Globalization and religious resurgence: a comparative analysis

Brendan Szendrő

Abstract

Why does religion continue to emerge as a flashpoint in the age of secularization? Although models of religious resurgence suggest that religious cleavages are more prominent in the modern era, other models continue to show declining religious involvement. What is needed is a theory that can observe both resurgence and secularization at the same time. I argue that globalization—and the flow of people across borders, in particular—provokes a religious backlash at the societal level due to its secularizing effects. As the public is exposed to new and diverse religious traditions, religiosity declines; as a result, however, religious practitioners become more aggressive toward other religious groups. I test this theory using data on globalization, religious discrimination, and religious practice. I find that types of globalization dealing with the flow of people and information across borders have an outsize effect on societal religious discrimination, or SRD. This effect, however, is contingent on a decline in religious practice. This study suggests that religious resurgence can take place in secularizing environments, and that both resurgence and secularization share root causes.

Keywords: globalization; migration; religious discrimination; religious resurgence

Introduction

As states continue to secularize, why has religion emerged as one of the most prominent political flashpoints? Older theories of secularization suggest that religious practice should decline in relation to human development (Gaskins *et al*., 2013; Gill, 2021). Although long-standing trends in state religious policy (SRP) have drastically decreased the popularity of such theories, scholars continue to find support for a less-sweeping trend toward secularization in modernizing environments (Fox, 2016; Stolz, 2020; Dhima and Golder, 2021). But while religious practice has declined in certain contexts, religious minorities have faced increased discrimination by both government and societal actors (Fox, 2013, 2020; Fox *et al*., 2018). What is needed, then, is a theory that can observe both processes at the same time.

I argue that refocusing the question of secularization from modernization to globalization can provide key insights for the study of religious resurgence. Qualitative

and theoretical research suggests that the backlash against globalization may lead to a form of "counter-secularization" in which religious movements encourage hostility toward other belief systems (Barber, 1995; Fordahl and Ragnarsdóttír, 2021). Although previous quantitative research has linked the religious resurgence to globalization, it has done so only at the government level and has not tackled the question of counter-secularization in society (Bloom *et al.*, 2013). Where secularization and resurgence have been examined at the societal level, they have not been examined in relation to counter-secularization or socio-economic structures (Fox *et al.*, 2021). Furthermore, previous studies have treated this relationship as effectively uniform across diverse geographic regions and political environments.

Based on literature surrounding counter-secularization, I argue that globalization facilitates secularization not through modernization mechanisms such as economic growth, but through increased contact between religious groups. As members of the dominant religion are exposed to diverse religious traditions, primarily through immigration and international communication, the dominant religion becomes less influential in society. As a result, however, religious actors may encourage hostility or discrimination against other religions in order to protect their status. If that is the case, then the relationship between religious resurgence and globalization should occur as a bottom-up, rather than top-down process. Furthermore, this relationship should be stronger in geographic regions where the social aspects of globalization have contributed to the process of secularization. In effect, I argue that that globalization does not drive religious resurgence in spite of secularization, but because of it.

I test this theory using data from the Religion and State (RAS) project, World Values Survey (WVS), and KOF Globalisation [*sic*] Index. I find that globalization exacerbates societal religious discrimination, or SRD, over time, but this effect is not uniform across types of globalization or geographic regions. Globalization types dealing with standards of living such as economic trade or finance show lower and less consistent effects, while those dealing with social issues, such as immigration and international communication, show the largest and most consistent effects. This is particularly true in regions that have been named hotbeds of religious resurgence. In addition, I find that various measures of religious practice decline in relation to the same mechanisms. Finally, the effect of globalization on SRD appears to be dependent on secularization, suggesting that secularization is a link in a chain—not something that can be viewed in isolation.

This study proceeds as follows: first, I review literature surrounding secularization theory and the religious resurgence. Here, I outline key findings that continue to show *certain types* of secularization despite a scholarly consensus that religion is resurgent in modern politics. Second, I discuss the literature surrounding counter-secularization and globalization, highlighting prior theoretical and qualitative contributions while further demonstrating key gaps in quantitative literature. Next, I present a research design and discuss the results. The first set of results compares the effects of different types of globalization on SRD, across varying regions. The second set of results compares the effect of each type on aggregate levels of religious practice. The third set of results demonstrates that the effect of key globalization types on SRD is contingent upon declining religious practice. Additional findings in the Appendix

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

compare alternate hypotheses. Following a presentation of the results, I conclude with a summary of the findings and suggestions for further research.

Secularization and resurgence

A common narrative suggests that secularization theory—the theory that modernization reduces religious practice—held a hegemonic influence over the social sciences until the 21st century (cf. Swatos and Christiano, 1999; Gorski and Altinordu, 2008). Since then, however, a scholarly consensus has emerged regarding the unexpected resurgence of religiosity and the failure of secularization theory (e.g., Fox, 2016). In this telling, an increase not only in religious practice, but also in SRP, points to the continued importance of religious cleavages. If scholars conceive of secularization as an increasingly strong separation of religion and state, then states' increasing involvement religious institutions and practices points to renewed competition between religious and secular forces (cf. Fox, 2013, 2019a, 2019b, 2020).[1]

Such analyses discuss many aspects of SRP, including both the state's support for religious institutions as well as the regulation of religious institutions. The most common focus, however, is religious discrimination—policies directed toward a state's religious minorities but not its majority religion. Because it represents a tangible cleavage between religious groups, the rise in discrimination directly challenges secularization theory (Fox, 2013, 2020). Existing studies using data from the RAS project, have explored both government religious discrimination, or GRD, and SRD (cf. Fox *et al.*, 2018, 2021). While the former describes the prevalence of discriminatory policies in government, the latter describes the prevalence of discriminatory practices in society. These studies demonstrate that such discriminatory practices have increased in recent years, in some cases even in tandem with declining rates of religious practice.

