Example: critical aortic or pulmonary stenosis, hypoplastic left heart syndrome, transposition of the great arteries any CHD requiring intervention within 6 months of life Example: large VSD, atrioventricular septal defect tetralogy of fallot
Minor (n = 517)	any CHD expected to resolve spontaneously or unlikely to require intervention Example: small PDA, ASD or small muscular VSD.
Normal (n = 249)	No CHD Example: PPO, very small PDA and normal variants

Table 3. Distribution of Congenital Heart Disease by Type of Murmur and ECG Findings.

	No ECG	**Normal ECG**	**Abnormal ECG (QRS abnomality**	**Abnormal ECG (Other abnormalities**	**Total**

P2439 - DEVELOPMENT OF A NOVEL INKJET PRINTING SYSTEM TO REALIZE MASS PRODUCTION OF SUPER FLEXIBLE HEART REPLICAS FOR SURGICAL SIMULATION OF COMPLICATED CONGENITAL HEART DISEASE

Isao Shiraishi[1], *Kennichi Kurosaki*[1], *Suzu Kanzaki*[2], *Takaya Hoashi*[3], *Hajime Ichikawa*[3]
National Cerebral and Cardiovasuclar Center, Pediatric Cardiology, Suita-Japan[1]; *National Cerebral and Cardiovasuclar Center, Radiology, Suita-Japan*[2]; *National Cerebral and Cardiovasuclar Center, Pediatric Cardiac Surgery, Suita-Japan*[3]

Backgrounds: Precise understanding of 3D anatomy is crucial for successful surgical operation of congenital heart diseases. We have developed a new technology that reproduces extremely flexible polyurethane replicas of congenital heart disease by employing stereolithography 3D printing followed by vacuum casting techniques. However, this technique takes approximately one week of time and costs considerable amount of money. Here we introduce a new inkjet printing system which is exclusively devised for manufacturing super flexible heart replicas for congenital and adult heart diseases.

Methods: In collaboration with Japanese companies SCREEN Holdings Co., Ltd., cross Effect Inc., and Kyoeisha Chemical Co., Ltd., we developed a new ink jet printing machine which consists of 4 print heads being able to manufacture 200mmx500mm super flexible heart replicas for surgical simulation. Four replicas of congenital heart diseases including VSD, sinus venosus ASD, TOF after BT-shunt, and congenitally corrected TGA were experimentally manufactured with this new technique.

Results: The new inkjet printing system allowed to reproducing faithfully these congenital heart diseases within 24 hours, resulting in possible reduction of the manufacturing costs. The texture and elasticity of the replicas were similar to the real heart of children. These heart replicas with ink jet printing enabled surgeons to cut and suture, facilitating the simulation of the surgical operation.

Conclusions: We have successfully devised a new inkjet 3D printing machine as an academia-industry collaboration. Further improvement in 3D printing system, ink, and support materials are necessary to be safely used and approved in the clinical filed.

P2452 - TRICUSPID VALUE SIZE IN FETUSES WITH PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM SEVERE PULMONARY STENOSIS IS A STRONG PREDICTOR OF POSTNATAL OUTCOME

Tomiko Toyokawa[1], *Noboru Inamura*[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Osaka Medical Center For Maternal and Child, Pediatric Cardiology, Osaka-Japan[1]; Kinki University, Pediatrics, Osaka-Japan[2]

Background: Pulmonary atresia with intact ventricular septum (PAIVS) and severe pulmonary stenosis (SPS) are strongly influenced by the prediction of univentricular (UV) or not-UV.
Objective: The purpose of this study was to determine the morphologic and physiological predictors of post-natal surgical pathway, presence or absence of ventriculocoronary connections (VCC) of fetuses with PAIVS and SPS.
Materials: We identified 16 fetuses (gestational age 29.3 weeks), with a fetal diagnosis of PAIVS and SPS from 2002 to 2015.
Methods: Using a z-scores of fetal cardiac measurememts,we calculated tricuspid valve (TV), tricuspid valve/mitral valve(TV/MV) ratio, pulmonary valve/aortic valve (PV/AV) ratio and pulmonary valve, to facilitate prediction of UV or not-UV circulation. We also assessed the presence or absence of VCC.
Result: Two groups; UV included 13 fetuses, not-UV included 3 fetuses. TV ; -3.1 SD ~ -10.8 SD(median -7.7 SD) vs –3.4 SD ~ -2.9 SD (median -3.2 SD)(p = 0.01)(UV vs not-UV). TV/MV ratio; 0.26 ~ 0.63(median0.34) vs 0.55 ~ 0.67 (median0.57) (p = 0.03).PV/AV ratio ; 0.28 ~ 0.90 (median0.43) vs 0.82 ~ 0.98 (median 0.91)(p = 0.01). PV; -11.0 SD ~ 0.27 SD (median-8.7 SD) vs -2.3 SD ~ -1.2 SD (median-1.6 SD)(p = 0.06). A cut-off value of -5SD for TVwas highly predictive of UV circulation, with sensitivity of 92% and a specificity of 100%. A cut-off value of -5.5 SD for TV was highly predictive of VCC during fetal life, with sensitivity of 100% and a specificity of 58%.
Conclusion: Tricuspid valve in fetuses affected by PAIVS andSPS is a strong prenatal echocardiographic predictor of UV circulation and VCC.

P2460 - MORPHOMETRY OF DUCTUS ARTERIOSUS AND ITS ASSOCIATION TO FLOW DYNAMICS A FETAL DOPPLER ECHOCARDIOGRAPHIC CAVEAT

Paulo Zielinsky, Luciana Rodrigues, Augusto Shimanoe, Antonio Piccoli Jr, Luiz Henrique Nicoloso, Jesús Zurita-peralta, Natássia Sulis, Luiza Van Der Sand, Fernanda Greinert, Victória Antunes
Institute of Cardiology, Fetal Cardiology Unit, Porto Alegre-Brazil

Background/Hypothesis: The shape of fetal ductus arteriosus is cuneiform, but there is no information correlating flow dynamics to ductal morphometry. This study test the hypotheses that ductal velocities are higher and pulsatility index (PI) is lower at the distal (pulmonary) extremity than at the proximal (aortic) end of the vessel, and that there is correlation between flow dynamics and ductal diameter.
Material and Methods: Normal fetuses from mothers without any comorbities, at any gestational age, were recruited to the study. Difficulty to assess both ductal extremities were cause for exclusion. 2-D echocardiography with color mapping was aimed at determining maximal ductal diameters both at aortic (proximal) and pulmonary (distal) ends of the ductus. Doppler analysis of SV and DV, as well as PI determination, was also performed at both ductal extremities in every case.
Results: The sample was made up of 77 fetuses. Proximal mean ductal diameter was 4.5 ±1.3 mm and distal mean diameter was 2.3 ± 0.7mm, p < 0.001. Proximal mean ductal velocities were : SV = 0.75 ± 0,2 m/s; DV = 0.13 ± 0.04 m/s and distal mean velocities were: SV = 1.03 ± 0.21 m/s; DV = 0.20 ± 0.04 m/s, p < 0.001. Mean PI was 2.70 at the aortic end and 2.30 at the pulmonary end, p < 0.001. Proximal and distal ductal diameters were positively correlated (r = 0.80, p < 0.01). There were inverse correlations between ductal diameter and SV (r = 0.28, p = 0.001) and DV (r = 0.40, p = 0.001). A positive correlation between ductal diameter and flow PI (r = 0.65 p = 0.001) was shown.
Conclusions: This original study demonstrates that, since the ductus is cuneiform in shape, flow impedance is higher (higher velocities and lower pulsatility index) at the distal end, which is the correct place to position the Doppler sample-volume during flow analysis, especially when ductal constriction is sought.

P2463 - LONGITUDINAL SYSTOLIC STRAIN AND DEFORMATION GRADIENT ON 4 CHAMBER 2 D SPECKLE TRACKING IN THALASSEMIA MAJOR

Devyani Chowdhury[1], Najveen Alvi[2], Sergi Cesar[3], Bart Bijnens[4], Babar Hasan[5]
Cardiology Care for Children, Pediatric Cardiology, Lancaster-United States[1]; Aga Khan University, Pediatric Cardiology Cardiology, Karachi-Pakistan[2]; Hospital Sanitas Cima, Pediatric Cardiology, Barcelona-Spain[3]; UPF, Cardiology, Barcelona-Spain[4]; Aga Khan University, Pediatric Cardiology, Karachi-United States[5]

Background: Myocardial siderosis secondary to recurrent blood transfusions contributes to >70% of the morbidity and mortality in Thalassemia Major (TM) patients. 2D Speckle Tracking Echocardiography (2D STE) may be useful for assessment of preclinical myocardial dysfunction.
Methods: TM patients were recruited for the AMIT study (efficacy of amlodipine with chelation in reducing myocardial iron). All patients underwent standard echocardiographic imaging at baseline, 6 and 12 months. Global and segmental longitudinal systolic strain (LSsys) was measured in the left ventricle (LV) (apical 4 chamber). The ratio between mean apical LSsys and basal LSsys (LSsys api/bas) (medial and lateral wall) was calculated.
Results: A total of 19 TM patients completed the AMIT study. The median age was 16 (8-21) years. 25 data points were available from 2D STE. The mean global LSsys was -20.9% ± 2.2. The medial basal LSsys (-17.3% ± 2.2) and lateral basal LSsys (-16.7% ± 4.4) strain was significantly lower when compared with mean apical LSsys strain (-24.9% ± 4.0) (p <0.01). Deformation gradient in the LV was seen by a lateral LSsys api/bas ratio of 1.5 ±0.3 and medial LSsys api/bas ratio of 1.6 ±05.
Conclusion: 2D STE demonstrated a pattern of systolic septal longitudinal base-to-apex strain gradient with preserved LSsys at apical segments and significantly reduced basal strain in TM patients. This gradient may help in differentiating TM patients who are at risk for increased cardiovascular morbidity and mortality.

Fontan failure as a late complication of Fontan operation represents a significant challenge to manage. We evaluated

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

load-dependent mechanical dyssynchrony, myocardial deformation of left ventricle (LV) and the change of Fontan circulation in asymptomatic adults with tricuspid atresia (TA) after Fontan procedure. Comparative analysis was performed between 29 asymptomatic tricuspid atresia (type 1) patients with normal LV ejection fraction (>50%) and 23 normal healthy controls. After baseline measurements, isometric hand grip test (IHGT) was used to increase LV afterload. Subsequently, sublingual nitroglycerin was administered to modify preload. Conventional echocardiographic parameters, LV strain, LV dyssynchrony index and LV torsion, were calculated under each condition. At baseline, in the TA group diastolic sphericity index increased (0.74 ± 0.13 vs. 0.51 ± 0.03; $P < 0.001$)and LV longitudinal strain decreased ($-16.7 \pm 2.3\%$ vs. $-20.0 \pm 2.0\%$; $P < 0.001$). The difference in time-to-peak radial strain between the anteroseptal and posterior segments (LVdys-2) (32.4 ± 73.4 ms vs. 3.5 ± 9.9 ms; $P = 0.045$) and the absolute difference in time-to-peak radial strain for 6 segments (LVdys-6) (62.3 ± 88.9 ms vs. 8.2 ± 15.0 ms; $P = 0.003$) increased in the TA groups compared to the control group. At baseline, LV torsion ($12.6 \pm 7.9°$ vs. $19.2 \pm 8.4°$; $P = 0.006$), basal rotation ($-1.1 \pm 2.4°$ vs. $-4.1 \pm 2.6°$; $P = 0.0001$), twist rate ($50.9 \pm 27.0°/s$ vs. $84.5 \pm 30.3°/s$; $P < 0.0001$), untwist rate ($51.2 \pm 28.7°/s$ vs. $73.9 \pm 30.1°/s$; $P = 0.008$), and torsional rate ($76.0 \pm 36.9°/s$ vs. $124.0 \pm 37.9°/s$; $P < 0.0001$) decreased in the TA patients. The repetitive measured-ANOVA by Greenhouse-Geisser method among baseline, IHGT, and nitroglycerin administration showed the different load-dependent responses between two groups about LV longitudinal strain (group $P < 0.001$,within $P = 0.848$, interaction $P = 0.045$), LVdys-6 (group $P = 0.042$, within $P = 0.026$, interaction $P = 0.379$), and LV torsion (group $P = 0.027$ within $P = 0.106$, interaction $P = 0.058$). In conclusion, although asymptomatic adult TA patients after Fontan procedure had normal LV ejection fraction, their LV deformations were impaired and abnormal load-dependent responses were also demonstrated.

P2476 - NORMAL SEGMENTAL MYOCARDIAL DEFORMATION IS NOTED IN PATIENTS WITH ANOMALOIS AORTIC ORIGIN OF CORONARY ARTERIES DESPITE MALIGNANT COURSE AND ISCHEMIC SYMPTOMS

Anas Abdul Kayoum[1], *Madhusudan Ganigara*[1], *H. Helen Ko*[2], *Santosh Uppu*[2], *Ira Parness*[2], *Shubhika Srivastava*[2]
Mount Sinai Medical Center, Pediatrics, New York-United States[1]; *Mount Sinai Medical Center, Pediatric Cardiology, New York-United States*[2]

Background: Sudden cardiac death is the first presenting symptom in few with Anomalous aortic origin of coronary artery (AAOCA), Most being incidentally diagnosed for non-ischemic complaints. We hypothesized segmental longitudinal (SLS) and circumferential strain (SCS) abnormalities would be present at baseline in AAOCA patients with past ischemic events.
Method: Two-dimensional speckle tracking (2DSTE) derived strain assessment was performed using GE Echopac software on 16 left ventricular segments from apical and 6 mid wall segments from the short axis views. Less than 10% shortening for SLS and SCS was considered abnormal. Descriptive analysis of segmental strain abnormalities during rest, correlation with the presence of baseline symptoms, exercise stress test and finding on CT angiogram were performed.
Results: 25 Pts. with AAOCA. 20(80%) males, 5(20%) females. Age range 7-19. 9(36%)pts. were symptomatic. 20(80%)Pts. with AAO of Right coronary (AAORCA), 3(12%)Pts. had AAOLCA, 2(8%)Pts. had both. 1(4%)Pts. had abnormal Exercise stress test. 5 (20%)Pts. had significant coronary stenosis (>50%) on CT angiogram. 3(12%)Pts. needed surgical intervention. No abnormalities in SLS were noted by 2DSTE in those with AAORCA. Only 3 (15%)Pts. had SCS abnormalities (figure). Out of three patients with abnormal findings only one presented with ischemic symptom's and another one had >50% luminal narrowing. The basal lateral and inferolateral segment abnormalities in the circumflex territory were noted in 85% patients with AAORCA.
Conclusion: Normal SLA and SCS was noted in the anomalous coronary territory in patients with AAORCA despite presence of symptoms or evidence of >50% stenosis on CTA. False positive results are noted by this technique in areas not supplied by the anomalous coronary. Two patients with AAOLCA did have ischemic symptoms and abnormal segmental findings. Further studies are recommended in a larger cohort to assess the prognostic value of segmental deformation in patients with AAOLCA.