Nevertheless, proponents of secularization such as Inglehart and Norris (2004) remain a focal point for scholarly debate. Gaskins *et al.* (2013) find that although modernization decreases religious practice, it also increases conservatism among those who continue to practice. Such findings indicate the possibility that religious actors and religious institutions may continue to exert influence even as the overall number of practitioners declines. Still, findings relating to modernization tend to produce mixed results depending on how secularization is defined (Stolz, 2020). Although increased standards of living at the country level do appear to reduce rates of religiosity, the same results do not hold for individuals (Höllinger and Muckenhuber, 2019). In other words, as with comparisons of secularization and resurgence, government, society, and individual all appear to react to these stimuli differently.

Crucially, additional findings by Dhima and Golder (2021) and Lüchau (2014) further demonstrate that religious self-identification has *not* declined in relation to modernization, although *institutional involvement* in religion has.[2] In short, the Gaskins, Golder, and Siegel model, or GGS, continues to find support for a particular *type* of secularization theory; despite this, it is often taken for granted that secularization theory has been discredited due to the upsurge of religious policy-making in the 21st century. The RAS model continuously finds support for an increase in religious policy-making even in secularizing environments.[3] I have illustrated these two models in Figure 1.

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

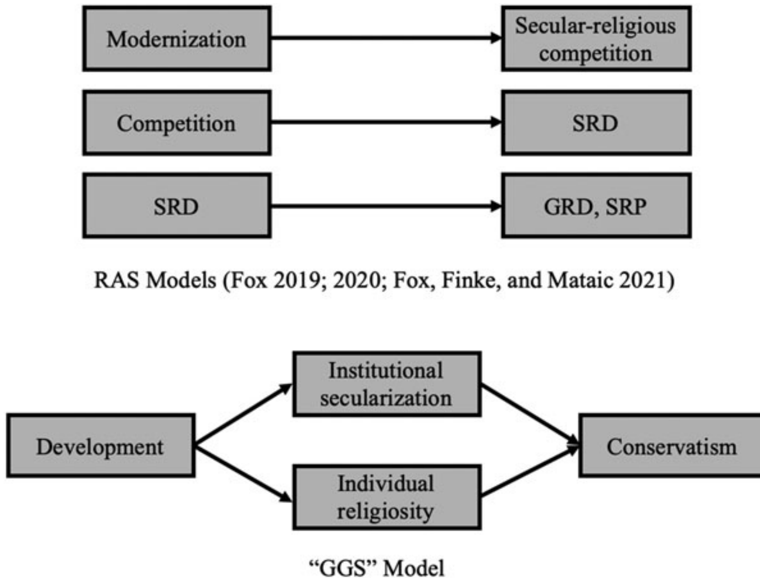

Figure 1. RAS and GGS models.

Despite the apparent contradiction between the two, the GGS and RAS models have not been explored in relation to each other. The GGS model is largely concerned with microfoundations—behaviors by individuals—while the RAS model deals with macro-level structures—institutions. What the two literatures, secularization and resurgence, have failed to do is to observe the two phenomena at the same time—not as polar opposites but as two sides of the same coin.

In this study, I seek to further explore another area of literature that can potentially bridge this gap. Rather than modernization producing secularism, I suggest refocusing the framework toward globalization. The shift from modernization to globalization as a causal mechanism enables an examination of both secularization and resurgence in relation to different aspects of social, economic, and political change. As I will discuss, this framework has gone under-explored in quantitative analysis, and the research that has been done has either concentrated on theoretical or qualitative analyses or has yet to receive significant extensions from its foundational literatures. In the following section, I review this body of literature, using the terminology "counter-secularization" to describe the broader framework.

Counter-secularization and globalization

Globalization brings disparate groups into contact with each other. When new interactions between groups emerge, they can take on both hostile or amicable characteristics depending on the context of these new interactions. The long-standing "contact hypothesis" suggests that if groups interact on a level playing field, they will become more accepting of each other. By the same token, the "group threat" hypothesis suggests that if members of one or both of the groups fear for their status, they will not be

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

able to find common ground.[4] The effect of globalization, then, largely depends upon the conditions of contact between groups (Kaya and Karakoc, 2012). In a religious context, however, there is reason to believe that it has had both effects. I argue that globalization facilitates secularization according to two principles: first, it allows religious practitioners to experience life outside of their own community; second—as a byproduct of the first principle—it exposes religious practitioners to different faiths.

The "contact hypothesis" has been discussed at length in relation to religion and religious freedom. Both Berger and Zijderveld (2009) and Grim and Finke (2010) argue that globalization naturally leads to religious diversity. These authors suggest that such diversity will reduce religious tensions. If societal actors fear for their status, however, this line of reasoning may not hold. In a study of non-state actors, Feinberg (2020) demonstrates that discrimination against religious minorities is more likely when there is opportunity, distinguishability, stimuli, and organization.

Globalization can provide each of these, especially opportunity and stimuli. If newfound religious diversity is also associated with a decline in the status of the dominant religious group, the dominant religious group may seek to re-assert itself. According to Gill (2008), religious diversity lends itself to greater religious freedom, which undermines the dominant religious group's influence. Both Gill and Grim and Finke further argue that the lasting influence of dominant religious groups under threat may cause a "tyranny of the majority" effect in which the dominant religious group pressures government into adopting restrictive policies against their competitors. Such grievances are borne out when examining the dynamics of religious communities and religious actors' critiques of globalization, secularism, and religious diversity.

Religious communities revolve around kinship ties and dense social networks, hence the term "parochial" (cf. Fukuyama, 2001). Globalization, by contrast, encourages a vast network of cosmopolitan social organizations that transcends local identities—and often treats them as irrelevant (cf. Dryzek, 2012). The freedom of movement and the free flow of ideas across borders allow individuals to remove themselves from their traditional communities, which—at least in theory—revolve more heavily around religion (Hochschild, 2003, 2006). Critics contend that removing individuals from a communal context homogenizes cultures (Deneen, 2018). This further extends to critiques that globalization pressures non-Western cultures to integrate into Western systems (Mazrui, 1998).

Among religious ideologues, critiques of globalization and secularism alike outweigh critiques against modernization. Evangelical preacher Robertson (1991), for example, decried globalized institutions as a means of separating individuals from their parochial communities and exposing them to alternative lifestyles. Similar complaints have been made by the Ayatollah Khomeini (1970), Jewish extremist Kahane (1987), Bin Laden (2016), and Myanmar's infamous extremist monk Ashin Wirtahu (cf. Foxeus, 2019). Although these thinkers possess a wide range of ideological and religious identities, they each share common critiques of globalization—as well as invocations against religious minorities.

In each of these examples, ideologues accused religious minorities of using globalized institutions to water down the majority population's religious identity while preserving their own unique identities. Because religious identities traditionally

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

have exclusive characteristics, exposure to other faiths can open a dominant religion to new lines of questioning.[5] Robertson, for example, argued that "globalists" sought to "erase the minds of the students, to tell them that everything is relative," adding that "the million gods of the Hindus, and the Allah of the Muslims is not the God of Jacob" (217–231). Khomeini complained that the secular "agents of imperialism… are not converting [Muslims] into Jews and Christians; they are corrupting them, making them irreligious and indifferent" (79). As religious ideologues draw parallels between religious minorities, secularism, and globalization, they also broadly conflate religious out-groups. Rather than targeting specific religious minorities, these actors tend to view all forms of religious diversity as a threat to the status of the dominant religion.

These theoretical foundations lay the groundwork for two simultaneous phenomena. Secularization may follow from the contact hypothesis; that the influence of religious choice and the removal of barriers between religious communities allows much of the public to "opt-out" of religion. However, religious actors and practitioners who see their communities shrinking may instead focus their ire on the influx of other religions due to the perception of threat. The two processes—secularization and resurgence—can occur simultaneously because religious discrimination can occur within the context of a secularizing environment, as part of a backlash against secularization itself.

Globalization matters for both secularization and resurgence because it is the driving force behind the two impulses of "contact" and "group-threat." It is functionally distinct from "modernization" as a causal mechanism because the two concepts measure different phenomena. In its broad strokes, globalization refers to the institutional links across national borders (Potrafke, 2014). Although these can include economic indicators related to standards of living, they focus on a country's openness to the flow of goods, services, people, and information. Because these phenomena are regulated by a country's laws, this method of examining social, economic, and political change speaks to institutional environments more than indicators of modernization. They therefore consider broad mechanisms of change in terms of standards of living *and* the relationship between individuals, society, and government.

Although a substantial body of literature discusses the role of globalization in facilitating religious cleavages, these discussions have historically focused on theoretical foundations or "big-picture" clashes in the international arena. According to this camp, evidence suggests that the religious sects that are growing are the ones that reject progressivism (Berger, 1999). Sects or practices that reject progressivism act as forces of a "counter-secularization" process that often targets religious minorities as an out-group (Karpov, 2010).[6] Barber (1995) argues that these ideologies arise as a reaction to globalized institutions, in an effort to protect decentralized communities.

Other scholars famously see modern religious tensions as a product of civilizational fault lines (Huntington, 1996). These scholars view the "clash of civilizations" as a form of "cultural resurgence" as globalization brings religious and national groups into contact with each other (Collet and Inoguchi, 2012). Brubaker (2017), for example, argues that widespread immigration from non-Christian countries has led many secular politicians in the "West" to embrace a secularized Christian identity. Although Western Europe is a largely secular culture, Christian religious identity serves as the dividing line between "Western" and "Islamic" civilization. Both Huntington (1996, 201–202) and Kinnvall (2004) argue that a similar process has

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

taken place in the Muslim-majority world, as globalization has facilitated greater contact between Christianity and Islam; as proselytizing religions, each civilizational identity experiences newfound tension due to this increased contact.[7]

Connecting the disparate strands of this literature, Fordahl and Ragnarsdóttir (2021) interpret the development of aggressive religious identities as part of a "post-secularization" process; here, globalization drives newfound religious practices in secularizing environments—most critically, forms of religion that seek to exclude members of other religions from the body politic. This work, however, is tailored to a particular case study and has yet to be utilized in a broader, comparative context.

Discrimination is the logical outcome of these exacerbated cleavages, because it is a frequent means of reasserting collective identity given threats to group cohesion (Brewer, 1999). Some prior work has incorporated elements of discrimination, globalization, counter-secularization, but thus far these studies have not received proper follow-ups. Critically, Bloom *et al.* (2013) argue that religious resurgence is a response to "globalization threat"—the sense of threat that the public feels due to globalizing institutions' potentially homogenizing effect on dominant cultures. In this model, the public's fear of globalization manifests itself as opposition to religious pluralism, and the public's opposition to religious pluralism leads to SRP as a response.

Bloom, Arikan, and Sommer's model tests this theory at the government and individual levels, and not at the societal level. Given that previous studies such as Fox (2020) have named SRD as a precursor to GRD, this is an important step to be filled.[8] The societal level, acting as an intermediary level between government and individuals, is key to bridging the GGS and RAS models. However, these findings do not differentiate between distinct geographic regions, political environments, or religious settings, and their definition of globalization relies on older data that is less specific than modern data. Subsequent studies have largely focused on the findings' implications for religious identity or even the quality of democracy as a whole (cf. Fox *et al.*, 2019; Jerabek, 2022). More recently, Zhiang (2020) provides a direct follow-up to Bloom, Arikan, and Sommer's findings, but focuses on religious policies and does not examine the societal level.

In this study, I offer a ground-up model of counter-secularization. In doing so, I seek to reconcile GGS models with RAS models. I argue that specific mechanisms of globalization—particularly migration and information—both reduce institutional involvement in religion as well as spark backlashes from religious practitioners. In other words, while religious practice is indeed declining, the remaining religious practitioners are growing more aggressive toward other religions.