Background: Neonates with CHD studied with MRI in the neonatal period are recognized to be at high risk of brain injuries pre- and post-operatively, reported in 30% to 50%. However, the frequency of brain abnormalities in unselected clinical cohorts of neonates with CHD remains unknown. These data are needed to

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

appropriately evaluate the use of brain MRI in routine clinical practice for neonates with CHD requiring cardiac surgery.
Objective: To determine the rate of injury and developmental anomalies on clinical pre- and post-operative MRI obtained routinely in a consecutive series of term neonates with CHD.
Design/Methods: Since March 2015, brain MRI has been introduced as the standard of care in a large tertiary pediatric hospital. Neonates undergoing cardiac surgery in the first few weeks of life undergo an MRI before and after the surgical intervention as soon as they are stable enough for transportation. Brain abnormalities, such as white matter lesions (WMI), intraventricular hemorrhage (IVH), arterial stroke, sinus venous thrombosis (SVT), hydrocephalus, hematomas, and developmental anomalies are recorded systematically. Key demographic and clinical data are collected from the clinical charts, independent of the MRI reviews.
Results: 106 neonates underwent clinical brain MRI: median gestational age 39 weeks, birth weight 3.3 kg, and 67 males. The types of CHD were: 39 transposition of the great arteries (TGA), 28 single ventricle physiology (SVP) and 39 other cardiac lesions. Preoperative brain injury was common: WMI in 8 (2 TGA, 2 SVP, 4 others), IVH in 3 (1 TGA, 1 SVP, 1 others), stroke in 6 neonates (2 TGA, 2 SVP, 2 others). Sinus venous thrombosis was seen in 1 neonates with SVP. Subdural hematoma was diagnosed in 7 (2 TGA, 2 SVP, 3 others). Brain anomalies consistent with tubulinopathy were seen in 1 patient. New post-operative injuries were similarly frequent: WMI in 4 children (3 TGA,

P2485 - HIGH INCIDENCE OF ABNORMAL TEI INDEX IN THE FETUSES WITH MATERNAL ANTI SS A ANTIBODY

Yasuki Maeno[1], Akiko Hirose[2], Yozo Teramachi[2], Yoshiyuki Kagiyama[1], Shintaro Kishimoto[1], Yusuke Koteda[1], Kenji Suda[1]
Kurume University School of Medicine, Department of Pediatrics, Kurume-Japan[1]; St. Marry Hospital, Department of Neonatology, Kurume-Japan[2]

Maternal anti SS-A antibody affects to the fetal heart and causes heart block and myocarditis. Detection of the damage to the atrioventricular node is well documented. However, the incidence of the myocardial damage is not well known. Therefore, we investigated the cardiac function in the fetuses with maternal anti SS-A antibody.
Method: This is a retrospective study in single center. We reviewed our clinical record of fetal echocardiography in 5 years from Jan. 2012 to Dec 2016. In this period, 24 cases had fetal echocardiography due to maternal positive anti SS-A antibody without fetal heart block. Of the 24, 18 cases had sequential examination from second trimester. Tei index of the right and left ventricle were measured. Postnatal data were available in 20 cases.
Results: Of the 24, first examination were 18w3d to 38w1d (median 22w0d). During pregnancy, 2 cases (8%) had high Tei index >0.7, and other 10 (42%) had relatively high Tei index >0.6. Of these 12, 6 had Tei index >0.6 also at the last examination before birth, but, the other had transient elevation. 20 with the postnatal data were born at 36w5d to 41w2d (median 39w2d), and their birth weight were 1918g to 3336 g (mean 2778 g). No case had clinical symptom of cardiac dysfunction, although one had transient tachypnea, one had small for gestational age, and the other had premature rupture of membrane.
Conclusions: Our data suggest high incidence of abnormal Tei index in the fetuses with maternal anti SS-A antibody. Although the cardiac dysfunction seems to be transient and subclinical in most of the cases, further study with more detail fetal cardiac functional study and postnatal follow-up are required.

P2495 - QUANTIFICATION OF RIGHT VENTRICULAR ELECTRO MECHANICAL DYSSYNCHRONY AND ITS RELATION TO CLINICAL OUTCOMES IN CHILDREN WITH REPAIRED TETRALOGY OF FALLOT

Deane Yim, Wei Hui, Guillermo Larios[1], Andreea Dragulescu, Bart Bijnens, Lars Grosse-Wortmann, Luc Mertens, Mark Friedberg
The Hospital for Sick Children, Pediatric Cardiology, Toronto-Canada

Introduction: Electro-mechanical dyssynchrony occurs in patients following tetralogy of Fallot (TOF). The rightward septal flash, with early septal activation and post-systolic shortening of the right ventricular (RV) basal lateral wall, is ubiquitous in this population and contributes to inefficient RV mechanics. The aim of the study was to quantify the severity of electro-mechanical dyssynchrony in relation to RV remodelling, dysfunction and clinical outcomes in a pediatric cohort following TOF repair.
Methods and Results: A retrospective review of prospectively collected data was performed in 81 children post-TOF repair, aged 13.6 ± 2.9 years, and compared to 50 pediatric controls. Two-dimensional echocardiography speckle-tracking, cardiac magnetic resonance (CMR) and clinical details were obtained. Patients had higher pre-stretch and post-systolic strain (PSS) amplitude and duration, mechanical dispersion and basal lateral-septal wall time-to-peak strain differences than controls (p-values all <0.001). All intra-RV dyssynchrony timing parameters were associated with reduced RV ejection fraction (EF) by CMR and/or global RV longitudinal strain. The pre-stretch duration as a percentage of total shortening time and the time-to-peak strain differences between the basal lateral RV and mid-septal segments were independently associated with RV EF using multivariate analysis. PSS amplitude was higher in patients with arrhythmias compared to arrhythmia-free patients (7.8(4.2-13)% vs 2.0(0-12.5)%, $p = 0.03$). Intraventricular dyssynchrony parameters were not associated with myocardial fibrosis by late gadolinium enhancement on CMR.
Discussion: The right-sided septal flash is viewed as a dichotomous variable, however we sought to describe a continuum of dyssynchrony severity and its relationship to pathophysiology and clinical outcomes in repaired TOF patients. RV basal lateral-septal timing delays, pre-stretch and PSS may provide a practical approach to assessing RV electro-mechanical dyssynchrony severity and one which reflects the underlying pathophysiology.

P2511 - ECHOCARDIOGRAPHIC PREDICTION OF USE TRANSANNULAR PATCH DURING TETRALOGY OF FALLOT REPAIR

Sowmya Kasturi[1], Seshadri Balaji[2], Abish Sudhakar[1], Gopalraj Sunil[3], Brijesh Kottayil[4], Praveen Reddy[4], Raman Krishna Kumar[1]
Amrita Institute of Medical Sciences and Research Centre, Pediatric Cardiology, Cochin-India[1]; Oregon Health and Science University, Pediatrics, Portland-United States[2]; Mrita Institute of Medical Sciences and Research Centre, Pediatric Cardiothoracic and Vascular Surgery, Cochin-India[3]; Amrita Institute of Medical Sciences and Research Centre, Pediatric Cardiothoracic and Vascular Surgery, Cochin-India[4]

Background: The long-term outcome after repair of tetralogy of Fallot (TOF) is critically dependent on the competence of the pulmonary valve that is compromised by trans-annular patch (TAP).
Objectives: To determine the echocardiographic predictors of TAP in infants undergoing TOF repair.
Methods: Consecutive infants operated for TOF were prospectively included. Aortic and pulmonary annuli (PAnn), and

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

main pulmonary artery (MPA) were measured preoperatively and their z scores were determined from published nomograms. A novel index, the pulmonary annulus index (PAI) was calculated by dividing observed PAnn from expected PAnn [(Aortic + PA annulus) /2]. The decision to place a TAP was based on intraoperative sizing with Hegar dilators with surgeons blinded to PAI values. Aggressive valve preservation was attempted in borderline situations. Receiver operator curves (ROC) were generated for all three indices.
Results: Of 69 infants (8 ± 2 months), 32 needed TAP (46%). In-hospital mortality was 2/32 in the TAP group and 1/39 in the rest. The performance of individual indices is shown (table). Of 27 infants with PAI ≥ 0.8, three needed a TAP. Their MPA z scores were -5.8, -6 and -6. A PAI < 0.8 was however not consistently associated with requirement of TAP. Of the 42 with PAI <0.8, TAP could still be avoided in 13 patients. The performance of both PAI and PAnn Z scores (cut off: -1.67) were quite similar in predicting the need for TAP (table).
Conclusions: A pulmonary annulus index of ≥ 0.8 can be used to predict the avoidance of TAP in infants undergoing TOF repair especially when combined with MPA z scores. However a low PAI (<0.8) does not necessarily mandate the requirement of a TAP.

Table. Performance of individual echo parameters in predicting need for Trans-Annular Patch.

Variable	Sensitivity (%)	Specificity (%)	Positive predictive value (%)	Negative predictive value (%)	Odds ratio with 95% CI	Area under the curve
PAnn z <-1.67	87	64.9	68.3	85.7	12.9 (3.7-44.9)	0.79
PAI <0.8	87.5	65	68	85.7	11.3 (4 – 47)	0.80
MPA z <-3.0	72	65	64	72	4.7 (1.7-13.1)	0.81

PAnn: Pulmonary Annulus; PAI: Pulmoary Annulus Index, MPA: Main Pulmonary Artery, CI: Confidence Intervals.

P2513 - EXPERIMENTAL PULMONARY INSUFFICIENCY LEADS TO LEFT VENTRICULAR COMPRESSION AND IMPAIRED RELAXATION

Tao Fujioka[1], Haruki Ide[2], Mark Friedberg[1]
Labatt Family Heart Centre, Hospital for Sick Children, Cardiology, Toronto-Canada[1]; Labatt Family Heart Centre, Hospital for Sick Children, Cardiovascular Surgery, Toronto-Canada[2]

Background: In repaired tetralogy of Fallot with pulmonary insufficiency (PI) left ventricular (LV) dysfunction is a recognized risk factor for exercise intolerance, morbidity, and sudden death. However, the role of PI in the development of LV dysfunction is incompletely understood. The aim of this study is to assess serial changes in LV function and interventricular interactions in an experimental rat model of isolated severe PI.
Methods: Severe PI, defined by echo-Doppler color flow reversal starting in the branch pulmonary arteries, was induced in 6-week-old male Sprague-Dawley rats by puncturing the pulmonary valve leaflets with a 22.5 G needle inserted through main pulmonary artery. Rats underwent echocardiography before, and every 2 weeks after the procedure for 12 weeks (Vivid-E9 (GE)) using a 12-MHz phased array transducer. RV and LV end-diastolic area (RVEDa/LVEDa) were measured in a short axis view and corrected for BSA. Both ventricular systolic and diastolic event timing corrected for cardiac cycle length (CCL) and Tei-index were analyzed using spectral Doppler. LV ejection fraction (LVEF), peak LV free-wall s' and e' velocities, mitral inflow E and A wave peak Doppler velocities were measured and the E/A and E/e' ratios were calculated. LV global longitudinal (LVGLS) and circumferential (LVGCS) strain were measured using 2-D speckle tracking. Results were compared with sham controls using two-way repeated measures ANOVA.
Results: In PI rats (n = 5), RVEDa was larger, while LVEDa was smaller vs. shams (n = 5), and there was a negative correlation between RVEDa and LVEDa (r = -0.41, P = 0.014). Isovolumic relaxation time (IRT) was longer in PI rats vs. shams . As a result, the LV-Tei index was higher in PI rats vs. shams. Other parameters were similar between the groups (Table 1).
Conclusions: Experimental isolated severe PI induces RV dilatation, which compresses the LV and leads to impaired LV relaxation.

Table 1. Results of serial cchocardiographic measurements

P2516 - CHANGE OF MYOCARDIAL DEFORMATION AS AN EARLY MARKER OF MYOCARDIAL DYSFUNCTION IN HYPERTROPHIC CARDIOMYOPATHY IN CHILDREN

Olga Groznova[1], Nadegda Chernykh[1], Mikhail Dovgan[2], Vladislav Podolsky[3]
Academician Yu.E.Veltishchev Research Clinical Institute of Pediatrics, N.i.pirogov Russian National Research Medical University, Cardiology, Moscow-Russia[1]; Academician Yu.E.Veltishchev Research Clinical Institute of Pediatrics, N.I.Pirogov Russian National Research Medical University, Ultrasound Diagnostic, Moscow-Russia[2]; Moscow Technological University, Physics, Moscow-Russia[3]

Background: currently, according to the recommendations of the ESC Guidelines, the treatment of hypertrophic cardiomyopathy is exclusively symptomatic. Symptomatic treatment of the disease is not optimal for the patient. It is necessary to prevent his disease progression, but not to «go on about the symptoms». This requires to identify the earliest markers of myocardial systolic dysfunction that will assist in determining the indications for an early start of treatment.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: 38 children with hypertrophic cardiomyopathy were examined. The mediana of age was 9 years. We studied left ventricular segmental radial deformation and thickness of myocardial segments. The greatest clinical and diagnostic interest is the thickness of the myocardium segment, in which happened the most rapid (critical) decrease in radial strain values. For this derivative was estimated regression on the data and find the minimum point of the derivative function of myocardial deformation depending on its thickness.
Results: we present a new methodological approach to the examination of children with hypertrophic cardiomyopathy, aimed at early detection of local myocardial systolic dysfunction. For its base taken the study of radial myocardial segmental strain, which is most informative reflects the change in systolic function of the hypertrophic heart wall. The number of patients (N = 38) is currently insufficient to make reasoned opinion about the obtained values of the critical point (at the moment it is found to be Z = 4.24). However, the number of observations is enough to talk about the possibility of applying the method and its use for the future perspectives to obtain the critical value of the myocardium segment thickness in which firstly appears systolic segmental myocardial dysfunction in children with hypertrophic cardiomyopathy.

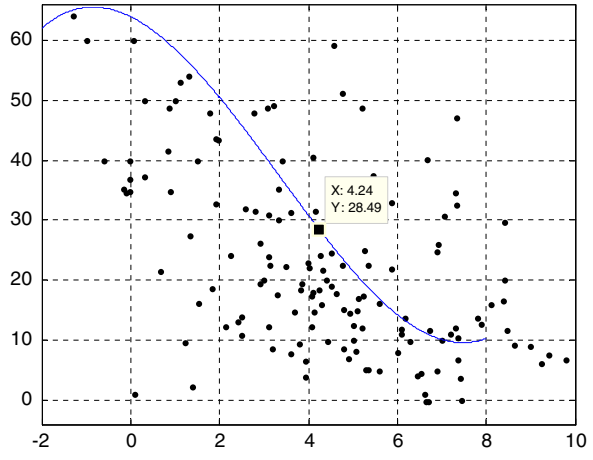

Figure 1.
The radial deformation in depending on the myocardial segment thickness (with the critical point of the myocardium segment thickness, in which happened the most rapid (critical) decrease in radial strain values). Vertical axis – radial segmental strain in %; horizontal axis –thickness of myocardial segment in Z-score).

P2520 - IS THREE DIMENSIONAL TRANSESOPHAGEAL ECHOCARDIOGRAPHY NECESSARY IN TRANSCATHETER DEVICE CLOSURE OF MULTIPLE ATRIAL SEPTAL DEFECTS

Jo Won Jung, Se Yong Jung, Jae Young Choi
Severance Cardiovascular Hospital Yonsei University College of Medicine, Pediatric Cardiology, Seoul-Korea, South

Background: Real time three-dimensional transesophageal echocardiography (RT 3D TEE) allows for evaluation of various shapes of atrial septal defect (ASD) especially in patients with multiple ASDs. During procedure of transcatheter device closure, intracardiac echocardiography (ICE) and/or TEE are integral parts of the assessment of patients with ASD undergoing intervention. In this study, the feasibility, efficacy of RT 3D TEE for transcatheter device closure of multiple ASD was evaluated retrospectively.
Methods: Between January 2005 and March 2016, transcatheter ASD closure with device was attempted in 1169 patients in single center institution. Patients who underwent transcatheter device closure as diagnosed multiple ASD were enrolled retrospectively.
Results: Transcatheter device implantations for multiple ASDs were required in 177(15.1%) of total 1169 cases. Among 177 patients, 41(23.1%) patients had more than three defects. 99(55.9%) patients with multiple ASDs were those under 18 years of ages. Of total 177, only 28 patients (15.8%) had the guidance of RT 3 D TEE during transcatheter closure, and for the others ICE was applied for the guidance of transcatheter closure for even multiple ASD. During procedure using RT 3D TEE, the analysis of ASDs successfully demonstrated rims but was limited for visualized whole defect even real time. Full-volume mode of RT 3D TEE had the best views of large/ multiple defects and surrounding anatomy. However, it was limited for postero-inferior defect by artifact around IVC. For applying RT 3D TEE in children, relatively big size of probe tip had the restriction. Under the guidance of ICE without 3D TEE, there was no adverse effect and also residual defects remained insignificantly.
Conclusion: For transcatheter closure of multiple ASD with device, RT 3D TEE provides important information for evaluation of complexed ASD. However,its application during procedure is relatively limited for successful closure.

P2526 - PRENATAL DETECTION AND EARLY OUTCOME OF SERIOUS AND CRITICAL CONGENITAL HEART DISEASE IN HAWAII FROM 2012 2016

Colin Petko[1], Keith Ogasawara[2], William Goh[2], David Milnes[3], Malia Meredith[3], Christopher Stefanelli[1]
Hawaii Permanente Medical Group, Pediatric Cardiology, Honolulu-United States[1]; Hawaii Permanente Medical Group, Perinatology, Honolulu-United States[2]; Kaiser Permanente Hawaii, Pediatric Cardiology, Honolulu-United States[3]

Background: Prenatal diagnosis of congenital heart disease (CHD) improves neonatal outcomes. In Hawaii, the benefit of prenatal diagnosis is greatly enhanced because neonatal heart surgery is not available. If critical CHD is detected in a fetus, it is recommended that the mother be transferred to a cardiac surgical center on the mainland prenatally.
Methods: We reviewed databases for the total number of initial (per pregnancy) antenatal screening ultrasounds and initial fetal echocardiograms done June 2012 through May 2016 at Kaiser Permanente Hawaii (KPHI). We reviewed the fetal and transthoracic echocardiography databases for diagnoses for which intervention is necessary in the neonatal period (critical CHD) or in the first six months (serious CHD). Fetal and postnatal outcomes of all identified patients were documented.
Results: From 6/2012-5/2016, 11873 initial obstetric screening ultrasounds and 583 initial fetal echocardiograms were performed in the KPHI system. The prenatal detection rate of 31 patients (serious + critical CHD) requiring intervention by 6 months of age was 77%. The diagnoses missed prenatally by obstetric screening included 4 moderate-large ventricular septal defects (VSD), 2 coarctation/VSD, and one simple form of tetralogy of Fallot. None were missed by fetal echocardiography. Thus 1 serious/critical CHD diagnosis was missed per 1696 obstetric screening ultrasounds. Of 20

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

critical CHD diagnoses requiring neonatal intervention, 18 (90%) were diagnosed by prenatal screening. There were 9 elective terminations and 2 in utero fetal deaths. The remaining 9 patients underwent neonatal surgery, 5 were delivered at the surgical center on the mainland and 4 needed postnatal transport from Hawaii to the mainland. All patients who had surgery are currently alive and well.
Conclusions: Prenatal screening for critical and serious CHD at KPHI in the last 4 years has been successful with higher detection rates than previously reported in the US and internationally.

P2528 - CONTRAST ENHANCED CAROTID ULTRASONOGRAPHY FOR EVALUATION OF VASA VASORUM IN CHILDREN WITH LARGE CORONARY ANEURYSMS DUE TO KAWASAKI DISEASE

Akiko Komori, Nobutaka Noto, Akiko Iida, Masataka Kato, Takahiro Nakamura, Shino Jinbo, Hiroshi Kamiyama, Mamoru Ayusawa, Shori Takahashi
Pediatrics and Child Health, Nihon University School of Medicine, Tokyo-Japan

Background: The vasculitis in patients with Kawasaki disease (KD) is suspected to involve the vasa vasorum (VV). The VV network provides a critical route for inflammatory cell infiltration. We recently performed carotid contrast-enhanced ultrasonography (CEUS) in patients with KD and concurrent coronary artery lesions to compare the heterogeneity of the VV network proliferation between patients with KD and controls.
Case: We evaluated a 2-year-old boy with a large left anterior descending coronary aneurysm (z-score: 9.15) and large right coronary aneurysm (z-score: 9.55) due to KD. He had been diagnosed with KD at 19 months of age. In the acute phase, he received intravenous immunoglobulin (2 g/kg/dose), aspirin (30 mg/kg/day), and prednisolone (2 mg/kg/day) on the third day of illness. At the time of this writing, he was receiving anticoagulants (warfarin, aspirin, and clopidogrel) to prevent coronary thrombosis and had experienced no major adverse cardiovascular events. Six months after the acute onset of KD, he exhibited a greater mean carotid intima-media thickness (0.55 mm) than that in age-matched controls. CEUS using perflubutane (Sonazoid; GE Healthcare, Oslo, Norway) enabled real-time visualization and semi-quantitative evaluation of the carotid VV by setting the regions of interest in the lumen (L) and wall (W) of the common carotid artery. These values were used to calculate the ratio (EIW/EIL) of enhanced intensity (EI) (EI = peak intensity − baseline intensity) derived from a time-intensity curve. He developed no side effects of perflubutane administration.
Conclusions: Carotid CEUS may be useful for noninvasive assessment of the proliferation of neovascularization. Such neovascularization suggests active vascular remodeling of the coronary arteries in patients with KD, even small children. Future investigation of the prognostic value of CEUS is warranted.

P2530 - MORPHOANATOMY OF COMMON ARTERIAL TRUNK – A COMPUTED TOMOGRAPHIC STUDY

Saurabh Kumar Gupta[1], Abhinav Aggarwal[1], Gurpreet Singh Gulati[2], Rajnish Juneja[1], S Ramakrishnan[1], Shyam S Kothari[1], Anita Saxena[1], Sanjiv Sharma[2], Sachin Talwar[3], Balram Airan[3]
All India Institute of Medical Sciences, Cardiology, New Delhi-India[1]; All India Institute of Medical Sciences, Cardiovascular Imaging, New Delhi-India[2]; All India Institute of Medical Sciences, Cardiothoracic Vascular Surgery, New Delhi-India[3]

Background: Common arterial trunk is classified based on the variation in the origin of pulmonary arteries (PA). Recent reports have brought out difficulties in following these standard classifications. Sinusal origin of PAs as well as crossed PAs is increasingly being recognized. Nevertheless, there is paucity of data from living hearts so as to realize the potential benefits of this knowledge in improving the surgical outcomes of patients with common arterial trunk.
Materials & Methods: In this prospective observational study, 21 patients with common arterial trunk have been recruited so far. Following detailed clinical and echocardiographic examination all these patients underwent computed tomography. All the morphoanatomic details of various components of the anomaly were studied with an emphasis on the origin of coronary and PA with reference to the circumference of the truncal valve as well as the sinotubular junction (STJ).
Results: Fourteen (66%) patients were classified as Collette-Edwards type I while remaining 7 (34%) were Type 2. Truncal valve was tricuspid in 13 (62%), quadricuspid in 6 (28%) and bicuspid in 2 (10%). Majority of patients had left sided aortic arch while it was right sided in 6 (28%). In one patient, right sided arch was interrupted. Sinusal origin of PAs was seen in 11 of 14 (78%) patients with type I. Right PA was seen arising from truncal sinus in 2 (28%) patients with type II. Three (14%) patients had crossed PAs. Two patients of type I had origin of left coronary artery within 2 mm of the PA orifice.
Conclusion: The anatomy of pulmonary and coronary arteries is highly variable in patients with common arterial trunk. Sinusal origin of PAs, seen in high number of patients, may allow direct reimplantation of PA on to the right ventricular outflow tract, possibly without a conduit.

P2535 - LARGE LEFT VENTRICULAR MYXOMA DIAGNOSED BY ECHOCARDIOGRAPHY NAWAL A. M. ALABDULKARIM ABDULRAOOF ALSAEEDI MPRINCE SULTAN CARDIAC CENTER RIYADH SAUDI ARABIA

Nawal Alabdulkarim[1], Abdulraoof Alsaeedi[2]
PSCC, Pediatric Cardiology, Riyadh-Saudi Arabia[1]; PSCC, Cardiac Surgery, Riyadh-Saudi Arabia[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Clinical Presentation: 9 years old girl presented with sudden hemiparesis due to stroke without previous health problems.
Imaging Findings: Transthoracic Echocardiogram was performed to role out cardiac source of emboli, It showed huge mass filling the whole LV and protruding through aortic valve, it was not homogeneous suggestive of a myxoma.
Role of Imaging in Patient Care: Utilization of echocardiography allowed rapid accurate diagnosis and surgical management then assessment of surgery result via intraoperative transesophageal echocariography and monitoring recurrence at follow up.
Summary and Discussion Points: -This is a case of severe LV outflow tract obstruction due to a LV myxoma originating from the apex. -LV myxoma is extremely rare, accounting for 2.5-4% of all cases. - Left ventricular myxomas present with left ventricular outflow tract obstruction in 55%, embolic phenomena in 55%, and other systemic manifestations in 10%.
Transthoracic parasternal long axis images preoperatively: -The shape, the extension, the site of attachment, the involvement of valve leaflets and the functional obstruction to LV outflow tract could promptly and easily be assessed by echocardiography. -This myxoma required urgent transaortic resection. -The patient was at an increased risk of sudden death and systemic embolization due to the systolic prolapse of the mass through the aortic valve with severe obstruction, the characteristics of the myxoma, and the high pressure within the left ventricle during systole. -The mass was removed by using the transaortic approach in order to avoid a left ventriculotomy and its potential complications. This approach allowed the complete resection of the LV myxoma.

P2543 - LARGE NEONATAL PULMONARY ARTERY THROMBUS DIAGNOSED BY ECHOCARIOGRAPHY

Nawal Alabdulkarim
PSCC, Pediatric Cardiology, Riyadh-Saudi Arabia

Clinical Presentation: Full term baby girl delivered to G8P6 + 1 mom by caesarean section due to failure to progress in labour. Baby noted post delivery to have desaturation and heart murmur. Echocardiography confirmed Huge mass seen at distal main pulmonary artery protruding into branch pulmonary arteries causing pulmonary stenosis. No other masses neither abnormalities noted.
Summary: -Pulmonary artery thrombosis in neonates is a rare entity. -Very few cases of spontaneous neonatal pulmonary arterial thrombosis have ever been described. -(The most frequent important risk factor for the development of thrombosis in the neonate is the presence of an indwelling central line. The other important risk factors are asphyxia, septicemia, dehydration, maternal diabetes, and inherited thrombophilias). -When assessing a cyanotic neonate with a structurally normal heart echocardiographically, it is important to look for pulmonary artery thrombi before labeling the study as PPHN. -Most cases of spontaneuous Pulmonary artery thrombosis as in this case located at the bifurcation of the main pulmonary artery in the region of a closed ductus arteriosus with subsequent distal thromboemboli that may have contributed to cyanosis in this neonate. - We expect that the sensitivity for echocardiographic detection of main pulmonary arterythrombi in newborns is higher, as this region is routinely imaged well on newborn echocardiograms,unlike the umbilical vein and ductus venosus.

P2551 - REDUCTION IN CORONARY BLOOD FLOW IN HOSPITALIZED ADOLESCENTS WITH ANOREXIA NERVOSA COMPARED TO HEALTHY CONTROLS

Liat Gelernter Yaniv[1], Dawod Sharif[2], Jenny Garkaby[3], Camilia Shahla[4], Ameen Khalil[4], Nogah Kerem[1]
Bnai Zion Medical Center, Rappaport Faculty of Medicine, Technion, Pediatrics, Haifa-Israel[1]; Bnai Zion Medical Center, Rappaport Faculty of Medicine, Technion, Cardiology, Haifa-Israel[2]; Bnai Zion Medical Center, Pediatrics, Haifa-Israel[3] Bnai Zion Medical Center, Cardiology, Haifa-Israel[4]

Anorexia nervosa (AN) is an eating disorder characterized by excessive concern about food and body shape and weight. Cardiovascular complications of AN may be life threatening. Reduction in the Coronary Blood Flow (CBF) can lead to ischemia, valve regurgitation, cardiomyopathy, and arrhythmias. The purpose of our study was to characterize the CBF in adolescents with AN.
Methods: Coronary flow velocities (peak diastolic (Vd) and systolic (Vs)) in the left anterior descending (LAD) coronary artery were prospectively studied with 2D/pulsed Doppler ultrasound in adolescents with AN during their malnourished state. Control group consisted of healthy age and sex matched adolescents. Significance was set at $p < 0.05$
Results: 42 adolescents with AN were included; 11/31 males/females, mean age: 15.3 ± 2.4y, mean weight loss: $22.3 \pm 11\%$, mean admission BMI 16.8 ± 2.9Kg/m2, median percentile BMI for age and gender $84.5 \pm 13.3\%$, minimal nocturnal heart rate of 38 ± 6 beats per minute (bpm). 28 healthy controls were compared to the AN group. LAD Peak Vd was 23.3 ± 7.5 cm/sec in the AN group versus 35.9 ± 8.9 cm/sec in the controls and peak systolic velocity was 11.7 ± 5 in AN and 18.4 ± 4.5 in the controls; $p < 0.00001$. Reduced CBF was found to be correlated to lower BMI percentile ($p = 0.009$), nocturnal bradycardia ($p = 0.039$) and diurnal bradycardia ($p = 0.003$). Anorectic males were significantly more medically unstable than the females (nocturnal bradycardia of 34.3 ± 4.7bpm versus 39.1 ± 5.7bpm, hospitalization days for reaching minimal heart rate of 45: 16.1 ± 5.2 Vs. 10 ± 5 days), yet no statistically significant difference was found in coronary flow between the genders.
Conclusions: A significant decrease in LAD diastolic and systolic flow velocities was found in adolescents with AN, and to the best of our knowledge is the first report of this potentially hazardous complication that may lead to papillary muscle dysfunction, valve regurgitation, arrhythmia and potential cardiomyopathy.

P2560 - LATE PNEUMOCCOCAL ENDOCARDITIS OF ATRIAL SEPTAL OCCLUDERS

Liat Gelernter- Yaniv[1], Mordechai Pollak[2], Isaac Srugo[3], Ellen Bamberger[4], Dawod Sharif[5]
Bnai Zion Medical Center, Rappaport Faculty of Medicie, Technion, Pediatrics, Haifa-Israel[1]; Bnai Zion Medical Center, Pediatrics, Haifa-Israel[2]; Bnai Zion Medical Center,rappaport Faculty of Medicine, Technion, Pediatrics, Haifa-Israel[3]; Bnai Zion Medical Centerrappaport Faculty of Medicine, Technion, Pediatrics, Haifa-Israel[4]; Bnai Zion Medical Centerrappaport Faculty of Medicine, Technion, Cardiology, Haifa-Israel[5]

Late (>12months post implantation) bacterial endocarditis (SBE) following trans-catheter atrial septal defect (ASD) closure is rare. SBE prophylaxis is recommended for 6-12 months to allow full endothelialization. We present a patient with ASD occluder endocarditis and review the literature using PUBMED database. A 16-year-old obese male presented with 5-days of frontal headaches and fatigue. He had trans-catheter patent ductus arteriosus occlusion and ASD closure by Amplatzer device at 4-years of age. He was afebrile, tachycardic and tachypneic, had elevated CRP and a positive culture for intermediately-resistant Streptococcus-pneumoniae, subtype 17 f. A transesophageal echocardiogram showed a hypermobile 1X1.5 cm mass compatible with vegetation, at the left lower posterior edge of the ASD occluder (fig.1) and no residual shunt. The patient underwent extraction of the occluder and vegetectomy, followed by ASD closure. PCR from the vegetation was positive for S. pneumoniae. Notably, the occluder was completely endothelialized. The patient received 6 weeks of broad-spectrum antibiotics and fully recovered.
Results: 7 cases of late SBE of ASD occluders have been published (table 1). Only two in children. The organism was MRSA in 3, MSSA in two, unknown in two. Only our patient had pneumococcal endocarditis. In only two patients (including ours), the device was fully endothelialized.
Discussion: Late endocarditis of ASD occluders is exceedingly rare. Sporadic cases were mostly attributed to Staphylococcus species. This is the first report of Pneumococcal endocarditis. Incomplete

device endothelialization and residual shunt are well-established risk factors for endocarditis; this patient's device was completely endothelialized with no shunt.
Conclusion: although rare, endocarditis of ASD occluders must be considered. Regarding the number of new cases of device related endocarditis, long term follow-up and a high index of suspicion in patients with intra-cardiac devices is necessary. Guidelines for antibiotic prophylaxis should be reconsidered if more cases of late occluders endocarditis are reported.