If this is the case, then religious discrimination should rise in conjunction with specific types of globalization and not others, while religious practice should fall in relation to the same types. We can expect these globalization types to be those related to increased social contact across borders, particularly immigration and information. The hypotheses are as follows:

Hypothesis 1 (H1). *Social types of globalization will increase SRD over time.*

Hypothesis 2 (H2). *Social types of globalization will decrease religious practice over time.*

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

At the same time, the theory above suggests that globalization exacerbates SRD *because* of secularization—that is, that these phenomena are intricately linked. To that end, a third hypothesis examines the effect of globalization in conjunction with declining religious practice:

Hypothesis 3A (H3A). *The effect of social globalization types on SRD requires a concurrent decline in religiosity.*

This hypothesis does not suggest that societies with high levels of religiosity are more tolerant of religious minorities; rather it suggests that globalization produces a change in the *status* of religion—and religious actors—and therefore invites a backlash. Therefore, a parallel hypothesis must be considered:

Hypothesis 3B (H3b). *The effect of religiosity on SRD will be dependent on the level of social globalization.*

If declining religiosity is a necessary condition for the relationship between globalization and SRD, this could imply that higher levels of religiosity *reduce* SRD. I suggest, however, that this is only true within the context of globalizing societies. Examining the effect of these variables in relation to each other will demonstrate that their effects are contingent upon each other. Rather than independently affecting SRD, these variables can be viewed as part of a series of events.

Data and methods

I use a series of ordinary least-squares (OLS) model to gauge the impact of globalization on SRD and religiosity by country-year. In order to observe within-unit change over time, I have deployed country-year fixed effects (cf. Fox *et al*., 2017). Both the primary dependent variable as well as two control variables are taken from the RAS project round 3, or RAS3, which encompasses 183 countries spanning the years 1990–2014. RAS data are also coded by region. Although initial findings by Bloom *et al*. (2013) include all countries, more recent studies, such as Fox (2020), use these regions to group results, allowing for a more reliable analysis. Thus, regarding H1, I conduct tests according to regional groupings rather than pooled into one sample. These are further presented according to varying categories of the independent variable. The first hypothesis is examined on a comparative basis. As I will discuss, this is not feasible concerning H2 or H3 given the limited availability of data. For H3—both A and B—I further include an interactive effect between causal mechanisms—globalization types and rates of religious practice—to establish a causal pathway rather than simultaneous causation. I limit these tests to types of globalization that have established effects according to H1 and H2 (Table 1).

The first dependent variable is Societal Religious Discrimination, or SRD. This variable, which appears in the RAS3, measures discriminatory practices against minority religions at the societal level. Although other RAS3 variables typically describe regulation of religious practices, SRD is one of the few based on actions, not policies. As such, it tends to change more from year-to-year than other variables

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

Table 1. Descriptive statistics for dependent variables

Variables	Mean	Std. deviation	Minimum	Maximum
Societal Religious Discrimination (SRD)	6.862	9.641	0	62
Service attendance rate	59.587	26.639	1.087	98.383
Regular prayer rate	41.134	24.431	0.8	95.62

in the dataset.[9] It also describes acts of physical violence that cannot be captured by government policy alone.

The RAS3 measure of SRD is an index composed of 27 items encompassing a wide range of discriminatory behaviors by non-state actors toward religious minorities.[10] Each item is rated on a scale of 0–3, 0 indicating that the discriminatory behavior is not present, and 3 indicating that it is frequent toward all religious minority groups. Discriminatory actions include a wide variety of items, including types of economic discrimination, hate speech, non-violent acts, and violent acts. Some actions included in the index involve attacks or vandalism of property, while others involve people with visible affiliations to the religion.

The overall index is the sum of each item.[11] As a result, the potential values for the SRD index range from 0 to 81. A value of 81 would indicate that all forms of religious discrimination are widespread and affect all religious minorities. In actuality, however, no country-year features a score higher than 62—a distinction belonging to Egypt from 2009–2014. A score of 62 suggests that most forms of SRD are widespread and affect all religious minority groups rather than particular groups, but not all forms of SRD are practiced (Akbaba and Fox, 2019). Small SRD scores, in the range of 3–7, typically imply that religious groups have been selectively targeted on a limited basis. Lower scores of SRD are more common outside of Europe, North America, and the Middle East–North Africa, although in some countries such as the United Arab Emirates, SRD is quite low even though levels of government policy-making on religion are quite high. Latin America and sub-Saharan Africa show the lowest levels of SRD.

The other dependent variables concerning indicators of religiosity are from the WVS (Inglehart *et al.* 2014). The first is the aggregate percent of WVS respondents attending religious services at least once a month (cf. Cingranelli and Kalmick, 2019; Fox *et al*., 2021). It covers the first seven waves of the project, encompassing all available data as of November 2021. In order to observe within-unit change over time, I used linear interpolation to fill values between years. Observed values range from just over 1% to 98.383%, with the average at 59.587. Although service attendance is frequently used to gauge religiosity, critics contend that this primarily describes Western religious practices rather than religious practice as a whole (Verghese, 2020). To account for the potential disparity, I have also included the rate of regular prayer. This is the percent of WVS respondents who report praying at least several times a week—the next lowest rating being "only at religious services." This variable ranges from 0.8% to 95.62%, with an average of 41.134 (Table 2).

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

Table 2. Globalization types

Globalization types	Description
Aggregates	
Total	Composite of all disaggregated components
Economic	Describes the interconnection between national economies, including two disaggregate indexes of trade and finance
Social	Describes the transnational flow of people and knowledge; disaggregated into interpersonal, informational, and cultural types.
Political	Comprised of connections between national institutions as well as connections to transnational institutions. This includes items such as the number of embassies in a country; the number of treaties signed, diversity of treaty partners, presence of international NGOs and contributions to UN peacekeeping missions
Disaggregates	
Trade	The degree to which a country trades with other countries relative to internal trade
Financial	The degree to which a country either houses or invests in transnational finance
Interpersonal	Describes human traffic across borders, such as migration, tourism, mobile phone use, and presence of international students
Informational	Encompasses developments in the field of communication such as internet bandwidth usage, television access, technology exports, or international patents
Cultural	Includes trade in cultural goods, international trademarks, gender parity, human capital, and freedom of expression

The independent variables consist of several measures of globalization, divided into different types. These measures are drawn from the index categories in the KOF Globalisation [*sic*] Index (Dreher, 2006; Gygli *et al*., 2019). Each index is based on a series of variables related to an aspect of globalization. Taken together, each index can be compiled into a single value indicating the level of globalization in a given country. At the same time, the data also group these variables into specific types: economic, social, and political. The economic index of globalization can be further broken down into financial and trade-related variables, while the social index can be broken down into interpersonal, informational, and cultural variables.