P2565 - TYPE 1 TRUNCUS ARTERIOSUS WITH POSTERIOR SINUSAL ORIGIN OF THE MAIN PULMONARY ARTERY AND LEFT CORONARY ARTERY

Zoe Vetten[1], Darshan Kothari[1], Nelson Alphonso[2], Andrew Bullock[1]
Princess Margaret Hospital for Children, Cardiology, Subiaco-Australia[1]; Lady Cilento Children's Hospital, Cardiac Surgery, South Brisbane-Australia[2]

Introduction: Truncus arteriosus (TA) is an uncommon congenital heart defect with a solitary ventriculo-arterial connection giving rise to the systemic, pulmonary and coronary circulations. We present a unique case of TA with the pulmonary artery originating from the posterior truncal valve sinus.
Case Report: A 23-year-old woman was referred for fetal echocardiography at 22 weeks gestation following an abnormal obstetric ultrasound. A common arterial trunk overriding a large ventricular septal defect (VSD) with proximal origin of the main pulmonary artery (MPA) was identified. A diagnosis of TA was made. Amniocentesis demonstrated 22q11 microdeletion. A female infant weighing 2850 g was delivered by normal vaginal delivery at 39 weeks gestation. She was mildly cyanosed with saturations of 85%. Transthoracic echocardiogram confirmed the diagnosis of TA. A solitary trileaflet truncal valve with trivial incompetence was overriding a large VSD. The MPA arose below the sinotubular junction from the posterior truncal sinus, with confluent left and right branch pulmonary arteries. During systole, the pulmonary orifice was partially occluded by the posterior cusp. The left coronary artery (LCA) arose anomalously from the posterior sinus, close to the anterior-posterior commissure. No left anterior descending artery was identified: the LCA coursed along the atrioventricular groove as the circumflex artery. The right coronary artery (RCA) arose from the centre of the anterior sinus. Cardiac CT angiogram confirmed the echocardiographic findings and demonstrated a left anterior descending coronary artery arising from the RCA. Successful surgical repair occurred on day 18 of life.
Conclusion: This anatomy is unique given the origin of the pulmonary trunk below the sinotubular junction from the posterior truncal sinus. There are no previous reports of posterior sinus origin of the common pulmonary orifice in Type 1 TA. Early identification of anatomical variants is essential in the successful surgical management of such infants.

P2570 - TEE DIAGNOSIS OF RIGHT ATRIAL THROMBUS IN A CASE OF CHRONIC CONSTRICTIVE PERICARDITIS

Rajarajan Ganesan, Ganesh Kumar M, Srinath Damodaran, Imran Bhatt H, Bhupesh Kumar
Pgimer, Cardiac Anesthesia, Chandigarh-India

Background: Chronic constrictive pericarditis is a debilitating condition with tuberculosis being the major cause in developing countries. Dyspnea and congestive symptoms are the common complaints at presentation requiring further evaluation and confirmation by imaging and clinical data. Association of right atrial thrombus with constrictive pericarditis is rare but needs to be ruled out as it can dislodge during manipulation or cannulation for cardiopulmonary bypass potentially causing massive pulmonary thromboembolism.
Material and Method: A 14 year old male presented with history of abdominal distension and pedal edema of 5 months duration. Physical examination revealed raised jugular venous pulse with sinus rhythm, normal heart sounds and no murmurs. Transthoracic echocardiography revealed constrictive physiology and thickened pericardium. Transesophageal echocardiography revealed an irregular hyperechoic mass of maximum dimensions 50x36 × 30mm in the right atrial free wall which was not detected on transthoracic examination and computed tomography. Pericardectomy followed by surgical removal of the thrombus using cardiopulmonary bypass was performed and the patient was discharged home after an uneventful course.
Result: Endocardial damage and intracardiac blood stasis secondary to decreased diastolic compliance can cause thrombus formation in constrictive pericarditis. Tranesophageal echocardiography in addition to confirming the pericardial pathology revealed the thrombus which was not detected earlier. Calcified pericardium distorting the right ventricle obscured the mass when transthoracic echocardiography was done from the apical window, while it not could be differentiated from the thickened pericardium on computed tomography. Right atrial thrombus can be associated with tricuspid valve obstruction, systemic and pulmonary thromboemboli and has an 4% early mortality rate warranting surgical removal under cardiopulmonary bypass. BIcaval cannulation was necessary in our case to avoid dislodging the thrombus.
Conclusion: Transesophageal echocardiography was instrumental in our case in the diagnosis of the thrombus resulting in a major change in surgical plan thus averting significant morbidity and possibly mortality.

P2573 - APICAL NON COMPACTION ASSOCIATED WITH CONGENITAL HEART DISEASES DIAGNOSED BY ECHOCARDIOGRAPHY

Balekundri Vijayalakshmi
PMSSY, Super Speciality Hospital, Bengaluru Medical College and Research Institute, Cardiology, Bengaluru-India

Background: Isolated left ventricular non-compaction (LVNC) is reported extensively. But apical non-compaction (ANC) of both the ventricles and inter ventricular septum (IVS), is not reported much in literature as it is said to be common in reptiles but rare in human beings. Aim of our study is to analyze and evolve the echocardiographic (TTE) diagnostic criteria for "apical non-compaction ".
Material and Results: From January 2011 to February 2016, 100 consecutive cases that fulfilled standard echocardiographic criteria for LVNC and the additional criteria 1) Swiss cheese appearance of IVS, looking like a delta of the river 2) non-compaction of right ventricle on TTE, formed material for this study. Age ranged from 3 days to 35 years, with 37 males and 33 females. The associated lesions were present in all almost all cases. 86 patients had acyanotic heart disease (86%) and 14 patients had cyanotic heart disease (14%). 21 of 100 cases had pump failure (21%). 10 cases had LV

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

dysfunction, 8 had RV dysfunction and 3 had biventricular dysfunction, 38 patients (38%) had pulmonary hypertension; two had thrombus. 3 cases of Swiss cheese VSDs were post-operative residual shunts. ANC is known to happen in the chicken heart, but thus far there has been no evidence to suggest a similar mechanism in human beings. ANC was totally ignored by the echocardiographer or only specific lesions like Swiss cheese VSD were diagnosed in the past. For the first time we report a large series of 100 cases of ANC diagnosed by TTE only
Conclusion: TTE with color Doppler is an excellent modality to diagnose ANC with additional criteria. Probably ANC is ignored. ANC is invariably associated with other serious congenital cardiac malformations, which worsen the pump failure.

P2578 - ROLE OF CONTRAST ECHOCARDIOGRAPHY WITH AGITATED SALINE INJECTION FOR ANTEMORTEM DIAGNOSIS OF CORTRIATRIATUM DEXTER

Balekundri Vijayalakshmi
PMSSY, Super Speciality Hospital, Bengaluru Medical College and Research Institute, Cardiology, Bengaluru-India

Background: Cor triatriatum dexter (CTD) is an extremely rare congenital anomaly (0.025%), in which the right atrium (RA) is divided into two chambers by a septum. Anomaly is usually diagnosed either on autopsy or during surgery as diagnosis is missed clinically. We report a series of 16 cases of CTD diagnosed antemortem by 2D transthoracic echocardiography (TTE) with contrast echo.
Objective: To describe varied clinical presentations and highlight importance of TTE with contrast prepared with patient's blood agitated with 0.9% saline, injected from upper and lower limbs for precise antemortem diagnosis of CTD.
Material, Methods and Results: Sixteen consecutive patients of CTD diagnosed with TTE, formed the material. Age ranged from 2 days to 51 years. All patients underwent detailed TTE interrogation especially in RV inflow view with agitated saline contrast injected from both upper and lower limbs separately to demonstrate membrane in right atrium. Two cases referred as primary pulmonary hypertension (PPH), another two with hemoptysis and pulmonary embolism turned out to be CTD. One had multiple thrombi in right atrial appendage. Seven patients had atrial septal defect (ASD). 2 days old neonate with severe cyanosis(SPO2-54%) died, as both SVC and IVC were opening in proximal chamber and desaturated blood was shunting to left atrium. 9 days old Ebstein's anomaly with ASD, the CTD was suspected, prenatally by fetal echo. CTD is not always be benign, as described in the literature, because it was fatal in 3 cases (20%) in our series.
Conclusion: Ante mortem diagnosis of CTD with agitated saline contrast echocardiography can be precise and lifesaving. CTD should be looked for in RV inflow view in all cases of Ebstein's anomaly and ASD, who present with PAH or pulmonary embolism.

P2580 - RIGHT VENTRICULAR FUNCTION ASSESSED BY THREE DIMENSIONAL ECHOCARDIOGRAPHY AFTER CONE PROCEDURE COMPARISON WITH MAGNETIC RESONANCE IMAGING

Alessandro Lianza[1], Samira Morhy[1], Tania Afonso[1], Wercules Oliveira[1], Ana Clara Rodrigues[1], Marcelo Vieira[1], Glaucia Tavares[1], Cesar Nomura[2], Jose Pedro Silva[3], Luciana Silva[3]
Hospital Israelita Albert Einstein, MDP, São Paulo-Brazil[1]; Hospital Israelita Albert Einstein, Radiology Unit, São Paulo-Brazil[2]; Hospital Beneficencia Portuguesa De São Paulo, Cardiovascular Surgery, São Paulo-Brazil[3]

Background: Assessing right ventricular (RV) systolic function using echocardiography is challenging due to its complex morphology. Although cardiac magnetic resonance (CMR) is the "gold standard" to evaluate RV, three dimensional echocardiography (3D Echo) has been shown to be an alternative to accurately evaluate cardiac function. We aimed to compare parameters of RV function by two dimensional echocardiography (2DEcho) and 3DEcho to CMR in patients with Ebstein´s anomaly after surgical treatment with Cone procedure.
Methods: We assessed patients during late post-operative follow-up (median 7 years, range 1-21 years) from Cone procedure regarding clinical status, 2DEcho RV parameters including TAPSE, fractional area change (FAC), tissue Doppler S velocity, Tei index and longitudinal Strain and RV volumes and ejection fraction (EF) using 3DEcho and CMR (performed within 4 hours of echocardiography). Pearson´s correlation was used for analysis.
Results: Out of 27 patients (13 male, median age 20 years, range 8-54 years), 2 were excluded from analysis due to inadequate echocardiographic window. All patients were in regular cardiac rhythm. Most patients (44,4%) complained of effort dyspnea. None of 2DEcho parameters showed a good correlation to EF using CMR. Pearson's correlation between 3DEcho and CMR was good for RV volumes and moderate for EF (Table 1).
Conclusion: Compared to CMR, 3DEcho was able to adequately evaluate RV systolic volumes and function in operated Ebstein's anomaly. Systolic function parameters from 2DEcho did not correlate well to CMR. Despite good surgical results, RV function remained impaired in this specific set of patients.

Table 1. Comparison of RV volumes and EF between 3DEcho and CMR.

	3DEcho	CMR	r	p
RV end diastolic volume	126 ml (60-325)	177 ml (76-423)	0.7	<0.001
RV end systolic volume	87 ml (265-33)	101 ml (41-334)	0.8	<0.001
EF	32% (19-54)	41% (21-53)	0.6	<0.001

P2581 - 3D ECHO EVALUATION OF RIGHT VENTRICULAR VOLUMES IN THE LATE POSTOPERATIVE FOLLOW UP OF TETRALOGY OF FALLOT REPAIR WITH PULMONARY INSUFFICIENCY

Vanessa Canuto, Carlos Jesus, Renata Chaccur, Juliana Valentim, Gisele Moreira, David Bihan, Rodrigo Barretto, Simone Pedra
Instituto Dante Pazzanese De Cardiologia, Echocardiography Laboratory, São Paulo-Brazil

Introduction: Right ventricular (RV) functional and volumes evaluation is one of the major concerns in the follow-up of patients who underwent tetralogy of Fallot (ToF) repair. Chronic pulmonary insufficiency (PI) results in RV dilation and dysfunction. Timing for re-intervention has been defined mainly by RV diastolic and systolic indexed volumes (RVEDVi and RVESVi) assessed by magnetic resonance (MRI). The specific RV 3-D echo

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Tomtec@ software is an advanced tool that allows calculation of the same parameters and may be applied in this specific population. This study aimed to test the correlation between RVEDVi and RVESVi of patients with PI in the late follow-up of ToF repair assessed by MRI and 3-D echo.
Methods: 30 patients were enrolled in the study. Patients with moderate to severe residual lesions except for PI were excluded. 3-D echo was performed in our echo lab and the MRI in outside hospitals.
Results: Time between surgery and study was 18 years (6–44 years). Time between the 2 studies was 1 year (1 month – 4 years). PI was moderate in 13% and severe in 70% of the cohort. The correlation of the RVEDVi and RVESVi between the two images methods was $r = 0{,}7 - p < 0{,}001$ and $r = 0{,}68 - p < 0{,}001$ respectively with greater discrepancies observed in larger volumes. RVEDVi $\geq$ 99 ml/m^2 had sensitive and specificity values of 69 and 93% respectively in estimating RVEDVi $\geq$ 140 ml/m^2 measured by MRI.
Conclusion: There is reasonable correlation between RMI and 3D-echo in the assessment of RV volumes. It seems that 3D-echo may be an option for the regular monitoring of the RV volumes in the late postoperative period of ToF repair until critical volumes are reached, when MRI should be performed to identify the optimal timing to intervene in the RV outflow tract.

P2594 - UNEARTHING THE UNIQUENESS OF CONGENITAL HEART DISEASE CREATIVE PARTICIPATORY PRACTICES CARDIOVASCULAR MAGNETIC RESONANCE IMAGING AND 3D PRINTING

Sofie Layton[1], Giovanni Biglino[2], Lindsay-Kay Leaver[1], Andrew Taylor[1], Jo Wray[1]
Great Ormond Street Hospital for Children, Cardiorespiratory Division, London-United Kingdom[1]; University of Bristol, Bristol Heart Institute, Bristol-United Kingdom[2]

Background: Patients with congenital heart disease (CHD) require life-long follow-up. Adolescents transitioning from the pediatric to adult centre need to gain an appreciation of their cardiovascular anatomy and the lifestyle implications of their CHD. We propose that an interdisciplinary approach merging medical imaging, 3D printing technology and artistic methodologies could be beneficial for CHD patients to get in touch and engage with the uniqueness of their condition.
Methods: CHD patients (n = 14, 14-18 years, 6 males) participated in one of two, two-part, creative workshops (7 young people in each) facilitated by an artist, a health psychologist, a bioengineer and an adolescent nurse specialist. The two sessions were run 1.5 months apart. Creative exercises included blindfolded drawing and sculpting self-portraits, creative writing, body mapping and metal embossing. These activities facilitated the development of imagery and language to explore individual uniqueness. Patient-specific heart images were derived from the participants' MRI data. MRI-derived patient-specific heart models were manufactured by means of 3D printing. Heart images were re-interpreted artistically and 3D models were discussed, in an effort to explore heart-related imagery and narratives.
Results: CHD patients engaged extremely well with the inter-disciplinary process. The creative output was charged with experiential and medical connotations, and was articulate and confident. Patients found 3D vs. 2D a more immediate form of expression. Heart narratives were potent and unique, including eloquent metaphors of survival, resilience, strength, fragility and structural complexity. 3D heart models aided the conversation around anatomy and understanding it. Participants' feedback highlighted enjoyment, the opportunity to get in touch with one's self, the possibility of working with peers and the privilege of reflecting on uniqueness.
Conclusions: An interdisciplinary approach, including artist-led workshops and MRI-derived models, can aid adolescent CHD patients to explore individual uniqueness as well as the form and significance of their own heart.

P2600 - QUANTITATIVE EVALUATION USING LUNG PERFUSION SCINTIGRAPHY FOR FONTAN CIRCULATION

Osamu Matsuo[1], Hisashi Sugiyama[2], Isao Shiraishi[2]
Kumamoto City Hospital, Pediatric Cardiology, Kumamoto-Japan[1]; National Cerebral and Cardiovascular Center, Pediatric Cardiology, Osaka-Japan[2]

Background: After the Fontan procedure, a right-to-left (R-L) shunt by venous-venous shunt or pulmonary arteriovenous fistula could develop, which causes hypoxemia. In the present study, we tried to evaluate the R-L shunt in patinets with fontan procedure on lung perfusion scintigraphy.
Subjects: Total 25 patients (13males, 12females; age,2.4-25.3years) who underwent lung perfusion scintigraphy after Fontan procedure, respectively.
Methods: 60% amount of isotope 99mTc-MAA was injected into lower extremities and the other 40% amount of isotope was injected into upper extremities. The R-L shunt rate ((whole body count - lung count)/whole body count x 100%) was calculated and was compared with hemodynamic date from simultaneous cardiac catheterization.
Results: the R-L shunt rate and arterial oxygen saturation (SpO2) showed a linear, reverse correlation ($Y = -0.26x + 98.2$ and $r = 0.78$, $p < 0.01$). Furthermore, in comparison between high central venous pressure (CVP) group (≥12mmH) and low CVP group (<12 mmHg), the R-L shunt in high CVP group was significantly higher than that in low CVP group ($36.2 \pm 17.5\%$ vs. $17.8 \pm 9.9\%$, respectively, $p < 0.01$). There was not statistically significant difference between the R-L shunt rate and pulmonary vascular resistance or postoperative period.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Conclusion: Quantitatively evaluatation of the right to left shunt using lung perfusion scintigraphy is feasible and useful after Fontan procedure.

P2608 - CONGENITAL DOUBLE LUMEN AORTIC ARCH A RARE ANAMOLY

Nadeem Aslam, Babar Sultan Hasan
Aga Khan University and Hospital, Paediatric Cardiology, Karachi-Pakistan

Background/Hypothesis: Persistence of fifth aortic arch is extremely rare anomaly presenting as double lumen aortic arch.
Material and Methods: Case report.
Results: We report a case of double lumen aortic arch best explained by persistence of left fifth aortic arch. It was associated with membranous ventricular septal defect. The patient underwent successful repair of septal defect, while arch anomaly was asymptomatic and left untreated.
Conclusion: Double lumen aortic arch is extremely rare anomaly due to persistence of left fifth aortic arch, if asymptomatic, does not require any treatment.

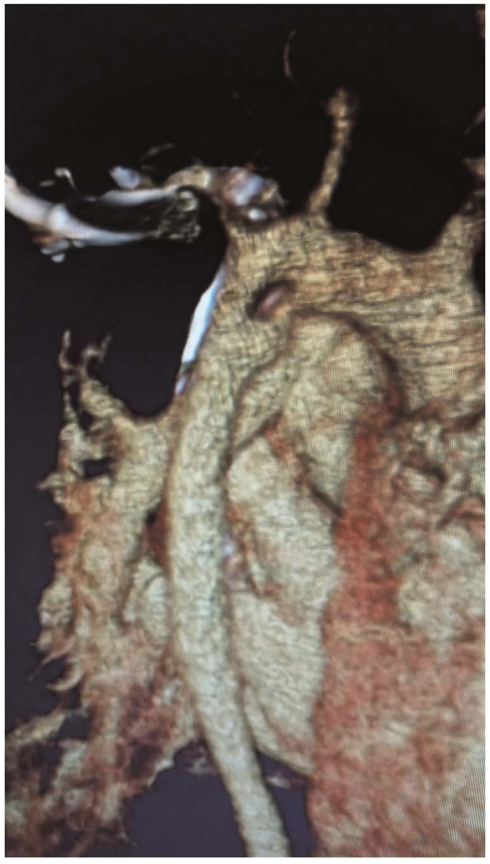

Figure.

P2619 - POSTNATAL FINDINGS IN RIGHT TO LEFT HEART SIZE DISPROPORTION IN FETAL ECHOCARDIOGRAPHY – A GENERAL HOSPITAL EXPERIENCE

Claudia Gallafrio[1], Samira Morhy[1], Alessandro Lianza[1], Glaucia Tavares[1], Rita Sanchez[2], Wercules Oliviera[1], Tania Afonso[1], Ana Rodrigues[1], Marcelo Vieira[1], Claudio Fischer[1]
Hospital Albert Einstein, Echocardiography, Sao Paulo-Brazil[1]; Hospital Albert Einstein, Fetal Medicine, Sao Paulo-Brazil[2]

Background/Hypothesis: In fetal echocardiography, right to left heart size disproportion, with the right heart larger than the left (R-L/HD), may be associated with left-side obstructive disease, such as coarctation of the aorta (CoA). These findings isolated are nonspecific for predicting postnatal diagnose of CoA, and often need repeated echocardiograms, leading to significant parents stress. The objective of this study is to identify associations R-L/HD and left-sided obstructive disease.
Methods: From April 2011 to February 2016, 64 out of 1555 fetal echocardiograms were identified with isolated L-R/HD, with 18 delivered in our hospital. Pre and postnatal echocardiograms and the medical records were reviewed. Medium gestational age was 31 weeks (25 to 36). Echocardiography measurements included: tricuspid/mitral valve diameters, left/right ventricle mid-cavitary width dimensions, pulmonary/aortic valve diameters, pulmonary/aorta dimensions, transverse aortic arch and aortic isthmus diameters. Flow directions at atrial level and across aortic and ductal arches were analyzed.
Results: Two fetuses presented with arch obstruction, one of them critical, requiring neonatal intervention. Another presented with isolated quadricuspid aortic valve. None of the parameters distinguished critical CoA from a normal heart, though there was a tendency for the aortic isthmus diameter to be smaller in fetus with CoA(2,3mm vs 3,8mm respectively),
Conclusion: In our institution, most cases with isolated R-L/HD in fetal echocardiography presented with normal hearts after birth, suggesting this might not be an accurate means of antenatal detection of CoA.

P2621 - ASSESSMENT OF LINEAR INSERTION OF ATRIOVENTRICULAR VALVES IN FETUSES BY POSTMORTEM CARDIAC MRI

Eleonore Blondiaux[1], Gwenael Autret[2], Ferdinand Dhombres[3], Marie Gonzales[3], Olivier Clement[2], Jean-Marie Jouannic[3], Lucile Houyel[4]
Hôpital Trousseau, Université Pierre Et Marie Curie, Radiologie, Paris-France[1]; Université Paris Descartes, Sorbonne Paris Cité, Plateforme Imagerie Vivant, Inserm U970, Paris-France[2]; Hôpital Trousseau, Université Pierre Et Marie Curie, Médecine Foetale, Paris-France[3]; Hôpital Marie-lannelongue, Chirurgie Des Cardiopathies Congénitales, Le Plesis-robinson-France[4]

Background: Linear insertion of the atrioventricular valves (LIAVV) on foetal echocardiography was described in 2002 by Fredouille in association with aneuploidy, and could represent a minor form of atrioventricular septal defect (AVSD). However, no anatomic or embryologic explanation has been provided to confirm this hypothesis. To elucidate the pathological significance of LIAVV, we compared postmortem high-spatial resolution cardiac magnetic resonance imaging (MRI) with foetopathological examination for visualizing LIAVV in human fetal hearts. This work will be a preliminary step for a larger scale study, with as a final aim to confirm or not whether LIAVV belongs to the spectrum of AVSD.
Material and Methods: Two normal hearts (N), 1 AVSD and 2 LIAVV (gestational age 17-34 weeks) were randomly selected among the anatomic collection of the French Reference Center for Complex CHD. Postmortem cardiac MRI was performed with a 4.7-T imager. Specimens were rinsed and placed in airtight bags filled with 1-2 ml of distilled water. 3D and 2D Turbo-RARE sequences in four-chamber, short axis and left ventricular long-axis planes were performed with a minimal isotropic or

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

in-plane resolution of 156 μm. MR images were compared to foetopathological examination. Quantitative analysis included measurement of the distance between the insertion of the medial leaflets of the tricuspid and mitral valves, and of the left ventricular inlet/outlet distance ratio.
Results: MRI and pathology findings agreed perfectly in identifying valve insertion, evaluating mean mitral valve-tricuspid valve distance (N: 1.63 mm; LIAVV: 0.89 mm) and inlet-outlet distance ratio (N: >0.9, LIAVV: < 0.80, AVSD: <0.5). Both LIAVV had a deficiency of the inlet ventricular septum closed by the insertions of a bi-leaflet mitral valve, explaining the lack of offsetting of the AV valves.
Conclusions: Postmortem cardiac MRI provides results similar to pathology for assessing LIAVV in fetuses without requiring specific preparation of the heart.

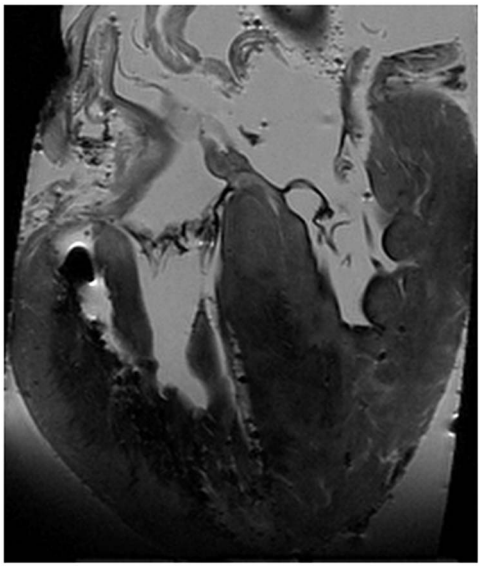

Figure.

P2628 - EBSTEIN'S ANOMALY AND MORPHOLOGY VARIATION (A ROLE OF PEDIATRIC CARDIOLOGIST IN FETAL ECHOCARDIOGRAPHY)

Syarif Rohmi[1], *Winda Azwani*[1], *Gatot Abdurrazak*[2], *Poppy Roebiono*[3], *Dicky Fachri*[4]
Harapan Kita, Children and Women Hospital, Pediatric Cardiology, Jakarta-Indonesia[1]*; Harapan Kita, Children And Women Hospital, Obstetric and Ginecology, Jakarta-Indonesia*[2]*; National Heart Center, Harapan Kita Hospital, Pediatric Cardiology, Jakarta-Indonesia*[3]*; National Heart Center, Harapan Kita, Pediatric Cardiac Surgery, Jakarta-Indonesia*[4]

Background: Ebstein's Anomaly (AE) is a rare congenital cardiac defect and characterized by remarkable morphologic variability, a broad spectrum of clinical presentations and treatment. Detailed fetal echocardiography plays important rule to make an accurate diagnosis. During 2012-2016, there were 4 AE cases, 1st three cases easily to diagnosed. The 4th case was referred to evaluate the diagnosis. Here, we present the 1st and the last case.
Case 1: 25 years healthy mother, G2P1AoH1, full gestational age, estimated weight 3200 gr, referred for reevaluation Ebstein's Anomaly. Four chamber view (4CV): very dilated RA and RV, severe TR, severe downward septal leaflet tricuspid valve (TV), PFO and smallish LV. Five chamber and trachea view: normal. Normal PA, PFO, small PDA and left aortic arch.
Case 4: 24 years full gestational healthy mother with very dilated RA and RV, severe TR, slight smallish RV compare to normal LV dimension on 4 CV. Further detailed examination revealed severe downward TV septal leaflet, severe TR and PFO. Five chamber and trachea view were transposed Great arteries, PFO and PDA. Diagnosis was severe Ebstein's anomaly, transposed GA (?), PFO and PDA.
Management: Case 1. Nasal CPAP, flow 5, FiO2 0.6. Laboratories: normal, SaO2 76-88%. Patient underwent Starness procedure and patient died on 6th day due to heart failure. AS 9/10 Case 2. Underwent caesarean delivery and transferred to NICU, spontaneous breathing. TTE: EA, ccTGA, large PDA and postductal coarctation of aorta (?).
Laboratories: normal. Team decided to start PGE1 with SaO2 68%. MSCT was planed and ongoing discussion to decide the appropriate procedure.
Conclusion: Detailed Ebstein's anomaly fetal echocardiogram is very important to assess accurate diagnosis for early treatment and intervention.

P2632 - A UNIQUE CASE SERIES OF CHILDREN WITH CONGENITAL PULMONARY VEIN STENOSIS FROM AN AFRICAN CENTER

Mamaila Lebea, Antoinette Cilliers, Hopewell Ntsinjana
University of Witwatersrand, Paediatrics and Child Health, Johannesburg-South Africa

Background: Congenital pulmonary vein stenosis (PVS) is a rare condition, which results from abnormal embryological incorporation of the common pulmonary vein into the left atrium.
Methods: A retrospective descriptive case series study was conducted with the aim of describing the characteristics and outcome of children with congenital pulmonary vein stenosis at an African tertiary care center over a 25-year period. A Computerized paediatric cardiology database initiated in the early 1990s was sourced to identify patients whose hard copy clinical notes were retrieved and reviewed.
Results: Five cases of congenital PVS were identified between January 1990 and January 2016. Congenital PVS accounted for 0.07% of all congenital heart defects seen at the center during the study period. The age at diagnosis ranged from 22 months to 13 years. The majority of patients manifested with respiratory symptoms, with two patients presenting with recurrent haemoptysis. The diagnosis of PVS was confirmed by cardiac catheterization and pulmonary angiography in all patients. All cases were right-sided unilateral PVS and all were associated with one or more congenital heart defects. Mild pulmonary hypertension and elevated capillary wedge pressures were found in all patients. Only one patient underwent specific surgery to relieve the PVS, which subsequently recurred. The other patient operated on was for lobectomy following recurrent haemoptysis, this patient subsequently died of sepsis.
Conclusion: Congenital pulmonary vein stenosis is a rare condition often associated with other congenital cardiac defects. Respiratory symptoms are common at presentation, with haemoptysis forming part of the presenting clinical spectrum, in keeping with the published literature.Moreover, elevated pulmonary artery pressures and increased ipsilateral pulmonary capillary wedge pressures are a common finding at catheterization.