For the purpose of this study, interpersonal and informational types of globalization are the most important. The former describes the flow of people across borders. It is compiled from a number of measures that broadly describe freedom of movement, such as the number of foreign-born residents, strength of international tourism, and transfers of goods and services, along with a handful of other items. The latter describes the public's access to information, relating both to internet and television as well as items such as freedom of press and relative frequency of international patents. These concepts are particularly important when analyzing the resurgence of religious identity, because they directly challenge dominant religions in two ways: first,

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

by exposing the public to a diverse array of outsiders with a diverse set of practices, and second, by introducing the general public to narratives that run counter to dominant ideologies, including religious dogmas.

The broader index compiles a total of 40 variables into a handful of categories describing types of globalization.[12] I have detailed the composition of these types in Table 2. Each index is scaled from 0 to 100. For H1, the effect of each type of globalization is presented according to regional groupings.[13] In other words, I have presented nine different types of globalization across six different regions to examine the relationship between globalization and religious resurgence on a fine-grained level. This is not possible for H2 and H3, due to the relatively small number of country-year observations in each region.

In addition to the variables above, I have deployed a standard set of control variables previously utilized by Fox (2013, 2015, 2020) and Fox *et al.* (2021), excluding time-invariant variables rendered superfluous by fixed-effects models. For controls, I have included religious fractionalization, GDP per capita, population size, democracy scores, violent minority actions, and GRD. Religious fractionalization is a Herfindahl–Hirschman index of the Religious Characteristics of States dataset, based on the provided taxonomy (Brown and James, 2017). I use this measure in place of minority percent (cf. Fox, 2020; Fox *et al.*, 2021) because I am using countries as the unit of analysis rather than minority groups. GDP per capita and population numbers appear in the World Bank's (2021) World Development Indicators, logged for skew. Democracy scores are taken from Polity V; they range from −10 to 10, with higher scores indicating greater democracy (Marshall and Gurr, 2018). Finally, violent minority actions and GRD are both drawn from the RAS3. Violent minority actions include violence by religious minorities against majority religions; I have excluded values for minority–minority discrimination as it is not reliable at the country level (Fox *et al.*, 2018). GRD is calculated in the same vein as SRD, using a total of 36 categories.

Given that societal religious cleavages have previously been theorized as a source of restrictive government policies (Gill, 2008; Grim and Finke, 2010), most studies such as Fox (2020) control for SRD in tests of GRD but not vice-versa. Here, I control for GRD to account for cases where widespread religious observance and homogeneity are maintained through government coercion. This is particularly important for the Middle East–North Africa, where many states are more religiously homogenous than average, and GRD is significantly higher than SRD. To assuage any concerns regarding this decision, I have added an additional Appendix (Appendix 5) that compares results side-by-side.[14]

Results

Figure 2 compares the outputs of several OLS models using coefficient plots. Controls are suppressed for space. Full regression tables can be found in Appendix 1.

In the first set of tests, I present side-by-side results demonstrating the impact of several distinct types of globalization on SRD, grouped by each region codified in the RAS. These tests include each of the nine coded types of globalization—aggregate and disaggregate alike—across six regions. The combined set of 54 tests detailed here

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

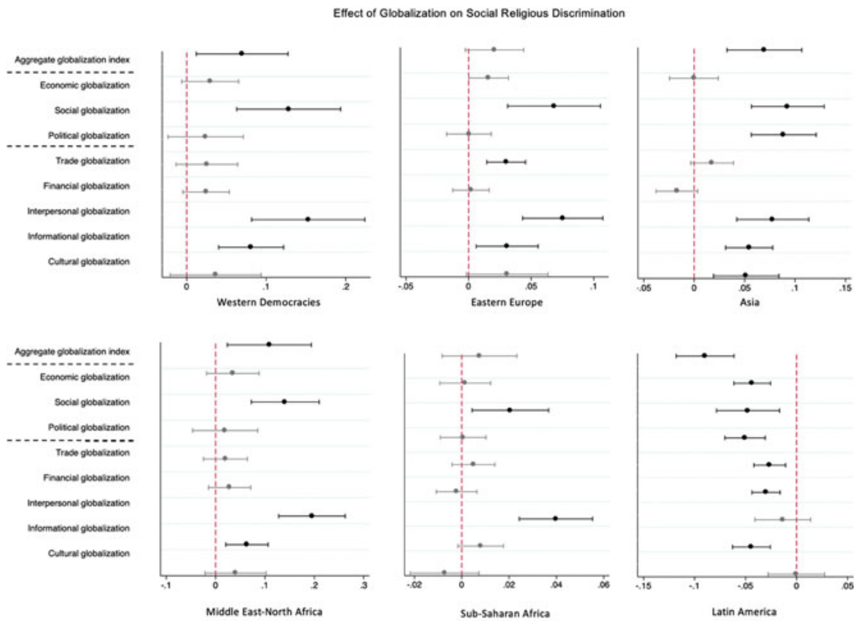

Figure 2. Coefficient plots for H1.

demonstrates significant variation across types of globalization and regions of particular impact, allowing for greater precision in exploring the relationship on a comparative level.[15]

Although largely consistent with H1, results vary considerably by region. Western democracies and the Middle East–North Africa each show the highest effect sizes, particularly as it concerns interpersonal globalization. In Western democracies, the range of interpersonal globalization predicts a 15-point increase in SRD; in the Middle East–North Africa, it predicts a nearly 20-point increase in SRD. In Western democracies, this relationship represents an increase from about 6 points on the SRD scale to about 14—representing a rise from 45th percentile to 77th within the region. The same numbers are even starker for the Middle East–North Africa. Here, the total range of interpersonal globalization values predicts a rise in SRD from roughly 3 to 22—or 25th percentile to 90th. This means that over the range of interpersonal globalization, countries in these regions move from relatively low- or medium-range levels of SRD to quite high levels. Both effects are significant at the 0.01 level ($p < 0.01$).[16] These effects are illustrated in Figure 3.