P2640 - MELODY VALVE PLACEMENT FOR MITRAL VALVE DYSPLASIA SYNDROME

Oluwatosin Fatusin[1], Sitaram Emani[2], Lindsay Freud[3], Wayne Tworetzky[1]
Boston Children, Pediatric Cardiology, Boston-United States[1]; Boston Children, Pediatric Cardiac Surgery, Boston-United States[2]; Columbia University Medical Center - Newyork-Presbyterian Morgan Stanley Children, Pediatric Cardiology, Newyork-United States[3]

Background: Mitral valve dysplasia syndrome includes a dilated left ventricle and a dysplastic mitral valve often necessitating repair or replacement. Options for neonatal mitral valve palliation are challenging, but the placement of Melody mitral valve shows promise in this patient population.
Case: A 6 week old female, born full term via an uncomplicated pregnancy, had normal prenatal ultrasounds. After birth, she failed the pulse oximetry test prompting a cardiac evaluation. The echocardiogram showed severe mitral valve regurgitation and a dilated left ventricle and atrium. She was medically managed and initially sent home but returned to the referring hospital with difficulty feeding and respiratory distress requiring intubation.
Decision-making: On review of her records, her echocardiogram was consistent with mitral valve dysplasia syndrome with severe mitral valve regurgitation. There was an arcade type defect of the mitral valve which was unlikely to improve with medical therapy alone. Alternative options included a heart transplant, primary repair and a prosthetic mitral valve, which would require anticoagulation. However, given her size and the lack of small mitral valve prostheses, she was not a candidate for the aforementioned options. After extensive case discussion, decision was made for placement of a stent mounted by prosthetic Melody valve in the mitral position, performed surgically. She tolerated the procedure well and her echocardiogram prior to discharge showed a well-functioning Melody valve in the mitral position with no stenosis or regurgitation. To date, there have been no episodes of respiratory distress, poor perfusion or syncope. Follow up echocardiograms have showed no significant mitral valve regurgitation or left ventricular dysfunction.
Conclusion: This case highlights the feasibility of a Melody valve placement in the mitral position, as a new option for infants with a dysplastic mitral valve.

P2641 - ACUTE MYOCARDITIS WITH INFARCT LIKE PRESENTATION IN A PAEDIATRIC POPULATION. ROLE OF CARDIOVASCULAR MAGNETIC RESONANCE

Maria Martinez-Villar[1], Ferran Gran[2], Anna Sabate-Rotes[2], Amparo Castellote[3], Marc Figueras-Coll[4], Rosa Collell[5], Queralt Ferrer[2], Ferran Roses-Noguer[2], Gemma Giralt[2], Dimpna Calila Albert Brotons[2]
Vega Baja Hospital, Pediatric Cardiology, Orihuela-Spain[1]; Vall D'hebron Hospital, Pediatric Cardiology, Barcelona-Spain[2]; Vall D'hebron Hospital, Pediatric Radiology, Barcelona-Spain[3]; Josep Trueta Hospital, Pediatric Cardiology, Girona-Spain[4]; Sant Joan De Reus Hospital, Pediatric Cardiology, Tarragona-Spain[5]

Background: Chest pain is a typical symptom of acute myocarditis in teenagers and young adults. It may be indistinguishable from myocardial ischemia so it is called "infarct-like pattern". Cardiovascular magnetic resonance has an important role as a non-invasive diagnostic tool. The aim of our study is the description of an acute myocarditis series with infarct-like pattern, and the evaluation of the cardiovascular magnetic resonance role in a paediatric population.
Material and Methods: We included all paediatric patients (0-16 years) admitted to our hospital (May 2007 - May 2016) with clinical diagnosis of acute myocarditis and infarct-like presentation (chest pain, ECG alterations and elevated cardiac biomarkers). Data about patient demographics, test results and outcomes were analyzed.
Results: We collected 7 patients (5 males, 2 females) with a median age of 14 years (12.5-15.2) were included. All patients showed ST-segment changes and elevated cardiac biomarkers. Three patients had left ventricular hypertrophy (50%) and 2 presented mild systolic left ventricular dysfunction (33.3%). All patients had at least 2 positive Lake-Louise criteria. Late gadolinium enhancement was positive in all of them. With a median follow-up of 23 months (8-47), all of them are alive, with no cardiac symptoms and free of heart transplant.
Conclusions: Chest pain is a typical symptom in teenagers with acute myocarditis. If it is suspected, cardiovascular magnetic resonance should be performed as a first line diagnostic tool. Unlike what was described in adults, late gadolinium enhancement does not imply worse outcome in teenagers.

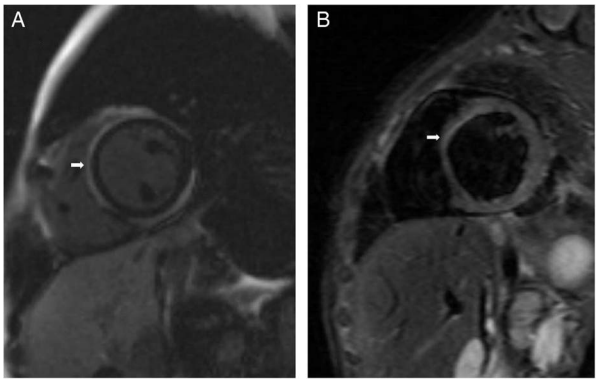

Figure.

P2653 - CLINICAL RADIOLOGICAL AND PATHOLOGICAL CORRELATIONS REVEAL A PATTERN OF INCREMENTAL BRAIN INJURY AND IMPAIRED CEREBRAL GROWTH IN PATIENTS WITH CONGENITAL HEART DISEASE

Davide Marini[1], Lili-Naz Hazrati[2], Jessie Mei Lim[1], David Chiasson[2], Helen Branson[3], Susan Blaser[4], Lars Grosse-Wortmann[1], Shi-Joon Yoo[4], Steven Miller[5], Mike Seed[1]
The Sick Kids Hospital, Pediatric Cardiology, Toronto-Canada[1]; The Sick Kids Hospital, Laboratory Medicine and Pathology, Toronto-Canada[2]; The Sick Kids Hospital, Pediatric Radiology, Toronto-Canada[3]; The Sick Kids Hospital, Pediatric Neuroradiology, Toronto-Canada[4]; The Sick Kids Hospital, Pediatric Neurology, Toronto-Canada[5]

Background: Impaired brain growth and white matter injury (WMI) are frequently seen on MRI in newborns with congenital heart disease (CHD) both before and after surgical treatment. However there is limited information available regarding the relationships between clinical, imaging and pathological findings in this setting. Here we report on three cases in which autopsy with the examination of the brain was performed from a larger cohort of children being prospectively studied with serial brain MRI.
Materials and Methods: Between 2013 and 2016, 95 newborns with CHD underwent brain MRI imaging both before and after surgery in our department. 44% had single ventricle physiology and 53% had transposition of great arteries. At a mean follow-up interval of 19 months, 11 patients had died (12%). Autopsy that included examination of the brain was performed in 3 patients (2.7%).

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Results: Subject 1 had double outlet right ventricle with mitral atresia, subaortic and aortic stenosis. Subject 2 had right isomerism with an atrioventricular septal defect and double outlet right ventricle with pulmonary stenosis and obstructed infracardiac total anomalous pulmonary venous return. Subject 3 had Tetralogy of Fallot with hypoplastic pulmonary arteries and Adams-Oliver Syndrome with a NOTCH 1 mutation. Mean pre-operative, post-operative, and post-mortem brain volume z-scores were -1, -2.5 and -2.9 respectively. In addition, there was evidence of punctate WMI following surgery but also present pre-operatively in Subject 3, and further watershed and embolic infarction following post-operative complications with hemodynamic instability. The key imaging and pathology findings are shown in Table 1.
Conclusions: CHD is associated with poor brain growth, which is present at birth but progresses following palliative surgery. While uncomplicated surgery is often associated with no new brain injury, periods of hemodynamic instability and cardiac arrest are frequently accompanied by further ischemic injury. As yet undefined predisposing genetic factors may influence the extent of the brain injury.

P2656 - USEFULNESS OF MYOCARDIAL STRAIN IMAGING IN SPINAL MUSCULAR ATROPHY

Carles Bautista
Hospital Sant Joan De Deu, Paediatric Cardiology, Barcelona-Spain

Background: Our aim was to evaluate left ventricular (LV) mechanics by using speckle tracking echocardiography (STE) in patients with Spinal Muscular Atrophy (SMA) in the presence of LV ejection fraction (EF) >50% and to compare it after 1 year of oral salbutamol.
Methods: We studied 51 patients with SMA (mean age 7.2 years; range 0-12 years, LVEF > 55%) and 59 age-matched normal controls (mean age 7.1 years; range 0-12 years). All underwent standard echocardiographic evaluation and STE.
Results: LVEF ($63.6 \pm 8.2\%$ vs. $64.1 \pm 5.1\%$, $p = 0.826$) was not different between patients and controls. Patients with SMA had higher heart rates and increased LV end-systolic dimensions compared with controls. Diastolic parameters were significantly abnormal in SMA patients versus controls (E/e' average: 11.9 ± 5.8 vs. 6.6 ± 3.0, $p = 0.0014$). Global LV longitudinal strain was significantly lower in SMA patients versus controls ($-17.6 \pm 3.5\%$ vs. $-23.4 \pm 3.1\%$, $p < 0.0001$). LV torsion ($9.1 \pm 4.9°$ vs. $11.9 \pm 3.3°$, $p = 0.046$) was significantly impaired in SMA patients. Diastolic parameters and global LV longitudinal strain values improved after 1-year-course of salbutamol in SMA patients ($p = 0.003$)
Conclusions: Diastolic function, LV longitudinal deformation and LV torsion are impaired in SMA patients compared to control group despite an LVEF >50%. A course of salbutamol improves all the previous parameters. We suggest including a detailed study of the diastolic function and cardiac mechanics in the clinical follow-up of these patients.

P2667 - COARCTATION OF AORTA AND VEIN OF GALEN ANEURYSMAL MALFORMATION IN A NEONATE

Melih Timuçin Doğan, Ercan Tutar, Tayfun Uçar, Semra Atalay
Ankara University School of Medicine, Pediatric Cardiology, Ankara-Turkey

Introduction: Galen ven aneurysm is a rare congenital intracranial vascular malformation. Aortic coarctation can be seen in Galen malformation. The reason is that the blood of the aorta is stolen by the brain due to the extensive malformation. We present a case of a newborn with coarctation of the aorta and a vein of Galen malformation (GM).
Case Report: A male infant was born spontaneously at 39 weeks. Echocardiography was performed on a patient who had a murmur on physical examination revealed a aortic coarctation, a PDA, and a PFO. Prostaglandin infusion was started and referred to our clinic for further treatment. Cardiac examination revealed 3/6 systolic murmur at the left sternal border. Pulses were described as strong in the upper and lower extremities. Repeated echocardiographic examination revealed severe aortic coarctation (figure 1) and large ductus with right to left shunt. There was also evidence of retrograde diastolic flow into the transverse aortic arch toward to head and neck vessels (figure 2). A brain computed tomograpy was also consistent with a very large vein of GM (figure 3). Interventional Radiology was consulted for vessel embolization; but the patient was referred to an advanced center because there was not enough equipment.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Discussion: Twenty-three cases with congenital cardiac anomalies associated with GM were reported in the literature. Today's survival rate with endovascular treatment is 70-80% and full recovery is around 50%. In the case of coexistence of GM and aortic coarctation, descending aorta blood flow is completely ductal dependent. At the same time, the ductus also decomprese the pulmonary vascular bed. For this reason, GM should be repaired firstly in patients and then intervened in aortic coarctation. Otherwise, inevitable and intractable congestive heart failure will occur.

P2699 - IMAGE COMPARISON OF CT AND ANGIOGRAPHY IN A 3 MONTHS OLD INFANT WITH ALCAPA AND HEART FAILURE

Chung-Chih Kao[1], Betau Hwang[2], Chun-Hsiang Ko[3], I-Hsin Lu[3], Shang-Yen Yang[4], Hua Guo[5]
Tungs' Taichung Metro Harbor Hospital, Department of Pediatric Cardiology, Taichung-Taiwan[1]; Tungs' Taichung Metro Harbor Hospital, Cardiovascular Center, Taichung-Taiwan[2]; Tungs' Taichung Metro Harbor Hospital, Department of Radiology, Taichung-Taiwan[3]; Tungs' Taichung Metro Harbor Hospital, Department of Pediatrics, Taichung-Taiwan[4]; Meiho University, Department of Nursing, Pintung-Taiwan[5]

Background: ALCAPA(Anomalous Left Coronary Artery from the Pulmonary Artery) is a rare congenital coronary artery disease with high mortality rate,especially when congestive heart failure occurs in young infancy and should be differentiated from dilated cardiomyopathy.Better left coronary artery image would be helpful for differential diagnosis and treatment.
Materials and Methods: A 3 months old female presented with chief complaint of dyspnea for more than 3 weeks.Her chest X-ray showed cardiomegaly and EKG showed left ventricular hypertrophy and ischemic change with T-wave inversion in V4, V5 and V6.Echocardiogram revealed heart failure and a dilated right coronary artery but the left coronary artery was obscure.The patient underwent CT(computed tomography) scan under the impression of ALCAPA.Due to heart failure associated with sinus tachycardia,the volume of contrast became an issue.Diagnostic angiography was performed after CT scan of which images were inconclusive.
Results: CT scan showed fair right coronary artery images,but the origin of the left coronary artery is obscure and equivocal for anatomically the pulmonary trunk is very much close to the ascending aorta in young infancy.The ascending aorta angiogram showed a single coronary artery from the right coronary cusp. Selective right coronary artery angiogram showed collaterals to the left coronary artery and outflow to the pulmonary artery confirming the diagnosis of ALCAPA.
Conclusions: CT scan is fast for acquiring left coronary artery images but they varies with different modalities and protocols especially when the volume of contrast matters in young infancy with heart failure.Diagnostic coronary angiography will provide more accurate,dynamic images and hemodynamic information in young infancy with ALCAPA and heart failure.

P2708 - EBSTEIN'S ANOMALY OF THE MITRAL VALVE REPORT OF A RARE CASE

Solange Gimenez[1], Camila Silva[1], Daniel Mascarenhas[1], Zilma Verçosa[2], Carlos Ferreiro[1], Adriano Carneiro[3], Valeria Moreira[3], Simone Pedra[4], Carlos Pedra[5], Marcelo Jatene[6]

Case Report: S. A. B. A., 2 years old, with Interrupted Aortic Arch (IAA), Ventricular Septal Defect (VSD) and Mitral Valve Malformation, was submitted to pulmonary artery banding and stent placement in the arteriosus ductus in the neonatal period. One year later, she underwent a new procedure that included correction of the aortic arch and removal of both the pulmonary artery bandages. The correction of the mitral valve was not possible at the occasion. The best option was therefore to perform atriosseptectomy and pulmonary trunk banding. One year later, she evolved with significant ventricular dysfunction and then underwent nuclear magnetic resonance, which showed severe aortic valve stenosis and single papillary muscle in the inferior part of the mitral valve, with chordae tendineae for both valve leaflets, discrete insufficiency, and left ventricle dysfunction. In the echocardiogram, the valve showed two papillary muscles, with apical displacement of their leaflets and shortened chords, central coaptation in the apical region (Ebstein of the mitral valve), with discrete insufficiency and important stenosis. She was submitted to percutaneous aortic valve balloon valvuloplasty, which resulted in left ventricular function recovery. Five months later, she underwent mitral valve replacement with a mechanical prosthesis. The surgical description corroborates the reports of the imaging tests on the low implantation of the mitral valve and the subsequent atrialization of the LV.

P2732 - DOES PRENATAL DETECTION SCREENING INFLUENCE THE INCIDENCE OF CONGENITAL HEART DISEASE (CHD)

Luzia Rovina[1], Melina Nauwerk[2], Luigi Rajo[3], Jean-pierre Pfammatter[4], Alexander Kadner[5], Damian Hutter [6]

Fello Pediatric Fellow Pediatric Cardiology, Cardiology, Bern-Switzerland[1]; Fellow Gynecology, Gynecology, Bern-Switzerland[2]; Staff Gynecology, Gynecology, Bern-Switzerland[3]; Head Pediatric Cardiology, Cardiology, Bern-Switzerland[4]; Head Pediatric Cardiac Surgery, Cardiology, Bern-Switzerland[5]; Staff Pediatric Cardiology, Cardiology, Bern-Switzerland[6]

Background: Detection rate for CHD in utero remains despite all efforts outside the perimeter of tertiary centers around 20-30% (FETCH data Switzerland 2005). To evaluate the screening success in the catchment area of the University Hospital in Bern we reviewed all in utero screenings from July 2009 to December 2014. In addition we looked at the incidence of CHD which should be around 0.8%. In Switzerland the current incidence of CHD is 0.5%.