Of all the types of globalization, the "interpersonal" type shows the most consistent pattern across regions, demonstrating a significant effect in every region except for Latin America ($p < 0.01$). Here, however, R^2 values prove substantially lower, with the highest additional value reaching only 0.267 in sub-Saharan Africa. Thus, outside of Western democracies and the Middle East–North Africa region, the effect of interpersonal globalization only accounts for about one-fifth to one-fourth of the variation in SRD. In terms of the variation in globalization types themselves, informational

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

globalization also demonstrates a robust impact, appearing significant at the 0.01 level ($p < 0.01$) in every region except for Latin America and sub-Saharan Africa. Here, too, the effect sizes are larger in Western democracies and the Middle East–North African regions, predicting rises in 8 and 6 points, respectively.

Other results are less consistent: trade globalization is only significant in Eastern Europe; political and cultural globalization are only significant in Asia. The effect size of interpersonal globalization, while still significant, is less than half of that in Eastern Europe and Asia as it is in Western democracies and the Middle East–North Africa. In Latin America, meanwhile, all globalization types are shown to exert a *negative* effect on SRD—significant at the 0.01 level ($p < 0.01$)—with the exception of interpersonal and cultural types. This sole holdout to the overall trend likely speaks to the role religious institutions played in Latin America's wave of democratization (cf. Huntington, 1991). It also indicates that this relationship is more heavily indebted to the structural interaction between religion, state, and society, rather than the dogmatic aspects of specific religions.

Ultimately, these tests indicate contextual support for H1; the relationship between globalization and religious cleavages as observed *through SRD* is contingent on a number of factors. First, specific types of globalization demonstrate outsize impact. Second, this impact varies considerably by region. Third, the *importance* of this impact itself also varies by region. Beyond particular cases of interest, other structural elements remain at work that are not captured by these models. Further research is thus needed to parse the confounding factors in regions with lesser impact, or particular structural factors that render particular regions especially vulnerable to this phenomenon.

These tests cannot and do not attempt to answer the question of whether it is religious or secular actors perpetuating SRD. Indeed, the literature surrounding countersecularization suggests that this distinction is not absolute. Nevertheless, I have sought to demonstrate a potential path forward in this area by comparing the relationship between SRD and globalization types to religiosity as whole. To this end, Figure 4 contains coefficient plots for H2. Full regression tables are again found in Appendix 1. In this case, I have not divided results by region due to an inefficient number of groupings in each. Full regression tables are available in Appendix 1.

Results indicate that aggregate globalization decreases both service attendance and prayer rates; but that specifically social, and interpersonal types in particular, demonstrate the largest deleterious impacts. Over the range of interpersonal globalization, service attendance rates drop nearly 18%, corresponding to about 66th percentile to 43rd; prayer rates, meanwhile, fall nearly 43%—from 72nd percentile to just 29th. Both effects are significant at the 0.01 level ($p < 0.01$).[17] Social globalization, and interpersonal globalization in particular, exerts a consistent effect across SRD, service attendance, and prayer. In other words, expressions of religiosity often respond to the same mechanisms as SRD. Every type of globalization that decreases service attendance also increases SRD, and every type of globalization except cultural decreases regular prayer.

But are these effects occurring simultaneously, or are they conditional on one another? Fox *et al.* (2021), for example, suggest that the inverse relationship between secularization and discrimination may be due to secular actors' hostility to religious actors. Regarding H3 (A and B), I have prepared an additional test that seeks to gauge

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

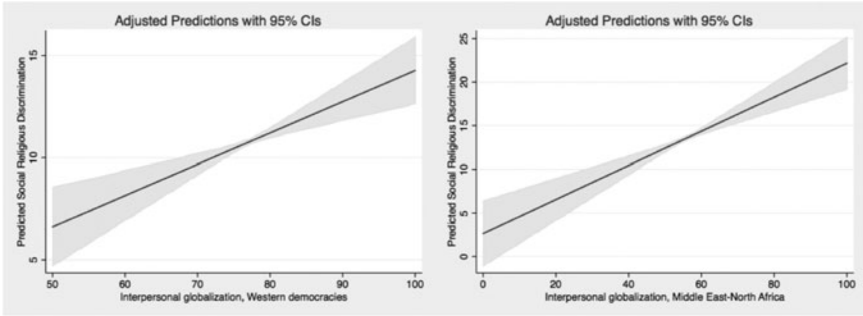

Figure 3. Illustrative effects of H1.

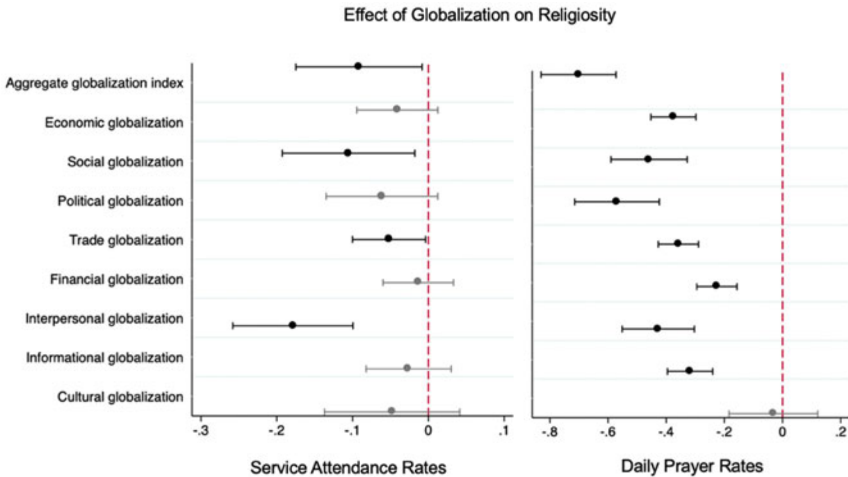

Figure 4. Coefficient plots for H2.

this question. Although the limited availability of data precludes a fine-grained comparison like that of H1, these tests include an interaction term between globalization and religiosity. This means that the effects of globalization and religiosity on SRD are each being viewed in relation to each other.