Methods: Retrospective data analysis from July 2009 to December 2014 including all in utero and postnatal diagnosed new CHD at the Center of Perinatal Medicine at the University Hospital in Bern.

Results: 1522 in utero screenings have been performed. Of n = 339 patients with new CHD, n = 130 were born with an in utero diagnosis of CHD. n = 43 died in utero (detection rate of 51.03%). Median RACHS for prenatal diagnosed children was higher than in the postnatal detected CHD patients (2.4 vs. 3.1). The current incidence of CHD in the catchment area of Bern lays with 0.25% signficantly below the expected incidence of 0.6% in Switzerland.

Conclusion: This data clearly show that prenatal screening in the last years significantly improved from around 25% to currently 51% detection rate. In utero detected CHD has an overall higher RACHS in comparison with prenatally missed CHD, indicating that complex CHD is as of today better diagnosed in utero. Interestingly with a higher in utero detection rate we observe a decrease in the incidence of CHD postnatally.

P2752 - ANOMALOUS AORTIC ORIGIN OF CORONARY ARTERY. ¿AS FEARSOME AS WE THINK

Estibaliz Valdeolmillos[1], Rebeca Sánchez[1], Belén Toral[1], Alberto Mendoza[1], M. Dolores Herrera[1], Paula De Vera[1], Isabel Barranco[1], Miguel Rasero[2], Carmen Gallego[2], Constanza Liébana[2]

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Hospital 12 Octubre, Deparment of Pediatric Cardiology (IPC), Madrid-Spain[1]; Hospital 12 Octubre, Department of Pediatric Radiology, Madrid-Spain[2]

Background: Anomalous aortic origin of a coronary artery (AAOCA) is a congenital anomaly in which a major coronary artery arises from the wrong sinus of Valsalva and has an abnormal course. AAOCA is a cause of concern because its association with sudden cardiac death (SCD) during exercise. AAOCA with interarterial and intramural course are those with higher risk of SCD. Currently, there are no treatment guidelines for its management.
Methods: Review of patients with diagnosis of AAOCA, as an isolated malformation, in a Tertiary Hospital in the last 7 years.
Results: From 2009 to 2016, 5 AACAOS's cases were detected. The average age at diagnosis was 6.5 years (range 2-13 years). Most cases were detected in the study of a heart murmur. Only two patients presented symptoms (dyspnoea, chest pain and palpitations). In our study AAOLCA was more frequent than AAORCA (Table 1). None had interarterial nor intramural course. After the diagnostic suspicion by transthoracic echocardiography, the study was completed with ECG, Holter, Ergometry, Multi-cut CT scan (MDCT) and/or cardiac MRI. Suggestive alterations of ischemia were not detected. SPECT was performed in three patients and none showed defects of myocardial perfusion. Regarding treatment, all patients were advised to avoid exhausting excersice. Only two, who had symptoms at diagnosis, initiated beta-blocker treatment. Surgical treatment was not indicated in any patient. After a median of 2 years of follow-up, no patient presented a lethal event.
Conclusions: Patients with ACAOS who do not present interarterial or intramural courses should be considered of low risk and managed conservatively. After initial suspicion, performing a MDCT or MRI will allow to accurately delineate the coronary course and rule out the presence of high-risk anomalies. The presence of a normal effort test, especially associated with normal SPECT, will reaffirm us in the benign nature of this disease.

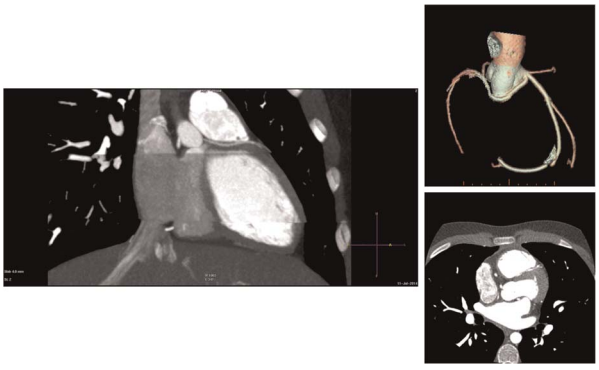

Figure 1.

P2754 - THE EVALUATION OF SYSTEMIC VENTRICULAR FUNCTION AFTER FONTAN OPERATION VIA CARDIOPULMONARY EXERCISE TEST AND TISSUE DOPPLER STUDY

Nimet Cindik[1], Birgul Varan[1], Kursat Tokel[1], Ilkay Erdogan[1], Mahmut Ozdemir[1], Murat Ozkan[2], Sait Aslamaci[2]
Baskent University, Pediatric Cardiology, Konya-Turkey[1]; Baskent University, Cardiovascular Surgery, Ankara-Turkey[2]

Background: Survival rates and quality of life of patients with single ventricle physiology were improved by Fontan operation. In our study, functional status and systemic ventricle function of patients with Fontan operation were evaluated.
Methods: 28 patients who underwent Fontan operation between January 1991 and December 2008 and who are capable of exercising were included. Cardiopulmonary exercise test, conventional echocardiography (ECHO), tissue Doppler Imaging (DTI), and PW Doppler ECHO were made and the relation between echocardiographic data, exercise capacity, and NT-proBNP levels were studied. 27 healthy children were the control group.
Results: The average age of operation was 5.6 ± 3.06 years, duration of follow up 6.85 ± 3.67, mean age 12.8 ± 4.36, mean age of control group 12.5 ± 3.76 years. There was a significant difference between patients and controls in terms of weight, height and BMI Z scores ($p < 0.05$). Cardiac output (CO), stroke volume (SV), systemic valve E velocity measured with PW, E/A ratio, systolic myocardial velocity (Sm), early diastolic myocardial velocity (Em), functional vital capacity (FVC), forced expiratory volume in 1 sec (FEV1), maximum voluntary ventilation (MVV), peak work, work at anaerobic threshold, peak heart rate, chronotropic index, peak oxygen consumption, peak carbondioxide production were all decreased in patients compared with control group ($p < 0.05$). Systemic ventricle myocardial performance index (MPI) calculated with DTI , septum MPI, MPI calculated with PW Doppler, dyssynchrony measurements, NT-proBNP levels were significantly higher in patients ($p < 0.05$).
Conclusion: Exercise test, NT-proBNP, dyssynchrony, and DTI measurements were found to be more sensitive than standard echocardiographic methods for the evaluation of clinical and functional status of the patients. Thus, serial measurements of NT-proBNP, dyssynchrony and DTI measurements of patients before operation and during follow up should be performed, cut-off values be determined and the relationship of the clinical and functional status with these parameters should be searched.

P2757 - FEASIBILITY AND REPRODUCIBILITY OF 3 DIMENSIONAL LEFT ATRIO VENTRICULAR VALVE SEGEMENTATION FROM TRANS THORACIC ECHOCARDIOGRAMS IN CHILDREN WITH CONGENITAL HEART DISEASE

Meena Nathan[1], David Harrild[2], Peter Hammer[1], Peter Higgins[3], Pedro Del Nido[4], John Mayer[4], Gerald Marx[3]
Boston Children's Hospital, Cardiac Surgery, Boston-United States[1]; Boston Children's Hospital, Cardiology, Boston-United States[2]; Children's Hospital, Cardiology, Boston-United States[3]; Children's Hospital, Cardiac Surgery, Boston-United States[4]

Background: Well developed algorithms/software exist for 3D segmentation of left atrioventricular valve (LAVV) using transesophageal echocardiography (TEE) in adults. However reproducibility of measurements is unknown in the pediatric population using transthoracic echocardiograms (TTE) particularly for precise annular diameter/annular angle measurements of the LAVV, that cannot be accurately determined from 2D images.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Hypothesis: It is feasible, utilizing existing software, to semi-automatically segment annulus and leaflet of LAVV in pediatric population using 3D TTE with good reproducibility.
Materials and Methods: Full volume 3D acquisitions in the apical 4 chamber view obtained during routine clinical TTE imaging in 14 studies from 10 children, acquired using Philips IE33 with X3/5/7 probes, were segmented 3 times each by 2 independent reviewers using the 4D mitral valve assessment package (TomTec 3.1). Maximum differences in the measurements between and within observers was determined. Error rates were calculated as follows: (maximum difference/mean)×100.
Results: Pathologic and normal mitral valves, in children aged 0.2 to 5.3 years, weight 4.4 to 29.3 kg were segmented. AP diameter, AL-PM diameter, sphericity index and nonplanar angles were derived. Error rates between and within observers are depicted in the figure and varied by quality of image, with smaller variation in higher quality imaging. The average error rates ranged between 10-18% for measurements of interest between observers with lower error rates within observers.
Conclusions: High quality transthoracic images of the LAVV can be reproducibly segmented using current commercial software, enabling better analysis of diseased LAVV in small children in whom 3D TEE is not applicable.

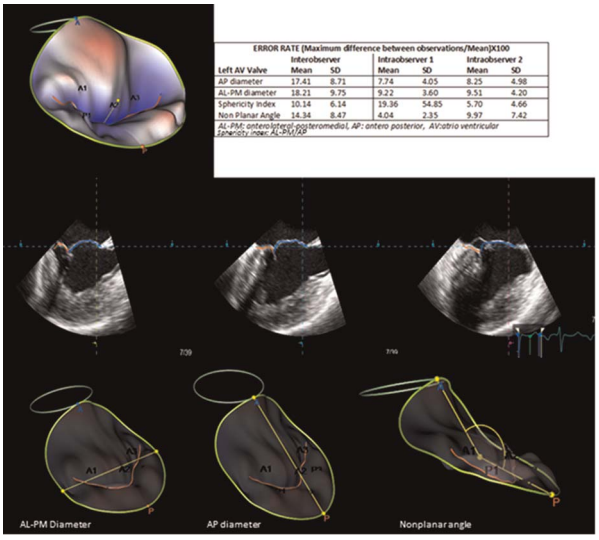

Figure.

P2761 - EXERCISE PERFORMANCE ASSESSED BY CPET IN FONTAN CHILDREN AND YOUNG ADULTS

Angeles Fuertes Moure[1], Luisa García-Cuenllas Álvarez[2], Miriam Centeno Jiménez[3], Reyes Álvarez García-Rovés[4], Enrique Maroto Álvaro[4], Constancio Medrano López[4], Juan Ignacio Castillo Martín[5]
Hospital Materno-Infantil Teresa Herrera, Pediatric Cardiology, A Coruña-Spain[1]; Hospital Universitario De Salamanca, Pediatric Cardiology, Salamanca-Spain[2]; Hospital Universitario Gregorio Marañon, Pediatric Cardiology, Madrid-Spain[3]; Hospital Universitario Gregorio Marañón, Pediatric Cardiology, Madrid-Spain[4]; Hospital 12 De Octubre, Pediatric Cardiology, Madrid-Spain[5]

Background: Exercise capacity(ExC) after the Fontan procedure (FP) is reduced. The following mechanisms explain why patients with Fontan physiology have a restricted ExC (reduced peak oxygen consumption, VO2): failure to increase stroke volumen, reduced preload(lack of subpulmonary pump), cronic hipoxemia, chronotropic impairment, musculoskeletal deconditioning(functional deficiency of the peripheric muscle pump).
Objectives: To define exercise performance quantitatively through cardio pulmonary exercise test (CPET) in children and young adults after FP.
Methods: Retrospective observational study of 72 children and young adults (56% male, average weight 41.9 ± 17 kg, average height 146.5 ± 17.5 cm) aged between 6-19 years (11.8 ± 3.4) who have undergone a FP. Ramp treadmill (Bruce protocol) was performed. Data were analyzed for population that achieved a maximal aerobic capacity. Inclusion criteria admited patients with either right or left systemic ventricles. 9 subjects with pacemakers, sinus node dysfunction or junctional rhythm were excluded.
Results: Submaximal exercise tests limited by symptoms were performed, clinically and electrically negative in all cases, with no significant arrhythmias. Effort time 10.22 ± 2.4 min (8.8 ± 2.4METs). Rest HR 95 ± 17bpm, maximal HR 164 ± 26bpm (HRR 69 ± 27bpm). 24 patients reached 85% predicted HR (mean 77 ± 13.5%). SBP/DBP at rest was 102 ± 14/59 ± 9 mmHg, maximum of 127 ± 19/69.5 ± 9 mmHg. DP was 20950 ± 5572.2. 39 patients had normal spirometric pattern,18 restrictive. Exercise function of these patients varied greatly. In some, exercise capacity was well preserved, with normal and even above-average peak VO2 whilst in other cases peak exercise capacity was significantly depressed. CPET showed decreased maxi VO2 (76 ± 19.8% predicted), with normal O2 pulse (102.16 ± 33% predicted, curves with early rise and maintained plateau). 39 patients did not reach MPHR, wich may suggest chronotropic impairment. The rise in Vslope and CO2Eq at VAT (38 ± 6.8 and 39.3 ± 7.5 respectively) translated ventilatory inefficiency(V/Q imbalance, according to Fontan physiology), with an appropriate respiratory reserve.
Conclusions: They remain limited in their physical abilities with maximum VO2 around 76% of predicted value compared to their peers in our sample. Decreased ventilatory efficiency its characteristical. CPET is an useful tool to assess ExC after the FP, providing relevant data: although cardiac otuput depends greatly on preload for these patients, in a sample without intrinsic limitations of the systemic ventricle chronotropic response is imperative to obtain a suitable VO2.

P2765 - REALIZING AUTOMATED ECHOCARDIOGRAPHY FOR NEWBORNS AND INFANTS

Annamarie Saarinen[1], Jamie Lohr[2], Paul Saarinen[3]
Newborn Foundation, University of Minnesota Children's, Research Division, Minneapolis, St. Paul-United States[1]; University of Minnesota, UMMCH, Pediatric Cardiology, Minneapolis-United States[2]; Newborn Foundation, University of Minnesota, Research Division, Minneapolis, St. Paul-United States[3]

Despite progress in reducing the size and cost of pediatric echocardiography, significant gaps remain in the ability to obtain quality pediatric heart and lung imaging for the youngest patients. Following a modest research grant from the from the Pediatric Device Innovation Consortium via the University of Minnesota's Office of Discovery and Translation, the Newborn Foundation and its program investigators have worked to develop a proof of concept for an automated array of transducers to provide simplified, quick and standardized acquisition of diagnostic-quality echo images to be obtained by individuals with little or no technical training or expertise. The aim is to facilitate highly automated image acquisition to improve access and outcomes with faster,

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

remote interpretation. The presentation will address the current stage of proof of concept software and hardware, along with the landscape of CHD and RHD requiring echo imaging for the youngest patients – and how such technology could improve care and outcomes for these patients. Images obtained can be shared with specialists or potentially evaluated with on-board machine learning technologies. Such a device has applications in the developed and developing world. Access to confirmatory pediatric echo for babies failing newborn CCHD screening is still difficult to obtain in many parts of the United States, while also providing a mechanism to better guide remote care and referrals for young children with suspected or confirmed heart disease that have no local access to pediatric cardiology specialists. In the developing world, the signs and symptoms of both newborn infections and pediatric cardiac abnormalities can be difficult for health workers to detect. This device would support an increased body of literature on the value of ultrasound in diagnosing both CHD and childhood pneumonia with greater sensitivity and specificity than existing methods, including x-ray/radiation.