These tests are illustrated in Figure 5, depicting H3A and H3B respectively. Full regression tables are found in Appendix 1. According to the results for H3A, depicted on the left-hand side, the effect of interpersonal globalization on SRD is contingent on a decline in religiosity—in other words, secularization. This is to say that when interpersonal globalization *is not* accompanied by a decline in religiosity, it *does not* predict SRD. These results are significant at the 0.01 level ($p < 0.01$). At high levels of religiosity, interpersonal globalization is actually weakly associated with a *decrease* in SRD ($p < 0.05$). In short, interpersonal globalization—the flow of people across borders—does not exacerbate religious cleavages unless it is also accompanied by a loss of religiosity in society writ large.

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

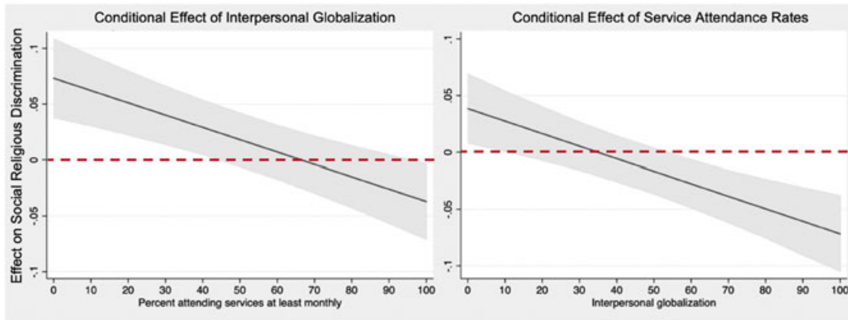

Figure 5. Test for H3.

The same logic holds when analyzing H3B, the relationship between religiosity and SRD, as depicted on the right-hand side. Findings thus far suggest that secularization exacerbates SRD; this means that the relationship between discrimination and religiosity should be inverse. This is only true, however, at high levels of interpersonal globalization. When interpersonal globalization is low, religiosity is in fact associated with an *increase* in SRD. In other words, while the relationship between globalization and SRD is contingent on declining levels of religiosity, the inverse relationship between religiosity and SRD is contingent on high levels of globalization. This suggests that neither declining religiosity nor globalization exacerbate SRD on their own. Rather, they form a sequence of causal events.[18]

In short, these findings offer some nuance to the hypotheses. Although these models suggest that globalization does increase SRD, they further suggest that this relationship is highly contextual. This is also the case with regard to the relationship between secularization and SRD. Globalization only exacerbates SRD insofar as it is accompanied by a decline in religiosity, while religiosity is only associated with a decrease in SRD if it is accompanied by globalization. At the same time, the variation in regional and typographical patterns suggests that this relationship should be further examined for structural elements that further condition results in one direction or another. Further study is needed to examine these structural elements on a fine-grained basis. Further study is also needed to disaggregate globalization types to their barest components to demonstrate highly specific relationships.

It is also worth noting that throughout these tests, the inclusion or exclusion of GRD rarely alters results. The fact that most model results are unaffected offers further support for previous theories such as Grim and Finke (2010) that suggest societal restrictions influence government restrictions, rather than the opposite. There are, however, caveats to this aspect, as discussed in Appendix 5.

Discussion

Although alternatives to secularization have grown increasingly prominent and popular, models such as the GGS continue to find support for a limited type of secularization. At the individual level, human development appears to reduce religiosity. Nevertheless, models of institutional structures like the RAS project have consistently

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

shown a resurgence of religious activity at the country level. In recent years, academic discourse has increasingly moved beyond the push-and-pull between theories of secularization and resurgence. Nonetheless, scholars continue to find evidence of both theories. As such, these ostensibly contradictory results may in fact be two halves of the same whole. Reconciling these models is key to building a cohesive picture of religion, state, and individual in a globalized age.

Referring to a third body of theoretical literature—here, dubbed "counter-secularization"—this article sought to bridge these models, as a first step toward reconciliation. According to the literature of counter-secularization, the forces of globalization, rather than the process of modernization, facilitates religious cleavages by bringing disparate religious groups into contact with each other. As dominant religious groups perceive a threat from religious diversity, they seek to protect their status.

Although previous studies examined the relationship between globalization threat and SRP, this article examines the relationship between globalization and societal expressions of both religiosity and religious cleavages. Results indicate that globalization is indeed associated with both SRD, as an expression of religious cleavages, as well as a decline in aggregate levels of religiosity. Nevertheless, these findings also presented several conditions for this relationship: first, that this relationship is stronger in some geographic regions than others; second, that this relationship largely stems from *interpersonal* and *informational* globalization, rather than globalization of markets or of political institutions; and finally, that globalization only exacerbates SRD if religiosity is declining. In other words, the connection between globalization and resurgence is not absolute, and neither is the connection between secularization and discrimination; instead, they are links in chain.

It is worth noting that the elements of globalization that show the greatest effect are those that increase diversity and pluralism. Interpersonal globalization, which demonstrated the strongest and most consistent effects in a wide variety of contexts, encompasses the flow of people across borders, including broad points of contact ranging from immigration to tourism. The second strongest in this regard, informational globalization, speaks to a population's access to a global marketplace of ideas.

Further study is needed to explore these findings. A broader structural analysis entailing both individual-level as well as aggregate data may provide further insight as to how macrolevel trends impact microlevel phenomena. For a full view of this subject matter, an analysis must account for intermediary variables within a multistage causal chain. This article thus lays the foundation for a broader effort to integrate schools of thought concerning the relationship between religion and state in the modern world.

Indeed, there are many connections between these concepts that are worth exploring further. It is impossible, for example, to remove interpersonal and informational globalization from the context of the transnational marketplace (cf. Helms, 2024). It is also impossible to remove the transnational marketplace from the context of transnational political institutions (cf. Gygli *et al.*, 2019). While social globalization appears to have an outsize effect, it must be recognized that social globalization can itself be part of a process that involves both political and economic elements. Beyond globalization itself, it is impossible to remove these developments from the context of

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

religious movements which both aided and opposed such developments in both developed and developing economies (cf. Dreher, 2020).

These findings, then, suggest that it is also impossible to fully extricate the religious resurgence from a broader environment of secularization. The relationship between the two may in fact be highly nested in nature. Individuals, religious families, and even administrative units may yield distinct trends and phenomena relative to religious institutions, countries, geographic regions, and larger religious blocs. These effects may be relatively inconsistent in some stages of development, and relatively consistent in others. Relationships between these variables, then, should be viewed in context rather than in isolation. Although this study seeks to clarify and reconcile existing arguments, it is not an end point. Rather, it points in the direction of potential future lines of inquiry.

Data. Replication files are available from the author upon request.

Acknowledgments. The author would like to thank professors Gregory A. Robinson, Ekrem Karakoc, and David Cingranelli (Binghamton University), and Dr. Joseph B. Phillips (University of Kent) for their support, and the reviewers and editors at *Politics and Religion* for many helpful comments.

Financial support. No funding was received to assist with the preparation of this manuscript.

Competing interests. None.

Notes

1. On viewing secularization in this capacity, see Chaves (1994).
2. This distinction is consistent with a broader theoretical foundation in "functionalist" or "substantive" schools of thought concerning religious identity. Cf. Berger (1974).
3. The contradiction between the two is especially striking given that religious markets theory (RMT) provides the blueprints for both the GGS and RAS models. RMT suggests that religious practice responds to market forces among religious firms (cf. Iannaccone, 1990; Stark and Iannaccone, 1994; Stark and Finke, 2000). As such, government regulation or deregulation of the market can impact practice. But although the GGS model argues that modernization creates substitutable goods that provide alternatives to religion, RAS literature suggests that government policy toward the market provides avenues of renewed competition.
4. A large body of literature is associated with each theory, first espoused by Allport (1954) on the one hand, and Blalock (1957) and Blumer (1958) on the other. For an overview of "contact" and "group-threat" theories, respectively, see Pettigrew (1998) and Chiricos *et al.* (2020).
5. On the exclusivity of religion, see Reynal-Querol (2002, 32).
6. Such ideologies are often referred to as "horizontal" to distinguish them from ideologies based on hierarchy—i.e., "vertical" ideologies.
7. Similarly, Juergensmeyer (2008) and Juergensmeyer *et al.* (2015) argue that both Christian and Islamic fundamentalism speak to a global trend toward religious nationalism in a post-Cold War setting. Although subsequent evidence calls many of Huntington's fundamental concepts into question, there does appear to be greater tension between Christian and Islamic identities, and both Western democracies and the Middle East–North Africa have shown greater levels of "religious resurgence" (Collet and Inoguchi, 2012; Fox, 2013).
8. Data regarding SRD was not yet available when Bloom *et al.*'s article was published; in addition, the data used to measure globalization have also become more developed since, as have conventions in research design for RAS data.
9. One stark example of this is the variable of Government Religious Discrimination, or GRD; only 12.05% of GRD observations change from year-to-year, compared to 25.32% of SRD observations.

https://doi.org/10.1017/S1755048324000324 Published online by Cambridge University Press

10. Several recent studies such as Fox (2020) and Fox *et al.* (2021) employ minority-specific discrimination measures; because I am seeking to establish a more general relationship regarding the religious majority's perception of status threat, I have used general discrimination rather than minority-specific versions. The alternative coding scheme has somewhat distinct theoretical implications, and as such is likely to return different results. This paper focuses on SRD at the country level, because the logic thus far suggests that under globalizing conditions, religious ideologues broadly conflate religious minorities as uniformly threatening to their hegemonic social position. Nevertheless, I have included additional tests with minority-level data in Appendix 6. These tests show that some effects are more difficult to observe using minority-level data. This is particularly true of hypothesis 3, which only returns results at the minority-level under certain conditions.

11. Thus, a three-unit rise in SRD could indicate either that three types of SRD have increased in prevalence or that a new type of SRD has appeared with a degree of frequency. According to Fox *et al.* (2018, 2021), the index should not be scaled, and its components should not be weighted, meaning that each type of discrimination included affects the index value equally.

12. Each type contains a de facto and de jure measure, with the former describing societal practices and the latter describing state policies and societal conditions that foster globalization. Thus, each type of globalization has two distinct measures. For the purpose of this study, I use on the overall average between the two.

13. Due to potential collinearity in some disaggregate categories, globalization variables may interfere with each other when included in a model together (cf. Dreher and Gaston, 2008). As such, I have included each in separate models (cf. Bergh and Nilsson, 2010). This is a difficult choice because each type of globalization is deeply linked to every other type. This means that whether they are included in the same model, or in separate models, scholars may encounter problems with either overstating or understating the impact of specific types of globalization rather than globalization *as a whole*. In order to account for potential discrepancies, I have also conducted additional tests including each type in the same model, which can be found in Appendix 2.

14. I believe that the inclusion of GRD as a control variable here is a necessary safeguard for such environments with heightened religious regulation. In this regard, it serves the same function as using the more commonly used religious support variable (cf. Fox, 2020). The religious support variable is unusable in a fixed-effects model because too few of its observations—only about half a percent—change year-to-year. As demonstrated in Appendix 5, the inclusion or exclusion of GRD does not affect the vast majority of results, but does affect the R^2 values of specific regions in important ways. While findings thus imply that the previously theorized relationship is largely correct, there may be contexts in which GRD is an important control.

15. An alternatively structured version of these tests, in which aggregate and disaggregate globalization types were included simultaneously across three respective models, can be found in Appendix 2. Another additional set of tests using Government Religious Discrimination, or GRD, as the dependent variable, appears in Appendix 4. These models are less informative than those using SRD as an outcome, as they present uniform patterns across types of globalization and regions.

16. R^2 values are 0.64 for Western democracies and 0.416 for the Middle East–North Africa, suggesting that a substantial portion of variation of SRD within these regions is attributable to the model. Although the effect size in Western democracies is smaller than in the Middle East–North Africa region, the model accounts for nearly two-thirds of the variation of SRD.

17. R^2 values range from just 0.155 to 0.173 for service attendance, but 0.444 to 0.556 for prayer rates. The latter indicates that over half of the variation in prayer rates is attributable to this model.

18. Such effects are not limited to the interpersonal type of globalization. As demonstrated in Appendix 1, the same pattern occurs when using the "informational" type as an interaction term, but the effect size is weaker.