P2767 - CONGENITALLY CORRECTED TRANSPOSITION OF THE GREAT ARTERIES IN THE FETUS. A RETROSPECTIVE ANALYSIS OF ECHOCARDIOGRAPHIC FEATURES AND OUTCOME IN A TWO CENTER SERIES OF 30 CASES

Giulia Tuo[1], Carmela Morelli[2], Dario Paladini[1], Gabriele Detonetti[3], Santoro Francesco[1], Russo Mariagiovanna[2], Marasini Maurizio[1]
Gaslini, Cardiology, Genoa-Italy[1]; Monaldi, Cardiology, Naple-Italy[2]; Gaslini, Intensive Care Unit, Genoa-Italy[3]

Objectives: to describe the echocardiographic features and outcome of fetuses with congenitally corrected transposition of the great arteries (ccTGA).
Methods: 30 consecutive fetuses were diagnosed with ccTGA at one of two referral centers between 2005 and 2015.
Results: median gestational age at diagnosis and at last fetal echocardiogram were respectively 23 and 35 weeks. Most fetuses were referred for suspicion of cardiac malformation. Only 2/30 (7%) fetuses presented an isolated form of ccTGA. Associated cardiac defects included: abnormal cardiac position in 11/30, ventricular septal defect (VSD) in 25/30, pulmonary atresia in 8/30 and pulmonary stenosis in 6/30, abnormal tricuspid valve in 7/30, right aortic arch in 2/30, suspicion of aortic coarctation in 4/30. Two fetuses developed a complete atrioventricular (AV) heart block in the third trimester and required a permanent pacemaker implantation at birth. Only one fetus presented an extracardiac anomaly. Karyotype was tested prenatally in 11/30 fetuses and resulted normal. Six pregnancies were interrupted and 2 fetuses were lost at follow up. Mean gestational age at birth was 39 weeks, mean birth-weight 3200 g and mean oxygen saturation 95%. 17/22 patients required one or more surgical procedures. Among them, 2 completed the Fontan circulation, 2 received a bidirectional cavopulmonary connection, 5 the anatomic repair and 2 the physiologic repair. At a mean follow up of 5,2 years (±3,5) 4/22 patients were lost at follow up whereas the others are alive and clinically well.
Conclusions: isolated cases of ccTGA and associated extracardiac or chromosomal anomalies were rare prenatally. The mid term outcome was reasonably good for all liveborn infants even if most of them needed one or more cardiac treatment. Prenatal counselling remains challenging because also fetuses with an apparently favorable condition may develop major changes particularly regarding to tricuspid valve and cardiac rhythm with significant changes in prognosis.

P2771 - PULMONARY PERFUSION IN PATIENTS WITH HYPOPLASTIC LEFT HEART SYNDROME AFTER FONTAN OPERATION

Anna Mazurek-Kula[1], Katarzyna Kovacevic-Kusmierek[2], Piotr Kula[3], Jacek Kusmierek[4], Jadwiga Moll[1], Jacek Moll[5], Tomasz Moszura[1]
Polish Mother's Memorial Hospital, Department of Cardiology, Lodz-Poland[1]; Medical University of Lodz, Department of Quality Control And Radiological Protection, Lodz-Poland[2]; Medical University of Lodz, Department of Cardiac Surgery, Lodz-Poland[3]; Medical University of Lodz, Department of Nuclear Medicine, Lodz-Poland[4]; Polish Mother's Memorial Hospital, Cardiosurgery Department, Lodz-Poland[5]

Introduction: Fontan operation results in diminished pulmonary blood flow pulsatility, affecting pulmonary blood distribution. Left pulmonary artery (LPA) stenosis is a common complication of multistage HLHS palliation. Aim: Assessment of lung perfusion in HLHS patients after Fontan completion using planar lung perfusion scintigraphy.
Material and Methods: 77 patients (55 boys – 71%), mean age 9.3 years ± 3.2 underwent planar lung perfusion scintigraphy: two injections of 99mTc – MAA into the right upper, then into the right lower extremity. Webster's formula was used to calculate the activity and Hawkeye hybrid gamma camera to perform lung perfusion studies. Percentage share of every lobe and lung in a global lung perfusion was calculated after averaging of counts in anterior and posterior projection (geometric mean) for inflow from superior and inferior cavopulmonary anastomosis. 58 patients (75%) had LPA stenting.
Results: Hypoperfusion (lung contribution to global lung perfusion $\leq 35\%$) of the left lung in 40,3% (31/77). Perfusion of the lungs and lobes wasn t significantly higher in patients with stent ($n = 58$). Lowest perfusion - upper lobe of the right lung. It was significantly lower than in the middle and lower lobes of the same lung and the upper and lower lobes of the left lung. ($p < 0.0001$). Perfusion of the left lung and respective lobes wasn't significantly higher in patients with stent ($n = 58$). Frequency of hypoperfusion of the left lung wasn't significantly lower in patients with stents than without: 37.9% (22/58) vs. 47.4% (9/19). ($p = 0.47$). Postoperative diaphragmatic paralysis was noted in 5 patients (6,5%).
Conclusions: 1. Non-physiological pulmonary blood flow, pulmonary artery obstruction and postoperative diaphragmatic paralysis contribute to abnormal pulmonary perfusion in patients with HLHS. 2. Hypoperfusion of the left lung is the most common finding despite successful LPA stenting. 3. Planar lung perfusion scintigraphy is a reliable tool in evaluation of patients after Fontan completion.

P2773 - EVALUATION OF THE VENTRICULAR FUNCTIONS ASCENDING AORTA AND AORTIC ROOT WIDTHS IN THE ASYMPTOMATIC PATIENTS WITH ISOLATED BICUSPID AORTIC VALVE

Sinem Altunyuva Usta[1], Ayse Yildirim[1], Aysu Turkmen Karaagac[2], Murat Sahin[1], Omer Ciftci[1], Metin Sungur[1]
Kartal Koşuyolu Heart Training and Research Hospital, Pediatric Cardiology, Istanbul-Turkey[1]; Kartal Koşuyolu Heart Training and Research Hospital, Pediatry, Istanbul-Turkey[2]

Objective: Aortic root and/or ascending aorta dilatation is frequently encountered in patients with bicuspid aortic valve(BAV). The aim of this study is to evaluate the ventricular functions, ascending aorta and aortic root widths in asymptomatic patients with isolated BAV to define their prognosis.
Method: 3 to17 years old (mean 9,5 ± 3,9) 49 patients (41 males, 8 females) with BAV with/out stenosis or insufficiency and 3 to

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

15 years old (mean 8,8 ± 2,9) 20 healthy controls (15 males,5 females) were enrolled in this study. Their aortic root, ascending and descending aorta widths, aorta and sinus valsalva elasticities were measured. Aortic valve morphology, valve regurgitation(AR) jet length and directions were recorded. Tissue Doppler Imaging(TDI) was performed to obtain views from interventricular septum(IVS), mitral and tricuspid free wall in apical four chamber position. Blood natriuretic peptide(BNP) levels were measured.
Results: No difference was found between the age, height, weight, systolic and diastolic blood pressures of two groups. The most common valve morphologies in these patients were: right to left cusp fusion (40.8%), right non-cusp fusion (36.7%), bicuspid (18.3%) and left non-coronary cusp fusion (4.08%). The most common two directions of AR jets were central (27%) and left eccentric (26%). Neither stenosis nor insufficiency was observed in 11(22.44%) patients. Ascending aorta systolic (2.29 ± 0.36 and 2.06 ± 0.29 cm, $p < 0.05$) and diastolic (2.08 ± 0.36 and 1.90 ± 0.27 cm, $p < 0.05$) measurements of the patient group were found significantly higher than the control group. Mitral valve early and late diastolic (MA) flow velocities of the patient group were significantly lower than the controls (E:0.97 ± 0.13 A = 0.59 ± 0.13, E:0.89 ± 0.13 A: 0.50 ± 0.07 m/sn). IVS early diastolic flow velocity of the patient group was significanly lower than the controls in TDI (11.28 ±1.82 and 12.9 ± 1.73, $p < 0.05$). A positive correlation was found between BNP and ascending aorta stiffness, ascending aorta systolic, descending aorta systolic and diastolic diameters, also betweenAR length.

P2775 - RADIATION DOSE IN THE HYBRID OPERATING ROOM USED FOR PEDIATRIC CARDIAC SURGERY

Magdalena Czerżyńska, Tomasz Mroczek, Julita Sacharczuk, Elżbieta Wójcik, Janusz Skalski
Jagiellonian University Collegium Medicum, Pediatric Cardiac Surgery, Kraków-Poland

Nowadays we can observe an increasing number of hybrid procedures in treatment of complex congenital heart defects (CHD). The radiation dose of hybrid procedures is still underrated. There are no guidelines determining radiation dose levels for pediatrics hybrid procedures. The main purpose of this study was to assess the radiation dose during hybrid procedures in CHD correction. We retrospectively analyzed 81 patients who had had hybrid CHD surgery in a hybrid operating room (Siemens Axiom Luminous). Fifty-seven (70.37%) had been subjected to CHD correction without stent implantation, 10 patients (12.34%) had undergone pulmonary arterioplasty; six (7.4%) - stent implantation; three (3.7%) heart valvuloplasty, and five (6.17%) - ECMO implantation. Boys predominated (65.43%). Forty-four patients (54.32%) were treated during the first year of life, the median weight was 7.4 kg. 7778% of the patients had combined CHD, at least 70% of them had Hypoplastic Left Heart Syndrome (HLHS).The median fluoroscopy time for all the procedures was 3.8 min. The median Skin Entrance Dose (SED) for all the procedures was 38 mGy; Air Kerma (K)-74.3 mGy and Dose Area Product (DAP) 516.34 μGym2. The median exposure time for HLHS treatment was 1.9 min. for the Norwood (SED = 31; DAP = 270.06; K = 63.5) procedure; 2.8 min. for hemi-Fontan (SED = 74; DAP 447.65; K = 71.7) and 3.8 min. for Fontan (SED = 211; DAP 1178.3; K = 456). Hybrid procedures for CHD treatment appear to be a radiation-safe method. The mean radiation doses are much lower than doses used in computed tomography scans and comparable to doses received during several chest X-ray procedures. Radiation monitoring is an important component of pediatric cardiac surgery. Further studies are needed to evaluate the radiation levels in hybrid pediatric cardiac surgery.

P2780 - EPIDEMIOLOGY CORONARY ARTERY LESIONS AND TREATMENT OF KAWASAKI DISEASE IN CHILDREN FROM ARGENTINA PERIOD JUNE 2014 TO DECEMBER 2016

Carlos Sáenz Herrera", Servicio De Infectología Pediátrica, San José-Costa Rica[7]

Background: Although Kawasaki disease (KD) is the leading cause of pediatric acquired heart disease in many countries, there are few indexed published studies from Latin America (LA). We describe the epidemiology, coronary findings and treatment of children with KD at two centers as part of the prospective REKAMLATINA-1 Network surveillance study of KD in LA.
Methods: Prospective descriptive study of patients (pts) with a hospital discharge diagnosis of KD according to AHA criteria, who were admitted at 2 hospitals in Argentina. Study period: June-1-2014 to Dec-31-2016
Results: 19 pts were analyzed, 11 (57.9%) were male. All were hospitalized; mean length of hospitalization was 5.5 (3-12) days. Median age was 45 (7-98) months. Distribution by age groups was: <6 months, 0 (0%) pts; 7-24 m, 3 (15.8%) pts; 25-60 m, 12 (63.2%), and >60 m, 4 (21.0%) pts. Mean duration of fever at admission was 5.5 (1-12) days. Prior to KD final diagnosis, 9 pts (47.4%) received antibiotics for other presumed diagnoses. Baseline echocardiogram (ECHO) was performed in all pts, of which 6 (31.6%) pts had >1 abnormality documented, including coronary artery lesions (CALs) in 4 (21.1%) pts: dilation (3 pts) and giant coronary aneurysms (1 pt). A second follow-up ECHO was performed in all 19 pts, of which CALs were documented in 1 (5.3%) pt. All 19 pts received IVIG: 1 dose, 18 (94.7%), and 2 doses, 1 (5.3%), respectively. Among those pts treated with IVIG at admission, 1 (5.3%) had >10 days of fever. Aspirin was given in 100% and none received steroids. No deaths occurred.
Conclusions: The percentage of CALs in this analyzed group is higher than similar patients from other LA centers who were adequately treated with IVIG and aspirin.

P2784 - MANAGEMENT AND OUTCOMES IN BORDERLINE LEFT VENTRICLE A SINGLE CENTER 6 YEAR EXPERIENCE

Gemma Giralt[1], Paola Dolader[1], Irene Isern[1], Mariona Ferrer[1], Queralt Ferrer[1], Ferran Rosés[1], Ferran Gran[1], Anna Sabaté, Dimpna C. Albert[1], Joaquin Perez[2]

Background: Patients with borderline left ventricle represent, the most challenging group when determining a surgical management strategy since no scoring system reliably predict long-term outcomes. We assess echocardiographic characteristics, surgical management and outcomes of this patients.

https://doi.org/10.1017/S104795111700110X Published online by Cambridge University Press

Materials and Methods: Retrospective descriptive analysis of patients with borderline left heart presenting between January 2010-April 2016. Echocardiographic features were reviewed, Rhodes's, Collan's and UVR-SA scores were applied. The outcome regarding the surgical election, recruitment procedures and the need for reintervention at follow-up were evaluated.
Results: A total of 26 patients were included, 65% of them were male. One patient died before surgery because of comorbidities (Edward's syndrome and prematurity)and was excluded. Biventricular repair surgery was performed in 23 patients (92%). Of those, two patients died due to failed bi-ventricular repair and one died due to hemochromatosis. Recruitment procedures were performed in 92% of biventricular repair. The need for reintervention was 52% and all had a good functional class at 6 years of follow-up. Two (8%)patients had univentricular repair which initially hybrid procedure due to prematurity. Both patients died. Rodhes's score classified correctly 7 out of 25, Collan's 13 and UVR-SA 4.
Conclusions: From our serie,we conclude that echocardiographic scores don't predict long-term outcomes in patients with borderline left ventricle, probably because of the high percentage of recruitment procedures that allowed a successful biventricular surgery. In the 2 cases of failed biventricular repair, the three analysed scores would have predicted a greater survival with single ventricle palliation. Nowadays survival with univentricular surgery improved meaningfully, but long-term results are already poor. Our patients were a high risk group with a lot of comorbidities. We observed low mortality (4.5%) with biventricular surgery despite the high need for reintervention. We speculate that biventricular physiology should be preserved with accurate patient selection. We believe the echocardiographic score systems should be revised to include left ventricle recruitment strategies in order to accurately predict overall surgical management and long term outcomes of patients with borderline left ventricle.

İntraPHACE syndrome (posterior fossa anomalies, hemangioma, arterial lesions, cardiac abnormalities/coarctation of the aorta, eye anomalies) is characterized by large infantile hemangiomas (IH) of the face, neck, and/or scalp that are associated with developmental defects. The case of a 5-month-old male infant with PHACES syndrome is reported. On physical examination the infant had infantile hemangioma (6 × 7 cm) extending from the left temporal region of the scalp to his neck. Frontal bossing, plagiocephaly, micrognathia, sternal pit and tag were noted . Cardiac computed tomographic angiography (3D-CTA) and catheter angiography revealed left-sided cervical aortic arch, aortic arch dysplasia (kinking, looping, tortuosity, aneurysma , hypoplasia), coarctation of the aorta (at the level transverse arch) and aberrant left subclavian artery originates from a proximal descending aorta. Segmental absence of left internal carotid artery (ICA) and

moya-moya like collateral arteries, absence of right posterior communicating artery were detected on the 3D cranial CTA. Ophthalmological examination was normal. Cranial magnetic resonance imaging (MRI) showed no cerebral and posterior fossa anomaly. In conclusion, PHACE is associated with a high risk of congenital heart disease and cerebral arterial anomalies. Cardiac and aortic arch imaging with detailed assessment of arch patency and brachiocephalic origins is essential for any patient suspected of having PHACE.
